The musical note known as A_4 or "the A above middle C" is produced with a frequency of 440 vibrations per second, or 440 hertz (Hz) (this is the note most often used in the tuning of pianos and other musical instruments). For any given note, the same note one octave higher will have double the frequency, and the same note one octave lower will have one-half the frequency. In addition, with $f = \dfrac{1}{P}$ the value of $B = 2\pi\left(\dfrac{1}{P}\right)$ can always be expressed as $B = 2\pi f$, so A_4 has the equation $y = \sin[440(2\pi t)]$ (after rearranging the factors). The same note one octave lower is A_3 and has the equation $y = \sin[220(2\pi t)]$, with one-half the frequency. To draw the representative graphs, we must scale the t-axis in very small increments (seconds $\times 10^{-3}$) since $P = \dfrac{1}{440} \approx 0.0023$ for A_4, and $P = \dfrac{1}{220} \approx 0.0045$ for A_3. Both are graphed in Figure 6.111, where we see that the higher note completes two cycles in the same interval that the lower note completes one.

Figure 6.111

EXAMPLE 7 ▶ **Applications of Sine and Cosine: Sound Frequencies**

The table here gives the frequencies for three octaves of the 12 "chromatic" notes with frequencies between 110 Hz and 840 Hz. Two of the 36 notes are graphed in the figure. Which two?

	Frequency by Octave		
Note	**Octave 2**	**Octave 3**	**Octave 4**
A	110.00	220.00	440.00
A#	116.54	233.08	466.16
B	123.48	**246.96**	493.92
C	130.82	261.64	523.28
C#	138.60	277.20	554.40
D	146.84	293.68	587.36
D#	155.56	311.12	622.24
E	**164.82**	329.24	659.28
F	174.62	349.24	698.48
F#	185.00	370.00	740.00
G	196.00	392.00	784.00
G#	207.66	415.32	830.64

Solution ▶ Since amplitudes are equal, the only differences are the frequency and period of the notes. It appears that y_1 has a period of about 0.004 sec, giving a frequency of $\frac{1}{0.004} = 250$ Hz—very likely a B_3 (in bold). The graph of y_2 has a period of about 0.006, for a frequency of $\frac{1}{0.006} \approx 167$ Hz—probably an E_2 (also in bold).

Now try Exercises 59 through 62 ▶

D. Vertical and Horizontal Translations of Other Trig Functions

In Section 6.4, we used the graphs of $y = A\sin(Bt)$ and $y = A\cos(Bt)$ to help graph $y = A\csc(Bt)$ and $y = A\sec(Bt)$, respectively. If a vertical or horizontal translation is being applied to a cosecant/secant function, we simply apply the same translations to the underlying sine/cosine function as an aid to graphing the function at hand.

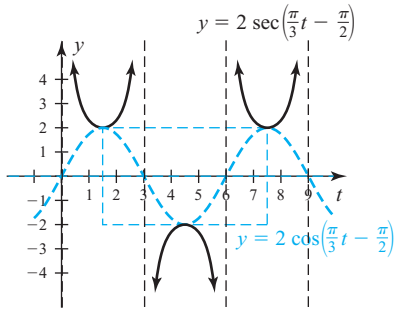
EXAMPLE 8 ▶ **Graphing $y = A\sec(Bt + C) + D$**

Draw a sketch of $y = 2\sec\left(\frac{\pi}{3}t - \frac{\pi}{2}\right) - 3$ for t in $[0, 9]$.

Solution ▶ To graph this secant function, consider the function $y = 2\cos\left(\frac{\pi}{3}t - \frac{\pi}{2}\right) - 3$. In shifted form, we have $y = 2\cos\left[\frac{\pi}{3}\left(t - \frac{3}{2}\right)\right] - 3$. With an amplitude of $|A| = 2$ and period of $P = \frac{2\pi}{\pi/3} = 6$, the reference rectangle will be 4 units high and 6 units wide. The *rule of fourths* shows the zeroes and max/min values of the unshifted graph will occur at 0, $\frac{3}{2}$, 3, $\frac{9}{2}$, and 6. Applying a horizontal shift of $+\frac{3}{2}$ units gives

the values $\frac{3}{2}$, 3, $\frac{9}{2}$, 6, and $\frac{15}{2}$, which we combine with the reference rectangle to produce the cosine and secant graphs shown next. Note the vertical asymptotes of the secant function occur at the zeroes of the cosine function (Figure 6.112). By shifting these results 3 units downward (centered on the line $y = -3$), we obtain the graph of $y = 2\sec\left(\frac{\pi}{3}t - \frac{\pi}{2}\right) - 3$ (Figure 6.113).

Figure 6.112



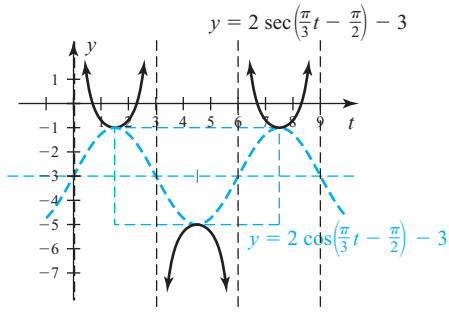


Figure 6.113

Now try Exercises 45 through 48 ▶

To horizontally and/or vertically translate the graphs of $y = A\tan(Bt)$ and $y = A\cot(Bt)$, we once again apply the translations to the basic graph. Recall for these two functions:

1. The primary interval of $y = \tan t$ is $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$, while that of $y = \cot t$ is $[0, \pi]$.
2. $y = \tan t$ increases while $y = \cot t$ decreases on their respective domains.

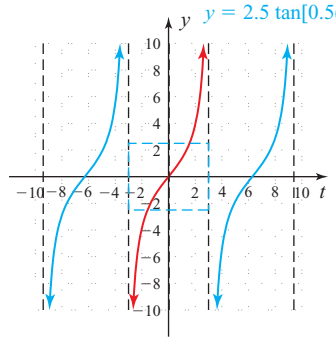
EXAMPLE 9 ▶ **Graphing $y = A\tan(Bt + C)$**

Draw a sketch of $y = 2.5\tan(0.5t + 1.5)$ over two periods.

Solution ▶ In shifted form, this equation is $y = 2.5\tan[0.5(t + 3)]$. With $A = 2.5$ and $B = 0.5$, the graph is vertically stretched with a period of 2π (see Figure 6.114). Note that $t = -\pi$ and π gives the location of the asymptotes for the unshifted graph, while $t = -\frac{\pi}{2}$ and $\frac{\pi}{2}$ gives -2.5 and 2.5, respectively.

Shifting the graph 3 units left produces the one shown in Figure 6.115 ($-\pi - 3 \approx -6.14$, $-\frac{\pi}{2} - 3 \approx -4.57$, $0 - 3 = -3$, $\frac{\pi}{2} - 3 \approx -1.43$, and $\pi - 3 \approx 0.14$).

Figure 6.114



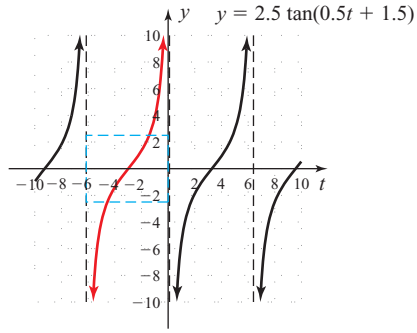


Figure 6.115

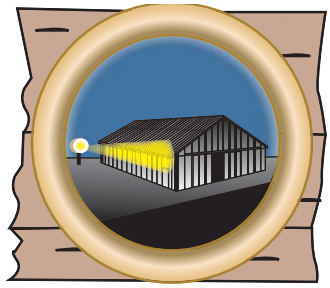
WORTHY OF NOTE
The reference rectangle shown is 5 units high by 2π units wide.



☑ **D.** You've just seen how we can apply vertical and horizontal translations to cosecant, secant, tangent, and cotangent functions

Now try Exercises 49 through 52 ▶

E. Applications of the Remaining Trig Functions

We end this section with two examples of how tangent, cotangent, secant, and cosecant functions can be applied. Numerous others can be found in the exercise set.

EXAMPLE 10 ▶ **Applications of $y = A\tan(Bt)$: Modeling the Movement of a Light Beam**

One evening, in port during a *Semester at Sea,* Richard is debating a project choice for his Precalculus class. Looking out his porthole, he notices a revolving light turning at a constant speed near the corner of a long warehouse. The light throws its beam along the length of the warehouse, then disappears into the air, and then returns time and time again. Suddenly—Richard has his project. He notes the time it takes the beam to traverse the warehouse wall is very close to 4 sec, and in the morning he measures the wall's length at 127.26 m. His project? Modeling the distance of the beam from the corner of the warehouse as a function of time using a tangent function. Can you help?

Solution ▶ The equation model will have the form $D(t) = A\tan(Bt)$, where $D(t)$ is the distance (in meters) of the beam from the corner after t sec. The distance along the wall is measured in positive values so we're using only $\frac{1}{2}$ the period of the function, giving $\frac{1}{2}P = 4$ (the beam "disappears" at $t = 4$) so $P = 8$. Substitution in the period formula gives $B = \dfrac{\pi}{8}$ and the equation $D = A\tan\left(\dfrac{\pi}{8}t\right)$.

Knowing the beam travels 127.26 m in about 4 sec (when it disappears into infinity), we'll use $t = 3.9$ and $D = 127.26$ in order to solve for A and complete our equation model (see note following this example).

$$A\tan\left(\frac{\pi}{8}t\right) = D \qquad \text{equation model}$$

$$A\tan\left[\frac{\pi}{8}(3.9)\right] = 127.26 \qquad \text{substitute 127.26 for } D \text{ and 3.9 for } t$$

$$A = \frac{127.26}{\tan\left[\dfrac{\pi}{8}(3.9)\right]} \qquad \text{solve for } A$$

$$\approx 5 \qquad \text{result}$$

One equation approximating the distance of the beam from the corner of the warehouse is $D(t) = 5\tan\left(\dfrac{\pi}{8}t\right)$.

Now try Exercises 63 through 66 ▶

For Example 10, we should note the choice of 3.9 for t was arbitrary, and while we obtained an "acceptable" model, different values of A would be generated for other choices. For instance, $t = 3.95$ gives $A \approx 2.5$, while $t = 3.99$ gives $A \approx 0.5$. The true value of A depends on the distance of the light from the corner of the warehouse wall. In any case, it's interesting to note that at $t = 2$ sec (one-half the time it takes the beam to disappear), the beam has traveled only 5 m from the corner of the building: $D(2) = 5\tan\left(\dfrac{\pi}{4}\right) = 5$ m. Although the light is rotating at a constant angular speed, the speed of the beam along the wall increases *dramatically* as t gets close to 4 sec.

EXAMPLE 11 ▶ **Applications of $y = A\csc(Bt)$: Modeling the Length of a Shadow**

During the long winter months in southern Michigan, Daniel begins planning for his new solar-powered water heater. He needs to choose a panel location on his roof, and is primarily concerned with the moving shadows of the trees throughout the day. To this end, he begins studying the changing shadow length of a tree in front of his house. At sunrise, the shadow is too long to measure. As the morning progresses, the shadow decreases in length, until at midday it measures its shortest length of 7 ft. As the day moves on, the shadow increases in length, until at sunset it is again too long to measure. If on one particular day sunrise occurs at 6:00 A.M. and sunset at 6:00 P.M.:

a. Use the cosecant function to model the tree's shadow length.

b. Approximate the shadow length at 10:00 A.M.

Solution ▶

a. It appears the function $L(t) = A\csc(Bt)$ will model the shadow length, since the shadow decreases from an "infinitely large" length to a minimum length, then returns to an infinite length. Let $t = 0$ correspond to 6:00 A.M. and note Daniel's observations over the 12 hr of daylight. Since the length of the shadow is measured in positive values, we need only $\frac{1}{2}$ the period of the function, giving $\frac{1}{2}P = 12$ (so $P = 24$). The period formula gives $B = \dfrac{\pi}{12}$ and the equation model is $L(t) = A\csc\left(\dfrac{\pi}{12}t\right)$. We solve for A to complete the model, using $L = 7$ when $t = 6$ (noon).

$$\begin{aligned}
L(t) &= A\csc\left(\frac{\pi}{12}t\right) && \text{equation model}\\
7 &= A\csc\left[\frac{\pi}{12}(6)\right] && \text{substitute 7 for } L \text{ and 6 for } t\\
A &= \frac{7}{\csc\left(\dfrac{\pi}{2}\right)} && \text{solve for } A;\ \frac{6\pi}{12} = \frac{\pi}{2}\\
&= \frac{7}{1} && \csc\left(\frac{\pi}{2}\right) = 1\\
&= 7 && \text{result}
\end{aligned}$$

The equation modeling the shadow length of the tree is $L(t) = 7\csc\left(\dfrac{\pi}{12}t\right)$.

b. Evaluating the model at $t = 4$ (10 A.M.) gives $L = 7\csc\left(\dfrac{\pi}{3}\right) = 7\left(\dfrac{2\sqrt{3}}{3}\right) \approx 8.08$, meaning the shadow is approximately 8 ft, 1 in. long at 10 A.M.

E. You've just seen how we can solve applications involving the tangent, cotangent, secant, and cosecant functions

Now try Exercises 67 and 68 ▶

6.5 EXERCISES

▶ CONCEPTS AND VOCABULARY

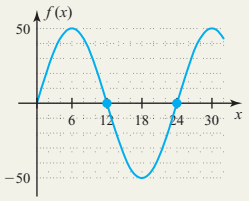
Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. A sinusoidal wave is one that can be modeled by functions of the form _____ or _____.

2. Given $h, k > 0$, the graph of $y = \sin x + k$ is the graph of $y = \sin x$ shifted _____ k units. The graph of $y = \sin(x - h)$ is the graph of $y = \sin x$ shifted _____ h units.

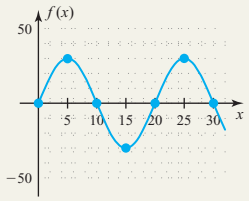
3. To find the primary interval of a sinusoidal graph, solve the inequality _____.

4. Given the period P, the frequency is _____, and given the frequency f, the value of B is _____.



5. Explain/Discuss the difference between the *standard form* of a sinusoidal equation, and the *shifted form*. How do you obtain one from the other? For what benefit?

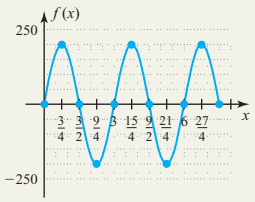
6. Write out a step-by-step procedure for sketching the graph of $y = 30 \sin\left(\frac{\pi}{2}t - \frac{1}{2}\right) + 10$. Include use of the reference rectangle, primary interval, zeroes, max/mins, and so on. Be complete and thorough.



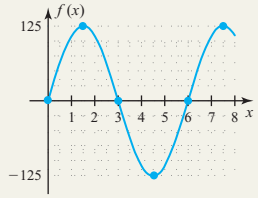
▶ DEVELOPING YOUR SKILLS

Use the graphs given to (a) state the amplitude A and period P of the function; (b) estimate the value at $x = 14$; and (c) estimate the interval in $[0, P]$ where $f(x) \geq 20$.

7.



8.



Use the graphs given to (a) state the amplitude A and period P of the function; (b) estimate the value at $x = 2$; and (c) estimate the interval in $[0, P]$, where $f(x) \leq -100$.

9.

10.

Use the information given to write a sinusoidal equation and sketch its graph. Use $B = \frac{2\pi}{P}$.

11. Max: 100, min: 20, $P = 30$

12. Max: 95, min: 40, $P = 24$

13. Max: 20, min: 4, $P = 360$

14. Max: 12,000, min: 6500, $P = 10$

Use the information given to write a sinusoidal equation, sketch its graph, and answer the question posed.

15. In Geneva, Switzerland, the daily temperature in January ranges from an average high of 39°F to an average low of 29°F. (a) Find a sinusoidal equation model for the daily temperature; (b) sketch the graph; and (c) approximate the time(s) each January day the temperature reaches the freezing point (32°F). Assume $t = 0$ corresponds to noon.

16. In Nairobi, Kenya, the daily temperature in January ranges from an average high of 77°F to an average low of 58°F. (a) Find a sinusoidal equation model for the daily temperature; (b) sketch the graph; and (c) approximate the time(s) each January day the temperature reaches a comfortable 72°F. Assume $t = 0$ corresponds to noon.

17. In Oslo, Norway, the number of hours of daylight reaches a low of 6 hr in January, and a high of nearly 18.8 hr in July. (a) Find a sinusoidal equation model for the number of daylight hours each month; (b) sketch the graph; and (c) approximate the number of *days* each year there are more than 15 hr of daylight. Use 1 month $\approx$ 30.5 days. Assume $t = 0$ corresponds to January 1.

Source: www.visitnorway.com/templates.

18. In Vancouver, British Columbia, the number of hours of daylight reaches a low of 8.3 hr in January, and a high of nearly 16.2 hr in July. (a) Find a sinusoidal equation model for the number of daylight hours each month; (b) sketch the graph; and (c) approximate the number of *days* each year there are more than 15 hr of daylight. Use 1 month $\approx$ 30.5 days. Assume $t = 0$ corresponds to January 1.

19. Recent studies seem to indicate the population of North American porcupine (*Erethizon dorsatum*) varies sinusoidally with the solar (sunspot) cycle due to its effects on Earth's ecosystems. Suppose the population of this species in a certain locality is modeled by the function $P(t) = 250\cos\left(\frac{2\pi}{11}t\right) + 950$, where $P(t)$ represents the population of porcupines in year t. Use the model to (a) find the period of the function; (b) graph the function over one period; (c) find the maximum and minimum values; and (d) estimate the number of years the population is less than 740 animals.

Source: Ilya Klvana, McGill University (Montreal), Master of Science thesis paper, November 2002.

20. The population of mosquitoes in a given area is primarily influenced by precipitation, humidity, and temperature. In tropical regions, these tend to fluctuate sinusoidally in the course of a year. Using trap counts and statistical projections, fairly accurate estimates of a mosquito population can be obtained. Suppose the population in a certain region was modeled by the function $P(t) = 50\cos\left(\frac{\pi}{26}t\right) + 950$, where $P(t)$ was the mosquito population (in thousands) in week t of the year. Use the model to (a) find the period of the function; (b) graph the function over one period; (c) find the maximum and minimum population values; and (d) estimate the number of weeks the population is less than 915,000.

21. Use a horizontal translation to shift the graph from Exercise 19 so that the average population of the North American porcupine begins at $t = 0$. Verify results on a graphing calculator, then find a sine function that gives the same graph as the shifted cosine function.

22. Use a horizontal translation to shift the graph from Exercise 20 so that the average population of mosquitoes begins at $t = 0$. Verify results on a graphing calculator, then find a sine function that gives the same graph as the shifted cosine function.

Identify the amplitude (A), period (P), horizontal shift (HS), vertical shift (VS), and endpoints of the primary interval (PI) for each function given.

23. $y = 120\sin\left[\frac{\pi}{12}(t - 6)\right]$

24. $y = 560\sin\left[\frac{\pi}{4}(t - 4)\right]$

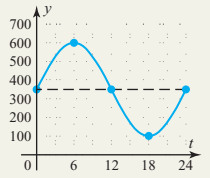
25. $h(t) = \sin\left(\frac{\pi}{6}t - \frac{\pi}{3}\right)$ **26.** $r(t) = \sin\left(\frac{\pi}{10}t - \frac{2\pi}{5}\right)$

27. $y = \sin\left(\frac{\pi}{4}t + \frac{\pi}{6}\right)$ **28.** $y = \sin\left(\frac{\pi}{3}t + \frac{5\pi}{12}\right)$

29. $f(t) = 24.5\sin\left[\frac{\pi}{10}(t - 2.5)\right] + 15.5$

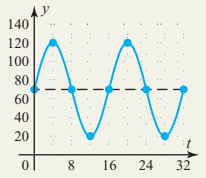
30. $g(t) = 40.6\sin\left[\frac{\pi}{6}(t - 4)\right] + 13.4$

31. $g(t) = 28\sin\left(\frac{\pi}{6}t - \frac{5\pi}{12}\right) + 92$



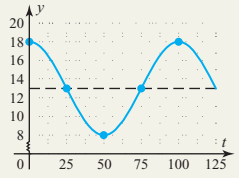
32. $f(t) = 90\sin\left(\frac{\pi}{10}t - \frac{\pi}{5}\right) + 120$

33. $y = 2500\sin\left(\frac{\pi}{4}t + \frac{\pi}{12}\right) + 3150$

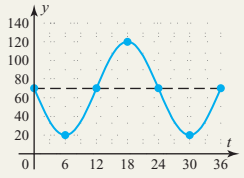


34. $y = 1450\sin\left(\frac{3\pi}{4}t + \frac{\pi}{8}\right) + 2050$

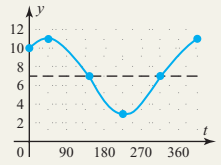
Find an equation of the graph given. Write answers in the form $y = A\sin(Bt + C) + D$ and check with a graphing calculator.



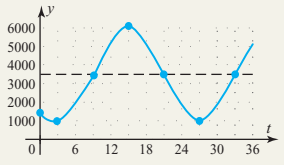
35.



36.



37.



38.

39.

40.

Sketch one complete period of each function.

41. $f(t) = 25 \sin\left[\frac{\pi}{4}(t - 2)\right] + 55$

42. $g(t) = 24.5 \sin\left[\frac{\pi}{10}(t - 2.5)\right] + 15.5$

43. $h(t) = 3 \sin(4t - \pi)$

44. $p(t) = 2 \sin\left(3t - \frac{\pi}{2}\right)$

Sketch the following functions over the indicated intervals.

45. $y = 5 \sec\left[\frac{1}{3}\left(t + \frac{3\pi}{2}\right)\right] + 2; [-3\pi, 6\pi]$

46. $y = 3 \csc\left[\frac{1}{2}(t + \pi)\right] + 1; [-2\pi, 4\pi]$

47. $y = 0.7 \csc\left(\pi t - \frac{\pi}{4}\right) - 1.2; [-1.25, 1.75]$

48. $y = 1.3 \sec\left(\frac{\pi}{3}t - \frac{\pi}{6}\right) - 1.6; [-2, 6]$

Sketch two complete periods of each function.

49. $y = 0.5 \tan\left[\frac{\pi}{4}(t + 2)\right]$

50. $y = 1.5 \cot\left[\frac{\pi}{2}(t + 1)\right]$

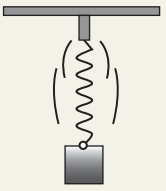
51. $y = 10 \cot(2t - 1)$

52. $y = 8 \tan(3t - 2)$

▶ WORKING WITH FORMULAS

53. The relationship between the coefficient *B*, the frequency *f*, and the period *P*

In many applications of trigonometric functions, the equation $y = A \sin(Bt)$ is written as $y = A \sin[(2\pi f)t]$, where $B = 2\pi f$. Justify the new equation using $f = \frac{1}{P}$ and $P = \frac{2\pi}{B}$. In other words, explain how $A \sin(Bt)$ becomes $A \sin[(2\pi f)t]$, as though you were trying to help another student with the ideas involved.



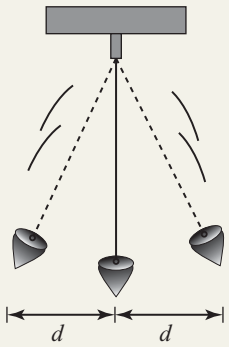
54. Number of daylight hours:

$$D(t) = \frac{K}{2} \sin\left[\frac{2\pi}{365}(t - 79)\right] + 12$$

The number of daylight hours for a particular day of the year is modeled by the formula given, where $D(t)$ is the number of daylight hours on day t of the year and K is a constant related to the total variation of daylight hours, latitude of the location, and other factors. For the city of Reykjavik, Iceland, $K \approx 17$, while for Detroit, Michigan, $K \approx 6$. How many hours of daylight will each city receive on June 30 (the 182nd day of the year)?

▶ APPLICATIONS

55. Harmonic motion: A weight on the end of a spring is oscillating in harmonic motion. The equation model for the oscillations is $d(t) = 6 \sin\left(\frac{\pi}{2}t\right)$, where d is the distance (in centimeters) from the equilibrium point in t sec.



a. What is the period of the motion? What is the frequency of the motion?

b. What is the displacement from equilibrium at $t = 2.5$? Is the weight moving toward the equilibrium point or away from equilibrium at this time?

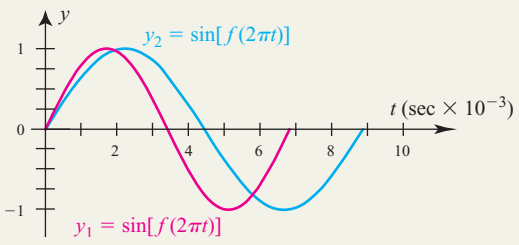
c. What is the displacement from equilibrium at $t = 3.5$? Is the weight moving toward the equilibrium point or away from equilibrium at this time?

d. How far does the weight move between $t = 1$ and $t = 1.5$ sec? What is the average velocity for this interval? Do you expect a greater or lesser velocity for $t = 1.75$ to $t = 2$? Explain why.

56. Harmonic motion: The bob on the end of a 24-in. pendulum is oscillating in harmonic motion. The equation model for the oscillations is $d(t) = 20\cos(4t)$, where d is the distance (in inches) from the equilibrium point, t sec after being released from one side.

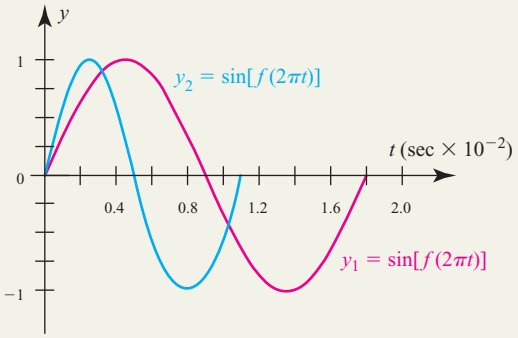
a. What is the period of the motion? What is the frequency of the motion?

b. What is the displacement from equilibrium at $t = 0.25$ sec? Is the weight moving toward the equilibrium point or away from equilibrium at this time?



c. What is the displacement from equilibrium at $t = 1.3$ sec? Is the weight moving toward the equilibrium point or away from equilibrium at this time?

d. How far does the bob move between $t = 0.25$ and $t = 0.35$ sec? What is its average velocity for this interval? Do you expect a greater velocity for the interval $t = 0.55$ to $t = 0.6$? Explain why.



57. Harmonic motion: A simple pendulum 36 in. in length is oscillating in harmonic motion. The bob at the end of the pendulum swings through an arc of 30 in. (from the far left to the far right, or one-half cycle) in about 0.8 sec. What is the equation model for this harmonic motion?

58. Harmonic motion: As part of a study of wave motion, the motion of a float is observed as a series of uniform ripples of water move beneath it. By careful observation, it is noted that the float bobs up and down through a distance of 2.5 cm every $\frac{1}{3}$ sec. What is the equation model for this harmonic motion?

59. Sound waves: Two of the musical notes from the chart on page 586 are graphed in the figure. Use the graphs given to determine which two.

60. Sound waves: Two chromatic notes *not on the chart from page* 586 are graphed in the figure. Use the graphs and the discussion regarding octaves to determine which two. Note the scale of the t-axis *has been changed* to hundredths of a second.

Sound waves: Use the chart on page 586 to write the equation for each note in the form $y = \sin[f(2\pi t)]$ and clearly state the period of each note.

61. notes D_2 and G_3 **62.** the notes A_4 and C_2

Tangent function data models: Model the data in Exercises 63 and 64 using the function $y = A\tan(Bx)$. State the period of the function, the location of the asymptotes, the value of A, and name the point (x, y) used to calculate A (answers may vary). Use your equation model to evaluate the function at $x = -2$ and $x = 2$. What observations can you make? Also see Exercise 73.

65. As part of a lab setup, a laser pen is made to swivel on a large protractor as illustrated in the figure. For their lab project, students are asked to take the instrument to one end of a long hallway and measure the distance of the projected beam relative to the angle the pen is being held, and collect the data in a table. Use the data to find a function of the form $y = A\tan(B\theta)$. State the period of the function, the location of the asymptotes, the value of A, and name the point (θ, y) you used to calculate A (answers may vary). Based on the result, can you approximate the length of the laser pen? Note that in degrees, the period formula for tangent is $P = \dfrac{180°}{B}$.

Exercise 65

89	687.5

66. Use the equation model obtained in Exercise 65 to compare the values given by the equation with the actual data. As a percentage, what was the largest deviation between the two?

67. Shadow length: At high noon, a flagpole in Oslo, Norway, casts a 10-m-long shadow during the month of January. Using information from Exercise 17, (a) find a cosecant function that models the shadow length, and (b) use the model to find the length of the shadow at 2:00 P.M.

68. Shadow length: At high noon, the "Living Shangri-La" skyscraper in Vancouver, British Columbia, casts a 15-m-long shadow during the month of June. Given there are 16 hr of daylight that month, (a) find a cosecant function that models the shadow length, and (b) use the model to find the length of the shadow at 7:30 A.M.

Daylight hours model: Solve using a graphing calculator and the formula given in Exercise 54.

69. For the city of Caracas, Venezuela, $K \approx 1.3$, while for Tokyo, Japan, $K \approx 4.8$.

- **a.** How many hours of daylight will each city receive on January 15th (the 15th day of the year)?
- **b.** Graph the equations modeling the hours of daylight on the same screen. Then determine (i) what days of the year these two cities will have the same number of hours of daylight, and (ii) the number of days each year that each city receives 11.5 hr or less of daylight.

70. For the city of Houston, Texas, $K \approx 3.8$, while for Pocatello, Idaho, $K \approx 6.2$.

- **a.** How many hours of daylight will each city receive on December 15 (the 349th day of the year)?
- **b.** Graph the equations modeling the hours of daylight on the same screen. Then determine (i) how many days each year Pocatello receives more daylight than Houston, and (ii) the number of days each year that each city receives 13.5 hr or more of daylight.

▶ EXTENDING THE CONCEPT

71. The formulas we use in mathematics can sometimes seem very mysterious. We know they "work," and we can graph and evaluate them—but where did they come from? Consider the formula for the number of daylight hours from Exercise 54:

$$D(t) = \frac{K}{2}\sin\left[\frac{2\pi}{365}(t - 79)\right] + 12.$$

- **a.** We know that the addition of 12 represents a vertical shift, but what does a vertical shift of 12 mean *in this context*?
- **b.** We also know the factor $(t - 79)$ represents a phase shift of 79 to the right. But what does a horizontal (phase) shift of 79 mean *in this context*?
- **c.** Finally, the coefficient $\dfrac{K}{2}$ represents a change in amplitude, but what does a change of amplitude mean *in this context*? Why is the coefficient bigger for the northern latitudes?

72. Use a graphing calculator to graph the equation

$$f(x) = \frac{3x}{2} - 2\sin(2x) - 1.5.$$

a. Determine the interval between each peak of the graph. What do you notice?

b. Graph $g(x) = \frac{3x}{2} - 1.5$ on the same screen and comment on what you observe.

c. What would the graph of

$$f(x) = -\frac{3x}{2} + 2\sin(2x) + 1.5$$ look like? What is the x-intercept?

73. Rework Exercises 63 and 64, obtaining a new equation for the data using a different ordered pair to compute the value of A. What do you notice? Try yet another ordered pair and calculate A once again for another equation Y_2. Complete a table of values using the given inputs, with the outputs of the three equations generated (original, Y_1, and Y_2). Does any one equation seem to model the data better than the others? Are all of the equation models "acceptable"? Please comment.

74. Regarding Example 10, we can use the standard distance/rate/time formula $D = RT$ to compute the average velocity of the beam of light along the wall in any interval of time: $R = \frac{D}{T}$. For example, using $D(t) = 5\tan\left(\frac{\pi}{8}t\right)$, the average velocity in the interval $[0, 2]$ is $\frac{D(2) - D(0)}{2 - 0} = 2.5$ m/sec. Calculate the average velocity of the beam in the time intervals $[2, 3]$, $[3, 3.5]$, and $[3.5, 3.8]$ sec. What do you notice? How would the average velocity of the beam in the interval $[3.9, 3.99]$ sec compare?

▶ MAINTAINING YOUR SKILLS

75. (6.1) In what quadrant does the arc $t = 3.7$ terminate? What is the reference arc?

76. (3.2) Given $f(x) = -3(x + 1)^2 - 4$, name the vertex and solve the inequality $f(x) > 0$.

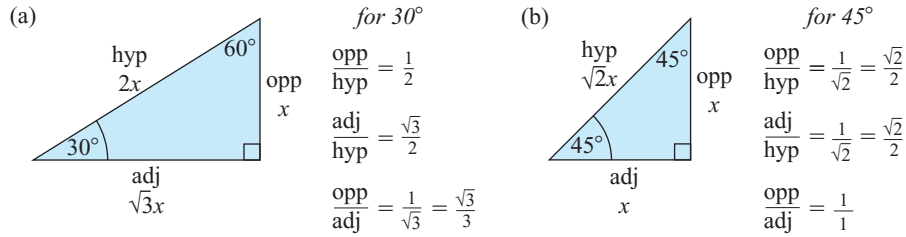
77. (3.1) Compute the sum, difference, product, and quotient of $-1 + i\sqrt{5}$ and $-1 - i\sqrt{5}$.

78. (6.3/6.4) Sketch the graph of (a) $y = \cos t$ in the interval $[0, 2\pi)$ and (b) $y = \tan t$ in the interval $\left(-\frac{\pi}{2}, \frac{3\pi}{2}\right)$.

6.6 The Trigonometry of Right Triangles

LEARNING OBJECTIVES

In Section 6.6 you will see how we can:



- ❑ **A.** Find values of the six trigonometric functions from their ratio definitions
- ❑ **B.** Solve a right triangle given one angle and one side
- ❑ **C.** Solve a right triangle given two sides
- ❑ **D.** Use cofunctions and complements to write equivalent expressions
- ❑ **E.** Solve applications of right triangles

Over a long period of time, what began as a study of chord lengths by Hipparchus, Ptolemy, Aryabhata, and others became a systematic application of the ratios of the sides of a right triangle. In this section, we develop the sine, cosine, and tangent functions from a right triangle perspective, and explore certain relationships that exist between them. This view of the trig functions also leads to a number of significant applications.

A. Trigonometric Ratios and Their Values

In Section 6.1, we looked at applications involving 45-45-90 and 30-60-90 triangles, using the fixed ratios that exist between their sides. To apply this concept more generally using other right triangles, each side is given a specific name using its location relative to a specified angle. For the 30-60-90 triangle in Figure 6.116(a), the side **opposite (opp)** and the side **adjacent (adj)** are named with respect to the 30° angle, with the **hypotenuse (hyp)** always across from the right angle. Likewise for the 45-45-90 triangle in Figure 6.116(b).

Figure 6.116

Using these designations to define the various trig ratios, we can now develop a systematic method for applying them. Note that the x's "cancel" in each ratio, reminding us the ratios are independent of the triangle's size (if two triangles are similar, the ratio of corresponding sides is constant).

Ancient mathematicians were able to find values for the ratios corresponding to *any acute angle* in a right triangle, and realized that *naming* each ratio would be helpful. These names are $\frac{\text{opp}}{\text{hyp}} \rightarrow$ **sine,** $\frac{\text{adj}}{\text{hyp}} \rightarrow$ **cosine,** and $\frac{\text{opp}}{\text{adj}} \rightarrow$ **tangent.** Since each ratio depends on the measure of an acute angle θ, they are often referred to as **functions of an acute angle** and written in function form.

$$\text{sine } \theta = \frac{\text{opp}}{\text{hyp}} \qquad \text{cosine } \theta = \frac{\text{adj}}{\text{hyp}} \qquad \text{tangent } \theta = \frac{\text{opp}}{\text{adj}}$$

The reciprocal of these ratios, for example, $\frac{\text{hyp}}{\text{opp}}$ instead of $\frac{\text{opp}}{\text{hyp}}$, also play a significant role in this view of trigonometry, and are likewise given names:

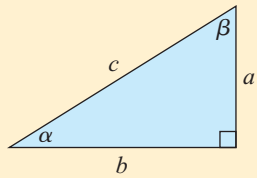
$$\text{cosecant } \theta = \frac{\text{hyp}}{\text{opp}} \qquad \text{secant } \theta = \frac{\text{hyp}}{\text{adj}} \qquad \text{cotangent } \theta = \frac{\text{adj}}{\text{opp}}$$

The definitions hold regardless of the triangle's orientation or which of the acute angles is used.

As before, each function name is written in abbreviated form as $\sin\theta$, $\cos\theta$, $\tan\theta$, $\csc\theta$, $\sec\theta$, and $\cot\theta$ respectively. Note that based on these designations, we have the following reciprocal relationships:

$$\sin\theta = \frac{1}{\csc\theta} \qquad \cos\theta = \frac{1}{\sec\theta} \qquad \tan\theta = \frac{1}{\cot\theta}$$

$$\csc\theta = \frac{1}{\sin\theta} \qquad \sec\theta = \frac{1}{\cos\theta} \qquad \cot\theta = \frac{1}{\tan\theta}$$



WORTHY OF NOTE

Over the years, a number of memory tools have been invented to help students recall these ratios correctly. One such tool is the acronym SOH CAH TOA, from the first letter of the function and the corresponding ratio. It is often recited as, "Sit On a Horse, Canter Away Hurriedly, To Other Adventures." Try making up a memory tool of your own.

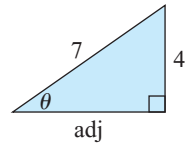
In general:

Trigonometric Functions of an Acute Angle

$$\sin\alpha = \frac{a}{c} \qquad \cos\alpha = \frac{b}{c} \qquad \tan\alpha = \frac{a}{b}$$

$$\sin\beta = \frac{b}{c} \qquad \cos\beta = \frac{a}{c} \qquad \tan\beta = \frac{b}{a}$$

Now that these ratios have been formally named, we can state values of all six functions given sufficient information about a right triangle.



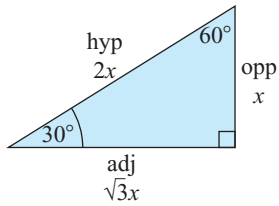
EXAMPLE 1 ▶ **Finding Function Values Using a Right Triangle**

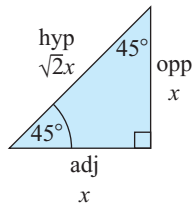
Given $\sin\theta = \frac{4}{7}$, find the values of the remaining trig functions.

Solution ▶ For $\sin\theta = \frac{4}{7} = \frac{\text{opp}}{\text{hyp}}$, we draw a triangle with a side of 4 units opposite a designated angle θ, and label a hypotenuse of 7 (see the figure). Using the Pythagorean theorem we find the length of the adjacent side: $\text{adj} = \sqrt{7^2 - 4^2} = \sqrt{33}$. The ratios are

$$\sin\theta = \frac{4}{7} \quad \cos\theta = \frac{\sqrt{33}}{7} \quad \tan\theta = \frac{4}{\sqrt{33}}$$

$$\csc\theta = \frac{7}{4} \quad \sec\theta = \frac{7}{\sqrt{33}} \quad \cot\theta = \frac{\sqrt{33}}{4}$$





Now try Exercises 7 through 12 ▶

A. You've just seen how we can find values of the six trigonometric functions from their ratio definitions

Note that due to the properties of similar triangles, identical results would be obtained using any ratio of sides that is equal to $\frac{4}{7}$. In other words, $\frac{2}{3.5} = \frac{4}{7} = \frac{8}{14} = \frac{16}{28}$ and so on, will all give the same value for $\sin\theta$.

B. Solving Right Triangles Given One Angle and One Side

Example 1 gave values of the trig functions for an *unknown angle* θ. Using the special triangles, we can state the value of each trig function for 30°, 45°, and 60° based on the related ratio (see Table 6.10). These values are used extensively in a study of trigonometry and must be committed to memory.

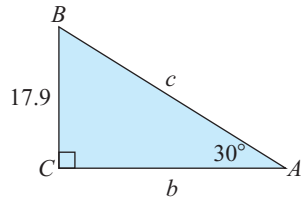
Table 6.10

θ	$\sin\theta$	$\cos\theta$	$\tan\theta$	$\csc\theta$	$\sec\theta$	$\cot\theta$
30°	$\frac{1}{2}$	$\frac{\sqrt{3}}{2}$	$\frac{1}{\sqrt{3}} = \frac{\sqrt{3}}{3}$	2	$\frac{2}{\sqrt{3}} = \frac{2\sqrt{3}}{3}$	$\sqrt{3}$
45°	$\frac{\sqrt{2}}{2}$	$\frac{\sqrt{2}}{2}$	1	$\sqrt{2}$	$\sqrt{2}$	1
60°	$\frac{\sqrt{3}}{2}$	$\frac{1}{2}$	$\sqrt{3}$	$\frac{2}{\sqrt{3}} = \frac{2\sqrt{3}}{3}$	2	$\frac{1}{\sqrt{3}} = \frac{\sqrt{3}}{3}$

To **solve a right triangle** means to find the measure of all three angles and all three sides. This is accomplished using a combination of the Pythagorean theorem, the properties of triangles, and the trigonometric ratios. We will adopt the convention of naming each angle with a capital letter at the vertex or using a Greek letter on the interior. Each side is labeled using the related lowercase letter from the angle opposite. The complete solution should be organized in table form as in Example 2. Note the quantities shown in **bold** were given, and the remaining values were found using the relationships mentioned.

EXAMPLE 2 ▶ Solving a Right Triangle

Solve the triangle shown in the figure.



Solution ▶ Applying the sine ratio (since the side opposite 30° is given), we have: $\sin 30° = \frac{\text{opp}}{\text{hyp}}$.

$$\sin 30° = \frac{17.9}{c} \qquad \sin 30° = \frac{\text{opposite}}{\text{hypotenuse}}$$

$$c \sin 30° = 17.9 \qquad \text{multiply by } c$$

$$c = \frac{17.9}{\sin 30°} \qquad \text{divide by } \sin 30° = \frac{1}{2}$$

$$= 35.8 \qquad \text{result}$$

Using the Pythagorean theorem shows $b \approx 31$, and since $\angle A$ and $\angle B$ are complements, $B = 60°$. Note the results would have been identical if the special ratios from the 30-60-90 triangle were applied. The hypotenuse is twice the shorter side: $c = 2(17.9) = 35.8$, and the longer side is $\sqrt{3}$ times the shorter: $b = 17.9(\sqrt{3}) \approx 31$.

Angles	Sides
$A = 30°$	$a = 17.9$
$B = 60°$	$b \approx 31$
$C = 90°$	$c = 35.8$

Now try Exercises 13 through 16 ▶

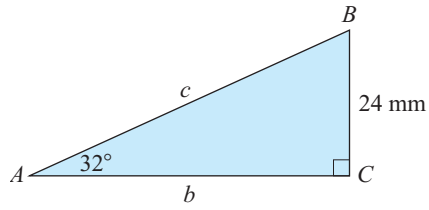
Prior to the widespread availability of handheld calculators, tables of values were used to find $\sin\theta$, $\cos\theta$, and $\tan\theta$ for nonstandard angles. Table 6.11 shows the sine of 49° 30′ is approximately 0.7604.

Table 6.11
sin θ

θ	0′	10′	20′	30′
45°	0.7071	0.7092	0.7112	0.7133
46	0.7193	0.7214	0.7234	0.7254
47	0.7314	0.7333	0.7353	0.7373
48	0.7431	0.7451	0.7470	0.7490
49	0.7547	0.7566	0.7585	0.7604

Today these trig values are programmed into your calculator and we can retrieve them with the push of a button (or two). To find the sine of 49° 30′, recall the degree and minute symbols are often found in the 2nd APPS **(ANGLE)** menu. A calculator in degree MODE can produce the screen shown in Figure 6.117 and provide an even more accurate approximation of sin 49° 30′ than the table.

Figure 6.117



EXAMPLE 3 ▶ **Solving a Right Triangle**

Solve the triangle shown in the figure.

Solution ▶ We know $\angle B = 58°$ since A and B are complements (Figure 6.118). We can find length b using the tangent function:

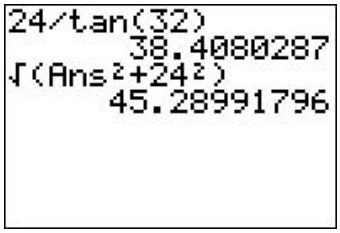


Figure 6.118

$$\begin{aligned} \tan 32° &= \frac{24}{b} && \tan 32° = \frac{\text{opp}}{\text{adj}} \\ b \tan 32° &= 24 && \text{multiply by } b \\ b &= \frac{24}{\tan 32°} && \text{divide by } \tan 32° \\ &\approx 38.41 \text{ mm} && \text{result} \end{aligned}$$

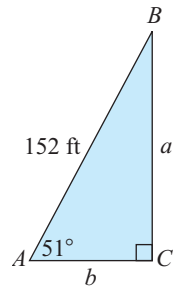
We can find the length c by simply applying the Pythagorean theorem, as shown in the third line of Figure 6.119. Alternatively, we could find c by using another trig ratio and a known angle.

Figure 6.119

$$\begin{aligned} \text{For side } c\text{:}\quad \sin 32° &= \frac{24}{c} && \sin 32° = \frac{\text{opp}}{\text{hyp}} \\ c \sin 32° &= 24 && \text{multiply by } c \\ c &= \frac{24}{\sin 32°} && \text{divide by } \sin 32° \\ &\approx 45.29 \text{ mm} && \text{result} \end{aligned}$$

The complete solution is shown in the table.

Angles	Sides
$A = 32°$	$a = 24$
$B = 58°$	$b \approx 38.41$
$C = 90°$	$c \approx 45.29$



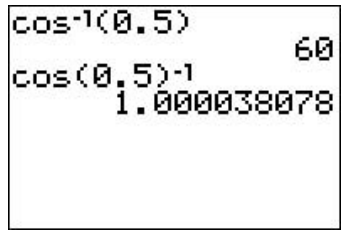
Now try Exercises 17 through 22 ▶

When solving a right triangle, any combination of the known triangle relationships can be employed:

1. The angles in a triangle must sum to 180°: $A + B + C = 180°$.
2. The sides of a right triangle are related by the Pythagorean theorem: $a^2 + b^2 = c^2$.
3. The 30-60-90 and 45-45-90 special triangles.
4. The six trigonometric functions of an acute angle.

However, the resulting equation must have only one unknown or it cannot be used. For the triangle shown in Figure 6.120, we cannot begin with the Pythagorean theorem since sides a and b are unknown, and $\tan 51°$ is unusable for the same reason. Since the hypotenuse is given, we could begin with $\cos 51° = \frac{b}{152}$ and solve for b, or with $\sin 51° = \frac{a}{152}$ and solve for a, then work out a complete solution. Verify that $a \approx 118.13$ ft and $b \approx 95.66$ ft.

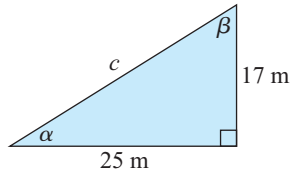
Figure 6.120



☑ **B.** You've just seen how we can solve a right triangle given one angle and one side

C. Solving Right Triangles Given Two Sides

In Section 6.2, we used our experience with the special values to find an angle given only the value of a trigonometric function. Unfortunately, if we did not have (or recognize) a special value, we could not determine the angle. In times past, the partial table for $\sin\theta$ given earlier was also used to find an angle whose sine was known, meaning if $\sin\theta \approx 0.7604$, then θ must be 49.5° (see the last line of Table 6.11). The modern



notation for "an angle whose sine is known" is $\theta = \sin^{-1}x$ or $\theta = \arcsin x$, where x is the known value for $\sin\theta$. The values for the acute angles $\theta = \sin^{-1}x$, $\theta = \cos^{-1}x$, and $\theta = \tan^{-1}x$ are also programmed into your calculator and are generally accessed using the 2nd key with the related SIN, COS, or TAN key. With these we are completely equipped to find all six measures of a right triangle, given at least one side and any two other measures.

CAUTION ▶ When working with the inverse trig functions, be sure to use the inverse trig keys, and not the reciprocal key x^{-1}. For instance, using special triangles, $\cos^{-1}(0.5) = 60°$. Compare this with $[\cos(0.5)]^{-1} = \dfrac{1}{\cos 0.5} = \sec 0.5$. Both calculations are done in degree MODE and shown in the figure.

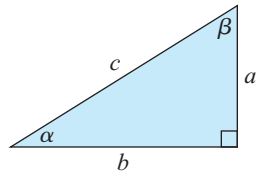
EXAMPLE 4 ▶ **Solving a Right Triangle**

Solve the triangle given in the figure.

Solution ▶ Since the hypotenuse is unknown, we cannot begin with the sine or cosine ratios. The opposite and adjacent sides for α *are* known, so we use $\tan\alpha$. For $\tan\alpha = \dfrac{17}{25}$ we find $\alpha = \tan^{-1}\left(\dfrac{17}{25}\right) \approx 34.2°$ [verify that $\tan(34.2°) \approx 0.6795992982 \approx \dfrac{17}{25}$]. Since α and β are complements, $\beta \approx 90° - 34.2° = 55.8°$. The Pythagorean theorem shows the hypotenuse is about 30.23 m (verify).

Angles	Sides
$\alpha \approx 34.2°$	$a = 17$
$\beta \approx 55.8°$	$b = 25$
$\gamma = 90°$	$c \approx 30.23$

C. You've just seen how we can solve a right triangle given two sides



Now try Exercises 23 through 54 ▶

D. Using Cofunctions and Complements to Write Equivalent Expressions

WORTHY OF NOTE

The word *cosine* is actually a shortened form of the words "*complement of sine*," a designation suggested by Edmund Gunter around 1620 since the sine of an angle is equal to the cosine of its complement [sine(θ) = cosine($90° - \theta$)].

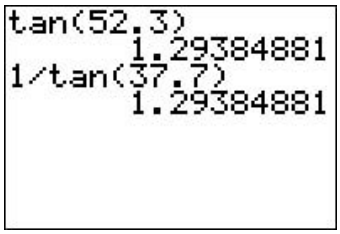


Figure 6.121

For the right triangle in Figure 6.121, $\angle\alpha$ and $\angle\beta$ are complements since the sum of the three angles must be 180°. The complementary angles in a right triangle have a unique relationship that is often used. Specifically, since $\alpha + \beta = 90°$, $\beta = 90° - \alpha$. Note that $\sin\alpha = \dfrac{a}{c}$ and $\cos\beta = \dfrac{a}{c}$. This means $\sin\alpha = \cos\beta$ or $\sin\alpha = \cos(90° - \alpha)$ by substitution. In words, "The sine of an angle is equal to the cosine of its complement." For this reason sine and cosine are called **cofunctions** (hence the name **co**sine), as are secant/cosecant, and tangent/cotangent. As a test, we use a calculator to check the statement $\sin 52.3° = \cos(90° - 52.3°)$

$$\sin 52.3° \stackrel{?}{=} \cos 37.7°$$
$$0.791223533 = 0.791223533 \checkmark$$

Figure 6.122

To verify the cofunction relationship for sec θ and csc θ, recall their reciprocal relationship to cosine and sine, respectively.

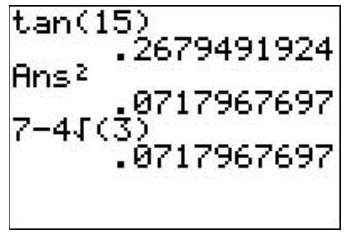
$$\sec 52.3^\circ \stackrel{?}{=} \csc 37.7^\circ$$
$$\frac{1}{\cos 52.3^\circ} \stackrel{?}{=} \frac{1}{\sin 37.7^\circ}$$
$$1.635250666 = 1.635250666 \checkmark$$

The cofunction relationship for tan θ and cot θ is similarly verified in Figure 6.122.

Summary of Cofunctions

sine and cosine	tangent and cotangent	secant and cosecant
$\sin\theta = \cos(90^\circ - \theta)$	$\tan\theta = \cot(90^\circ - \theta)$	$\sec\theta = \csc(90^\circ - \theta)$
$\cos\theta = \sin(90^\circ - \theta)$	$\cot\theta = \tan(90^\circ - \theta)$	$\csc\theta = \sec(90^\circ - \theta)$

For use in Example 5 and elsewhere in the text, note the expression $\tan^2 15^\circ$ is simply a more convenient way of writing $(\tan 15^\circ)^2$.



EXAMPLE 5 ▶ **Applying the Cofunction Relationship**

Given $\cot 75^\circ = 2 - \sqrt{3}$ in exact form, find the exact value of $\tan^2 15^\circ$ using a cofunction. Check the result using a calculator.

Solution ▶ Using $\cot 75^\circ = \tan(90^\circ - 75^\circ) = \tan 15^\circ$ gives

$$\begin{aligned} \tan^2 15^\circ &= \cot^2 75^\circ && \text{cofunction; square both sides} \\ &= (2 - \sqrt{3})^2 && \text{substitute known value} \\ &= 4 - 4\sqrt{3} + 3 && \text{square as indicated} \\ &= 7 - 4\sqrt{3} && \text{result} \end{aligned}$$

Check ▶ To clearly calculate the square of the tangent, note we first evaluate tan 15° and then square the **Ans**wer. As the screen shows, the approximate forms of $\tan^2 15^\circ$ and $7 - 4\sqrt{3}$ are equal. ✓

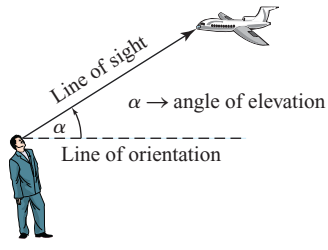
Now try Exercises 55 through 68 ▶

☑ **D.** You've just seen how we can use cofunctions and complements to write equivalent expressions

E. Applications of Right Triangles

While the name seems self-descriptive, in more formal terms an **angle of elevation** is defined to be the acute angle formed by a **horizontal line of orientation** (parallel to level ground) and the line of sight (see Figure 6.123). An **angle of depression** is likewise defined but involves a line of sight that is below the horizontal line of orientation (Figure 6.124).

Figure 6.123



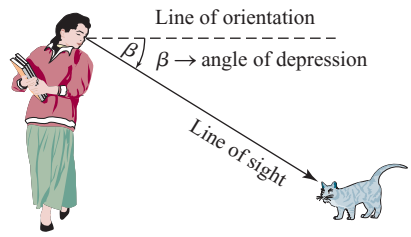


Figure 6.124

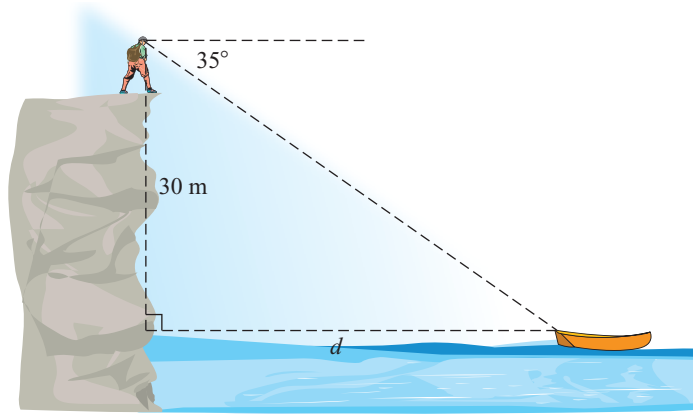
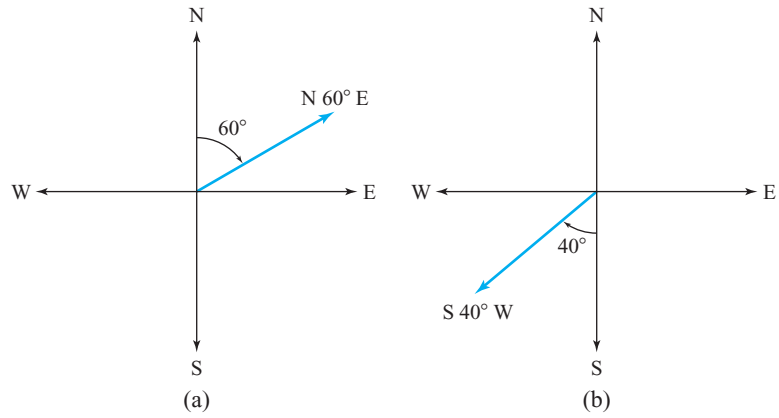


Angles of elevation and depression make distance and length computations of all sizes a relatively easy matter and are extensively used by surveyors, engineers, astronomers, and even the casual observer who is familiar with the basics of trigonometry.

EXAMPLE 6 ▶ Applying Angles of Depression

From the edge of the Perito Moreno glaciar in Patagonia, Argentina, Gary notices a kayak on the lake 30 m below. If the angle of depression at that point is 35°, what is the distance d from the kayak to the glacier?

Solution ▶ From the diagram, we note that d is the side opposite a 55° angle (the complement of the 35° angle). Since the adjacent side is known, we use the tangent function to solve for d.



$$\tan 55° = \frac{d}{30} \quad \tan 55° = \frac{\text{opp}}{\text{adj}}$$
$$30 \tan 55° = d \quad \text{multiply by 30 (exact form)}$$
$$42.8 \approx d \quad \text{result (approximate form)}$$

The kayak is approximately 42.8 m (141 ft) from the glacier.

Now try Exercises 71 through 74 ▶

Closely related to angles of elevation/depression are acute angles of *rotation* from a fixed line of orientation to a fixed line of sight. In this case, the movement is simply horizontal rather than vertical. Land surveyors use a special type of measure called **bearings,** where they indicate the acute angle the line of sight makes with a due north or due south line of reference. For instance, Figure 6.125(a) shows a bearing of N 60° E and Figure 6.125(b) shows a bearing of S 40° W.

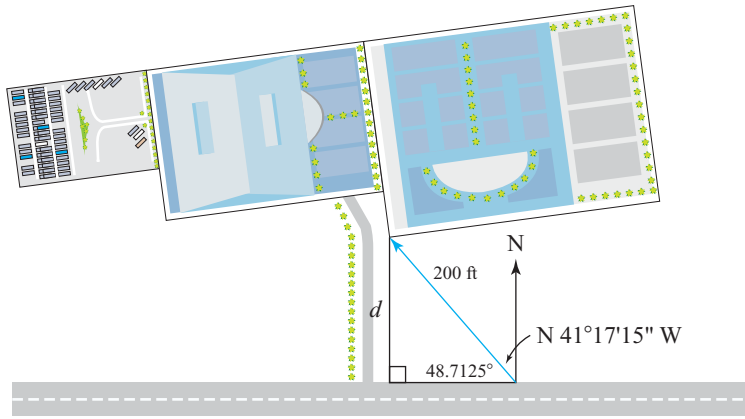


Figure 6.125

EXAMPLE 7 ▶ **Applying Angles of Rotation**

A city building code requires a new shopping complex to be built at least 150 ft from an avenue that runs due east and west. Using a modern theodolite set up on the avenue, a surveyor finds the tip of the shopping complex closest to the avenue lies 200 ft away on a bearing of N 41°17′15″ W. How far from the avenue is this tip of the building?

Solution ▶ To find the distance d, we first convert the given angle to decimal degrees, then find its complement. For 41° 17′ 15″ we have $[41 + 17(1/60) + (15/3600)]° = 41.2875°$. The complement of this angle is $90° - 41.2875° = 48.7125°$. Since we need the side opposite this angle and the hypotenuse is known, we use a sine function to solve for d.

$$\sin 48.7125° = \frac{d}{200} \qquad \sin 48.7125° = \frac{\text{opp}}{\text{hyp}}$$

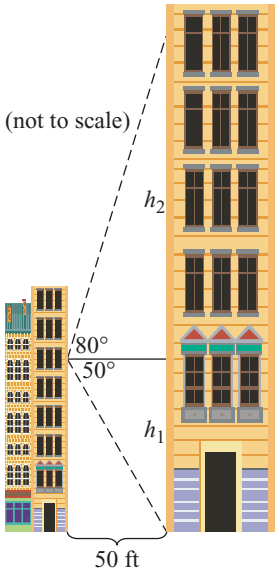
$$200 \sin 48.7125° = d \qquad \text{multiply by 200 (exact form)}$$

$$150.28 \approx d \qquad \text{result (approximate form)}$$

The shopping complex is approximately 150.28 ft from the avenue, just barely in compliance with the city code.

Now try Exercises 75 and 76 ▶

In their widest and most beneficial use, the trig functions of acute angles are used with other problem-solving skills, such as drawing a diagram, labeling unknowns, working the solution out in stages, and so on. Example 8 serves to illustrate some of these combinations.



EXAMPLE 8 ▶ **Applying Angles of Elevation and Depression**

From his hotel room window on the sixth floor, Singh notices some window washers high above him on the hotel across the street. Curious as to their height above ground, he quickly estimates the buildings are 50 ft apart, the angle of elevation to the workers is about 80°, and the angle of depression to the base of the hotel is about 50°.

a. How high above ground is the window of Singh's hotel room?

b. How high above ground are the workers?

Solution ▶

a. Begin by drawing a diagram of the situation (see figure). To find the height of the window we'll use the tangent ratio, since the adjacent side of the angle is known, and the opposite side is the height we desire.

For the height h_1:

$$\tan 50° = \frac{h_1}{50} \qquad \tan 50° = \frac{\text{opp}}{\text{adj}}$$

$$50 \tan 50° = h_1 \qquad \text{solve for } h_1$$

$$59.6 \approx h_1 \qquad \text{result } (\tan 50° \approx 1.1918)$$

The window is approximately 59.6 ft above ground.

b. For the height h_2:

$$\tan 80° = \frac{h_2}{50} \qquad \tan 80° = \frac{\text{opp}}{\text{adj}}$$

$$50 \tan 80° = h_2 \qquad \text{solve for } h_2$$

$$283.6 \approx h_2 \qquad \text{result } (\tan 80° \approx 5.6713)$$

The workers are approximately $283.6 + 59.6 = 343.2$ ft above ground.

Now try Exercises 77 through 80 ▶

There are a number of additional interesting applications in the Exercise Set.

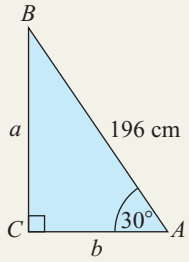
E. You've just seen how we can solve applications of right triangles

6.6 EXERCISES

▶ CONCEPTS AND VOCABULARY

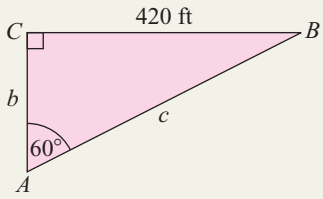
Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. The phrase, "an angle whose tangent is known," is written notationally as _____.
2. Given $\sin\theta = \frac{7}{24}$, $\csc\theta =$ _____ because they are _____.
3. The sine of an angle is the ratio of the _____ side to the _____.
4. The cosine of an angle is the ratio of the _____ side to the _____.
5. Discuss/Explain exactly what is meant when you are asked to "solve a triangle." Include an illustrative example.
6. Given an acute angle and the length of the adjacent leg, which four (of the six) trig functions could be used to begin solving the triangle?



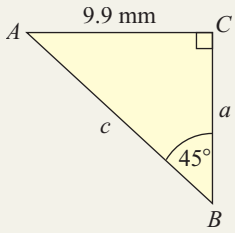
▶ DEVELOPING YOUR SKILLS

Use the function value given to determine the values of the other five trig functions of the acute angle θ. Answer in exact form (a diagram will help).

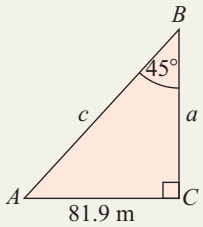


7. $\cos\theta = \frac{5}{13}$
8. $\sin\theta = \frac{20}{29}$
9. $\tan\theta = \frac{84}{13}$
10. $\sec\theta = \frac{53}{45}$
11. $\cot\theta = \frac{2}{11}$
12. $\cos\theta = \frac{2}{3}$

Solve each triangle using trig functions of an acute angle θ. Give a complete answer (in table form) using exact values.

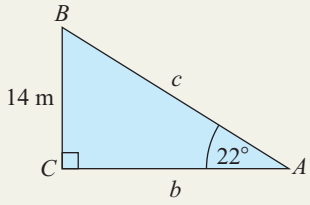


13.

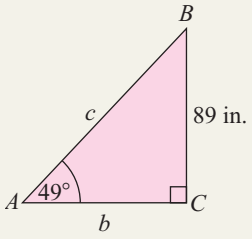


14.

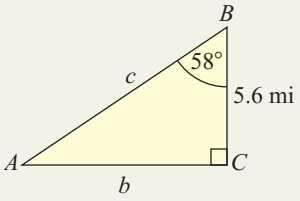
15.



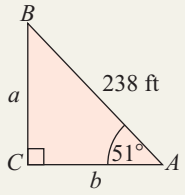
16.



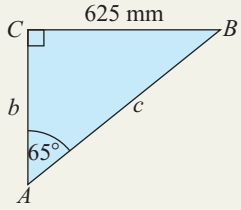
Solve the triangles shown and write answers in table form. Round sides to the nearest 100th of a unit. Verify that angles sum to 180° and that the three sides satisfy (approximately) the Pythagorean theorem.



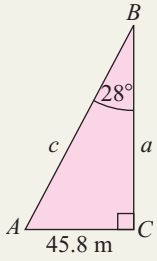
17.



18.



19.



20.

21.

22.

Use a calculator to find the value of each expression, rounded to four decimal places.

23. sin 27°

24. cos 72°

25. tan 40°

26. cot 57.3°

27. sec 40.9°

28. csc 39°

29. sin 65°

30. tan 84.1°

Use a calculator to find the acute angle whose corresponding ratio is given. Round to the nearest 10th of a degree. For Exercises 31 through 38, use Exercises 23 through 30 to answer.

31. $\sin A = 0.4540$

32. $\cos B = 0.3090$

33. $\tan \theta = 0.8391$

34. $\cot A = 0.6420$

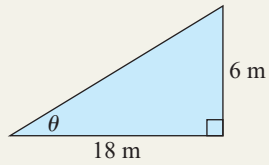
35. $\sec B = 1.3230$

36. $\csc \beta = 1.5890$

37. $\sin A = 0.9063$

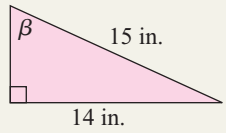
38. $\tan B = 9.6768$

39. $\tan \alpha = 0.9896$



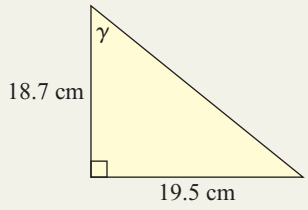
40. $\cos \alpha = 0.7408$

41. $\sin \alpha = 0.3453$

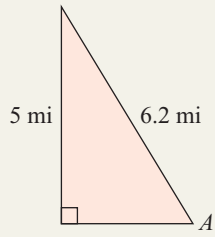


42. $\tan \alpha = 3.1336$

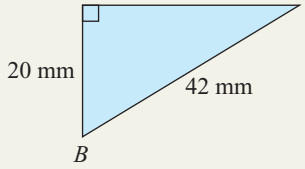
Select an appropriate function to find the angle indicated (round to 10ths of a degree).



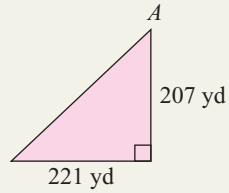
43.



44.

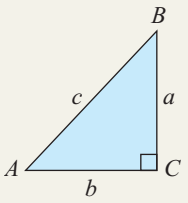


45.



46.

47.



48.

Draw a right triangle ABC as shown, using the information given. Then select an appropriate ratio to find the side indicated. Round to the nearest 100th.

Exercises 49 to 54

49. $\angle A = 25°$
$c = 52$ mm
find side a

50. $\angle B = 55°$
$b = 31$ ft
find side c

51. $\angle A = 32°$
$a = 1.9$ mi
find side b

52. $\angle B = 29.6°$
$c = 9.5$ yd
find side a

53. $\angle A = 62.3°$
$b = 82.5$ furlongs
find side c

54. $\angle B = 12.5°$
$a = 32.8$ km
find side b

Use a calculator to evaluate each pair of functions and comment on what you notice.

55. sin 25°, cos 65°

56. sin 57°, cos 33°

57. tan 5°, cot 85°

58. sec 40°, csc 50°

Based on your observations in Exercises 55 to 58, fill in the blank so that the functions given are equal.

59. sin 47°, cos ___

60. cos ___, sin 12°

61. cot 69°, tan ___

62. csc 17°, sec ___

Complete the following tables without referring to the text or using a calculator.

63.

$\theta = 30°$	sin θ	cos θ	tan θ	sin(90° − θ)
cos(90° − θ)	tan(90° − θ)	csc θ	sec θ	cot θ

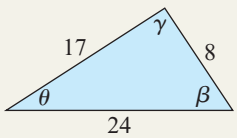
64.

$\theta = 45°$	sin θ	cos θ	tan θ	sin(90° − θ)
cos(90° − θ)	tan(90° − θ)	csc θ	sec θ	cot θ

Evaluate the following expressions without a calculator, using the cofunction relationship and the following exact forms: sec 75° = $\sqrt{6} + \sqrt{2}$; tan 75° = $2 + \sqrt{3}$.

65. $\sqrt{6}\csc 15°$

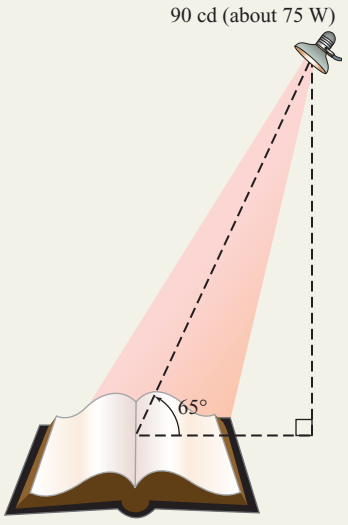
66. $\csc^2 15°$



67. $\cot^2 15°$

68. $\sqrt{3}\cot 15°$

▶ WORKING WITH FORMULAS



69. The sine of an angle between two sides of a triangle: $\sin\theta = \dfrac{2\mathcal{A}}{ab}$

If the area $\mathcal{A}$ and two sides a and b of a triangle are known, the sine of the angle between the two sides is given by the formula shown. Find the angle θ for the triangle shown given $\mathcal{A} \approx 38.9$, and use it to solve the triangle. (*Hint:* Apply the same concept to angle β or γ.)

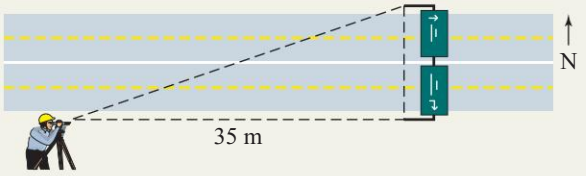
70. Illumination of a surface: $E = \dfrac{I\cos\theta}{d^2}$

The illumination E of a surface by a light source is a measure of the luminous flux per unit area that reaches the surface. The value of E [in lumens (lm) per square foot] is given by the formula shown, where d is the distance from the light source (in feet), I is the intensity of the light [in candelas (cd)], and θ is the angle the light source makes with the vertical. For reading a book, an illumination E of at least 18 lm/ft^2 is recommended. Assuming the open book is lying on a horizontal surface, how far away should a light source be placed if it has an intensity of 90 cd (about 75 W) and the light flux makes an angle of 65° with the book's surface (i.e., $\theta = 25°$)?

▶ APPLICATIONS

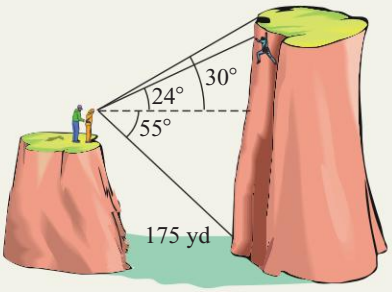
71. Angle of elevation: For a person standing 100 m from the center of the base of the Eiffel Tower, the angle of elevation to the top of the tower is 71.6°. How tall is the Eiffel Tower?

72. Angle of elevation: In 2001, the tallest building in the world was the Petronas Tower I in Kuala Lumpur, Malaysia. For a person standing 25.9 ft from the base of the tower, the angle of elevation to the top of the tower is 89°. How tall is the Petronas tower?



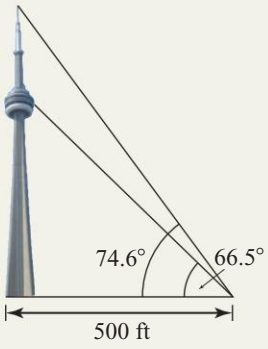
73. Angle of depression: A person standing near the top of the Eiffel Tower notices a car wreck some distance from the tower. If the angle of depression from the person's eyes to the wreck is 32°, how far away is the accident from the base of the tower? See Exercise 71.

74. Angle of depression: A person standing on the top of the Petronas Tower I looks out across the city and pinpoints her residence. If the angle of depression from the person's eyes to her home is 5°, how far away (in feet and in miles) is the residence from the base of the tower? See Exercise 72.



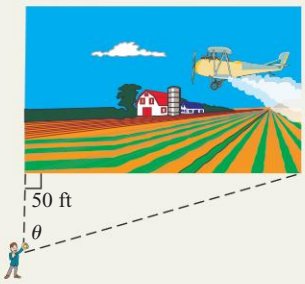
75. Angles of rotation: From a point 110 ft due south of the eastern end of a planned east/west bridge spanning the Illinois river, a surveyor notes the western end lies on a bearing of N 38°35′15″ W. To the nearest inch, how long will the bridge be?

76. Angles of rotation: A large sign spans an east/west highway. From a point 35 m due west of the southern base of the sign, a surveyor finds the northern base lies on a bearing of N 67°11′42″ E. To the nearest centimeter, how wide is the sign?



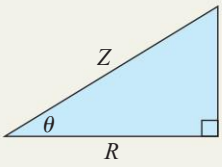
77. Height of a climber: A local Outdoors Club has just hiked to the south rim of a large canyon, when they spot a climber attempting to scale the taller northern face. Knowing the distance between the sheer walls of the northern and southern faces of the canyon is approximately 175 yd, they attempt to compute the distance remaining for the climbers to reach the top of the northern rim. Using a homemade transit, they sight an angle of depression of 55° to the bottom of the north face, and angles of elevation of 24° and 30° to the climbers and top of the northern rim respectively. (a) How high is the southern rim of the canyon? (b) How high is the northern rim? (c) How much farther until the climber reaches the top?

78. Observing wildlife: From her elevated observation post 300 ft away, a naturalist spots a troop of baboons high up in a tree. Using the small transit attached to her telescope, she finds the angle of depression to the bottom of this tree is 14°, while the angle of elevation to the top of the tree is 25°. The angle of elevation to the troop of baboons is 21°. Use this information to find (a) the height of the observation post, (b) the height of the baboons' tree, and (c) the height of the baboons above ground.



79. Angle of elevation: The tallest free-standing tower in the world is the CNN Tower in Toronto, Canada. The tower includes a rotating restaurant high above the ground. From a distance of 500 ft the angle of elevation to the pinnacle of the tower is 74.6°. The angle of elevation to the restaurant from the same vantage point is 66.5°. How tall is the CNN Tower? How far below the pinnacle of the tower is the restaurant located?

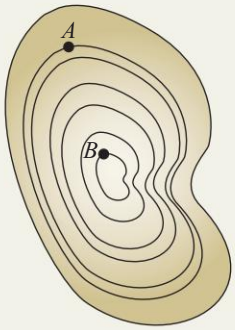
80. Angle of elevation: In January 2009, Burj Dubai unofficially captured the record as the world's tallest building, according to the Council on Tall Buildings and Urban Habitat (*Source:* www.ctbuh.org). Measured at a point 159 m from its base, the angle of elevation to the top of the spire is 79°. From a



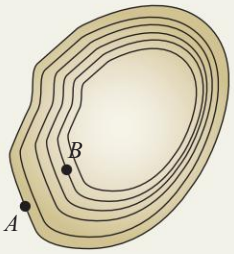
distance of about 134 m, the angle of elevation to the top of the roof is also 79°. How tall is Burj Dubai from street level to the top of the spire? How tall is the spire itself?

81. Crop duster's speed: While standing near the edge of a farmer's field, Johnny watches a crop duster dust the farmer's field for insect control. Curious as to the plane's speed during each drop, Johnny attempts an estimate using the angle of rotation from one end of the field to the other, while standing 50 ft from one corner. Using a stopwatch he finds the plane makes each pass in 2.35 sec. If the angle of rotation was 83°, how fast (in miles per hour) is the plane flying as it applies the insecticide?

82. Train speed: While driving to their next gig, Josh and the boys get stuck in a line of cars at a railroad crossing as the gates go down. As the sleek, speedy express train approaches, Josh decides to pass the time estimating its speed. He spots a large oak tree beside the track some distance away, and figures the angle of rotation from the crossing to the tree is about 80°. If their car is 60 ft from the crossing and it takes the train 3 sec to reach the tree, how fast is the train moving in miles per hour?



Alternating current: In AC (alternating current) applications, the relationship between measures known as the impedance (Z), resistance (R), and the phase angle (θ) can be demonstrated using a right triangle. Both the resistance and the impedance are measured in ohms (Ω).

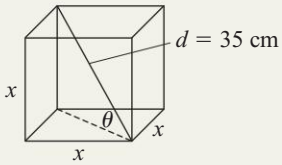


83. Find the impedance Z if the phase angle θ is 34°, and the resistance R is 320 Ω.

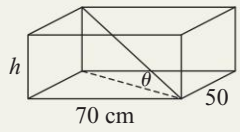
84. Find the phase angle θ if the impedance Z is 420 Ω, and the resistance R is 290 Ω.

85. Contour maps: In the figure shown, the *contour interval* is 175 m (each concentric line represents an increase of 175 m in elevation), and the scale of horizontal distances is 1 cm = 500 m. (a) Find the vertical change from A to B (the increase in elevation); (b) use a proportion to find the horizontal change between points A and B if the measured distance on the map is 2.4 cm; and (c) draw the corresponding right triangle and use it to estimate the length of the trail up the mountain side that connects A and B, then use trig to compute the approximate angle of incline as the hiker climbs from point A to point B.

86. Contour maps: In the figure shown, the *contour interval* is 150 m (each concentric line represents an increase of 150 m in elevation), and the scale of horizontal distances is 1 cm = 250 m. (a) Find the vertical change from A to B (the increase in elevation); (b) use a proportion to find the horizontal change between points A and B if the measured distance on the map is 4.5 cm; and (c) draw the corresponding right triangle and use it to estimate the length of the trail up the mountain side that connects A and B, then use trig to compute the approximate angle of incline as the hiker climbs from point A to point B.

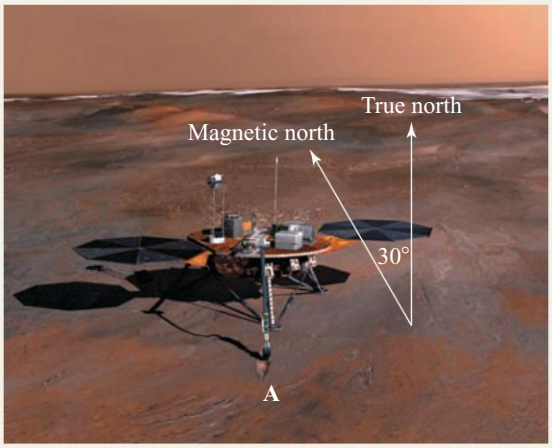


87. Height of a rainbow: While visiting the Lapahoehoe Memorial on the island of Hawaii, Bruce and Carma see a spectacularly vivid rainbow arching over the bay. Bruce speculates the rainbow is 500 ft away, while Carma estimates the angle of elevation to the highest point of the rainbow is about 42°. What was the approximate height of the rainbow?



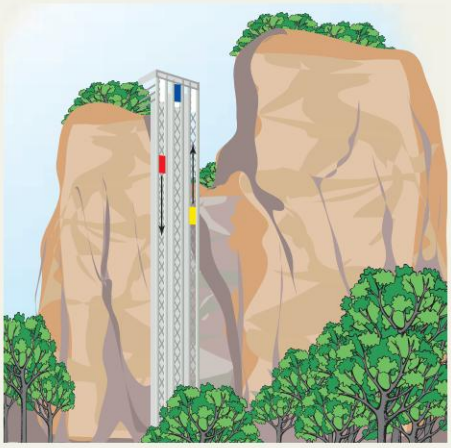
88. High-wire walking: As part of a circus act, a high-wire walker not only "walks the wire," she walks a wire that is *set at an incline of* 10° to the horizontal! If the length of the (inclined) wire is 25.39 m, (a) how much higher is the wire set at the destination pole than at the departure pole? (b) How far apart are the poles?

89. Diagonal of a cube: A cubical box has a diagonal measure of 35 cm. (a) Find the dimensions of the box and (b) the angle θ that the diagonal makes at the lower corner of the box.



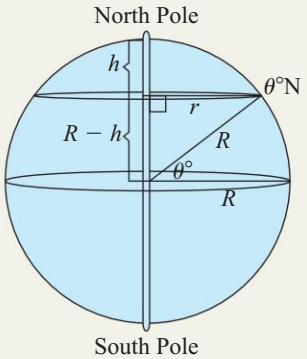
90. Diagonal of a rectangular parallelepiped: A rectangular box has a width of 50 cm and a length of 70 cm. (a) Find the height h that ensures the diagonal across the middle of the box will be 90 cm and (b) the angle θ that the diagonal makes at the lower corner of the box.

▶ EXTENDING THE CONCEPT



91. One of the challenges facing any terrestrial exploration of Mars is its weak and erratic magnetic field. An unmanned rover begins a critical mission at landing site **A** where magnetic north lies on a bearing of N 30° W of true (polar) north (see figure). The rover departs in the magnetic direction of S 20° E and travels straight for 1.4 km to site **B**. At this point, magnetic north lies on a bearing of N 45° E of true north. The rover turns to magnetic direction of N 5° W and travels 2 km straight to site **C**. At **C**, magnetic north lies on a bearing of N 10° W of true north. In what magnetic direction should the rover head to return to site **A**?

Exercise 91



92. As of the year 2009, the Bailong elevator outside of Zhangjiajie, China, was the highest exterior glass elevator in the world. While Christine was descending in the red car, she noticed Simon ascending in the yellow car, below her at an angle of depression of 50°. Seven seconds later, Simon was above her at an angle of elevation of 50°. If the cars have the same velocity ascending and descending, and the horizontal distance between the two cars is 47 ft, how fast do the cars travel?

Exercise 92

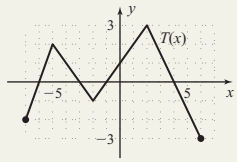
93. The radius of the Earth at the equator (0° N latitude) is approximately 3960 mi. Beijing, China, is located at 39.5° N latitude, 116° E longitude. Philadelphia, Pennsylvania, is located at the same latitude, but at 75° W longitude. (a) Use the diagram given and a cofunction relationship to find the radius r of the Earth (parallel to the equator) at this latitude; (b) use the arc length formula to compute the *shortest distance* between these two cities along this latitude; and (c) if the supersonic Concorde flew a direct flight between Beijing and Philadelphia along this latitude, approximate the flight time assuming a cruising speed of 1250 mph. Note: The shortest distance is actually traversed by heading northward, using the arc of a "great circle" that goes through these two cities.

Exercise 93

▶ MAINTAINING YOUR SKILLS

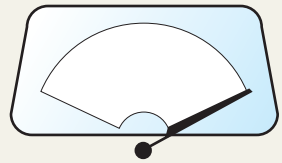
94. **(3.2)** Solve by factoring:

a. $g^2 - 9g = 0$



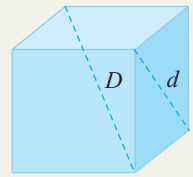
b. $g^2 - 9 = 0$

c. $g^2 - 9g - 10 = 0$



d. $g^2 + 9g - 10 = 0$

e. $g^3 - 9g^2 - 10g + 90 = 0$



95. **(2.1)** For the graph of $T(x)$ given, (a) name the local maximums and minimums, (b) the zeroes of T, (c) intervals where $T(x)\downarrow$ and $T(x)\uparrow$, and (d) intervals where $T(x) > 0$ and $T(x) < 0$.

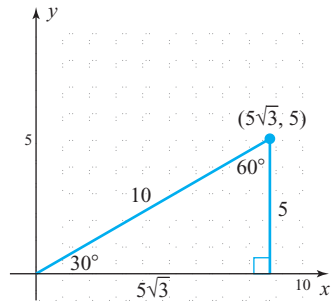
96. **(6.1)** The armature for the rear windshield wiper has a length of 24 in., with a rubber wiper blade that is 20 in. long. What area of my rear windshield is cleaned as the armature swings back-and-forth through an angle of 110°?

97. **(6.1)** The boxes used to ship some washing machines are perfect cubes with edges measuring 38 in. Use a special triangle to find the length of the diagonal d of one side, and the length of the interior diagonal D (through the middle of the box).

6.7 Trigonometry and the Coordinate Plane

LEARNING OBJECTIVES

In Section 6.7 you will see how we can:



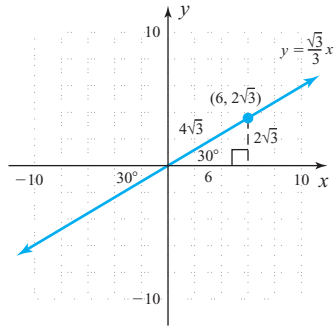
- ❑ **A.** Define the trigonometric functions using the coordinates of a point in QI
- ❑ **B.** Use reference angles to evaluate the trig functions for any angle
- ❑ **C.** Solve applications using the trig functions of any angle

This section tends to bridge the study of *static trigonometry* and the angles of a right triangle, with the study of *dynamic trigonometry* and the unit circle. This is accomplished by noting that the domain of the trig functions (unlike a triangle point of view) *need not be restricted to acute angles.* We'll soon see that the domain can be extended to include trig functions of *any* angle, a view that greatly facilitates our work in Chapter 8, where many applications involve angles greater than 90°.

A. Trigonometric Ratios and the Point $P(x, y)$

Regardless of where a right triangle is situated or how it is oriented, each trig function can be defined as a given ratio of sides with respect to a given angle. In this light, consider a 30-60-90 triangle placed in the first quadrant with the 30° angle at the origin and the longer side along the x-axis. From our previous review of similar triangles, the trig ratios will have the same value regardless of the triangle's size so for convenience, we'll use a hypotenuse of 10 giving sides of 5, $5\sqrt{3}$, and 10. From the diagram in Figure 6.126 we note the point (x, y) marking the vertex of the 60° angle has coordinates $(5\sqrt{3}, 5)$. Further, the diagram shows that sin 30°, cos 30°, and tan 30° can all be expressed in terms of triangle side lengths *or these coordinates* since $\frac{\text{opp}}{\text{hyp}} = \frac{5}{10} = \frac{y}{r}$ (sine), $\frac{\text{adj}}{\text{hyp}} = \frac{5\sqrt{3}}{10} = \frac{x}{r}$ (cosine), and $\frac{\text{opp}}{\text{adj}} = \frac{5}{5\sqrt{3}} = \frac{y}{x}$ (tangent), where r is the distance from (x, y) to the origin. Each result reduces to the more familiar values seen earlier: $\sin 30° = \frac{1}{2}$, $\cos 30° = \frac{\sqrt{3}}{2}$,

Figure 6.126



and $\tan 30° = \dfrac{1}{\sqrt{3}} = \dfrac{\sqrt{3}}{3}$. This suggests we can define the six trig functions in terms of x, y, and r, where $r = \sqrt{x^2 + y^2}$.

Consider that the slope of the line coincident with the hypotenuse is $\dfrac{\text{rise}}{\text{run}} = \dfrac{5}{5\sqrt{3}} = \dfrac{\sqrt{3}}{3}$, and since the line goes through the origin its equation must be $y = \dfrac{\sqrt{3}}{3}x$. Any point (x, y) on this line will be at the 60° vertex of a right triangle formed by drawing a perpendicular line from the point (x, y) to the x-axis. As Example 1 shows, we obtain the special values for sin 30°, cos 30°, and tan 30° regardless of the point chosen.

EXAMPLE 1 ▶ **Evaluating Trig Functions Using *x*, *y*, and *r***

Pick an arbitrary point in QI that satisfies $y = \dfrac{\sqrt{3}}{3}x$, then draw the corresponding right triangle and evaluate sin 30°, cos 30°, and tan 30°.

Solution ▶ The coefficient of x has a denominator of 3, so we choose a multiple of 3 for convenience. For $x = 6$ we have $y = \dfrac{\sqrt{3}}{3}(6) = 2\sqrt{3}$. As seen in the figure, the point $(6, 2\sqrt{3})$ is on the line and at the vertex of the 60° angle. Using the triangle and evaluating the trig functions at 30°, we obtain:

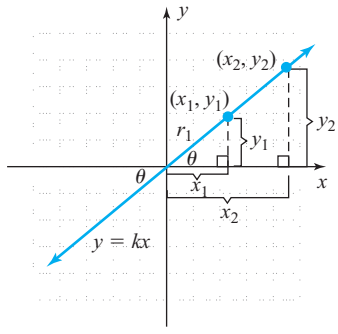
$$\sin 30° = \frac{y}{r} = \frac{2\sqrt{3}}{4\sqrt{3}} = \frac{1}{2} \qquad \cos 30° = \frac{x}{r} = \frac{6}{4\sqrt{3}} = \frac{6\sqrt{3}}{4\sqrt{3}\sqrt{3}} = \frac{\sqrt{3}}{2} \qquad \tan 30° = \frac{y}{x} = \frac{2\sqrt{3}}{6} = \frac{\sqrt{3}}{3}$$

Now try Exercises 7 and 8 ▶

In general, consider *any* two points (x_1, y_1) and (x_2, y_2) on an arbitrary line $y = kx$, at corresponding distances r_1 and r_2 from the origin (Figure 6.127). Because the triangles formed are similar, we have $\dfrac{y_1}{x_1} = \dfrac{y_2}{x_2}$, $\dfrac{x_1}{r_1} = \dfrac{x_2}{r_2}$, and so on, and we conclude that the values of the trig functions are indeed independent of the point chosen.

Viewing the trig functions in terms of x, y, and r produces significant results. In Figure 6.128, we note the line $y = \dfrac{\sqrt{3}}{3}x$ from Example 1 also extends into QIII, and

Figure 6.127



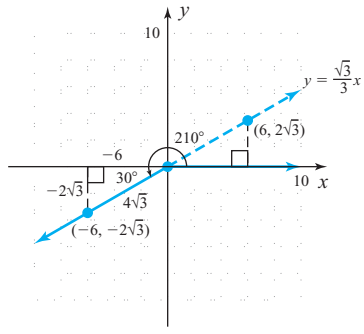


Figure 6.128

creates another 30° *angle whose vertex is at the origin* (since vertical angles are equal). The sine, cosine, and tangent functions can still be evaluated for this angle, but in QIII both x and y are negative. If we consider the angle in QIII to be a positive rotation of 210° (180° + 30°), we can evaluate the trig functions using the values of x, y, and r from any point on the terminal side, since these are fixed by the 30° angle created and are the same as those in QI except for their sign:

$$\sin 210° = \frac{y}{r} = \frac{-2\sqrt{3}}{4\sqrt{3}} = -\frac{1}{2} \qquad \cos 210° = \frac{x}{r} = \frac{-6}{4\sqrt{3}} = -\frac{\sqrt{3}}{2} \qquad \tan 210° = \frac{y}{x} = \frac{-2\sqrt{3}}{-6} = \frac{\sqrt{3}}{3}$$

For *any* rotation θ and a point (x, y) on the terminal side, the distance r can be found using $r = \sqrt{x^2 + y^2}$ and the six trig functions likewise evaluated. Note that evaluating them correctly depends on the quadrant of the terminal side, since this will dictate the signs for x and y. Students are strongly encouraged to make these quadrant and sign observations the *first step* in any solution process. In summary, we have

Trigonometric Functions of Any Angle

Given $P(x, y)$ is any point on the terminal side of angle θ in standard position, with $r = \sqrt{x^2 + y^2}$ $(r > 0)$ the distance from the origin to (x, y). The six trigonometric functions of θ are

$$\sin\theta = \frac{y}{r} \qquad \cos\theta = \frac{x}{r} \qquad \tan\theta = \frac{y}{x},\ x \neq 0$$

$$\csc\theta = \frac{r}{y},\ y \neq 0 \qquad \sec\theta = \frac{r}{x},\ x \neq 0 \qquad \cot\theta = \frac{x}{y},\ y \neq 0$$

EXAMPLE 2 ▶ **Evaluating Trig Functions Given the Terminal Side is on $y = mx$**

Given that $P(x, y)$ is a point on the terminal side of angle θ in standard position, find the values of $\sin\theta$ and $\cos\theta$, if

a. The terminal side is in QII and coincident with the line $y = -\frac{12}{5}x$,

b. The terminal side is in QIV and coincident with the line $y = -\frac{12}{5}x$.

Solution ▶

a. Select any convenient point in QII that satisfies this equation. We select $x = -5$ since x is negative in QII, which gives $y = 12$ and the point $(-5, 12)$. Solving for r gives $r = \sqrt{(-5)^2 + (12)^2} = 13$. The ratios are

$$\sin\theta = \frac{y}{r} = \frac{12}{13} \qquad \cos\theta = \frac{x}{r} = \frac{-5}{13}$$

b. In QIV we select $x = 10$ since x is positive in QIV, giving $y = -24$ and the point $(10, -24)$. Solving for r gives $r = \sqrt{(10)^2 + (-24)^2} = 26$. The ratios are

$$\sin\theta = \frac{y}{r} = \frac{-24}{26} = -\frac{12}{13} \qquad \cos\theta = \frac{x}{r} = \frac{10}{26} = \frac{5}{13}$$

Now try Exercises 9 through 12 ▶

In Example 2, note the ratios are the same in QII and QIV *except for their sign*. We will soon use this observation to great advantage.

EXAMPLE 3 ▶ Evaluating Trig Functions Given a Point *P*

Find the values of the six trigonometric functions given $P(-5, 5)$ is on the terminal side of angle θ in standard position.

Solution ▶ For $P(-5, 5)$ we have $x < 0$ and $y > 0$ so the terminal side is in QII. Solving for r yields $r = \sqrt{(-5)^2 + (5)^2} = \sqrt{50} = 5\sqrt{2}$. For $x = -5$, $y = 5$, and $r = 5\sqrt{2}$, we obtain

$$\sin\theta = \frac{y}{r} = \frac{5}{5\sqrt{2}} = \frac{\sqrt{2}}{2} \qquad \cos\theta = \frac{x}{r} = \frac{-5}{5\sqrt{2}} = -\frac{\sqrt{2}}{2} \qquad \tan\theta = \frac{y}{x} = \frac{5}{-5} = -1$$

The remaining functions can be evaluated using reciprocals.

$$\csc\theta = \frac{2}{\sqrt{2}} = \sqrt{2} \qquad \sec\theta = -\frac{2}{\sqrt{2}} = -\sqrt{2} \qquad \cot\theta = -1$$

Note the connection between these results and the special values for $\theta = 45°$.

Now try Exercises 13 through 28 ▶

Graphing calculators offer a number of features that can assist this approach to a study of the trig functions. On many calculators, the keystrokes 2nd APPS **(ANGLE)** will bring up a menu with **options 1 through 4** which are basically used for angle conversions. Of interest to us here are options 5 and 6, which can be used to determine the radius r (option 5) or the angle (option 6) related to a given point (x, y). For $(5, -5)$ from Example 3, CLEAR the home screen and press 2nd APPS **(ANGLE) 5:R▶Pr(,** which will place the option on the home screen. This feature supplies the left parenthesis of the ordered pair, and you simply complete it: **5:R▶Pr(–5, 5).** As shown in Figure 6.129, the calculator returns 7.07…, the decimal approximation of $5\sqrt{2}$. To find the related angle, it is assumed that θ is in standard position and (x, y) is on the terminal side. Pressing 2nd APPS **(ANGLE) 6:R▶Pθ(** and completing the ordered pair as before shows the corresponding angle is 135° (Figure 6.129). Note this is a QII angle as expected, since $x < 0$ and $y > 0$, and we can check the results of Example 3 by evaluating the trig functions of 135° (see Figure 6.130). **See Exercises 29 and 30.**

Figure 6.129

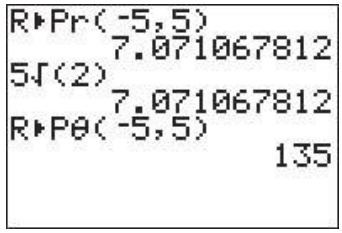

Figure 6.130

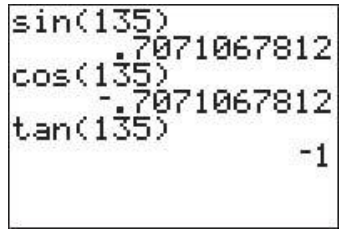

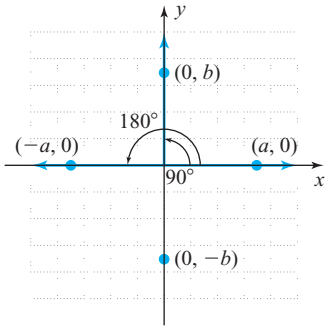

Figure 6.131

Now that we've defined the trig functions in terms of ratios involving x, y, and r, the question arises as to their value at the quadrantal angles. For 90° and 270°, any point on the terminal side of the angle has an *x-value* of zero, meaning tan 90°, sec 90°, tan 270°, and sec 270° are all undefined since $x = 0$ is in the denominator. Similarly, at 180° and 360°, the y-value of any point on the terminal side is zero, so cot 180°, csc 180°, cot 360°, and csc 360° are likewise undefined (see Figure 6.131).

EXAMPLE 4 ▶ **Evaluating the Trig Functions for $\theta = 90°k$, k an Integer**

Evaluate the six trig functions for $\theta = 270°$.

Solution ▶ Here, θ is the quadrantal angle whose terminal side separates QIII and QIV. Since the evaluation is independent of the point chosen on this side, we choose $(0, -1)$ for convenience, giving $r = 1$. For $x = 0$, $y = -1$, and $r = 1$ we obtain

$$\sin 270° = \frac{-1}{1} = -1 \qquad \cos 270° = \frac{0}{-1} = 0 \qquad \tan 270° = \frac{-1}{0} \ (\textit{undefined})$$

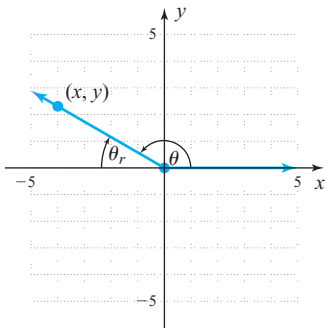
The remaining ratios can be evaluated using reciprocals.

$$\csc 270° = -1 \qquad \sec 270° = \frac{-1}{0} \ (\textit{undefined}) \qquad \cot 270° = \frac{0}{-1} = 0$$

Now try Exercises 31 and 32 ▶

Results for the quadrantal angles are summarized in Table 6.12.

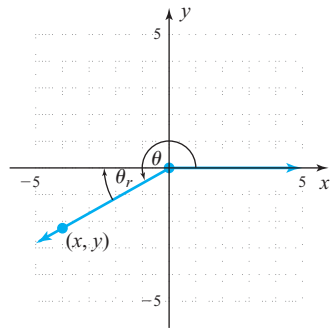
Table 6.12



θ	$\sin\theta = \frac{y}{r}$	$\cos\theta = \frac{x}{r}$	$\tan\theta = \frac{y}{x}$	$\csc\theta = \frac{r}{y}$	$\sec\theta = \frac{r}{x}$	$\cot\theta = \frac{x}{y}$
$0°/360° \rightarrow (1, 0)$	0	1	0	undefined	1	undefined
$90° \rightarrow (0, 1)$	1	0	undefined	1	undefined	0
$180° \rightarrow (-1, 0)$	0	-1	0	undefined	-1	undefined
$270° \rightarrow (0, -1)$	-1	0	undefined	-1	undefined	0

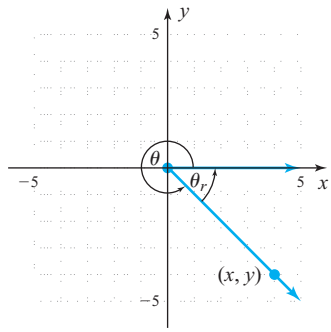
A. You've just seen how we can define the trigonometric functions using the coordinates of a point in QI

B. Reference Angles and the Trig Functions of Any Angle



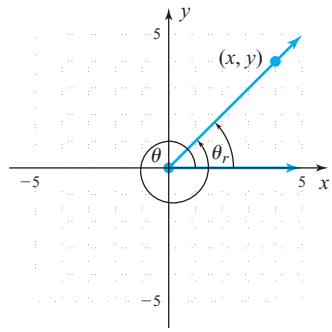
Recall that for any angle θ in standard position, the acute angle θ_r formed by the terminal side and the nearest x-axis is called the **reference angle.** Several examples of this definition are illustrated in Figures 6.132 through 6.135 for $\theta > 0°$ (note that if $0° < \theta < 90°$, then $\theta_r = \theta$).

Figure 6.132



$90° < \theta < 180°$
$\theta_r = 180° - \theta$

Figure 6.133



$180° < \theta < 270°$
$\theta_r = \theta - 180°$

Figure 6.134

$270° < \theta < 360°$
$\theta_r = 360° - \theta$

Figure 6.135

$360° < \theta < 450°$
$\theta_r = \theta - 360°$

EXAMPLE 5 ▶ **Finding Reference Angles**

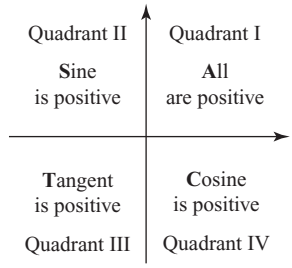
Determine the reference angle for

a. 315° **b.** 150° **c.** 239° **d.** 425°

Solution ▶ Begin by mentally visualizing each angle and the quadrant where it terminates.

a. 315° is a QIV angle:
$\theta_r = 360° - 315° = 45°$

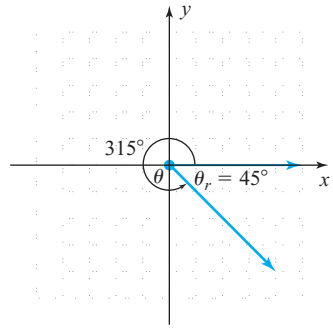
b. 150° is a QII angle:
$\theta_r = 180° - 150° = 30°$



c. 239° is a QIII angle:
$\theta_r = 239° - 180° = 59°$

d. 425° is a QI angle:
$\theta_r = 425° - 360° = 65°$

Now try Exercises 33 through 44 ▶



The reference angles from Examples 5(a) and 5(b) were special angles, which means we automatically know the absolute values of the trig ratios using θ_r. The best way to remember the signs of the trig functions is to keep in mind that sine is associated with y, cosine with x, and tangent with both x and y (r is always positive). In addition, there are several mnemonic devices (memory tools) to assist you. One is to use the first letter of the function that is positive in each quadrant and create a catchy acronym. For instance **ASTC** → **A**ll **S**tudents **T**ake **C**lasses (see Figure 6.136). Note that a trig function and its reciprocal function will always have the same sign. **See Exercises 45 through 48.**

Figure 6.136

EXAMPLE 6 ▶ **Evaluating Trig Functions Using θ_r**

Use a reference angle to evaluate sin θ, cos θ, and tan θ for $\theta = 315°$.

Solution ▶ The terminal side is in QIV where cosine is positive while sine and tangent are negative. With $\theta_r = 45°$, we have:

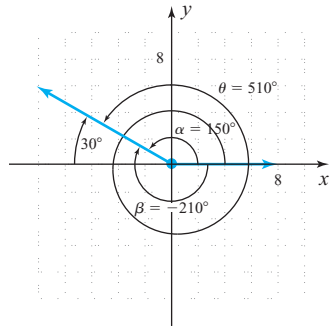
$$\begin{aligned} \sin 315° &= -\sin\theta_r && \text{QIV: } \sin\theta < 0 \\ &= -\sin 45° && \text{replace } \theta_r \text{ with } 45° \\ &= -\frac{\sqrt{2}}{2} && \sin 45° = \frac{\sqrt{2}}{2} \end{aligned}$$

Similarly, the values for cosine and tangent are

$$\begin{aligned} \cos 315° &= +\cos\theta_r \\ &= \cos 45° \\ &= \frac{\sqrt{2}}{2} \end{aligned} \qquad \begin{aligned} \tan 315° &= -\tan\theta_r \\ &= -\tan 45° \\ &= -1 \end{aligned}$$

Now try Exercises 49 through 56 ▶

EXAMPLE 7 ▶ **Finding Function Values Using a Quadrant and Sign Analysis**



Given $\sin\theta = \frac{5}{13}$ and $\cos\theta < 0$, find the value of the other ratios.

Solution ▶ Always begin with a quadrant and sign analysis: $\sin\theta$ is positive in QI and QII, while $\cos\theta$ is negative in QII and QIII. Both conditions are satisfied in QII only. For $r = 13$ and $y = 5$, the Pythagorean theorem shows $x = \pm\sqrt{13^2 - 5^2} = \pm\sqrt{144} = \pm 12$. With θ in QII, $x = -12$ and this gives $\cos\theta = \frac{-12}{13}$ and $\tan\theta = \frac{5}{-12}$. The reciprocal values are $\csc\theta = \frac{13}{5}$, $\sec\theta = \frac{13}{-12}$, and $\cot\theta = \frac{-12}{5}$.

Now try Exercises 57 through 64 ▶

In our everyday experience, there are many actions and activities where angles greater than or equal to 360° are applied. Some common instances are a professional basketball player who "does a three-sixty" (360°) while going to the hoop, a diver who completes a "two-and-a-half" (900°) off the high board, and a skater who executes a perfect triple axel ($3\frac{1}{2}$ turns or 1260°). As these examples suggest, angles greater than 360° must still terminate on a quadrantal axis, or in one of the four quadrants, allowing a reference angle to be found and the functions to be evaluated for any angle *regardless of size.* Figure 6.137 illustrates that $\alpha = 150°$, $\beta = -210°$, and $\theta = 510°$ are all coterminal, with *each having a reference angle of* 30°.

Figure 6.137

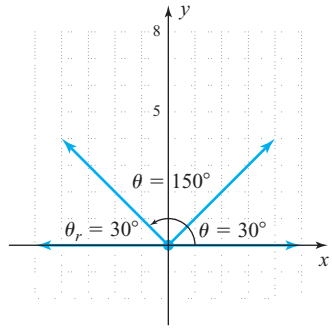
EXAMPLE 8 ▶ **Evaluating Trig Functions of Any Angle**

Evaluate $\sin 150°$, $\cos(-210°)$, and $\tan 510°$.

Solution ▶ The three angles are coterminal in QII where sine is positive while cosine and tangent are negative. With $\theta_r = 30°$, we have:

$$\begin{aligned}\sin 150° &= +\sin\theta_r \\ &= \sin 30° \\ &= \frac{1}{2}\end{aligned} \qquad \begin{aligned}\cos(-210°) &= -\cos\theta_r \\ &= -\cos 30° \\ &= -\frac{\sqrt{3}}{2}\end{aligned} \qquad \begin{aligned}\tan 510° &= -\tan\theta_r \\ &= -\tan 30° \\ &= -\frac{\sqrt{3}}{3}\end{aligned}$$

Now try Exercises 65 through 76 ▶



Since 360° is one full rotation, all angles $\theta + 360°k$ will be coterminal for any integer k. For angles with a very large magnitude, we can find the quadrant of the terminal side by adding or subtracting as many integer multiples of 360° as needed until $\theta < 360°$. For $\alpha = 1908°$, $\frac{1908°}{360°} = 5.3$ and $1908° - 360°(5) = 108°$. This angle is in QII with $\theta_r = 72°$. **See Exercises 77 through 92.**

☑ **B.** You've just seen how we can use reference angles to evaluate the trig functions for any angle

C. Applications of the Trig Functions of Any Angle

One of the most basic uses of coterminal angles is determining all values of θ that satisfy a stated relationship. For example, by now you are aware that if $\sin\theta = \frac{1}{2}$ (positive one-half), then $\theta = 30°$ or $\theta = 150°$ (see Figure 6.138). But this is also true for all angles coterminal with these two, and we would write the solutions as $\theta = 30° + 360°k$ and $\theta = 150° + 360°k$ for all integers k.

Figure 6.138

EXAMPLE 9 ▶ **Finding All Angles that Satisfy a Given Equation**

Find all angles satisfying the relationship given. Answer in degrees.

a. $\cos\theta = -\frac{\sqrt{2}}{2}$ **b.** $\tan\theta = -1.3764$

Solution ▶

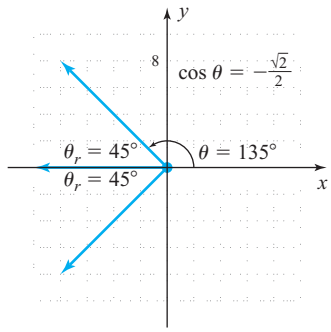
a. Cosine is negative in QII and QIII. Recognizing $\cos 45° = \frac{\sqrt{2}}{2}$, we reason $\theta_r = 45°$ and two solutions are $\theta = 135°$ from QII (see Example 3) and $\theta = 225°$ from QIII. For all values of θ satisfying the relationship, we have $\theta = 135° + 360°k$ and $\theta = 225° + 360°k$. See Figure 6.139.

b. Tangent is negative in QII and QIV. For -1.3764 we find θ_r using a calculator: 2nd TAN **(tan^{-1})** 1.3764 ENTER shows $\tan^{-1}(1.3764) \approx 54$, so $\theta_r = 54°$. Two solutions are $\theta = 180° - 54° = 126°$ from QII, and in QIV $\theta = 360° - 54° = 306°$. The result is $\theta = 126° + 360°k$ and $\theta = 306° + 360°k$. Note these can be combined into the single statement $\theta = 126° + 180°k$. See Figure 6.140.

WORTHY OF NOTE

Since reference angles are acute, we find them by using the $\sin^{-1}$, $\cos^{-1}$, or $\tan^{-1}$ keys with positive values.

Figure 6.139



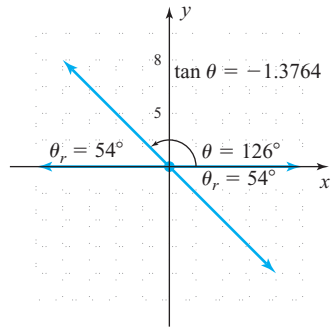


Figure 6.140

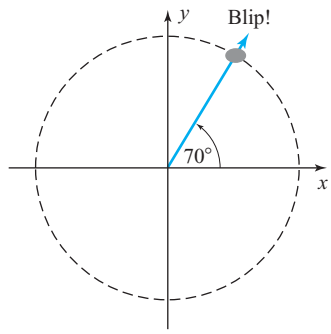


Now try Exercises 95 through 102 ▶

We close this section with an additional application of the concepts related to trigonometric functions of any angle.

EXAMPLE 10 ▶ **Applications of Coterminal Angles: Location on Radar**

A radar operator calls the captain over to her screen saying, "Sir, we have an unidentified aircraft at bearing N 20° E (a standard 70° rotation). I think it's a UFO." The captain asks, "What makes you think so?" To which the sailor replies, "Because it's at 5000 ft and not moving!" Name all angles for which the UFO causes a "blip" to occur on the radar screen.

Solution ▶ Since radar typically sweeps out a 360° angle, a blip will occur on the screen for all angles $\theta = 70° + 360°k$, where k is an integer.

☑ **C.** You've just seen how we can solve applications using the trig functions of any angle

Now try Exercises 103 through 108 ▶

6.7 EXERCISES

▶ CONCEPTS SQAND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. An angle is in standard position if its vertex is at the _____ and the initial side is along the _____.
2. A(n) _____ angle is one where the _____ side is coincident with one of the coordinate axes.
3. Angles formed by a counterclockwise rotation are _____ angles. Angles formed by a _____ rotation are negative angles.
4. For any angle θ, its reference angle θ_r is the positive _____ angle formed by the _____ side and the nearest x-axis.
5. Discuss the similarities and differences between the trigonometry of right triangles and the trigonometry of *any* angle.
6. Let $T(x)$ represent any one of the six basic trig functions. Explain why the equation $T(x) = k$ will always have exactly two solutions in $[0, 2\pi)$ if x is not a quadrantal angle.

▶ DEVELOPING YOUR SKILLS

7. Draw a 30-60-90 triangle with the 60° angle at the origin and the short side along the positive x-axis. Determine the slope and equation of the line coincident with the hypotenuse, then pick any point on this line and evaluate sin 60°, cos 60°, and tan 60°. Comment on what you notice.
8. Draw a 45-45-90 triangle with a 45° angle at the origin and one side along the positive x-axis. Determine the slope and equation of the line coincident with the hypotenuse, then pick any point on this line and evaluate sin 45°, cos 45°, and tan 45°. Comment on what you notice.

Graph each linear equation and state the quadrants it traverses. Then pick one point on the line from each quadrant and evaluate the functions sin θ, cos θ and tan θ using these points.

9. $y = \frac{3}{4}x$
10. $y = \frac{5}{12}x$
11. $y = -\frac{\sqrt{3}}{3}x$
12. $y = -\frac{\sqrt{3}}{2}x$

Find the values of the six trigonometric functions given $P(x, y)$ is on the terminal side of angle θ, with θ in standard position.

13. $(8, 15)$
14. $(7, 24)$
15. $(-20, 21)$
16. $(-3, -1)$
17. $(7.5, -7.5)$
18. $(9, -9)$
19. $(4\sqrt{3}, 4)$
20. $(-6, 6\sqrt{3})$
21. $(2, 8)$
22. $(6, -15)$
23. $(-3.75, -2.5)$
24. $(6.75, 9)$
25. $\left(-\frac{5}{9}, \frac{2}{3}\right)$
26. $\left(\frac{3}{4}, -\frac{7}{16}\right)$
27. $\left(\frac{1}{4}, -\frac{\sqrt{5}}{2}\right)$
28. $\left(-\frac{\sqrt{3}}{5}, \frac{22}{25}\right)$

29. Use the **R►Pr(** feature of a graphing calculator to find the radius corresponding to the point $(-5, 5\sqrt{3})$.

30. Use the **R►Pθ(** feature of a graphing calculator to find the angle corresponding to $(-28, -45)$, then evaluate $\sin\theta$, $\cos\theta$, and $\tan\theta$ for this angle. Compare each result to the values given by $\sin\theta = \frac{y}{r}$, $\cos\theta = \frac{x}{r}$, and $\tan\theta = \frac{y}{x}$.

31. Evaluate the six trig functions in terms of x, y, and r for $\theta = 90°$.

32. Evaluate the six trig functions in terms of x, y, and r for $\theta = 180°$.

Name the reference angle θ_r for the angle θ given.

33. $\theta = 120°$
34. $\theta = 210°$
35. $\theta = 135°$
36. $\theta = 315°$
37. $\theta = -45°$
38. $\theta = -240°$
39. $\theta = 112°$
40. $\theta = 179°$
41. $\theta = 500°$
42. $\theta = 750°$
43. $\theta = -168.4°$
44. $\theta = -328.2°$

State the quadrant of the terminal side of θ, using the information given.

45. $\sin\theta > 0, \cos\theta < 0$
46. $\cos\theta < 0, \tan\theta < 0$
47. $\tan\theta < 0, \sin\theta > 0$
48. $\sec\theta > 0, \tan\theta > 0$

Find the exact values of $\sin\theta$, $\cos\theta$, and $\tan\theta$ using reference angles.

49. $\theta = 330°$
50. $\theta = 390°$
51. $\theta = -45°$
52. $\theta = -120°$
53. $\theta = 240°$
54. $\theta = 315°$
55. $\theta = -150°$
56. $\theta = -210°$

For the information given, find the values of x, y, and r. Clearly indicate the quadrant of the terminal side of θ, then state the values of the six trig functions of θ.

57. $\cos\theta = \frac{4}{5}$ and $\sin\theta < 0$
58. $\tan\theta = -\frac{12}{5}$ and $\cos\theta > 0$
59. $\csc\theta = -\frac{37}{35}$ and $\tan\theta > 0$
60. $\sin\theta = -\frac{20}{29}$ and $\cot\theta < 0$
61. $\csc\theta = 3$ and $\cos\theta > 0$
62. $\csc\theta = -2$ and $\cos\theta > 0$
63. $\sin\theta = -\frac{7}{8}$ and $\sec\theta < 0$
64. $\cos\theta = \frac{5}{12}$ and $\sin\theta < 0$

Find two positive and two negative angles that are coterminal with the angle given. Answers will vary.

65. $52°$
66. $12°$
67. $87.5°$
68. $22.8°$
69. $225°$
70. $175°$
71. $-107°$
72. $-215°$

Evaluate in exact form as indicated.

73. $\sin 120°, \cos -240°, \tan 480°$
74. $\sin 225°, \cos 585°, \tan -495°$
75. $\sin -30°, \cos -390°, \tan -690°$
76. $\sin 210°, \cos 570°, \tan -150°$

Find the exact values of $\sin\theta$, $\cos\theta$, and $\tan\theta$ using reference angles.

77. $\theta = 600°$
78. $\theta = 480°$
79. $\theta = -840°$
80. $\theta = -930°$
81. $\theta = 570°$
82. $\theta = 495°$
83. $\theta = -1230°$
84. $\theta = 3270°$

For each exercise, state the quadrant of the terminal side and the sign of the function in that quadrant. Then evaluate the expression using a calculator. Round to four decimal places.

85. sin 719° **86.** cos 528° **87.** tan −419° **88.** sec −621°

89. csc 681° **90.** tan 995° **91.** cos 805° **92.** sin 772°

▶ WORKING WITH FORMULAS

93. The area of a parallelogram: $\mathcal{A} = ab \sin \theta$

The area of a parallelogram is given by the formula shown, where a and b are the lengths of the sides and θ is the angle between them. Use the formula to complete the following: (a) find the area of a parallelogram with sides $a = 9$ and $b = 21$ given $\theta = 50°$. (b) What is the smallest integer value of θ where the area is greater than 150 units^2? (c) State what happens when $\theta = 90°$. (d) How can you find the area of a triangle using this formula?

94. The angle between two intersecting lines: $\tan \theta = \dfrac{m_2 - m_1}{1 + m_2 m_1}$

Given line 1 and line 2 with slopes m_1 and m_2, respectively, the angle between the two lines is given by the formula shown. Find the angle θ if the equation of line 1 is $y_1 = \frac{3}{4}x + 2$ and line 2 has equation $y_2 = -\frac{2}{3}x + 5$.

▶ APPLICATIONS

Find all angles satisfying the stated relationship. For standard angles, express your answer in exact form. For nonstandard values, use a calculator and round function values to tenths.

95. $\cos \theta = \dfrac{1}{2}$ **96.** $\sin \theta = \dfrac{\sqrt{2}}{2}$

97. $\sin \theta = -\dfrac{\sqrt{3}}{2}$ **98.** $\tan \theta = -\dfrac{\sqrt{3}}{1}$

99. $\sin \theta = 0.8754$ **100.** $\cos \theta = 0.2378$

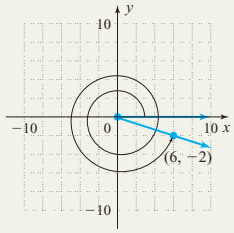
101. $\tan \theta = -2.3512$ **102.** $\cos \theta = -0.0562$

103. Nonacute angles: At a recent carnival, one of the games on the midway was played using a large spinner that turns clockwise. On Jorge's spin the number 25 began at the 12 o'clock (top/center) position, returned to this position five times during the spin and stopped at the 3 o'clock position. What angle θ did the spinner spin through? Name all angles that are coterminal with θ.

Exercise 103

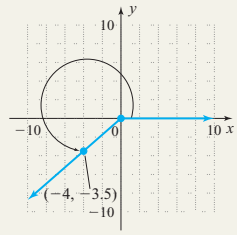
104. Nonacute angles: One of the four blades on a ceiling fan has a decal on it and begins at a designated "12 o'clock" position. Turning the switch on and then immediately off, causes the blade to make over three complete, counterclockwise rotations, with the blade stopping at the 8 o'clock position. What angle θ did the blade turn through? Name all angles that are coterminal with θ.

105. High dives: As part of a diving competition, David executes a perfect reverse two-and-a-half flip. Does he enter the water feet first or head first? Through what angle did he turn from takeoff until the moment he entered the water?



Exercise 105

106. Gymnastics: While working out on a trampoline, Charlene does three complete, forward flips and then belly-flops on the trampoline before returning to the upright position. What angle did she turn through from the start of this maneuver to the moment she belly-flops?



107. Spiral of Archimedes: The graph shown is called the spiral of Archimedes. Through what angle θ has the spiral turned, given the spiral terminates at $(6, -2)$ as indicated?

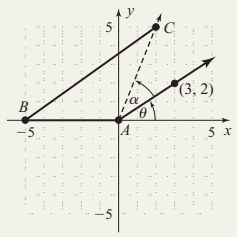
Exercise 107

108. Involute of a circle: The graph shown is called the involute of a circle. Through what angle θ has the involute turned, given the graph terminates at $(-4, -3.5)$ as indicated?

Exercise 108

▶ EXTENDING THE CONCEPT

109. In an elementary study of trigonometry, the hands of a clock are often studied because of the angle relationship that exists between the hands. For example, at 3 o'clock, the angle between the two hands is a right angle and measures 90°.



a. What is the angle between the two hands at 1 o'clock? 2 o'clock? Explain why.

b. What is the angle between the two hands at 6:30? 7:00? 7:30? Explain why.

c. Name four times at which the hands will form a 45° angle.

110. In the diagram shown, the indicated ray is of arbitrary length. (a) Through what additional angle α would the ray have to be rotated to create triangle ABC? (b) What will be the length of side AC once the triangle is complete?

Exercise 110

111. Referring to Exercise 104, suppose the fan blade has a radius of 20 in. and is turning at a rate of 12 revolutions per second. (a) Find the angle the blade turns through in 3 sec. (b) Find the circumference of the circle traced out by the tip of the blade. (c) Find the total distance traveled by the blade tip in 10 sec. (d) Find the speed, in miles per hour, that the tip of the blade is traveling.

▶ MAINTAINING YOUR SKILLS

112. (6.1) For emissions testing, automobiles are held stationary while a heavy roller installed in the floor allows the wheels to turn freely. If the large wheels of a customized pickup have a radius of 18 in. and are turning at 300 revolutions per minute, what speed is the odometer of the truck reading in miles per hour?

113. (5.4) Solve for t. Answer in both exact and approximate form:

$$-250 = -150e^{-0.05t} - 202.$$

114. (6.6) Jazon is standing 117 ft from the base of the Washington Monument in Washington, D.C. If his eyes are 5 ft above level ground and he must hold his head at a 78° angle from horizontal to see the top of the monument (the angle of elevation is 78°), estimate the height of the monument. Answer to the nearest tenth of a foot.

115. (1.4) Find an equation of the line perpendicular to $4x - 5y = 15$ that contains the point $(4, -3)$.

6.8 Trigonometric Equation Models

LEARNING OBJECTIVES

In Section 6.8 you will see how we can:

- ❑ **A.** Create a trigonometric model from critical points or data
- ❑ **B.** Create a sinusoidal model from data using regression

In the most common use of the word, a cycle is any series of events or operations that occur in a predictable pattern and return to a starting point. This includes things as diverse as the wash cycle on a washing machine and the powers of i. There are a number of common events that occur in *sinusoidal* cycles, or events that can be modeled by a sine wave. As in Section 6.5, these include monthly average temperatures, monthly average daylight hours, and harmonic motion, among many others. Less well-known applications include alternating current, biorhythm theory, and animal populations that fluctuate over a known period of years. In this section, we develop two methods for creating a sinusoidal model. The first uses information about the critical points (where the cycle reaches its maximum or minimum values); the second involves computing the equation of best fit (a regression equation) for a set of data.

A. Critical Points and Sinusoidal Models

Although future courses will define them more precisely, we will consider **critical points** to be *inputs* where a function attains a minimum or maximum value. If an event or phenomenon is known to behave sinusoidally (regularly fluctuating between a maximum and minimum), we can create an acceptable model of the form $y = A\sin(Bx + C) + D$ given these **critical points** (x, y) and the period. For instance, many weather patterns have a period of 12 months. Using the formula $P = \frac{2\pi}{B}$, we find $B = \frac{2\pi}{P}$ and substituting 12 for P gives $B = \frac{\pi}{6}$ (always the case for phenomena with a 12-month cycle). The maximum value of $A\sin(Bx + C) + D$ will always occur when $\sin(Bx + C) = 1$, and the minimum at $\sin(Bx + C) = -1$, giving this system of equations: max value $M = A(1) + D$ and min value $m = A(-1) + D$. Solving the system for A and D gives $A = \frac{M - m}{2}$ and $D = \frac{M + m}{2}$ as before. To find C, assume the maximum and minimum values occur at (x_2, M) and (x_1, m), respectively. We can substitute the values computed for A, B, and D in $y = A\sin(Bx + C) + D$, along with either (x_2, M) or (x_1, m), and solve for C. Using the minimum value (x_1, m), where $x = x_1$ and $y = m$, we have

$$y = A\sin(Bx + C) + D \qquad \text{sinusoidal equation model}$$

$$m = A\sin(Bx_1 + C) + D \qquad \text{substitute } m \text{ for } y \text{ and } x_1 \text{ for } x$$

$$\frac{m - D}{A} = \sin(Bx_1 + C) \qquad \text{isolate sine function}$$

Fortunately, for sine models constructed from critical points we have $\frac{y - D}{A} \to \frac{m - D}{A}$, which is always equal to -1 **(see Exercise 33).** This gives a simple result for C, since $-1 = \sin(Bx_1 + C)$ leads to $\frac{3\pi}{2} = Bx_1 + C$ or $C = \frac{3\pi}{2} - Bx_1$.

See Exercises 7 through 12 for practice with these ideas.

EXAMPLE 1 ▶ **Developing a Model for Polar Ice Cap Extent from Critical Points**

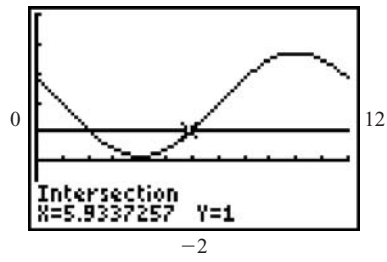
When the Spirit and Odyssey Rovers landed on Mars (January 2004), there was a renewed public interest in studying the planet. Of particular interest were the polar ice caps, which are now thought to hold frozen water, especially the northern cap. The Martian ice caps expand and contract with the seasons, just as they do here on Earth but there are about 687 days in a Martian year, making each Martian "month" just over 57 days long (1 Martian day $\approx$ 1 Earth day). At its smallest size, the northern ice cap covers an area of roughly 0.17 million square miles. At the height of winter, the cap covers about 3.7 million square miles (an area about the size of the 50 United States). Suppose these occur at the beginning of month 4 ($x = 4$) and month 10 ($x = 10$) respectively.

a. Use this information to create a sinusoidal model of the form $f(x) = A\sin(Bx + C) + D$.

b. Use the model to predict the area of the ice cap in the eighth Martian month.

c. Use a graphing calculator to determine the number of months the cap covers less than 1 million mi^2.

Solution ▶



a. Assuming a "12-month" weather pattern, $P = 12$ and $B = \frac{\pi}{6}$. The maximum and minimum points are (10, 3.7) and (4, 0.17). Using this information, $D = \frac{3.7 + 0.17}{2} = 1.935$ and $A = \frac{3.7 - 0.17}{2} = 1.765$. Using $C = \frac{3\pi}{2} - Bx_1$ gives $C = \frac{3\pi}{2} - \frac{\pi}{6}(4) = \frac{5\pi}{6}$. The equation model is $f(x) = 1.765\sin\left(\frac{\pi}{6}x + \frac{5\pi}{6}\right) + 1.935$, where $f(x)$ represents millions of square miles in month x.

b. For the size of the cap in month 8 we evaluate the function at $x = 8$.

$$f(8) = 1.765\sin\left[\frac{\pi}{6}(8) + \frac{5\pi}{6}\right] + 1.935 \quad \text{substitute 8 for } x$$
$$= 2.8175 \quad \text{result}$$

In month 8, the polar ice cap will cover about 2,817,500 mi^2.

c. Of the many options available, we opt to solve by locating the points where $Y_1 = 1.765\sin\left(\frac{\pi}{6}X + \frac{5\pi}{6}\right) + 1.935$ and $Y_2 = 1$ intersect. After entering the functions on the Y= screen, we set $x \in [0, 12]$ and $y \in [-2, 5]$ for a window with a frame around the output values. Press 2nd TRACE **(CALC) 5:intersect** to find the intersection points. To four decimal places they occur at $x = 2.0663$ and $x = 5.9337$. The ice cap at the northern pole of Mars has an area of less than 1 million mi^2 from early in the second month to late in the fifth month. The second intersection is shown in the figure.

Now try Exercises 19 and 20 ▶

While this form of "equation building" can't match the accuracy of a regression model (computed from a larger set of data), it does lend insight as to how sinusoidal functions work. The equation will always contain the maximum and minimum values, and using the period of the phenomena, we can create a smooth sine wave that "fills in the blanks" between these critical points.

EXAMPLE 2 ▶ Developing a Model of Wildlife Population from Critical Points

Naturalists have found that many animal populations, such as the arctic lynx, some species of fox, and certain rabbit breeds, tend to fluctuate sinusoidally over 10-year periods. Suppose that an extended study of a lynx population began in 2000, and in the third year of the study, the population had fallen to a minimum of 2500. In the eighth year the population hit a maximum of 9500.

a. Use this information to create a sinusoidal model of the form $P(x) = A\sin(Bx + C) + D$.

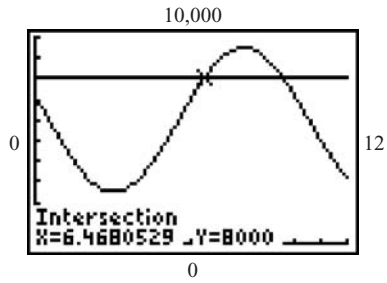
b. Use the model to predict the lynx population in the year 2006.

c. Use a graphing calculator to determine the number of years the lynx population is above 8000 in a 10-year period.

Solution ▶

a. Since $P = 10$, we have $B = \frac{2\pi}{10} = \frac{\pi}{5}$. Using 2000 as year zero, the minimum and maximum populations occur at (3, 2500) and (8, 9500). From the information given, $D = \frac{9500 + 2500}{2} = 6000$, and $A = \frac{9500 - 2500}{2} = 3500$. Using the minimum value we have $C = \frac{3\pi}{2} - \frac{\pi}{5}(3) = \frac{9\pi}{10}$, giving an equation model of $P(x) = 3500\sin\left(\frac{\pi}{5}x + \frac{9\pi}{10}\right) + 6000$, where $P(x)$ represents the lynx population in year x.

b. For the population in 2006 we evaluate the function at $x = 6$.



$$P(x) = 3500\sin\left(\frac{\pi}{5}x + \frac{9\pi}{10}\right) + 6000 \quad \text{sinusoidal function model}$$

$$P(6) = 3500\sin\left[\frac{\pi}{5}(6) + \frac{9\pi}{10}\right] + 6000 \quad \text{substitute 6 for } x$$

$$\approx 7082 \quad \text{result}$$

In 2006, the lynx population was about 7082.

c. Using a graphing calculator and the functions $Y_1 = 3500\sin\left(\frac{\pi}{5}X + \frac{9\pi}{10}\right) + 6000$ and $Y_2 = 8000$, we attempt to find points of intersection. Enter the functions (press Y=) and set a viewing window (we used $x \in [0, 12]$ and $y \in [0, 10{,}000]$). Press 2nd TRACE **(CALC) 5:intersect** to find where Y_1 and Y_2 intersect. To four decimal places this occurs at $x = 6.4681$ and $x = 9.5319$. The lynx population exceeded 8000 for roughly 3 years. The first intersection is shown.

Now try Exercises 21 and 22 ▶

This type of equation building isn't limited to the sine function. In fact, there are many situations where a sine model cannot be applied. Consider the length of the shadows cast by a flagpole or radio tower as the Sun makes its way across the sky. The shadow's length follows a regular pattern (shortening then lengthening) and "always returns to a starting point," yet when the Sun is low in the sky the shadow becomes (theoretically) infinitely long, unlike the output values from a sine function. If we consider *signed* shadow lengths at a latitude where the Sun passes directly overhead (in contrast with Example 11 in Section 6.5), an equation involving tan x might provide a good model. We'll attempt to model the data using $y = A\tan(Bx \pm C)$, with the D-term absent since a vertical shift in this context has no meaning. Recall that the period of the tangent function is $P = \frac{\pi}{|B|}$ and that $\pm\frac{C}{B}$ gives the magnitude and direction of the horizontal shift, in a direction opposite the sign.

EXAMPLE 3 ▶ Using Data to Develop a Function Model for Shadow Length

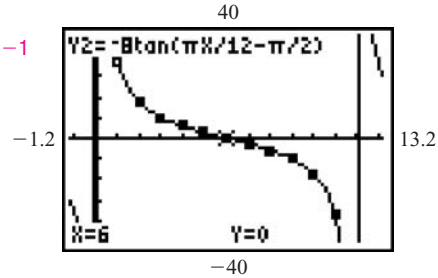
WORTHY OF NOTE
A gnomon is the protruding feature of a sundial, casting the shadow used to estimate the time of day (see photo).

The data given tracks the length of a gnomon's shadow for the 12 daylight hours at a certain location near the equator (positive and negative values indicate lengths before noon and after noon respectively). Assume $t = 0$ represents 6:00 A.M.

Hour of the Day	Length (cm)	Hour of the Day	Length (cm)
0	∞	7	−2.1
1	29.9	8	−4.6
2	13.9	9	−8.0
3	8.0	10	−13.9
4	4.6	11	−29.9
5	2.1	12	$-\infty$
6	0		

a. Use the data to find an equation model of the form $L(t) = A\tan(Bt \pm C)$.
b. Graph the function and scatterplot.
c. Find the shadow's length at 4:30 P.M.
d. If the shadow is 6.1 cm long, what time in the morning is it?

Solution ▶



a. We begin by noting this phenomenon has a period of $P = 12$. Using the period formula for tangent we solve for B: $P = \frac{\pi}{B}$ gives $12 = \frac{\pi}{B}$, so $B = \frac{\pi}{12}$. Since we want (6, 0) to be the "center" of the function [instead of (0, 0)], we desire a horizontal shift 6 units to the right. Using the ratio $\frac{C}{B}\left(\text{with } B = \frac{\pi}{12}\right)$ gives $-6 = \frac{12C}{\pi}$ so $C = -\frac{\pi}{2}$. To find A we use the equation built so far: $L(t) = A\tan\left(\frac{\pi}{12}t - \frac{\pi}{2}\right)$, and *any data point* to solve for A. Using (3, 8) we obtain $8 = A\tan\left(\frac{\pi}{12}(3) - \frac{\pi}{2}\right)$:

$$8 = A\tan\left(-\frac{\pi}{4}\right) \quad \text{simplify}$$
$$-8 = A \quad \text{solve for } A\text{: } \tan\left(-\frac{\pi}{4}\right) = -1$$

The equation model is $L(t) = -8\tan\left(\frac{\pi}{12}t - \frac{\pi}{2}\right)$.

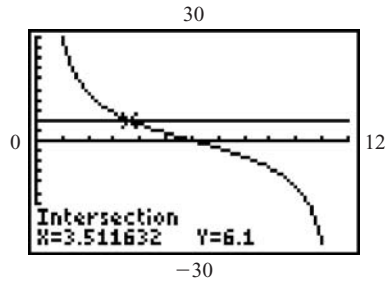
b. The scatterplot and graph are shown in Figure 6.141.

Figure 6.141

c. 4:30 P.M. indicates $t = 10.5$. Evaluating $L(10.5)$ gives

$$L(t) = -8\tan\left(\frac{\pi}{12}t - \frac{\pi}{2}\right) \quad \text{function model}$$

$$L(10.5) = -8\tan\left[\frac{\pi}{12}(10.5) - \frac{\pi}{2}\right] \quad \text{substitute 10.5 for } t$$



$$= -8\tan\left(\frac{3\pi}{8}\right) \quad \text{simplify}$$

$$\approx -19.31 \quad \text{result}$$

At 4:30 P.M., the shadow has a length of $|-19.31| = 19.31$ cm.

d. Substituting 6.1 for $L(t)$ and solving for t graphically gives the graph shown in Figure 6.142, where we note the day is about 3.5 hr old—it is about 9:30 A.M.

Figure 6.142

Now try Exercises 23 through 26 ▶

B. Data and Sinusoidal Regression

Most graphing calculators are programmed to handle numerous forms of polynomial and nonpolynomial regression, including **sinusoidal regression.** The sequence of steps used is the same regardless of the form chosen. **Exercises 13 through 16** offer further practice with regression fundamentals. Example 4 illustrates their use in context.

EXAMPLE 4 ▶ Calculating a Regression Equation for Seasonal Temperatures

The data shown give the record high temperature for selected months in Bismarck, North Dakota.

Month (Jan → 1)	Temp. (°F)	Month (Jan → 1)	Temp. (°F)
1	63	9	105
3	81	11	79
5	98	12	65
7	109		

a. Use the data to draw a scatterplot, then find a sinusoidal regression model and graph both on the same screen.

b. Use the equation model to estimate the record high temperatures for months 2, 6, and 8.

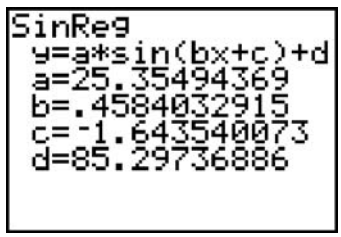
c. Determine what month gives the largest difference between the actual data and the computed results.

Source: NOAA Comparative Climate Data 2004.

Solution ▶

a. Entering the data and running the regression (in radian mode) results in the coefficients shown in Figure 6.143. After entering the equation in Y_1 and pressing ZOOM **9:Zoom Stat** we obtain the graph shown in Figure 6.144 (indicated window settings have been rounded).

Figure 6.143



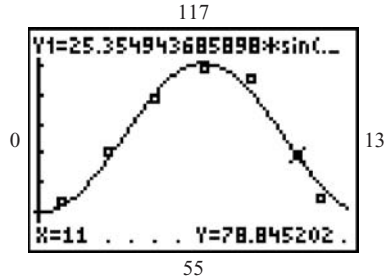


Figure 6.144

b. Using $x = 2$, $x = 6$, and $x = 8$ as inputs, the equation model projects record high temperatures of 68.5°, 108.0°, and 108.1°, respectively.

c. In the header of L3, use $Y_1(L1)$ ENTER to evaluate the regression model using the inputs from L1, and place the results in L3. Entering L2 − L3 in the header of L4 gives the results shown in Figure 6.145 and we note the largest difference occurs in September—about 4°.

Figure 6.145

L4(1)=1.195267717...

Now try Exercises 27 through 30 ▶

Weather patterns differ a great deal depending on the locality. For example, the annual precipitation received by Seattle, Washington, far exceeds that received by Cheyenne, Wyoming. Our final example compares the two amounts and notes an interesting fact about the relationship.

EXAMPLE 5 ▶ Calculating a Regression Model for Seasonal Precipitation

The average monthly precipitation (in inches) for Cheyenne, Wyoming, and Seattle, Washington, are shown in the table.

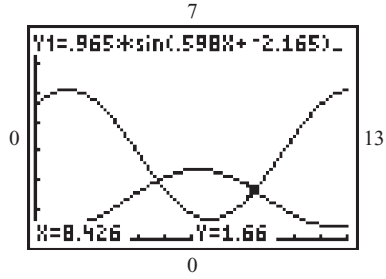
Month (Jan. → 1)	WY Precip.	WA Precip.
1	0.45	5.13
2	0.44	4.18
3	1.05	3.75
4	1.55	2.59
5	2.48	1.77
6	2.12	1.49
7	2.26	0.79
8	1.82	1.02
9	1.43	1.63
10	0.75	3.19
11	0.64	5.90
12	0.46	5.62

a. Use the data to find a sinusoidal regression model for the average monthly precipitation in each city. Enter or paste the equation for Cheyenne in Y_1 and the equation for Seattle in Y_2.

b. Graph both equations on the same screen (without the scatterplots) and use TRACE or 2nd TRACE **(CALC) 5:intersect** to help estimate the number of months Cheyenne receives more precipitation than Seattle.

Source: NOAA Comparative Climate Data 2004.

Solution ▶



a. Setting the calculator in **Float 0 1 2 3 4 5 6 7 8 9** MODE and running sinusoidal regressions gives the equations shown in Figure 6.146.

b. Both graphs are shown in Figure 6.147. Using the TRACE feature, we find the graphs intersect at approximately (4.7, 2.0) and (8.4, 1.7). Cheyenne receives more precipitation than Seattle for about 8.4 − 4.7 = 3.7 months of the year.

6.8 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. For $y = A\sin(Bx + C) + D$, the maximum value occurs when _____ $= 1$, leaving $y =$ _____.
2. For $y = A\sin(Bx + C) + D$, the minimum value occurs when _____ $= -1$, leaving $y =$ _____.
3. For $y = A\sin(Bx + C) + D$, the value of C can be found using $C = -Bx$, where x is a _____ point.
4. Any phenomenon with sinusoidal behavior regularly fluctuates between a _____ and a _____ value.
5. Discuss/Expand on Example 4. Why does the equation calculated from the maximum and minimum values differ from the regression equation, even though both use the same set of data?
6. Discuss/Explain: (1) How is data concerning average rainfall related to the average discharge rate of rivers? (2) How is data concerning average daily temperature related to water demand? Are both sinusoidal with the same period? Are there other associations you can think of?

▶ DEVELOPING YOUR SKILLS

Find a sinusoidal equation for the information as given.

7. minimum value at (9, 25); maximum value at (3, 75); period: 12 min
8. minimum value at (4.5, 35); maximum value at (1.5, 121); period: 6 yr
9. minimum value at (15, 3); maximum value at (3, 7.5); period: 24 hr
10. minimum value at (3, 3.6); maximum value at (7, 12); period: 8 hr
11. minimum value at (5, 279); maximum value at (11, 1285); period: 12 yr
12. minimum value at (6, 8280); maximum value at (22, 23,126); period: 32 yr

Data and sinusoidal regression models: For the following sets of data (a) find a sinusoidal regression equation using your calculator; (b) construct an equation manually using the period and maximum/minimum values; and (c) graph both on the same screen, then use a **TABLE** to find the largest difference between output values.

▶ WORKING WITH FORMULAS

17. Orbiting Distance North or South of the Equator: $D(t) = A\cos(Bt)$

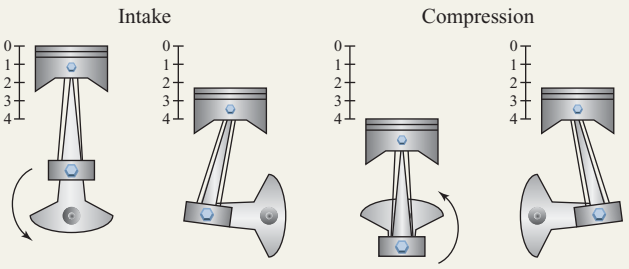
Unless a satellite is placed in a strict equatorial orbit, its distance north or south of the equator will vary according to the sinusoidal model shown, where $D(t)$ is the distance t *minutes* after entering orbit. Negative values indicate it is south of the equator, and the distance D is actually a two-dimensional distance, as seen from a vantage point in outer space. The value of B depends on the speed of the satellite and the time it takes to complete one orbit, while $|A|$ represents the maximum distance from the equator. (a) Find the equation model for a satellite whose maximum distance north of the equator is 2000 miles and that completes one orbit every *2 hours* ($P = 120$). (b) Is the satellite north or south of the equator 257 min after entering orbit? How far north or south?

18. Biorhythm Theory: $P(d) = 50\sin(Bd) + 50$

Advocates of biorhythm theory believe that human beings are influenced by certain biological cycles that begin at birth, have different periods, and continue throughout life. The classical cycles and their periods are: physical potential (23 days), emotional potential (28 days), and intellectual potential (33 days). On any given day of life, the percent of potential in these three areas is purported to be modeled by the function shown, where $P(d)$ is the percent of available potential on day d of life. Find the value of B for each of the physical, emotional, and intellectual potentials and use it to see what the theory has to say about your potential today. Use day $d = 365.25(\text{age}) +$ days since last birthday.

▶ APPLICATIONS

19. Record monthly temperatures: The U.S. National Oceanic and Atmospheric Administration (NOAA) keeps temperature records for most major U.S. cities. For Phoenix, Arizona, they list an average high temperature of 65.0°F for the month of January (month 1) and an average high temperature of 104.2°F for July (month 7). Assuming January and July are the coolest and warmest months of the year, (a) build a sinusoidal function model for temperatures in Phoenix, and (b) use the model to find the average high temperature in September. (c) If a person has a tremendous aversion to temperatures over 95°, during what months should they plan to vacation elsewhere?



20. Seasonal size of polar ice caps: Much like the polar ice cap on Mars, the sea ice that surrounds the continent of Antarctica (the Earth's southern polar cap) varies seasonally, from about 8 million mi^2 in September to about 1 million mi^2 in March. Use this information to (a) build a sinusoidal equation that models the advance and retreat of the sea ice, and (b) determine the size of the ice sheet in May. (c) Find the months of the year that the sea ice covers more than 6.75 million mi^2.

Exercise 20

21. Body temperature cycles: A phenomenon is said to be *circadian* if it occurs in 24-hr cycles. A person's body temperature is circadian, since there are normally small, sinusoidal variations in body temperature from a low of 98.2°F to a high of 99°F throughout a 24-hr day. Use this information to (a) build the circadian equation for a person's body temperature, given $t = 0$ corresponds to midnight and that a person usually reaches their minimum temperature at 5 A.M.; (b) find the time(s) during a day when a person reaches "normal" body temperature (98.6°); and (c) find the number of hours each day that body temperature is 98.4°F or less.

22. Position of engine piston: For an internal combustion engine, the position of a piston in the cylinder can be modeled by a sinusoidal function. For a particular engine size and idle speed, the piston head is 0 in. from the top of the cylinder (the minimum value) when $t = 0$ at the beginning of the intake stroke, and reaches a maximum distance of 4 in. from the top of the cylinder (the maximum value) when $t = \frac{1}{48}$ sec at the beginning of the compression stroke. Following the compression stroke is the power stroke ($t = \frac{2}{48}$), the exhaust stroke ($t = \frac{3}{48}$), and the intake stroke ($t = \frac{4}{48}$), after which it all begins again. Given the period of a four-stroke engine under these conditions is $P = \frac{1}{24}$ second, (a) find the sinusoidal equation modeling the position of the piston, and (b) find the distance of the piston from the top of the cylinder at $t = \frac{1}{9}$ sec. Which stroke is the engine in at this moment?

Data and tangent functions: Use the data given to find an equation model of the form $f(x) = A\tan(Bx + C)$. Then graph the function and scatterplot to help find (a) the output for $x = 2.5$, and (b) the value of x where $f(x) = 16$.

25. Distance and apparent height: While driving toward a Midwestern town on a long, flat stretch of highway, I decide to pass the time by measuring the apparent height of the tallest building in the downtown area as I approach. At the time the idea occurred to me, the buildings were barely visible. Three miles later I hold a 30-cm ruler up to my eyes at arm's length, and the apparent height of the tallest building is 1 cm. After three more miles the apparent height is 1.8 cm. Measurements are taken every 3 mi until I reach town and are shown in the table (assume I was 24 mi from the parking garage when I began this activity). (a) Use the data to come up with a tangent function model of the building's apparent height after traveling a distance of x mi closer. (b) What was the apparent height of the building after I had driven 19 mi? (c) How many miles had I driven when the apparent height of the building took up all 30 cm of my ruler?

Distance Traveled (mi)	Height (cm)

24	∞

26. Earthquakes and elastic rebound: The **theory of elastic rebound** has been used by seismologists to study the cause of earthquakes. As seen in the figure, the Earth's crust is stretched to a breaking point by the slow movement of one tectonic plate in a direction opposite the other along a fault line, and when the rock snaps—each half violently rebounds to its original alignment causing the Earth to quake.

x	y	x	y
−4.5	−61	1	2.1
−4	−26	2	6.8
−3	−14.8	3	15.3
−2	−7.2	4	25.4
−1	−1.9	4.5	59
0	0		

Suppose the *misalignment* of these plates through the stress and twist of crustal movement can be modeled by a tangent graph, where x represents the horizontal distance from the original stress line, and y represents the vertical distance from the fault line. Assume a "period" of 10.2 m. (a) Use the data from the table to come up with a trigonometric model of the deformed stress line. (b) At a point 4.8 m along the fault line, what is the distance to the deformed stress line (moving parallel to the original stress line)? (c) At what point along the fault line is the vertical distance to the deformed stress line 50 m?

27. Record monthly temperatures: The highest temperature of record for the even months of the year are given in the table for the city of Pittsburgh, Pennsylvania. (a) Use the data to draw a scatterplot, then find a sinusoidal regression model and graph both on the same screen. (b) Use the equation to estimate the record high temperatures for the odd-numbered months. (c) What month shows the largest difference between the actual data and the computed results?

Month (Jan. → 1)	High Temp. (°F)

29. Illumination of the moon's surface: The table given indicates the percent of the Moon that is illuminated for the days of a particular month, at a given latitude. (a) Use a graphing calculator to find a sinusoidal regression model. (b) Use the model to determine what percent of the Moon is illuminated on day 20. (c) Use the maximum and minimum values with the period and an appropriate horizontal shift to create your own model of the data. How do the values for A, B, C, and D compare?

Day	% Illum.	Day	% Illum.
1	28	19	34
4	55	22	9
7	82	25	0
10	99	28	9
13	94	31	30
16	68		

30. Connections between weather and mood: The mood of persons with SAD syndrome (seasonal affective disorder) often depends on the weather. Victims of SAD are typically more despondent in rainy weather than when the sun is out, and more comfortable in the daylight hours than at night. The table shows the average number of daylight hours for Vancouver, British Columbia, for 12 months of a year. (a) Use a calculator to find a sinusoidal regression model. (b) Use the model to estimate the *number of days* per year (use 1 month ≈ 30.5 days) with more than 14 hr of daylight. (c) Use the maximum and minimum values with the period and an appropriate horizontal shift to create a model of the data. How do the values for A, B, C, and D compare?

31. Average monthly rainfall: The average monthly rainfall (in inches) for Reno, Nevada, is shown in the table. (a) Use the data to find a sinusoidal regression model for the monthly rainfall. (b) Graph this equation model and the rainfall equation model for Cheyenne, Wyoming (from Example 5), on the same screen, and estimate the number of months that Reno gets more rainfall than Cheyenne.

Source: NOAA Comparative Climate Data 2004.

Month (Jan → 1)	Reno Rainfall	Month (Jan → 1)	Reno Rainfall
1	1.06	7	0.24
2	1.06	8	0.27
3	0.86	9	0.45
4	0.35	10	0.42
5	0.62	11	0.80
6	0.47	12	0.88

32. Hours of daylight by month: The number of daylight hours per month (as measured on the 15th of each month) is shown in the table for the cities of Beaumont, Texas, and Minneapolis, Minnesota. (a) Use the data to find a sinusoidal regression model of the daylight hours for each city. (b) Graph both equations on the same screen and use the graphs to estimate the number of days each year that Beaumont receives more daylight than Minneapolis (use 1 month = 30.5 days).

▶ EXTENDING THE CONCEPT

33. For the equations from Examples 1 and 2, use the minimum value (x, m) to show that $\frac{y - D}{A} \rightarrow \frac{m - D}{A}$ is equal to -1. Then verify this relationship in general by substituting $\frac{M - m}{2}$ for A and $\frac{M + m}{2}$ for D.

34. A *dampening factor* is any function whose product with a sinusoidal function causes a systematic reduction in amplitude. In the graph shown, the function $y = \sin(3x)$ has been dampened by the linear function $y = -\frac{1}{4}x + 2$ over the interval $[-2\pi, 2\pi]$. Notice that the peaks of the sine graph are points on the graph of this line. The table gives approximate points of intersection for $y = \sin(3x)$ with another dampening factor. Use the regression capabilities of a graphing calculator to find the approximate equation of the dampening factor. (*Hint:* It is not linear.)

x	y	x	y
$\frac{\pi}{6}$	2.12	$\frac{13\pi}{6}$	1.03
$\frac{5\pi}{6}$	1.58	$\frac{17\pi}{6}$	1.02
$\frac{3\pi}{2}$	1.22	$\frac{7\pi}{2}$	1.18

▶ MAINTAINING YOUR SKILLS

35. **(2.4)** State the domains of the following functions:

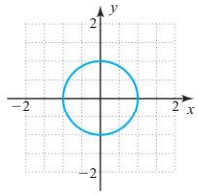
a. $f(x) = x^{1.7}$ **b.** $g(x) = x^{\frac{4}{5}}$

c. $h(x) = \sqrt[9]{x^3}$

36. **(5.4)** Use properties of logarithms to write the following as a single term.

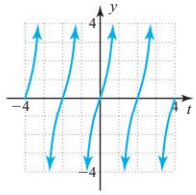
$$4 \log 2 - \frac{1}{2} \log 25$$

37. **(6.1)** The barrel on a winch has a radius of 3 in. and is turning at 30 rpm. As the barrel turns it winds in a cable that is pulling a heavy pallet across the warehouse floor. How fast is the pallet moving in feet per minute?



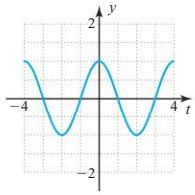
38. **(6.6)** Clarke is standing between two tall buildings. The angle of elevation to the top of the building to her north is 60°, while the angle of elevation to the top of the building to her south is 70°. If she is 400 m from the base of the northern building and 200 m from the southern, which one is taller?

MAKING CONNECTIONS

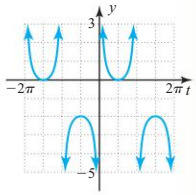


Making Connections: Graphically, Symbolically, Numerically, and Verbally

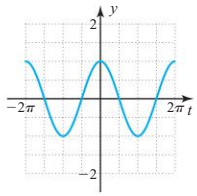
Eight graphs A through H are given. Match the characteristics given in 1 through 16 to one of the eight graphs.



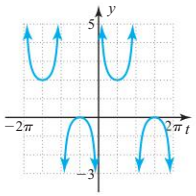
(a)



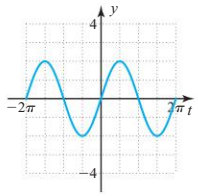
(b)



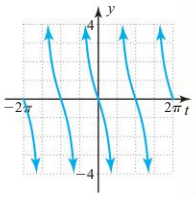
(c)



(d)



(e)



(f)

(g)

(h)

1. ____ period $= \pi$

2. ____ amplitude $= 2$

3. ____ $f(t) = \sec\left(t - \frac{\pi}{2}\right) - 1$

4. ____ $f(t) = 2 \sin t$

5. ____ minimum of -1 occurs at $t = -\pi$

6. ____ $x^2 + y^2 = 1$

7. ____ $f(t) = \sin\left(t + \frac{\pi}{2}\right)$

8. ____ period $= 2$

9. ____ period $= 4$

10. ____ $f(t) = \cos\left(\frac{\pi}{2}t\right)$

11. ____ $f(t) = 2 \tan\left(\frac{\pi}{2}t\right)$

12. ____ The point $\left(\frac{1}{2}, \frac{\sqrt{3}}{2}\right)$ is on the graph

13. ____ $t \neq k\pi$, shifted up 1 unit

14. ____ $f(t) = \csc t + 1$

15. ____ $f(t) = 2 \cot\left(t - \frac{\pi}{2}\right)$

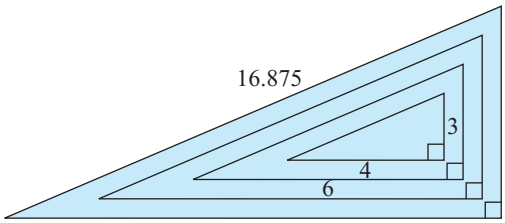
16. ____ $f(t) \downarrow$ for $t \in \mathbb{R}$

SUMMARY AND CONCEPT REVIEW

SECTION 6.1 Angle Measure, Special Triangles, and Special Angles

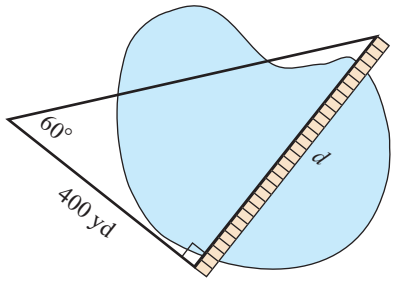
KEY CONCEPTS

- An angle is defined as the joining of two rays at a common endpoint called the vertex.
- An angle in standard position has its vertex at the origin and its initial side on the positive x-axis.
- Two angles in standard position are coterminal if they have the same terminal side.
- A counterclockwise rotation gives a positive angle, a clockwise rotation gives a negative angle.
- One (1°) degree is defined to be $\frac{1}{360}$ of a full revolution. One (1) radian is the measure of a central angle subtended by an arc equal in length to the radius.
- Degrees can be divided into a smaller unit called minutes: $1^\circ = 60'$; minutes can be divided into a smaller unit called seconds: $1' = 60''$. This implies $1^\circ = 3600''$.
- Two angles are complementary if they sum to 90° and supplementary if they sum to 180°.
- Properties of triangles: (I) the sum of the angles is 180°; (II) the combined length of any two sides must exceed that of the third side and; (III) larger angles are opposite longer sides.
- Given two triangles, if all three corresponding angles are equal, the triangles are said to be similar. If two triangles are similar, then corresponding sides are in proportion.
- In a 45-45-90 triangle, the sides are in the proportion $1x$: $1x$: $\sqrt{2}x$.
- In a 30-60-90 triangle, the sides are in the proportion $1x$: $\sqrt{3}x$: $2x$.
- The formula for arc length: $s = r\theta$, θ in radians.
- The formula for the area of a circular sector: $\mathcal{A} = \frac{1}{2}r^2\theta$, θ in radians.
- To convert degree measure to radians, multiply by $\frac{\pi}{180^\circ}$; for radians to degrees, multiply by $\frac{180^\circ}{\pi}$.
- Special angle conversions: $30^\circ = \frac{\pi}{6}$, $45^\circ = \frac{\pi}{4}$, $60^\circ = \frac{\pi}{3}$, $90^\circ = \frac{\pi}{2}$.
- A location north or south of the equator is given in degrees latitude; a location east or west of the Greenwich Meridian is given in degrees longitude.
- Angular velocity is a rate of rotation per unit time: $\omega = \frac{\theta}{t}$.
- Linear velocity is a change in position per unit time: $V = \frac{\theta r}{t}$ or $V = r\omega$.



EXERCISES

1. Convert $147^\circ\ 36'\ 48''$ to decimal degrees.



2. Convert 32.87° to degrees, minutes, and seconds.

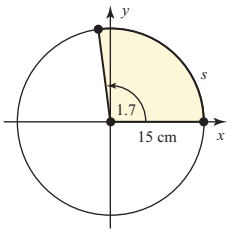
3. All of the right triangles given are similar. Find the dimensions of the largest triangle.

Exercise 3

Exercise 4

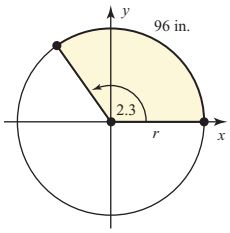
4. Use special angles/special triangles to find the length of the bridge needed to cross the lake shown in the figure.

5. Convert to degrees: $\frac{2\pi}{3}$.



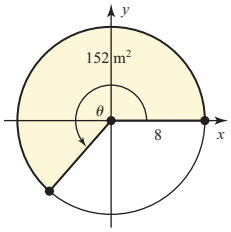
6. Convert to radians: 210°.

7. Find the arc length if $r = 5$ and $\theta = 57°$.



8. Evaluate without using a calculator: $\sin\left(\frac{7\pi}{6}\right)$.

Find the angle, radius, arc length, and/or area as needed, until all values are known.



9.

10.

11.

12. With great effort, 5-year-old Mackenzie has just rolled her bowling ball down the lane, and it is traveling painfully slow. So slow, in fact, that you can count the number of revolutions the ball makes using the finger holes as a reference. (a) If the ball is rolling at 1.5 revolutions per second, what is the angular velocity? (b) If the ball's radius is 5 in., what is its linear velocity in feet per second? (c) If the distance to the first pin is 60 feet and the ball is true, how many seconds until it hits?

SECTION 6.2 Unit Circles and the Trigonometry of Real Numbers

KEY CONCEPTS

- A central unit circle is a circle with radius 1 unit having its center at the origin.
- A central circle is symmetric to both axes and the origin. This means that if (a, b) is a point on the circle, then $(-a, b)$, $(-a, -b)$, and $(a, -b)$ are also on the circle and satisfy the equation of the circle.
- On the unit circle with θ in radians, the length of a subtended arc is numerically the same as the subtended angle, making the arc a "circular number line" and associating any given rotation with a unique real number.
- A reference angle is defined to be the acute angle formed by the terminal side of a given angle and the x-axis. For functions of a real number we refer to a reference arc rather than a reference angle.

- For any real number t and a point on the unit circle associated with t, we have:

$$\cos t = x \qquad \sin t = y \qquad \tan t = \frac{y}{x},\ x \neq 0 \qquad \sec t = \frac{1}{x},\ x \neq 0 \qquad \csc t = \frac{1}{y},\ y \neq 0 \qquad \cot t = \frac{x}{y},\ y \neq 0$$

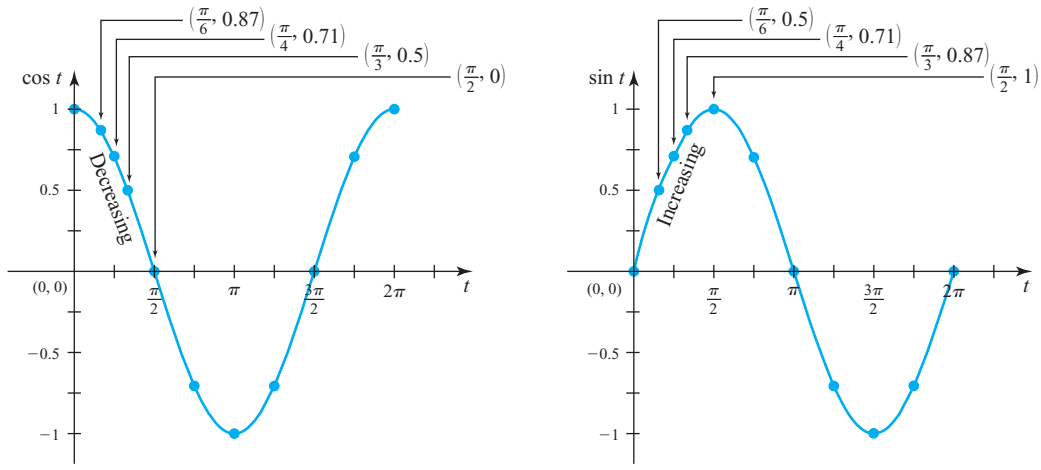
- Given the specific value of any function, the related real number t or angle θ can be found using a special reference arc/angle, or the $\sin^{-1}$, $\cos^{-1}$, or $\tan^{-1}$ features of a calculator.

EXERCISES

13. Given $\left(\frac{\sqrt{13}}{7}, y\right)$ is on the unit circle, find y if the point is in QIV, then use the symmetry of the circle to locate three other points.

14. Given $\left(\frac{3}{4}, -\frac{\sqrt{7}}{4}\right)$ is on the unit circle, find the value of all six trig functions of t without the use of a calculator.

15. Without using a calculator, find two values in $[0, 2\pi)$ that make the equation true: $\csc t = \frac{2}{\sqrt{3}}$.



16. Use a calculator to find the value of t that corresponds to the situation described: $\cos t = -0.7641$ with t in QII.

17. A crane used for lifting heavy equipment has a winch-drum with a 1-yd radius. (a) If 59 ft of cable has been wound in while lifting some equipment to the roof-top of a building, what radian angle has the drum turned through? (b) What angle must the drum turn through to wind in 75 ft of cable?

SECTION 6.3 Graphs of the Sine and Cosine Functions

KEY CONCEPTS

- Graphing sine and cosine functions using the special values from the unit circle results in a periodic, wavelike graph with domain $(-\infty, \infty)$.

- The characteristics of each graph play a vital role in their contextual application, and these are summarized on pages 546 and 550.
- The amplitude of a sine or cosine graph is the maximum displacement from the average value. For $y = A\sin(Bt)$ and $y = A\cos(Bt)$, the amplitude is $|A|$.
- The period of a periodic function is the smallest interval required to complete one cycle.

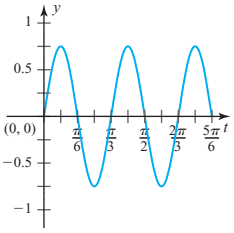
  For $y = A\sin(Bt)$ and $y = A\cos(Bt)$, $P = \frac{2\pi}{B}$ gives the period.

- If $|A| > 1$, the graph is vertically stretched, if $0 < |A| < 1$ the graph is vertically compressed, and if $A < 0$ the graph is reflected across the x-axis.
- If $B > 1$, the graph is horizontally compressed (the period is smaller/shorter); if $B < 1$ the graph is horizontally stretched (the period is larger/longer).
- To graph $y = A\sin(Bt)$ or $A\cos(Bt)$, draw a reference rectangle $2A$ units high and $P = \dfrac{2\pi}{B}$ units wide, centered on the x-axis, then use the *rule of fourths* to locate zeroes and max/min values. Connect these points with a smooth curve.

EXERCISES

Use a reference rectangle and the *rule of fourths* to draw an accurate sketch of the following functions through at least one full period. Clearly state the amplitude and period as you begin.

18. $y = 3\sin t$



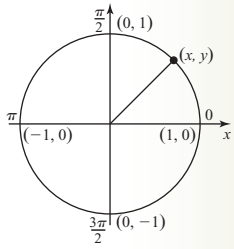
19. $y = -\cos(2t)$

20. $y = 1.7\sin(4t)$

21. $f(t) = 2\cos(4\pi t)$

22. $g(t) = 3\sin(398\pi t)$

23. The given graph is of the form $y = A\sin(Bt)$. Determine the equation of the graph.



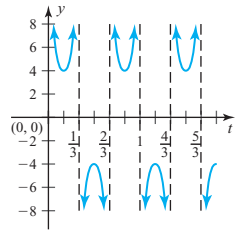
24. Referring to the chart of colors visible in the electromagnetic spectrum (page 559), what color is represented by the equation $y = \sin\left(\dfrac{\pi}{270}t\right)$?

By $y = \sin\left(\dfrac{\pi}{320}t\right)$?

SECTION 6.4 Graphs of the Cosecant, Secant, Tangent, and Cotangent Functions

KEY CONCEPTS

- The graph of $y = \sec t = \dfrac{1}{\cos t}$ will be asymptotic everywhere $\cos t = 0$, increasing where $\cos t$ is decreasing, and decreasing where $\cos t$ is increasing.
- The graph of $y = \csc t = \dfrac{1}{\sin t}$ will be asymptotic everywhere $\sin t = 0$, increasing where $\sin t$ is decreasing, and decreasing where $\sin t$ is increasing.
- Since $\tan t$ is defined in terms of the ratio $\dfrac{y}{x}$, the graph will be asymptotic everywhere $x = 0$ on the unit circle, meaning all odd multiples of $\dfrac{\pi}{2}$.
- Since $\cot t$ is defined in terms of the ratio $\dfrac{x}{y}$, the graph will be asymptotic everywhere $y = 0$ on the unit circle, meaning all integer multiples of π.
- The graph of $y = \tan t$ is increasing everywhere it is defined; the graph of $y = \cot t$ is decreasing everywhere it is defined.
- The characteristics of each graph play vital roles in their contextual application, and these are summarized on pages 563 and 567.



- For the more general tangent and cotangent graphs $y = A\tan(Bt)$ and $y = A\cot(Bt)$, if $|A| > 1$, the graph is vertically stretched, if $0 < |A| < 1$ the graph is vertically compressed, and if $A < 0$ the graph is reflected across the x-axis.
- If $B > 1$, the graph is horizontally compressed (the period is smaller/shorter); if $B < 1$ the graph is horizontally stretched (the period is larger/longer).
- To graph $y = A\tan(Bt)$, note $A\tan(Bt)$ is zero at $t = 0$. Compute the period $P = \dfrac{\pi}{B}$ and draw asymptotes a distance of $\dfrac{P}{2}$ on either side of the y-axis. Plot zeroes halfway between the asymptotes and use symmetry to complete the graph.
- To graph $y = A\cot(Bt)$, note it is asymptotic at $t = 0$. Compute the period $P = \dfrac{\pi}{B}$ and draw asymptotes a distance P on either side of the y-axis. Plot zeroes halfway between the asymptotes and use symmetry to complete the graph.

EXERCISES

25. Use a reference rectangle and the *rule of fourths* to draw an accurate sketch of $y = 3\sec t$ through at least one full period. Clearly state the period as you begin.

26. The given graph is of the form $y = A\csc(Bt)$. Determine the equation of the graph.

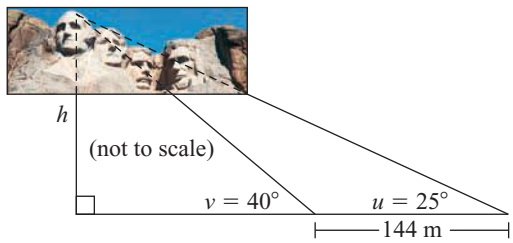
Exercise 26

27. State the value of each expression without the aid of a calculator:

a. $\tan\left(\dfrac{7\pi}{4}\right)$ **b.** $\cot\left(\dfrac{\pi}{3}\right)$

28. State the value of each expression without the aid of a calculator, given that t terminates in QII.

a. $\tan^{-1}(-\sqrt{3})$ **b.** $\cot^{-1}\left(-\dfrac{1}{\sqrt{3}}\right)$



29. Graph $y = 6\tan\left(\dfrac{1}{2}t\right)$ in the interval $[-2\pi, 2\pi]$.

30. Graph $y = \dfrac{1}{2}\cot(2\pi t)$ in the interval $[-1, 1]$.

31. Use the period of $y = \cot t$ to name three additional solutions to $\cot t = 0.0208$, given $t = 1.55$ is a solution. Many solutions are possible.

32. Given $t = 0.4444$ is a solution to $\cot^{-1} t = 2.1$, use an analysis of signs and quadrants to name an additional solution in $[0, 2\pi)$.

33. Find the approximate height of Mount Rushmore, using $h = \dfrac{d}{\cot u - \cot v}$ and the values shown.

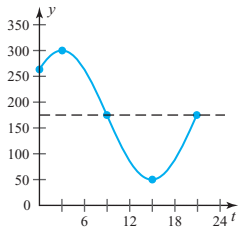
SECTION 6.5 Transformations and Applications of Trigonometric Graphs

KEY CONCEPTS

- Many everyday phenomena follow a sinusoidal pattern, or a pattern that can be modeled by a sine or cosine function (e.g., daily temperatures, hours of daylight, and more).
- To obtain accurate equation models of sinusoidal phenomena, vertical and horizontal shifts of a basic function are used.
- The equation $y = A\sin(Bt \pm C) + D$ is called the *standard form* of a general sinusoid. The equation $y = A\sin\left[B\left(t \pm \frac{C}{B}\right)\right] + D$ is called the *shifted form* of a general sinusoid.
- In either form, D represents the average value of the function and a vertical shift D units upward if $D > 0$, D units downward if $D < 0$. For a maximum value M and minimum value m, $\frac{M+m}{2} = D$, $\frac{M-m}{2} = A$.
- The shifted form $y = A\sin\left[B\left(t \pm \frac{C}{B}\right)\right] + D$ enables us to quickly identify the horizontal shift of the function: $\frac{C}{B}$ units in a direction opposite the given sign.
- To graph a shifted sinusoid, locate the primary interval by solving $0 \le Bt + C < 2\pi$, then use a reference rectangle along with the *rule of fourths* to sketch the graph in this interval. The graph can then be extended as needed, then shifted vertically D units.
- One basic application of sinusoidal graphs involves phenomena in harmonic motion, or motion that can be modeled by functions of the form $y = A\sin(Bt)$ or $y = A\cos(Bt)$ (with no horizontal or vertical shift).
- If the period P and critical points (X, M) and (x, m) of a sinusoidal function are known, a model of the form $y = A\sin(Bt + C) + D$ can be obtained:

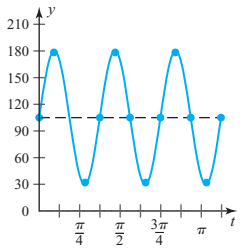
$$B = \frac{2\pi}{P} \qquad A = \frac{M-m}{2} \qquad D = \frac{M+m}{2} \qquad C = \frac{3\pi}{2} - Bx$$

EXERCISES



For each equation given, (a) identify/clearly state the amplitude, period, horizontal shift, and vertical shift; then (b) graph the equation using the primary interval, a reference rectangle, and *rule of fourths*.

34. $y = 240\sin\left[\frac{\pi}{6}(t-3)\right] + 520$

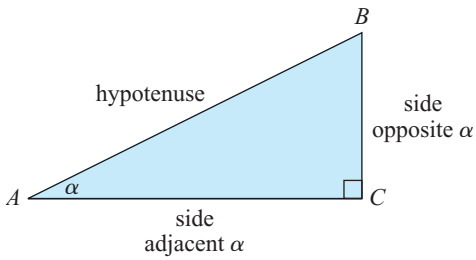


35. $y = 3.2\cos\left(\frac{\pi}{4}t + \frac{3\pi}{2}\right) + 6.4$

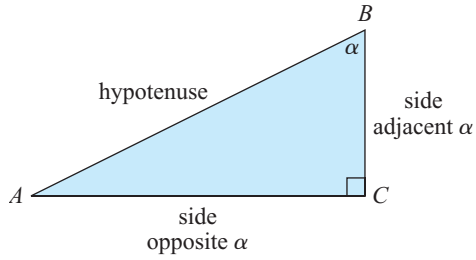
For each graph given, identify the amplitude, period, horizontal shift, and vertical shift, and give the equation of the graph.

36.

37.



38. Monthly precipitation in Cheyenne, Wyoming, can be modeled by a sine function, by using the average precipitation for June (2.26 in.) as a maximum (actually slightly higher in May), and the average precipitation for December (0.44 in.) as a minimum. Assume $t = 0$ corresponds to March. (a) Use the information to construct a sinusoidal model, and (b) use the model to estimate the inches of precipitation Cheyenne receives in August ($t = 5$) and September ($t = 6$).



Source: 2004 Statistical Abstract of the United States, Table 380.

SECTION 6.6 The Trigonometry of Right Triangles

KEY CONCEPTS

- The sides of a right triangle can be named relative to their location with respect to a given angle.

- The ratios of two sides with respect to a given angle are named as follows:

$$\sin\alpha = \frac{\text{opp}}{\text{hyp}} \qquad \cos\alpha = \frac{\text{adj}}{\text{hyp}} \qquad \tan\alpha = \frac{\text{opp}}{\text{adj}}$$

- The reciprocal of the ratios above play a vital role and are likewise given special names:

$$\csc\alpha = \frac{\text{hyp}}{\text{opp}} \qquad \sec\alpha = \frac{\text{hyp}}{\text{adj}} \qquad \cot\alpha = \frac{\text{adj}}{\text{opp}}$$

$$\csc\alpha = \frac{1}{\sin\alpha} \qquad \sec\alpha = \frac{1}{\cos\alpha} \qquad \cot\alpha = \frac{1}{\tan\alpha}$$

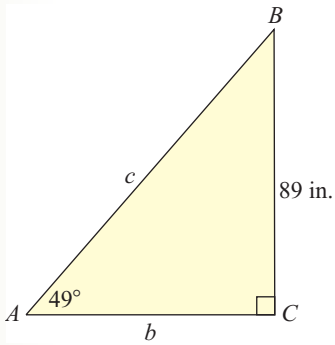
- Each function of α is equal to the cofunction of its complement. For instance, the complement of sine is *co*sine and $\sin\alpha = \cos(90° - \alpha)$.
- To solve a right triangle means to apply any combination of the trig functions, along with the triangle properties, until all sides and all angles are known.
- An angle of elevation is the angle formed by a horizontal line of sight (parallel to level ground) and the true line of sight. An angle of depression is likewise formed, but with the line of sight below the line of orientation.

EXERCISES

39. Use a calculator to solve for A:

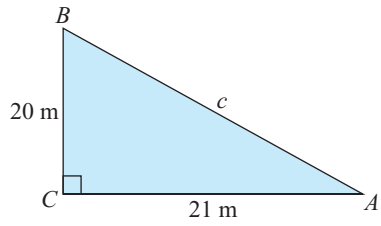
a. $\cos 37° = A$

b. $\cos A = 0.4340$



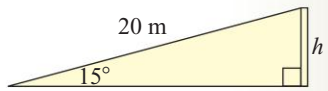
40. Rewrite each expression in terms of a cofunction.

a. $\tan 57.4°$

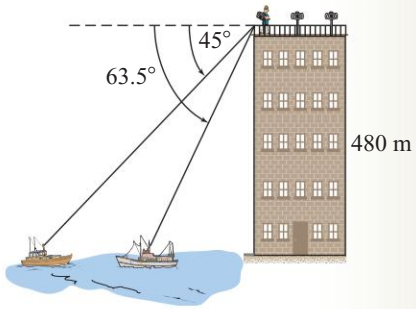


b. $\sin(19° 30' 15'')$

Solve each triangle. Round angles to the nearest tenth and sides to the nearest hundredth.



41.



42.

43. Josephine is to weld a vertical support to a 20-m ramp so that the incline is exactly 15°. What is the height h of the support that must be used?

44. From the observation deck of a seaside building 480 m high, Armando sees two fishing boats in the distance. The angle of depression to the nearer boat is 63.5°, while for the boat farther away the angle is 45°. (a) How far out to sea is the nearer boat? (b) How far apart are the two boats?

45. A slice of bread is roughly 14 cm by 10 cm. If the slice is cut diagonally in half, what acute angles are formed?

SECTION 6.7 Trigonometry and the Coordinate Plane

KEY CONCEPTS

- In standard position, the terminal sides of 0°, 90°, 180°, 270°, and 360° angles coincide with one of the axes and are called quadrantal angles.
- By placing a right triangle in the coordinate plane with one acute angle at the origin and one side along the x-axis, we note the trig functions can be defined in terms of a point $P(x, y)$ on the hypotenuse.
- Given $P(x, y)$ is any point on the terminal side of an angle θ in standard position. Then $r = \sqrt{x^2 + y^2}$ is the distance from the origin to this point. The six trigonometric functions of θ are defined as

$$\sin\theta = \frac{y}{r} \qquad \cos\theta = \frac{x}{r} \qquad \tan\theta = \frac{y}{x} \qquad \csc\theta = \frac{r}{y} \qquad \sec\theta = \frac{r}{x} \qquad \cot\theta = \frac{x}{y}$$
$$x \neq 0 \qquad\qquad y \neq 0 \qquad\qquad x \neq 0 \qquad\qquad y \neq 0$$

- A reference angle θ_r is defined to be the acute angle formed by the terminal side of a given angle θ and the x-axis.
- Reference angles can be used to evaluate the trig functions of any nonquadrantal angle, since the values are fixed by the ratio of sides and the signs are dictated by the quadrant of the terminal side.
- If the value of a trig function and the quadrant of the terminal side are known, the related angle θ can be found using a reference arc/angle, or the $\sin^{-1}$, $\cos^{-1}$, or $\tan^{-1}$ features of a calculator.
- If θ is a solution to $\sin\theta = k$, then $\theta + 360°k$ is also a solution for any integer k.

EXERCISES

46. Find two positive angles and two negative angles that are coterminal with $\theta = 207°$.

47. Name the reference angle for the angles given: $\theta = -152°$, $\theta = 521°$, $\theta = 210°$

48. Find the value of the six trigonometric functions, given $P(x, y)$ is on the terminal side of angle θ in standard position.

a. $P(-12, 35)$ **b.** $(12, -18)$

49. Find the values of x, y, and r using the information given, and state the quadrant of the terminal side of θ. Then state the values of the six trig functions of θ.

a. $\cos\theta = \frac{4}{5}$; $\sin\theta < 0$ **b.** $\tan\theta = -\frac{12}{5}$; $\cos\theta > 0$

50. Find all angles satisfying the stated relationship. For standard angles, express your answer in exact form. For nonstandard angles, use a calculator and round to the nearest tenth.

a. $\tan\theta = -1$ **b.** $\cos\theta = \frac{\sqrt{3}}{2}$ **c.** $\tan\theta = 4.0108$ **d.** $\sin\theta = -0.4540$

SECTION 6.8 Trigonometric Equation Models

KEY CONCEPTS

- If the period P and critical points (X, M) and (x, m) of a sinusoidal function are known, a model of the form $y = A\sin(Bt + C) + D$ can be obtained:

$$B = \frac{2\pi}{P} \qquad A = \frac{M - m}{2} \qquad D = \frac{M + m}{2} \qquad C = \frac{3\pi}{2} - Bx$$

- If an event or phenomenon is known to be sinusoidal, a graphing calculator can be used to find an equation model if at least four data points are given.

EXERCISES

For the following sets of data, (a) find a sinusoidal regression equation using your calculator; (b) construct an equation manually using the period and maximum/minimum values; and (c) graph both on the same screen, then use a TABLE to find the largest difference between output values.

51.

Day of Year	Output	Day of Year	Output
1	4430	184	90
31	3480	214	320
62	3050	245	930
92	1890	275	2490
123	1070	306	4200
153	790	336	4450

52.

Day of Month	Output	Day of Month	Output
1	69	19	98
4	78	22	92
7	84	25	85
10	91	28	76
13	96	31	67
16	100		

53. The highest temperature on record for the even months of the year are given in the table for the city of Juneau, Alaska. (a) Use a graphing calculator to find a sinusoidal regression model. (b) Use the equation to estimate the record high temperature for the month of July. (c) Compare the actual data to the results produced by the regression model. What comments can you make about the accuracy of the model?

Source: 2004 Statistical Abstract of the United States, Table 378.

Month (Jan → 1)	High Temp(°F)
2	57
4	72
6	86
8	83
10	61
12	54

PRACTICE TEST

1. Name the reference angle of each angle given.

a. $225°$ **b.** $-510°$

c. $\frac{7\pi}{6}$ **d.** $\frac{25\pi}{3}$

2. Find two negative angles and two positive angles that are coterminal with $\theta = 30°$. Many solutions are possible.

3. Convert from DMS to decimal degrees or decimal degrees to DMS as indicated.

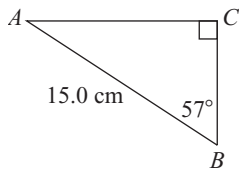
a. $100° 45' 18''$ to decimal degrees

b. $48.2125°$ to DMS

4. Four Corners USA is the point at which Utah, Colorado, Arizona, and New Mexico meet. The southern border of Colorado, the western border of Kansas, and the point P where Colorado, Nebraska, and Kansas meet, very nearly approximates a 30-60-90 triangle. If the western border of Kansas is 215 mi long, (a) what is the distance from Four Corners USA to point P? (b) How long is Colorado's southern border?

5. Complete the table from memory using exact values. If a function is undefined, so state.

t	sin t	cos t	tan t	csc t	sec t	cot t
0						
$\frac{2\pi}{3}$						
$\frac{7\pi}{6}$						
$\frac{5\pi}{4}$						
$\frac{5\pi}{3}$						
$\frac{13\pi}{6}$						

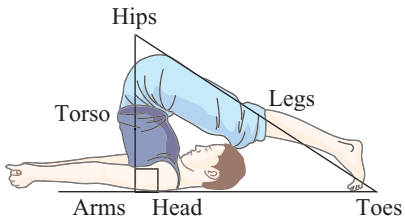


6. Given $\cos\theta = \frac{2}{5}$ and $\tan\theta < 0$, find the value of the other five trig functions of θ.

7. Verify that $\left(\frac{1}{3}, -\frac{2\sqrt{2}}{3}\right)$ is a point on the unit circle, then find the value of all six trig functions associated with this point.

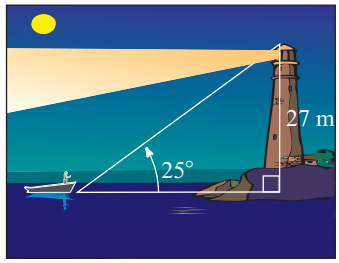
8. In order to take pictures of a dance troupe as it performs, a camera crew rides in a cart on tracks that trace a circular arc. The radius of the arc is 75 ft, and from end to end the cart sweeps out an angle of $172.5°$ in 20 seconds. Use this information to find (a) the length of the track in feet and inches, (b) the angular velocity of the cart, and (c) the linear velocity of the cart in both ft/sec and mph.

9. Solve the triangle shown. Answer in table form.



Exercise 9

10. The "plow" is a yoga position in which a person lying on their back brings their feet up, over, and behind their head and touches them to the floor. If distance from hip to shoulder (at the right angle) is 57 cm and from hip to toes is 88 cm, find the



distance from shoulders to toes and the angle formed at the hips.

Exercise 10

11. While doing some night fishing, you round a peninsula and a tall lighthouse comes into view. Taking a sighting, you find the angle of elevation to the top of the lighthouse is 25°. If the lighthouse is known to be 27 m tall, how far from the lighthouse are you?

Exercise 11

12. Find the value of $t \in [0, 2\pi]$ satisfying the conditions given.

a. $\sin t = -\frac{1}{2}$, t in QIII

b. $\sec t = \frac{2\sqrt{3}}{3}$, t in QIV

c. $\tan t = -1$, t in QII

13. In arid communities, daily water usage can often be approximated using a sinusoidal model. Suppose water consumption in the city of Caliente del Sol reaches a maximum of 525,000 gallons in the heat of the day, with a minimum usage of 157,000 gallons in the cool of the night. Assume $t = 0$ corresponds to 6:00 A.M. (a) Use the information to construct a sinusoidal model, and (b) use the model to approximate water usage at 4:00 P.M. and 4:00 A.M.

14. State the domain, range, period, and amplitude (if it exists), then graph the function over 1 period.

a. $y = 2\sin\left(\frac{\pi}{5}t\right)$ **b.** $y = \sec t$

c. $y = 2\tan(3t)$

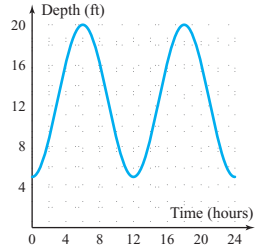
15. The lowest temperature on record for the even months of the year are given in the table for the city of Denver, Colorado. (a) Use a graphing calculator to find a sinusoidal regression model and (b) use the equation to estimate the record low temperature for the odd numbered months.

Source: 2004 Statistical Abstract of the United States, Table 379.

Month (Jan → 1)	Low Temp (°F)
2	−30
4	−2
6	30
8	41
10	3
12	−25

16. State the amplitude, period, horizontal shift, vertical shift, and endpoints of the primary interval. Then sketch the graph using a reference rectangle and the *rule of fourths:*

$$y = 12\sin\left(3t - \frac{\pi}{4}\right) + 19.$$



17. An athlete throwing the shot-put begins his first attempt facing due east, completes three and one-half turns and launches the shot facing due west. What angle did his body turn through?

18. State the domain, range, and period, then sketch the graph in $[0, 2\pi)$.

a. $y = \tan(2t)$ **b.** $y = \cot\left(\frac{1}{2}t\right)$

19. Due to tidal motions, the depth of water in Brentwood Bay varies sinusoidally as shown in the diagram, where time is in hours and depth is in feet. Find an equation that models the depth of water at time t.

Exercise 19

20. Find the value of t satisfying the given conditions.

a. $\sin t = -0.7568$; t in QIII

b. $\sec t = -1.5$; t in QII

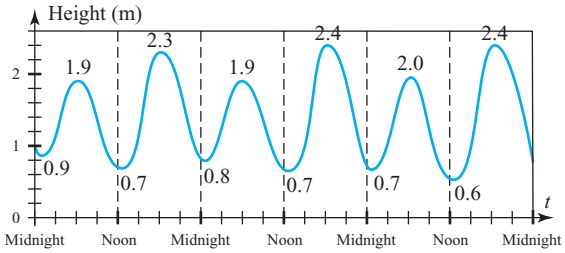
CALCULATOR EXPLORATION AND DISCOVERY

Variable Amplitudes and Modeling the Tides

Tidal motion is often too complex to be modeled by a single sine function. In this *Exploration and Discovery*, we'll look at a method that combines two sine functions to help model a tidal motion with variable amplitude. In the process, we'll use much of what we know about the amplitude, horizontal shifts, and vertical shifts of a sine function, helping to reinforce these important concepts and broaden our understanding about how they can be applied. The graph in Figure 6.148 shows three days of tidal motion for Davis Inlet, Canada.

As you can see, the amplitude of the graph varies, and there is no *single* sine function that can serve as a model. However, notice that the amplitude *varies predictably*, and that the high tides and low tides can independently be modeled by sine functions. To simplify our exploration, we will use the assumption that tides have an exact 24-hr period (close, but no), that variations between high and low tides takes place every 12 hr (again close but not exactly true), and the variation between the "low-high" (1.9 m) and the "high-high" (2.4 m) is uniform. A similar assumption is made for the low tides. The result is the graph in Figure 6.149.

Figure 6.148



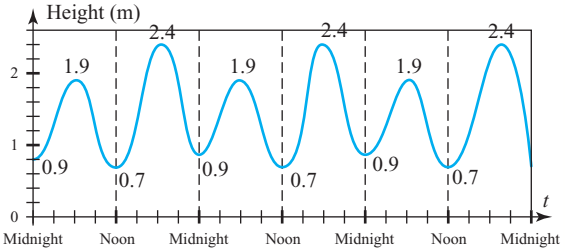


Figure 6.149

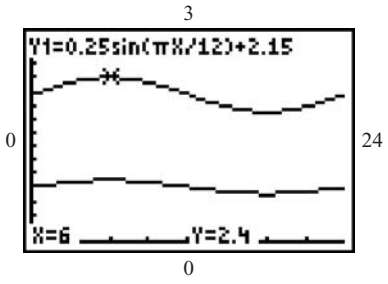
First consider the high tides, which vary from a maximum of 2.4 to a minimum of 1.9. Using the ideas from Section 6.7 to construct an equation model gives $A = \dfrac{2.4 - 1.9}{2} = 0.25$ and $D = \dfrac{2.4 + 1.9}{2} = 2.15$. With a period of $P = 24$ hr we obtain the equation $Y_1 = 0.25 \sin\left(\dfrac{\pi}{12}x\right) + 2.15$. Using 0.9 and 0.7 as the maximum and minimum low tides, similar calculations yield the equation $Y_2 = 0.1 \sin\left(\dfrac{\pi}{12}x\right) + 0.8$ (verify this). Graphing these two functions over a 24-hr period yields the graph in Figure 6.150, where we note the high and low values are correct, but the two functions are in phase with each other. As can be determined from Figure 6.149, we want the high tide model to start at the average value and decrease, and the low tide equation model to start at high-low and decrease. Replacing x with $x - 12$ in Y_1 and x with $x + 6$ in Y_2 accomplishes this result (see Figure 6.151). Now comes the fun part! Since Y_1 represents the low/high maximum values for high tide, and Y_2 represents the low/high minimum values for low tide,

Figure 6.150



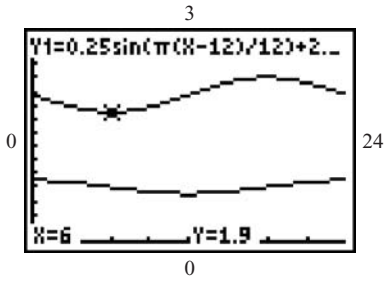


Figure 6.151

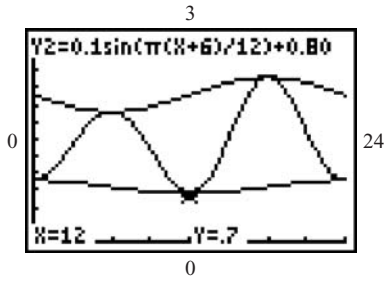
the amplitude and average value for the tidal motion at Davis Inlet are $A = \dfrac{Y_1 - Y_2}{2}$ and $D = \dfrac{Y_1 + Y_2}{2}$! By entering $Y_3 = \dfrac{Y_1 - Y_2}{2}$ and $Y_4 = \dfrac{Y_1 + Y_2}{2}$, the equation for the tidal motion (with its variable amplitude) will have the form $Y_5 = Y_3 \sin(Bx \pm C) + Y_4$, where the value of B and C must be determined. The key here is to note there is only a 12-hr difference between the changes in amplitude, so $P = 12$ (instead of 24) and $B = \dfrac{\pi}{6}$ for this function. Also, from the graph (Figure 6.149) we note the tidal motion begins at a minimum and increases, indicating a shift of 3 units to the right is required. Replacing x with $x - 3$ gives the equation modeling these tides, and the final equation is $Y_5 = Y_3 \sin\left[\dfrac{\pi}{6}(X - 3)\right] + Y_4$. Figure 6.152 gives a screen shot of Y_1, Y_2, and Y_5 in the interval [0, 24]. The tidal graph from Figure 6.149 is shown in Figure 6.153 with Y_1 and Y_2 superimposed on it.

Figure 6.152



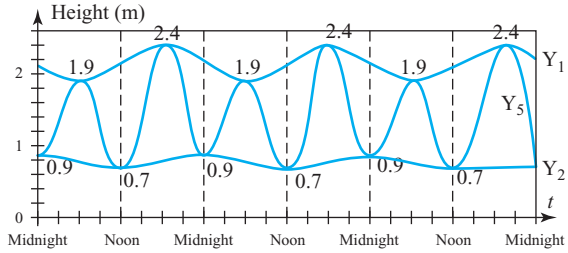


Figure 6.153

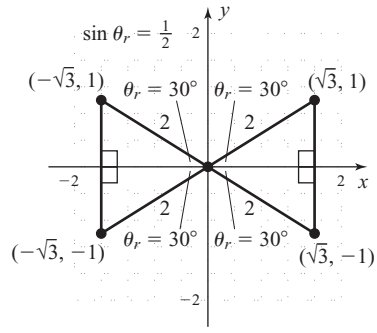

Exercise 1: The website www.tides.com/*tcpred*.htm offers both *t*ide and *c*urrent *pred*ictions for various locations around the world, in both numeric and graphical form. In addition, data for the "two" high tides and "two" low tides are clearly highlighted. Select a coastal area where tidal motion is similar to that of Davis Inlet, and repeat this exercise. Compare your model to the actual data given on the website. How good was the fit?

STRENGTHENING CORE SKILLS

Standard Angles, Reference Angles, and the Trig Functions

A review of the main ideas discussed in this chapter indicates there are four of what might be called "core skills." These are skills that (a) play a fundamental part in the acquisition of concepts, (b) hold the overall structure together as we move from concept to concept, and (c) are ones we return to again and again throughout our study. The first of these is *(1) knowing the standard angles and standard values.* These values are "standard" because no estimation, interpolation, or special methods are required to name their values, and each can be expressed as a single factor. This gives them a great advantage in that further conceptual development can take place without the main points being obscured by large expressions or decimal approximations. Knowing the values of the trig functions for each standard angle will serve you very well throughout this study. *Know* the chart on page 537 and the ideas that led to it.

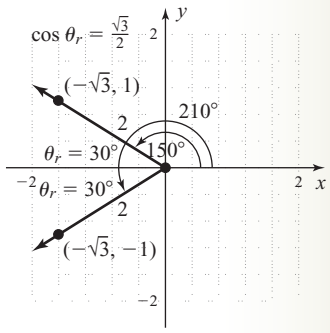

Figure 6.154

The standard angles/values brought us to the trigonometry of any angle, forming a strong bridge to the second core skill: *(2) using reference angles to determine the values of the trig functions in each quadrant.* For review, a 30-60-90 triangle will always have sides that are in the proportion $1x$: $\sqrt{3}x$: $2x$, regardless of its size. This means for any angle θ, where $\theta_r = 30°$, $\sin\theta = \frac{1}{2}$ or $\sin\theta = -\frac{1}{2}$ since the *ratio is fixed* but the sign *depends on the quadrant of* θ: $\sin 30° = \frac{1}{2}$ [QI], $\sin 150° = \frac{1}{2}$ [QII], $\sin 210° = -\frac{1}{2}$ [QIII], $\sin 330° = -\frac{1}{2}$ [QII], and so on (see Figure 6.154).

In turn, the reference angles led us to a third core skill, helping us realize that if θ was not a quadrantal angle, *(3) equations like* $\cos(\theta) = -\dfrac{\sqrt{3}}{2}$ *must have two solutions in* $[0, 360°)$. From the standard angles and standard values we learn to recognize that for $\cos\theta = -\dfrac{\sqrt{3}}{2}$, $\theta_r = 30°$, which will occur as a reference angle in the two quadrants where cosine is negative, QII and QIII. The solutions in $[0, 360°)$ are $\theta = 150°$ and $\theta = 210°$ (see Figure 6.155).

Figure 6.155

Of necessity, this brings us to the fourth core skill, *(4) effective use of a calculator.* The standard angles are a wonderful vehicle for introducing the basic ideas of trigonometry, and actually occur quite frequently in real-world applications. But by far, most of the values we encounter will be nonstandard values where θ_r must be found using a calculator. However, once θ_r is found, the reason and reckoning inherent in these ideas can be directly applied.

The *Summary and Concept Review Exercises*, as well as the *Practice Test* offer ample opportunities to refine these skills, so that they will serve you well in future chapters as we continue our attempts to explain and understand the world around us in mathematical terms.

Exercise 1: Fill in the table from memory.

t	0	$\frac{\pi}{6}$	$\frac{\pi}{4}$	$\frac{\pi}{3}$	$\frac{\pi}{2}$	$\frac{2\pi}{3}$	$\frac{3\pi}{4}$	$\frac{5\pi}{6}$	π	$\frac{7\pi}{6}$	$\frac{5\pi}{4}$
$\sin t = y$											
$\cos t = x$											
$\tan t = \frac{y}{x}$											

Exercise 2: Solve each equation in $[0, 2\pi)$ without the use of a calculator.

a. $2\sin t + \sqrt{3} = 0$

b. $-3\sqrt{2}\cos t + 4 = 1$

c. $-\sqrt{3}\tan t + 2 = 1$

d. $\sqrt{2}\sec t + 1 = 3$

Exercise 3: Solve each equation in $[0, 2\pi)$ using a calculator and rounding answers to four decimal places.

a. $\sqrt{6}\sin t - 2 = 1$

b. $-3\sqrt{2}\cos t + \sqrt{2} = 0$

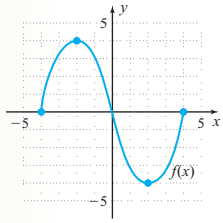
c. $3\tan t + \dfrac{1}{2} = -\dfrac{1}{4}$

d. $2\sec t = -5$

CUMULATIVE REVIEW CHAPTERS 1–6

1. Solve the inequality: $2|x + 1| - 3 < 5$

2. Find the domain of the function: $y = \sqrt{x^2 - 2x - 15}$



3. Given that $\tan\theta = \frac{80}{39}$, draw a right triangle that corresponds to this ratio, then use the Pythagorean theorem to find the length of the missing side. Finally, find the two acute angles.

4. Without a calculator, what values in $[0, 2\pi)$ make the equation true: $\sin t = -\frac{\sqrt{3}}{2}$?

5. Given $\left(\frac{3}{4}, -\frac{\sqrt{7}}{4}\right)$ is a point on the unit circle corresponding to t, find all six trig functions of t.

State the domain and range of each function:

6. $y = f(x)$

7. a. $f(x) = \sqrt{2x - 3}$

b. $g(x) = \frac{2x}{x^2 - 49}$

8. $y = T(x)$

x	$T(x)$
0	−7
1	−5
2	−3
3	−1
4	1
5	3
6	5

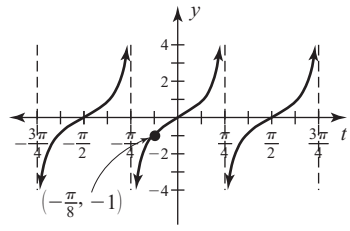
9. Analyze the graph of the function in Exercise 6, including: (a) local maximum and minimum values; (b) intervals where $f(x) \geq 0$ and $f(x) < 0$; (c) intervals where f is increasing or decreasing; and (d) any symmetry noted. Assume the features you are to describe have integer values.

10. The attractive force that exists between two magnets varies inversely as the square of the distance between them. If the attractive force is 1.5 newtons (N) at a distance of 10 cm, how close are the magnets when the attractive force reaches 5 N?

11. The world's tallest indoor waterfall is in Detroit, Michigan, in the lobby of the International Center Building. Standing 66 ft from the base of the falls, the angle of elevation to the top of the waterfall is 60°. How tall is the waterfall?

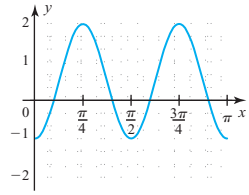
12. It's a warm, lazy Saturday and Hank is watching a county maintenance crew mow the park across the street. He notices the mower takes 29 sec to pass through 77° of rotation from one end of the park to the other. If the corner of the park is 60 ft directly across the street from his house, (a) how wide is the park? (b) How fast (in mph) does the mower travel as it cuts the grass?

13. Graph using transformations of a parent function: $f(x) = \frac{1}{x + 1} - 2$.



14. Graph using transformations of a parent function: $g(x) = e^{x-1} - 2$.

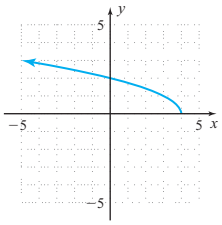
15. Find $f(\theta)$ for all six trig functions, given the point $P(-9, 40)$ is a point on the terminal side of the angle. Then find the angle θ in degrees, rounded to tenths.



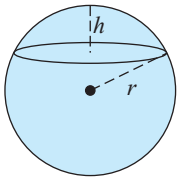
16. Given $t = 5.37$, (a) in what quadrant does the arc terminate? (b) What is the reference arc? (c) Find the value of $\sin t$ rounded to four decimal places.

17. A jet-stream water sprinkler shoots water a distance of 15 m and turns back-and-forth through an angle of $t = 1.2$ rad. (a) What is the length of the arc that the sprinkler reaches? (b) What is the area in m^2 of the yard that is watered?

18. Determine the equation of graph shown given it is of the form $y = A\tan(Bt)$.



19. Determine the equation of the graph shown given it is of the form $y = A\sin(Bt \pm C) + D$.



20. In London, the average temperatures on a summer day range from a high of 72°F to a low of 56°F. Use this information to write a sinusoidal equation model, assuming the low temperature occurs at 6:00 A.M. Clearly state the amplitude, average value, period, and horizontal shift.

21. The graph of a function $f(x)$ is given. Sketch the graph of $f^{-1}(x)$.

22. The volume of a spherical cap is given by $V = \frac{\pi h^2}{3}(3r - h)$. Solve for r in terms of V and h.

23. Find the slope and y-intercept: $3x - 4y = 8$.

24. Solve by factoring: $4x^3 - 8x^2 - 9x + 18 = 0$.

25. At what interest rate will \$1000 grow to \$2275 in 12 yr if compounded continuously?

Exercises 26 through 30 require the use of a graphing calculator

26. Determine the minimum value of the function $f(x) = 0.5x^4 - 3x^3 + e$. Round your answers to one decimal place.

27. Use the **TABLE** feature of a calculator to find the unknown coordinates of the following QII points on the unit circle. Round your answers to two decimal places when necessary.

x	y
−0.2	
−0.4	
−0.6	
−0.8	

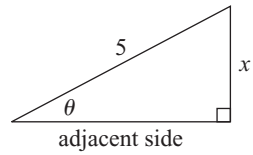
28. In 2006, the Podcast Alley directory had cataloged about 26,000 different podcasts with over a million episodes. In 2010, there were over 77,000 different podcasts in this directory. This exponential growth can be modeled by the equation $p = 19.82(1.31)^t$, where p is the number of podcasts (in thousands) registered in a given year t ($t = 0$ corresponds to 2005). According to this model, when did the number of registered podcasts exceed (a) 50,000 and (b) 100,000?

29. Solve the equation and round your answer to two decimal places.

$$-2x^2 + 27x + 62 = 11 \ln x$$

30. Use the **R → Pθ(** feature of a graphing calculator to find the angle corresponding to the point $(12, -32)$, then evaluate $\tan\theta$. Compare your result to $\tan\theta = \frac{y}{x}$.

CONNECTIONS TO CALCULUS



While right triangles have a number of meaningful applications as a problem-solving tool, they can also help to rewrite certain expressions in preparation for the tools of calculus, and introduce us to an alternative method for graphing relations and functions using polar coordinates.

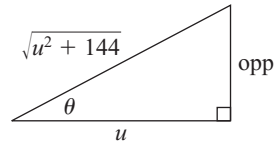
Right Triangle Relationships

Drawing a diagram to visualize relationships and develop information is an important element of good problem solving. This is no less true in calculus, where it is often a fundamental part of understanding the question being asked. As a precursor to applications involving *trig substitutions,* we'll illustrate how right triangle diagrams are used to rewrite trigonometric functions of θ as algebraic functions of x.

EXAMPLE 1 ▶ Using Right Triangle Diagrams to Rewrite Trig Expressions

Use the equation $x = 5 \sin \theta$ and a right triangle diagram to write $\cos \theta$, $\tan \theta$, $\sec \theta$, and $\csc \theta$ as functions of x.

Solution ▶ Using $x = 5 \sin \theta$, we obtain $\sin \theta = \dfrac{x}{5}$. From our work in Chapter 6, we know the right triangle definition of $\sin \theta$ is $\dfrac{\text{opp}}{\text{hyp}}$, and we draw a triangle with side x oriented opposite an angle θ, and label a hypotenuse of 5 (see figure). To find an expression for the adjacent side, we use the Pythagorean theorem:



$$\begin{aligned} (\text{adj})^2 + x^2 &= 5^2 && \text{Pythagorean theorem} \\ (\text{adj})^2 &= 25 - x^2 && \text{isolate term} \\ \text{adj} &= \sqrt{25 - x^2} && \text{result (length must be positive); } -5 < x < 5 \end{aligned}$$

Using this triangle and the standard definition of the remaining trig functions, we find $\cos \theta = \dfrac{\sqrt{25 - x^2}}{5}$, $\tan \theta = \dfrac{x}{\sqrt{25 - x^2}}$, $\sec \theta = \dfrac{5}{\sqrt{25 - x^2}}$, and $\csc \theta = \dfrac{5}{x}$.

Now try Exercises 1 through 4 ▶

EXAMPLE 2 ▶ Using Right Triangle Diagrams to Rewrite Trig Expressions

Find expressions for $\tan \theta$ and $\csc \theta$, given $\sec \theta = \dfrac{\sqrt{u^2 + 144}}{u}$.

Solution ▶ With $\sec \theta = \dfrac{\text{hyp}}{\text{adj}}$, we draw a right triangle diagram as in Example 1, with a hypotenuse of $\sqrt{u^2 + 144}$ and a side u adjacent to angle θ. For $\tan \theta = \dfrac{\text{opp}}{\text{adj}}$ and $\csc \theta = \dfrac{\text{hyp}}{\text{opp}}$, we use the Pythagorean theorem to find an expression for the opposite side:

$$\begin{aligned} (\text{opp})^2 + u^2 &= (\sqrt{u^2 + 144})^2 && \text{Pythagorean theorem} \\ (\text{opp})^2 + u^2 &= u^2 + 144 && \text{square radical} \\ (\text{opp})^2 &= 144 && \text{subtract } u^2 \\ \text{opp} &= 12 && \text{result (length must be positive)} \end{aligned}$$

With an opposite side of 12 units, the figure shows $\tan \theta = \dfrac{12}{u}$ and $\csc \theta = \dfrac{\sqrt{u^2 + 144}}{12}$.

Now try Exercises 5 and 6 ▶

Converting from Rectangular Coordinates to Trigonometric (Polar) Form

Using the equations $\cos\theta = \frac{x}{r}$, $\sin\theta = \frac{y}{r}$, and $r = \sqrt{x^2 + y^2}$ from Section 6.7, we can derive $x = r\cos\theta$, $y = r\sin\theta$, and $x^2 + y^2 = r^2$. With these equations, we can rewrite functions of x given in rectangular form as equations of θ in trigonometric (*polar*) form. In Chapter 10 we'll see how this offers us certain advantages. Note that while algebraic equations are often written with y in terms of x, polar equations are written with r in terms of θ.

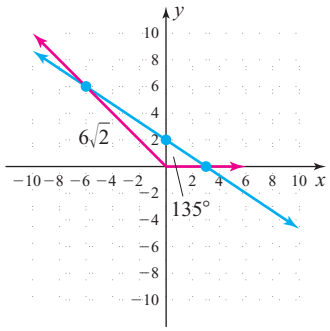
EXAMPLE 3 ▶ **Converting from Rectangular to Trigonometric Form**

Rewrite the equation $2x + 3y = 6$ in trigonometric form using the substitutions indicated and solving for r. Note the given equation is that of a line with x-intercept (3, 0) and y-intercept (0, 2).

Solution ▶ Using $x = r\cos\theta$ and $y = r\sin\theta$ we proceed as follows:

$$\begin{aligned} 2x + 3y &= 6 && \text{given}\\ 2(r\cos\theta) + 3(r\sin\theta) &= 6 && \text{substitute } r\cos\theta \text{ for } x,\ r\sin\theta \text{ for } y\\ r[2\cos\theta + 3\sin\theta] &= 6 && \text{factor out } r\\ r &= \frac{6}{2\cos\theta + 3\sin\theta} && \text{solve for } r \end{aligned}$$

This is the equation of the same line, but in trigonometric form.



Now try Exercises 7 through 10 ▶

While it is somewhat simplistic (there are other subtleties involved), we can verify the equation obtained in Example 3 produces the same line as $2x + 3y = 6$ by evaluating the equation at $\theta = 0°$ to find a point on the positive x-axis, $\theta = 90°$ to find a point of the positive y-axis, and $\theta = 135°$ to find a point in QII.

For $\theta = 0°$: $r = \dfrac{6}{2\cos 0° + 3\sin 0°} = \dfrac{6}{2(1) + 3(0)} = \dfrac{6}{2} = 3$

For $\theta = 90°$: $r = \dfrac{6}{2\cos 90° + 3\sin 90°} = \dfrac{6}{2(0) + 3(1)} = \dfrac{6}{3} = 2$

For $\theta = 135°$: $r = \dfrac{6}{2\cos 135° + 3\sin 135°} = \dfrac{6}{2\left(-\frac{\sqrt{2}}{2}\right) + 3\left(\frac{\sqrt{2}}{2}\right)} = \dfrac{6}{\frac{\sqrt{2}}{2}} = \dfrac{12}{\sqrt{2}} = 6\sqrt{2} \approx 8.5$

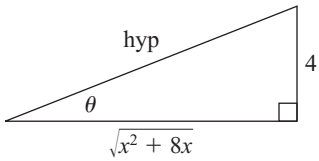
Using a distance r from the origin at each θ given, we note that all three points are on the line $2x + 3y = 6$, as shown in the figure.

EXAMPLE 4 ▶ Converting from Polar to Rectangular Form

Rewrite the equation $r = 4\cos\theta$ in rectangular form using the relationships $x = r\cos\theta$, $y = r\sin\theta$, and/or $x^2 + y^2 = r^2$. Identify the resulting equation.

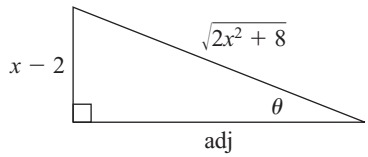
Solution ▶ From $x = r\cos\theta$ we have $\cos\theta = \frac{x}{r}$. Substituting into the given equation we have

$r = 4\cos\theta$	given
$r = 4\left(\frac{x}{r}\right)$	substitute $\frac{x}{r}$ for $\cos\theta$
$r^2 = 4x$	multiply by r
$x^2 + y^2 = 4x$	substitute $x^2 + y^2$ for r^2
$x^2 - 4x + y^2 = 0$	set equal to 0
$(x^2 - 4x + 4) + y^2 = 4$	complete the square in x
$(x - 2)^2 + y^2 = 4$	standard form



The result shows $r = 4\cos\theta$ is a trigonometric form for the equation of a circle with center at (2, 0) and radius $r = 2$.

Now try Exercises 11 through 14 ▶



Connections to Calculus Exercises

Use the diagram given to find the remaining side of the triangle. Then write the six trig functions as functions of x.

1.

2.

Use the equation given and a sketch of the corresponding right triangle diagram to write the remaining five trig functions as functions of x.

3. $x = 4\tan\theta$

4. $x = 5\sec\theta$

5. Find expressions for $\cot\theta$ and $\sec\theta$, given $\csc\theta = \frac{\sqrt{u^2 + 169}}{u}$.

6. Find expressions for $\sin\theta$ and $\cos\theta$, given $\cot\theta = \frac{2\sqrt{5}}{x}$.

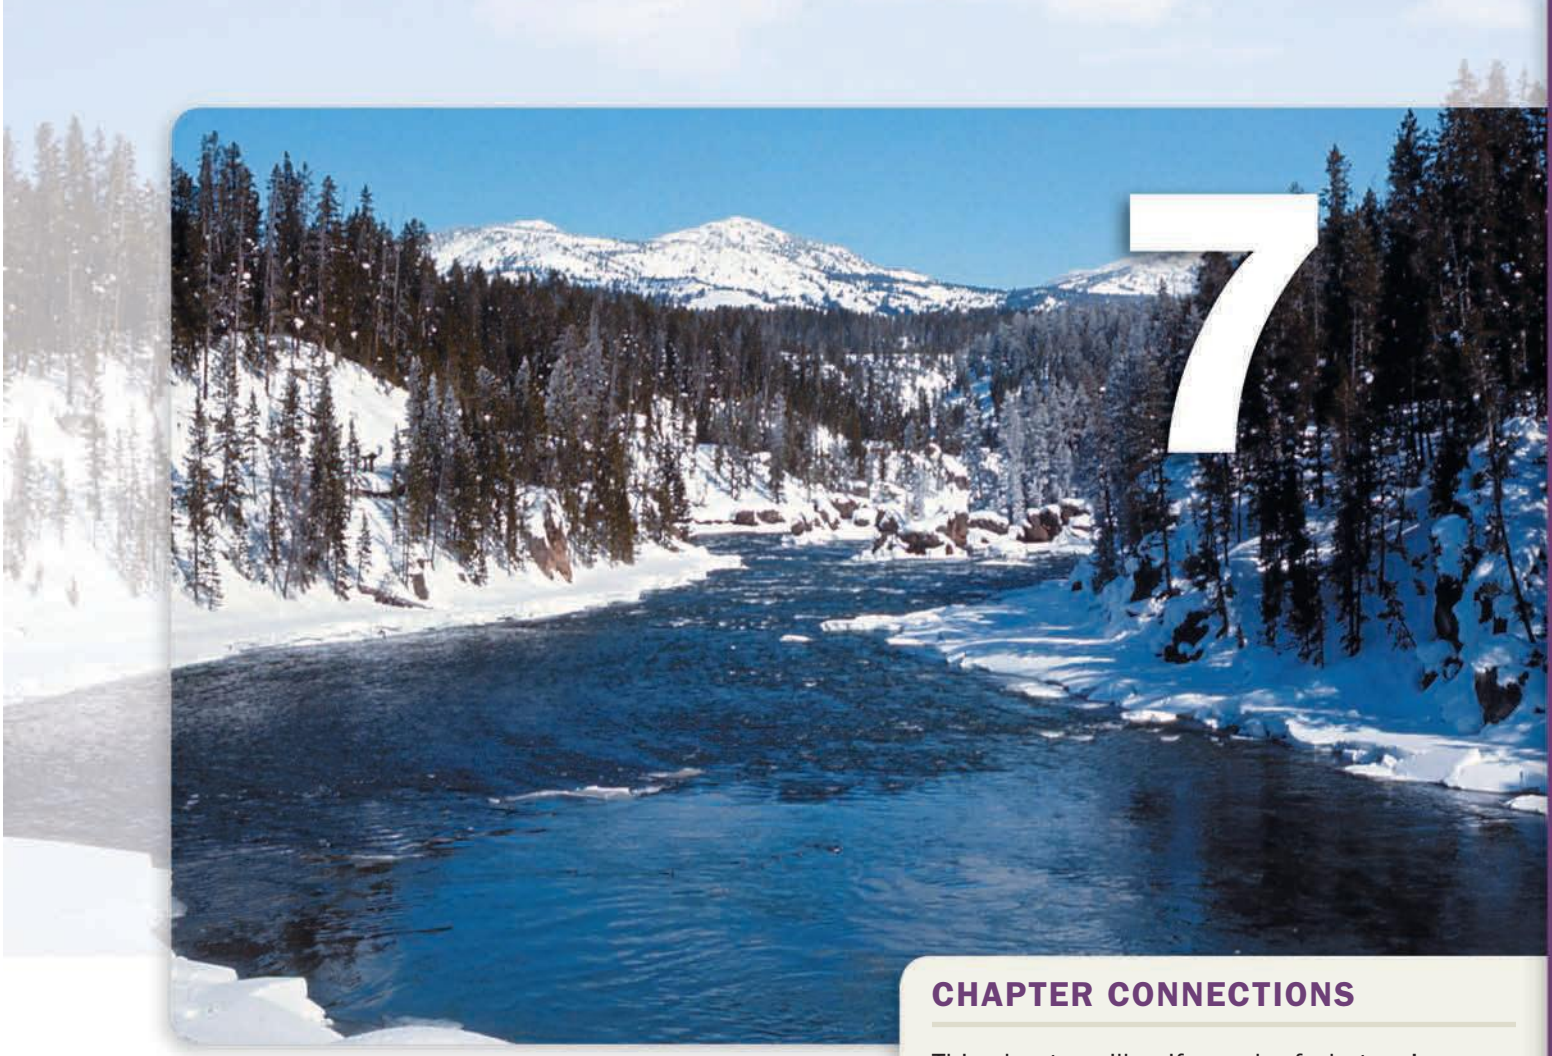
Use $x = r\cos\theta$, $y = r\sin\theta$, and $x^2 + y^2 = r^2$ to rewrite the expressions in trigonometric form.

7. $y = 2$

8. $y = \frac{1}{4}x^2$

9. $y = -2x + 3$

10. $(x - 2)^2 + y^2 = 4$



Use $x = r\cos\theta$, $y = r\sin\theta$ and $x^2 + y^2 = r^2$ to rewrite the expressions in rectangular form, then identify the equation as that of a line, circle, vertical parabola, or horizontal parabola.

11. $r = 5\sin\theta$

12. $r = \frac{4}{1 + \sin\theta}$ $\left(\textit{Hint}: \sin\theta = \frac{y}{r}.\right)$

13. $r(3\cos\theta - 2\sin\theta) = 6$

14. $r = \frac{4}{2 - 2\cos\theta}$ $\left(\textit{Hint}: \cos\theta = \frac{x}{r}.\right)$

7.6 Solving Basic Trig Equations 711
7.7 General Trig Equations and Applications 721

CHAPTER CONNECTIONS

This chapter will unify much of what we've learned so far, and lead us to some intriguing, sophisticated, and surprising applications of trigonometry. Defining the trig functions helped us study a number of new relationships not possible using algebra alone. Their graphs gave us insights into how the functions were related to each other, and enabled a study of periodic phenomena. We will now use identities to simplify complex expressions and show how trig functions often work together to model natural events. One such "event" is a river's seasonal discharge rate, which tends to be greater during the annual snow melt. In this chapter, we'll learn how to predict the discharge rate during specific months of the year, information of great value to fisheries, oceanographers, and other scientists.

▶ This application appears as Exercises 53 and 54 in Section 7.7

Connections to Calculus

Trigonometric equations, identities, and substitutions also play a vital role in a study of calculus, helping to simplify complex expressions, or rewrite an expression in a form more suitable for the tools of calculus. These connections are explored in the *Connections to Calculus* feature following Chapter 7.

7.1 Fundamental Identities and Families of Identities

LEARNING OBJECTIVES

In Section 7.1 you will see how we can:

- ❑ **A.** Use fundamental identities to help understand and recognize identity "families"
- ❑ **B.** Verify other identities using the fundamental identities and basic algebra skills
- ❑ **C.** Use fundamental identities to express a given trig function in terms of the other five

In this section, we begin laying the foundation necessary to work with identities successfully. The cornerstone of this effort is a healthy respect for the fundamental identities and vital role they play. Students are strongly encouraged to do more than memorize them—they should be *internalized,* meaning they must become a natural and instinctive part of your core mathematical knowledge.

A. Fundamental Identities and Identity Families

An **identity** is an equation that is true for all elements in the domain. In trigonometry, some identities result directly from the way the functions are defined. For instance, the reciprocal relationships we first saw in Section 6.2 followed directly from their definitions. We call identities of this type *fundamental identities*. Successfully working with *other* identities will depend a great deal on your mastery of these fundamental types. For convenience, the definitions of the trig functions are reviewed here, followed by the fundamental identities that result.

Given point $P(x, y)$ is on the terminal side of angle θ in standard position, with $r = \sqrt{x^2 + y^2}$ the distance from the origin to (x, y), we have

$$\cos\theta = \frac{x}{r} \qquad \sin\theta = \frac{y}{r} \qquad \tan\theta = \frac{y}{x};\ x \neq 0$$

$$\sec\theta = \frac{r}{x};\ x \neq 0 \qquad \csc\theta = \frac{r}{y};\ y \neq 0 \qquad \cot\theta = \frac{x}{y};\ y \neq 0$$

Fundamental Trigonometric Identities

Reciprocal identities	Ratio identities	Pythagorean identities
$\sin\theta = \dfrac{1}{\csc\theta}$	$\tan\theta = \dfrac{\sin\theta}{\cos\theta}$	$\cos^2\theta + \sin^2\theta = 1$
$\cos\theta = \dfrac{1}{\sec\theta}$	$\tan\theta = \dfrac{\sec\theta}{\csc\theta}$	$1 + \tan^2\theta = \sec^2\theta$
$\tan\theta = \dfrac{1}{\cot\theta}$	$\cot\theta = \dfrac{\cos\theta}{\sin\theta}$	$\cot^2\theta + 1 = \csc^2\theta$

EXAMPLE 1 ▶ **Proving a Fundamental Identity**

Use the coordinate definitions of the trigonometric functions to prove the identity $\cos^2\theta + \sin^2\theta = 1$.

Solution ▶ We begin with the left-hand side.

$$\cos^2\theta + \sin^2\theta = \left(\frac{x}{r}\right)^2 + \left(\frac{y}{r}\right)^2 \quad \text{substitute } \tfrac{x}{r} \text{ for } \cos\theta, \tfrac{y}{r} \text{ for } \sin\theta$$

$$= \frac{x^2}{r^2} + \frac{y^2}{r^2} \quad \text{square terms}$$

$$= \frac{x^2 + y^2}{r^2} \quad \text{add terms}$$

Noting that $r = \sqrt{x^2 + y^2}$ implies $r^2 = x^2 + y^2$, we have

$$= \frac{r^2}{r^2} = 1 \quad \text{substitute } x^2 + y^2 \text{ for } r^2, \text{ simplfy}$$

WORTHY OF NOTE

The Pythagorean identities are used extensively in future courses. See Example 1 of the *Connections to Calculus* feature at the end of this chapter.

Now try Exercises 7 through 10 ▶

The fundamental identities seem to naturally separate themselves into the three groups or families listed, with each group having additional relationships that can be inferred from the definitions. For instance, since $\sin\theta$ is the reciprocal of $\csc\theta$, $\csc\theta$ must be the reciprocal of $\sin\theta$. Similar statements can be made regarding $\cos\theta$ and $\sec\theta$ as well as $\tan\theta$ and $\cot\theta$. Recognizing these additional "family members" enlarges the number of identities you can work with, and will help you use them more effectively. In particular, since they *are* reciprocals: $\sin\theta\csc\theta = 1$, $\cos\theta\sec\theta = 1$, and $\tan\theta\cot\theta = 1$. **See Exercises 11 and 12.**

EXAMPLE 2 ▶ Identifying Families of Identities

Starting with $\cos^2\theta + \sin^2\theta = 1$, use algebra to write four additional identities that belong to the Pythagorean family.

Solution ▶

$$\cos^2\theta + \sin^2\theta = 1 \qquad \text{original identity}$$

$$1)\quad \sin^2\theta = 1 - \cos^2\theta \qquad \text{subtract } \cos^2\theta$$

$$2)\quad \sin\theta = \pm\sqrt{1 - \cos^2\theta} \qquad \text{take square root}$$

$$\cos^2\theta + \sin^2\theta = 1 \qquad \text{original identity}$$

$$3)\quad \cos^2\theta = 1 - \sin^2\theta \qquad \text{subtract } \sin^2\theta$$

$$4)\quad \cos\theta = \pm\sqrt{1 - \sin^2\theta} \qquad \text{take square root}$$

For the identities involving a radical, the choice of sign will depend on the quadrant of the terminal side.

Now try Exercises 13 and 14 ▶

A. You've just seen how we can use fundamental identities to help understand and recognize identity "families"

The fact that each new equation in Example 2 represents an identity gives us more options when attempting to verify or prove more complex identities. For instance, since $\cos^2\theta = 1 - \sin^2\theta$, we can replace $\cos^2\theta$ with $1 - \sin^2\theta$, or replace $1 - \sin^2\theta$ with $\cos^2\theta$, *any time they occur in an expression.* Note there are many other members of this family, since similar steps can be performed on the other Pythagorean identities. In fact, each of the fundamental identities can be similarly rewritten and there are a variety of exercises at the end of this section for practice.

B. Verifying an Identity Using Algebra

Note that we cannot *prove* an equation is an identity by repeatedly substituting input values and obtaining a true equation. This would be an infinite exercise and we might easily miss a value or even a range of values for which the equation is false. Instead we attempt to rewrite one side of the equation until we obtain a match with the other side, so there can be no doubt. As hinted at earlier, this is done using basic algebra skills combined with the fundamental identities and the substitution principle. For now we'll focus on verifying identities by using algebra. In Section 7.2 we'll introduce some guidelines and ideas that will help you verify a wider range of identities.

EXAMPLE 3 ▶ **Using Algebra to Help Verify an Identity**

Use the distributive property to verify that $\sin\theta(\csc\theta - \sin\theta) = \cos^2\theta$ is an identity.

Solution ▶ Use the distributive property to simplify the left-hand side.

$$\begin{aligned} \sin\theta(\csc\theta - \sin\theta) &= \sin\theta\csc\theta - \sin^2\theta && \text{distribute} \\ &= 1 - \sin^2\theta && \text{substitute 1 for } \sin\theta\csc\theta \\ &= \cos^2\theta && 1 - \sin^2\theta = \cos^2\theta \end{aligned}$$

Since we were able to transform the left-hand side into a duplicate of the right, there can be no doubt the original equation is an identity.

Now try Exercises 15 through 24 ▶

Often we must *factor* an expression, rather than multiply, to begin the verification process.

EXAMPLE 4 ▶ **Using Algebra to Help Verify an Identity**

Verify that $1 = \cot^2\alpha\sec^2\alpha - \cot^2\alpha$ is an identity.

Solution ▶ The left side is as simple as it gets. The terms on the right side have a common factor and we begin there.

$$\begin{aligned} \cot^2\alpha\sec^2\alpha - \cot^2\alpha &= \cot^2\alpha(\sec^2\alpha - 1) && \text{factor out } \cot^2\alpha \\ &= \cot^2\alpha\tan^2\alpha && \text{substitute } \tan^2\alpha \text{ for } \sec^2\alpha - 1 \\ &= (\cot\alpha\tan\alpha)^2 && \text{power property of exponents} \\ &= 1^2 = 1 && \cot\alpha\tan\alpha = 1 \end{aligned}$$

Now try Exercises 25 through 32 ▶

Examples 3 and 4 show you can begin the verification process on either the left or right side of the equation, whichever seems more convenient. Example 5 shows how the special products $(A + B)(A - B) = A^2 - B^2$ and/or $(A \pm B)^2 = A^2 \pm 2AB + B^2$ can be used in the verification process.

EXAMPLE 5 ▶ **Using a Special Product to Help Verify an Identity**

Use a special product and fundamental identities to verify that $(\sin\beta - \cos\beta)^2 = 1 - 2\sin\beta\cos\beta$ is an identity.

Solution ▶ Begin by squaring the left-hand side, in hopes of using a Pythagorean identity.

$$\begin{aligned} (\sin\beta - \cos\beta)^2 &= \sin^2\beta - 2\sin\beta\cos\beta + \cos^2\beta && \text{binomial square} \\ &= \cos^2\beta + \sin^2\beta - 2\sin\beta\cos\beta && \text{rewrite terms} \\ &= 1 - 2\sin\beta\cos\beta && \text{substitute 1 for } \cos^2\beta + \sin^2\beta \end{aligned}$$

Now try Exercises 33 through 38 ▶

☑ **B.** You've just seen how we can verify other identities using the fundamental identities and basic algebra skills

Another common method used to verify identities is simplification by combining terms, using the model $\frac{A}{B} \pm \frac{C}{D} = \frac{AD \pm BC}{BD}$. For $\sec\theta = \frac{\sin^2\theta}{\cos\theta} + \cos\theta$, the right-hand side immediately becomes $\frac{\sin^2\theta + \cos^2\theta}{\cos\theta}$, which gives $\frac{1}{\cos\theta} = \sec\theta$. **See Exercises 39 through 44.**

C. Writing One Function in Terms of Another

Any one of the six trigonometric functions can be written in terms of any of the other functions using fundamental identities. The process involved offers practice in working with identities, highlights how each function is related to the other, and has practical applications in verifying more complex identities.

EXAMPLE 6 ▶ **Writing One Trig Function in Terms of Another**

Write the function $\cos\theta$ in terms of the tangent function.

Solution ▶ Begin by noting these functions share "common ground" via $\sec\theta$, since $\sec^2\theta = 1 + \tan^2\theta$ and $\cos\theta = \dfrac{1}{\sec\theta}$. Starting with $\sec^2\theta$,

$$\begin{aligned} \sec^2\theta &= 1 + \tan^2\theta && \text{Pythagorean identity} \\ \sec\theta &= \pm\sqrt{1 + \tan^2\theta} && \text{square roots} \end{aligned}$$

We can now substitute $\pm\sqrt{1 + \tan^2\theta}$ for $\sec\theta$ in $\cos\theta = \dfrac{1}{\sec\theta}$.

$$\cos\theta = \frac{1}{\pm\sqrt{1 + \tan^2\theta}} \qquad \text{substitute } \pm\sqrt{1 + \tan^2\theta} \text{ for } \sec\theta$$

Note we have written $\cos\theta$ in terms of the tangent function.

Now try Exercises 45 through 50 ▶

WORTHY OF NOTE

Although identities are valid where both expressions are defined, this does not preclude a difference in the domains of each function. For example, the result of Example 6 is indeed an identity, even though the left side is defined at $\frac{\pi}{2}$ while the right side is not.

Example 6 also reminds us of a very important point—the sign we choose for the final answer is dependent on the terminal side of the angle. If the terminal side is in QI or QIV we chose the positive sign since $\cos\theta > 0$ in those quadrants. If the angle terminates in QII or QIII, the final answer is negative since $\cos\theta < 0$ in those quadrants.

Similar to our work in Section 6.7, given the value of $\cot\theta$ and the quadrant of θ, the fundamental identities enable us to find the value of the other five functions at θ. In fact, this is generally true for any given trig function and angle θ.

EXAMPLE 7 ▶ **Using a Known Value and Quadrant Analysis to Find Other Function Values**

Given $\cot\theta = \dfrac{-9}{40}$ with the terminal side of θ in QIV, find the value of the other five functions of θ. Use a calculator to check your answer.

Solution ▶ The function value $\tan\theta = -\dfrac{40}{9}$ follows immediately, since cotangent and tangent are reciprocals. The value of $\sec\theta$ can be found using $\sec^2\theta = 1 + \tan^2\theta$.

$$\begin{aligned} \sec^2\theta &= 1 + \tan^2\theta && \text{Pythagorean identity} \\ &= 1 + \left(-\frac{40}{9}\right)^2 && \text{substitute } -\tfrac{40}{9} \text{ for } \tan\theta \\ &= \frac{81}{81} + \frac{1600}{81} && \text{square } -\tfrac{40}{9}\text{, substitute } \tfrac{81}{81} \text{ for 1} \\ \sec^2\theta &= \frac{1681}{81} && \text{combine terms} \\ \sec\theta &= \pm\frac{41}{9} && \text{take square roots} \end{aligned}$$

Since sec θ is positive for a terminal side in QIV, we have sec $\theta = \frac{41}{9}$.

This automatically gives $\cos\theta = \frac{9}{41}$ (reciprocal identities), and we find $\sin\theta = -\frac{40}{41}$ using $\sin^2\theta = 1 - \cos^2\theta$ or the ratio identity $\tan\theta = \frac{\sin\theta}{\cos\theta}$ (verify).

This result and another reciprocal identity gives us our final value, $\csc\theta = -\frac{41}{40}$.

Check ▶ As in Example 9 of Section 6.7, we find θ_r using 2nd TAN **(TAN^{-1})** 40 ÷ 9) ENTER, which shows $\theta_r \approx 1.3495$ (Figure 7.1). Since the terminal side of θ is in QIV, one possible value for θ is $2\pi - \theta_r$. Note in Figure 7.1, the 2nd (−) **(ANS)** feature was used to compute θ, which we then stored as X. In Figure 7.2, we verify that $\tan\theta = -\frac{40}{9}$, $\cos\theta = \frac{9}{41}$, and $\sin\theta = -\frac{40}{41}$.

Figure 7.1

```

C. You've just seen how we can use fundamental identities to express a given trig function in terms of the other five

Now try Exercises 51 through 60 ▶

7.1 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. Three fundamental ratio identities are $\tan\theta = \frac{?}{\cos\theta}$, $\tan\theta = \frac{?}{\csc\theta}$, and $\cot\theta = \frac{?}{\sin\theta}$.

2. The three fundamental reciprocal identities are $\sin\theta = 1/$____, $\cos\theta = 1/$____, and $\tan\theta = 1/$____. From these, we can infer three additional reciprocal relationships: $\csc\theta = 1/$____, $\sec\theta = 1/$____, and $\cot\theta = 1/$____.

3. Starting with the Pythagorean identity $\cos^2\theta + \sin^2\theta = 1$, the identity $1 + \tan^2\theta = \sec^2\theta$ can be derived by dividing both sides by ____. Alternatively, dividing both sides of this equation by $\sin^2\theta$, we obtain the identity _____.

4. An _____ is an equation that is true for all elements in the _____. To show an equation is an identity, we employ basic algebra skills combined with the _____ identities and the substitution principle.

5. Use the pattern $\frac{A}{B} \pm \frac{C}{D} = \frac{AD \pm BC}{BD}$ to add the following terms, and comment on this process versus "finding a common denominator."
$\frac{\cos\theta}{\sin\theta} - \frac{\sin\theta}{\sec\theta}$

6. Name at least four algebraic skills that are used with the fundamental identities in order to rewrite a trigonometric expression. Use algebra to quickly rewrite $(\sin\theta + \cos\theta)^2$.

▶ DEVELOPING YOUR SKILLS

Use the definitions of the trigonometric functions to prove the following fundamental identities.

7. $1 + \tan^2\theta = \sec^2\theta$ **8.** $\cot^2\theta + 1 = \csc^2\theta$

9. $\tan\theta = \dfrac{\sin\theta}{\cos\theta}$ **10.** $\cot\theta = \dfrac{\cos\theta}{\sin\theta}$

Starting with the ratio identity given, use substitution and fundamental identities to write four new identities belonging to the ratio family. Answers may vary.

11. $\tan\theta = \dfrac{\sin\theta}{\cos\theta}$ **12.** $\cot\theta = \dfrac{\cos\theta}{\sin\theta}$

Starting with the Pythagorean identity given, use algebra to write four additional identities belonging to the Pythagorean family. Answers may vary.

13. $1 + \tan^2\theta = \sec^2\theta$ **14.** $\cot^2\theta + 1 = \csc^2\theta$

Verify the equation is an identity using multiplication and fundamental identities.

15. $\sin\theta\cot\theta = \cos\theta$ **16.** $\cos\theta\tan\theta = \sin\theta$

17. $\sec^2\theta\cot^2\theta = \csc^2\theta$ **18.** $\csc^2\theta\tan^2\theta = \sec^2\theta$

19. $\cos\theta(\sec\theta - \cos\theta) = \sin^2\theta$

20. $\tan\theta(\cot\theta + \tan\theta) = \sec^2\theta$

21. $\sin\theta(\csc\theta - \sin\theta) = \cos^2\theta$

22. $\cot\theta(\tan\theta + \cot\theta) = \csc^2\theta$

23. $\tan\theta(\csc\theta + \cot\theta) = \sec\theta + 1$

24. $\cot\theta(\sec\theta + \tan\theta) = \csc\theta + 1$

Verify the equation is an identity using factoring and fundamental identities.

25. $\tan^2\theta\csc^2\theta - \tan^2\theta = 1$

26. $\sin^2\theta\cot^2\theta + \sin^2\theta = 1$

27. $\dfrac{\sin\theta\cos\theta + \sin\theta}{\cos\theta + \cos^2\theta} = \tan\theta$

28. $\dfrac{\sin\theta\cos\theta + \cos\theta}{\sin\theta + \sin^2\theta} = \cot\theta$

29. $\dfrac{1 + \sin\theta}{\cos\theta + \cos\theta\sin\theta} = \sec\theta$

30. $\dfrac{1 + \cos\theta}{\sin\theta + \cos\theta\sin\theta} = \csc\theta$

31. $\dfrac{\sin\theta\tan\theta + \sin\theta}{\tan\theta + \tan^2\theta} = \cos\theta$

32. $\dfrac{\cos\theta\cot\theta + \cos\theta}{\cot\theta + \cot^2\theta} = \sin\theta$

Verify the equation is an identity using special products and fundamental identities.

33. $\dfrac{(\sin\theta + \cos\theta)^2}{\cos\theta} = \sec\theta + 2\sin\theta$

34. $\dfrac{(1 + \tan\theta)^2}{\sec\theta} = \sec\theta + 2\sin\theta$

35. $(1 + \sin\theta)(1 - \sin\theta) = \cos^2\theta$

36. $(\sec\theta + 1)(\sec\theta - 1) = \tan^2\theta$

37. $\dfrac{(\csc\theta - \cot\theta)(\csc\theta + \cot\theta)}{\tan\theta} = \cot\theta$

38. $\dfrac{(\sec\theta + \tan\theta)(\sec\theta - \tan\theta)}{\csc\theta} = \sin\theta$

Verify the equation is an identity using fundamental identities and $\dfrac{A}{B} \pm \dfrac{C}{D} = \dfrac{AD \pm BC}{BD}$ to combine terms.

39. $\dfrac{\cos^2\theta}{\sin\theta} + \dfrac{\sin\theta}{1} = \csc\theta$

40. $\dfrac{\sec\alpha}{1} - \dfrac{\tan^2\alpha}{\sec\alpha} = \cos\alpha$

41. $\dfrac{\tan\theta}{\csc\theta} - \dfrac{\sin\theta}{\cos\theta} = \dfrac{\sin\theta - 1}{\cot\theta}$

42. $\dfrac{\cot\theta}{\sec\theta} - \dfrac{\cos\theta}{\sin\theta} = \dfrac{\cos\theta - 1}{\tan\theta}$

43. $\dfrac{\sec\theta}{\sin\theta} - \dfrac{\csc\theta}{\sec\theta} = \tan\theta$

44. $\dfrac{\csc\theta}{\cos\theta} - \dfrac{\sec\theta}{\csc\theta} = \cot\theta$

Write the given function entirely in terms of the second function indicated.

45. $\tan\theta$ in terms of $\sin\theta$

46. $\tan\theta$ in terms of $\sec\theta$

47. $\sec\theta$ in terms of $\cot\theta$

48. $\sec\theta$ in terms of $\sin\theta$

49. $\cot\theta$ in terms of $\sin\theta$

50. $\cot\theta$ in terms of $\csc\theta$

For the given trig function $f(\theta)$ and the quadrant in which θ terminates, state the value of the other five trig functions. Use a calculator to verify your answers.

51. $\cos\theta = -\frac{20}{29}$ with θ in QII

52. $\sin\theta = \frac{12}{37}$ with θ in QII

53. $\tan\theta = \frac{15}{8}$ with θ in QIII

54. $\sec\theta = \frac{5}{3}$ with θ in QIV

55. $\cot\theta = \frac{x}{5}$ with θ in QI

56. $\csc\theta = \frac{7}{x}$ with θ in QII

57. $\sin\theta = -\frac{7}{13}$ with θ in QIII

58. $\cos\theta = \frac{23}{25}$ with θ in QIV

59. $\sec\theta = -\frac{9}{7}$ with θ in QII

60. $\cot\theta = -\frac{11}{2}$ with θ in QIV

▶ WORKING WITH FORMULAS

61. The versine function: $V = 2\sin^2\theta$

For centuries, the haversine formula has been used in navigation to calculate the nautical distance between any two points on the surface of the Earth. One part of the formula requires the calculation of V, where θ is *half the difference of latitudes* between the two points. Use a fundamental identity to express V in terms of cosine.

62. Area of a regular polygon: $A = \left(\frac{nx^2}{4}\right)\frac{\cos\left(\frac{180°}{n}\right)}{\sin\left(\frac{180°}{n}\right)}$

The area of a regular polygon is given by the formula shown, where n represents the number of sides and x is the length of each side.

a. Rewrite the formula in terms of a single trig function.

b. Verify the formula for a square with sides of 8 m given the point (2, 2) is on the terminal side of a 45° angle in standard position.

▶ APPLICATIONS

Writing a given expression in an alternative form is a skill used at all levels of mathematics. In addition to standard factoring skills, it is often helpful to decompose a power into smaller powers (as in writing A^3 as $A \cdot A^2$).

63. Show that $\cos^3\theta$ can be written as $\cos\theta(1 - \sin^2\theta)$.

64. Show that $\tan^3\theta$ can be written as $\tan\theta(\sec^2\theta - 1)$.

65. Show that $\tan\theta + \tan^3\theta$ can be written as $\tan\theta(\sec^2\theta)$.

66. Show that $\cot^3\theta$ can be written as $\cot\theta(\csc^2\theta - 1)$.

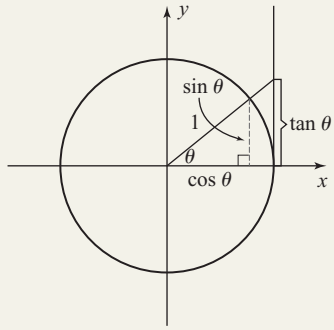
67. Show $\tan^2\theta\sec\theta - 4\tan^2\theta$ can be factored into $(\sec\theta - 4)(\sec\theta - 1)(\sec\theta + 1)$.

68. Show $2\sin^2\theta\cos\theta - \sqrt{3}\sin^2\theta$ can be factored into $(1 - \cos\theta)(1 + \cos\theta)(2\cos\theta - \sqrt{3})$.

69. Show $\cos^2\theta\sin\theta - \cos^2\theta$ can be factored into $-1(1 + \sin\theta)(1 - \sin\theta)^2$.

70. Show $2\cot^2\theta\csc\theta + 2\sqrt{2}\cot^2\theta$ can be factored into $2(\csc\theta + \sqrt{2})(\csc\theta - 1)(\csc\theta + 1)$.

71. Angle of intersection: At their point of intersection, the angle θ between any two nonparallel lines satisfies the relationship $(m_2 - m_1)\cos\theta = \sin\theta + m_1m_2\sin\theta$, where m_1 and m_2 represent the slopes of the two lines. Rewrite the equation in terms of a single trig function.



72. Angle of intersection: Use the result of Exercise 71 to find the tangent of the angle between the lines $Y_1 = \frac{2}{5}x - 3$ and $Y_2 = \frac{7}{3}x + 1$.

73. Angle of intersection: Use the result of Exercise 71 to find the tangent of the angle between the lines $Y_1 = 3x - 1$ and $Y_2 = -2x + 7$.

▶ EXTENDING THE CONCEPT

74. The word *tangent* literally means "to touch," which in mathematics we take to mean *touches in only and exactly one point.* In the figure, the circle has a radius of 1 and the vertical line is "tangent" to the circle at the x-axis. The figure can be used to verify the Pythagorean identity for sine and cosine, as well as the ratio identity for tangent. Discuss/Explain how.

Exercise 74

75. Simplify $-2\sin^4\theta + \sqrt{3}\sin^3\theta + 2\sin^2\theta - \sqrt{3}\sin\theta$ using factoring and fundamental identities.

▶ MAINTAINING YOUR SKILLS

76. **(5.5)** Solve for x:

$$2351 = \frac{2500}{1 + e^{-1.015x}}$$

77. **(6.6)** Standing 265 ft from the base of the Strastosphere Tower in Las Vegas, Nevada, the angle of elevation to the top of the tower is about 77°. Approximate the height of the tower to the nearest foot.

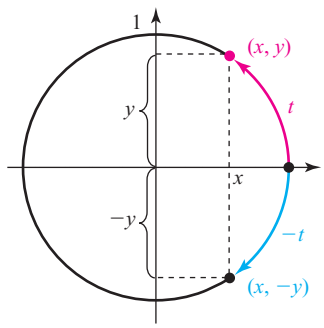
78. **(4.2)** Use the rational zeroes theorem and other "tools" to find all zeroes of the function $f(x) = 2x^4 + 9x^3 - 4x^2 - 36x - 16$.

79. **(6.3)** Use a reference rectangle and the *rule of fourths* to sketch the graph of $y = 2\sin(2t)$ for t in $[0, 2\pi)$.

7.2 More on Verifying Identities

LEARNING OBJECTIVES

In Section 7.2 you will see how we can:



- ❑ **A.** Identify and use identities due to symmetry
- ❑ **B.** Verify general identities
- ❑ **C.** Use counterexamples and contradictions to show an equation is not an identity

In Section 7.1, our primary goal was to illustrate how basic algebra skills can be used to rewrite trigonometric expressions and verify simple identities. In this section, we'll sharpen and refine these skills so they can be applied more generally, as we develop the ability to verify a much wider range of identities.

A. Identities Due to Symmetry

The symmetry of the unit circle and the wrapping function presented in Chapter 6's *Reinforcing Basic Skills* feature, lead us directly to the final group of fundamental identities. Given $t > 0$, consider the points on the unit circle associated with t and $-t$, as shown in Figure 7.3. From our definitions of the trig functions, $\sin t = y$ and $\sin(-t) = -y$, and we recognize sine is an odd function: $\sin(-t) = -\sin t$. The remaining identities due to symmetry can similarly be developed, and are shown here with the complete family of fundamental identities.

Figure 7.3

WORTHY OF NOTE

The identities due to symmetry are sometimes referred to as the even/odd properties. These properties can help express the cofunction identities in shifted form. For example,

$$\begin{aligned}\sin t &= \cos\left(\frac{\pi}{2} - t\right)\\ &= \cos\left[-\left(t - \frac{\pi}{2}\right)\right]\\ &= \cos\left(t - \frac{\pi}{2}\right).\end{aligned}$$

Fundamental Trigonometric Identities

Reciprocal identities	Ratio identities	Pythagorean identities	Identities due to symmetry
$\sin t = \frac{1}{\csc t}$	$\tan t = \frac{\sin t}{\cos t}$	$\cos^2 t + \sin^2 t = 1$	$\sin(-t) = -\sin t$
$\cos t = \frac{1}{\sec t}$	$\tan t = \frac{\sec t}{\csc t}$	$1 + \tan^2 t = \sec^2 t$	$\cos(-t) = \cos t$
$\tan t = \frac{1}{\cot t}$	$\cot t = \frac{\cos t}{\sin t}$	$\cot^2 t + 1 = \csc^2 t$	$\tan(-t) = -\tan t$

EXAMPLE 1 ▶ **Using Symmetry to Verify an Identity**

Verify the identity: $(1 - \tan t)^2 = \sec^2 t + 2\tan(-t)$

Solution ▶ Begin by squaring the left-hand side, in hopes of using a Pythagorean identity.

$$\begin{aligned}(1 - \tan t)^2 &= 1 - 2\tan t + \tan^2 t && \text{binomial square}\\ &= 1 + \tan^2 t - 2\tan t && \text{rewrite terms}\\ &= \sec^2 t - 2\tan t && \text{substitute } \sec^2 t \text{ for } 1 + \tan^2 t\end{aligned}$$

At this point, we appear to be off by two signs, but quickly recall that tangent is an odd function and $-\tan t = \tan(-t)$. By writing $\sec^2 t - 2\tan t$ as $\sec^2 t + 2(-\tan t)$, we can complete the verification.

$$\begin{aligned}&= \sec^2 t + 2(-\tan t) && \text{rewrite expression to obtain } -\tan t\\ &= \sec^2 t + 2\tan(-t) && \text{substitute } \tan(-t) \text{ for } -\tan t\end{aligned}$$

Now try Exercises 7 through 12 ▶

☑ **A.** You've just seen how we can identify and use identities due to symmetry

B. Verifying Identities

We're now ready to put these ideas and the ideas from Section 7.1 to work for us. When verifying identities we attempt to mold, change, or rewrite one side of the equality until we obtain a match with the other side. What follows is a collection of the ideas and methods we've observed so far, which we'll call the *Guidelines for Verifying Identities*. But remember, there really is no *right* place to start. Think things over for a moment, then attempt a substitution, simplification, or operation and see where it leads. If you hit a dead end, that's okay! Just back up and try something else.

WORTHY OF NOTE

When verifying identities, it is actually permissible to work on each side of the equality *independently,* in the effort to create a "match." But properties of equality can never be used, since we cannot assume an equality exists.

Guidelines for Verifying Identities

1. As a general rule, work on only one side of the identity.
   - We cannot assume the equation is true, so properties of equality cannot be applied.
   - We verify the identity by changing the form of one side until we get a match with the other.
2. Work with the more complex side, as it is easier to reduce/simplify than to "build."
3. If an expression contains more than one term, it is often helpful to combine terms using $\frac{A}{B} \pm \frac{C}{D} = \frac{AD \pm BC}{BD}$.
4. Converting all functions to sines and cosines can be helpful.
5. Apply other algebra skills as appropriate: distribute, factor, multiply by a conjugate, and so on.
6. *Know the fundamental identities inside out, upside down, and backward—they are the key!*

Note how these ideas are employed in Examples 2 through 5, particularly the frequent use of fundamental identities.

EXAMPLE 2 ▶ **Verifying an Identity**

Verify the identity: $\sin^2\theta \tan^2\theta = \tan^2\theta - \sin^2\theta$.

Solution ▶ As a general rule, the side with the greater number of terms or the side with rational terms is considered "more complex," so we begin with the right-hand side.

$$\begin{aligned}
\tan^2\theta - \sin^2\theta &= \frac{\sin^2\theta}{\cos^2\theta} - \sin^2\theta && \text{substitute } \frac{\sin^2\theta}{\cos^2\theta} \text{ for } \tan^2\theta \\
&= \frac{\sin^2\theta}{1} \cdot \frac{1}{\cos^2\theta} - \sin^2\theta && \text{decompose rational term} \\
&= \sin^2\theta \sec^2\theta - \sin^2\theta && \text{substitute } \sec^2\theta \text{ for } \frac{1}{\cos^2\theta} \\
&= \sin^2\theta (\sec^2\theta - 1) && \text{factor out } \sin^2\theta \\
&= \sin^2\theta \tan^2\theta && \text{substitute } \tan^2\theta \text{ for } \sec^2\theta - 1
\end{aligned}$$

Now try Exercises 13 through 18 ▶

In the first step of Example 2, we converted all functions to sines and cosines. Due to their use in the ratio identities, this often leads to compound fractions that we'll need to simplify to complete a proof.

EXAMPLE 3 ▶ **Verifying an Identity by Simplifying Compound Fractions**

Verify the identity $\dfrac{1 + \cot x}{\sec x + \csc x} = \cos x$

Solution ▶ Beginning with the left-hand side, we'll use the reciprocal and ratio identities to express all functions in terms of sines and cosines.

$$\begin{aligned}
\frac{1 + \cot x}{\sec x + \csc x} &= \frac{1 + \dfrac{\cos x}{\sin x}}{\dfrac{1}{\cos x} + \dfrac{1}{\sin x}} && \text{substitute } \frac{\cos x}{\sin x} \text{ for } \cot x, \ \frac{1}{\cos x} \text{ for } \sec x, \ \frac{1}{\sin x} \text{ for } \csc x \\
&= \frac{\left(1 + \dfrac{\cos x}{\sin x}\right)(\cos x \sin x)}{\left(\dfrac{1}{\cos x} + \dfrac{1}{\sin x}\right)(\cos x \sin x)} && \text{multiply numerator and denominator by } \cos x \sin x \text{ (the LCD for } \textit{all} \text{ fractions)} \\
&= \frac{(1)(\cos x \sin x) + \left(\dfrac{\cos x}{\cancel{\sin x}}\right)(\cos x \cancel{\sin x})}{\left(\dfrac{1}{\cancel{\cos x}}\right)(\cancel{\cos x} \sin x) + \left(\dfrac{1}{\cancel{\sin x}}\right)(\cos x \cancel{\sin x})} && \text{distribute} \\
&= \frac{\cos x \sin x + \cos^2 x}{\sin x + \cos x} && \text{simplify} \\
&= \frac{\cos x \cancel{(\sin x + \cos x)}}{\cancel{(\sin x + \cos x)}} && \text{factor out } \cos x \text{ in numerator} \\
&= \cos x && \text{simplify}
\end{aligned}$$

Now try Exercises 19 through 24 ▶

Examples 2 and 3 involved *factoring* out a common expression. Just as often, we'll need to *multiply* numerators and denominators by a common expression, as in Example 4.

EXAMPLE 4 ▶ **Verifying an Identity by Multiplying Conjugates**

Verify the identity: $\dfrac{\cos t}{1+\sec t} = \dfrac{\mathbf{1-\cos t}}{\mathbf{\tan^2 t}}$.

Solution ▶ Both sides of the identity have a single term and one is really no more complex than the other. As a matter of choice we begin with the left side. Noting the denominator on the left has the term $\sec t$, with a corresponding term of $\tan^2 t$ on the right, we reason that multiplication by a conjugate might be productive.

$$\frac{\cos t}{1+\sec t} = \left(\frac{\cos t}{1+\sec t}\right)\left(\frac{1-\sec t}{1-\sec t}\right)$$ multiply numerator and denominator by the conjugate

$$= \frac{\cos t - 1}{1-\sec^2 t}$$ distribute: $\cos t \sec t = 1$, $(A+B)(A-B) = A^2 - B^2$

$$= \frac{\cos t - 1}{-\tan^2 t}$$ substitute $-\tan^2 t$ for $1 - \sec^2 t$ ($1 + \tan^2 t = \sec^2 t \Rightarrow 1 - \sec^2 t = -\tan^2 t$)

$$= \frac{\mathbf{1-\cos t}}{\mathbf{\tan^2 t}}$$ multiply above and below by -1

Now try Exercises 25 through 28 ▶

Example 4 highlights the need to be very familiar with families of identities. To replace $1 - \sec^2 t$, we had to use $-\tan^2 t$, not simply $\tan^2 t$, since the related Pythagorean identity is $1 + \tan^2 t = \sec^2 t$.

As noted in the *Guidelines,* combining rational terms is often helpful. At this point, students are encouraged to work with the pattern $\dfrac{A}{B} \pm \dfrac{C}{D} = \dfrac{AD \pm BC}{BD}$ as a means of combing rational terms quickly and efficiently.

EXAMPLE 5 ▶ **Verifying an Identity by Combining Terms**

Verify the identity: $\dfrac{\sec x}{\sin x} - \dfrac{\sin x}{\sec x} = \dfrac{\mathbf{\tan^2 x + \cos^2 x}}{\mathbf{\tan x}}$.

Solution ▶ We begin with the left-hand side.

$$\frac{\sec x}{\sin x} - \frac{\sin x}{\sec x} = \frac{\sec^2 x - \sin^2 x}{\sin x \sec x}$$ combine terms: $\frac{A}{B} - \frac{C}{D} = \frac{AD - BC}{BD}$

$$= \frac{(1+\tan^2 x) - (1-\cos^2 x)}{\left(\dfrac{\sin x}{1}\right)\left(\dfrac{1}{\cos x}\right)}$$ substitute $1 + \tan^2 x$ for $\sec^2 x$, $1 - \cos^2 x$ for $\sin^2 x$, $\frac{1}{\cos x}$ for $\sec x$

$$= \frac{\mathbf{\tan^2 x + \cos^2 x}}{\mathbf{\tan x}}$$ simplify numerator, substitute $\tan x$ for $\frac{\sin x}{\cos x}$

Now try Exercises 29 through 34 ▶

Identities come in an infinite variety and it would be impossible to illustrate all variations. The general ideas and skills presented should prepare you to verify any of those given in the Exercise Set, as well as those you encounter in your future studies. **See Exercises 35 through 58.**

☑ **B.** You've just seen how we can verify general identities

C. Showing an Equation Is Not an Identity

To show an equation is *not* an identity, we need only find a single value for which the functions involved are defined but the equation is *false*. This can often be done by trial and error, or even by inspection. To illustrate the process, we'll use two common misconceptions that arise in working with identities.

EXAMPLE 6 ▶ Showing an Equation Is Not an Identity

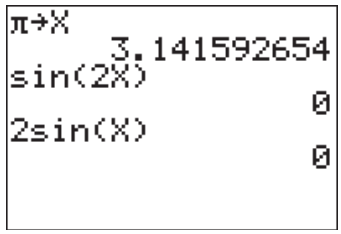
Show the equations given are *not* identities.

a. $\sin(2x) = 2\sin x$ **b.** $\cos(\alpha + \beta) = \cos\alpha + \cos\beta$

Solution ▶

a. The assumption here seems to be that we can factor out the coefficient from the argument. By inspection we note the amplitude of $\sin(2x)$ is $A = 1$, while the amplitude of $2\sin x$ is $A = 2$. This means they cannot possibly be equal for all values of x, although they are equal for integer multiples of π. For instance, substituting π for x shows the left- and right-hand sides of the equation *are equal* (see Figure 7.4). However, Figure 7.5 shows the two sides of the equation *are not equal* when $x = \frac{\pi}{6}$. This equation is not an identity.

Figure 7.4



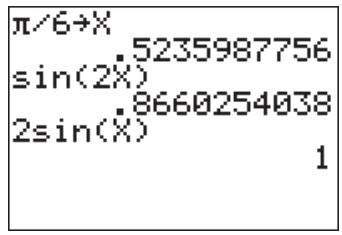


Figure 7.5

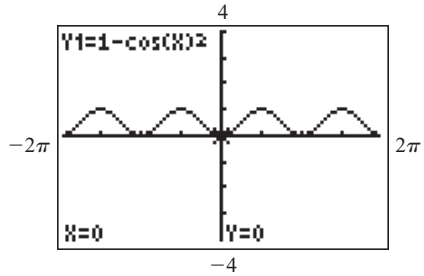
b. The assumption here is that we can distribute function values. This is similar to saying $\sqrt{x+4} = \sqrt{x} + 2$, a statement obviously false for all values except $x = 0$. Here we'll substitute convenient values to prove the equation false, namely, $\alpha = \frac{3\pi}{4}$ and $\beta = \frac{\pi}{4}$.

$$\cos\left(\frac{3\pi}{4} + \frac{\pi}{4}\right) = \cos\left(\frac{3\pi}{4}\right) + \cos\left(\frac{\pi}{4}\right) \quad \text{substitute } \tfrac{3\pi}{4} \text{ for } \alpha \text{ and } \tfrac{\pi}{4} \text{ for } \beta$$

$$\cos\pi = -\frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2} \quad \text{simplify}$$



$$-1 \neq 0 \quad \text{result is false}$$

Now try Exercises 59 through 64 ▶

Many times, a *graphical test* can be used to help determine if an equation is an identity. While not fool-proof, seeing if the graphs appear identical can either *suggest* the identity is true, or definitely show it is not. When testing identities, it helps to ENTER the left-hand side of the equation as Y_1 on the Y= screen, and the right-hand side as Y_2. We can then test whether an identity relationship might exist by graphing both relations, and noting whether two graphs or a single graph appears on the GRAPH screen.

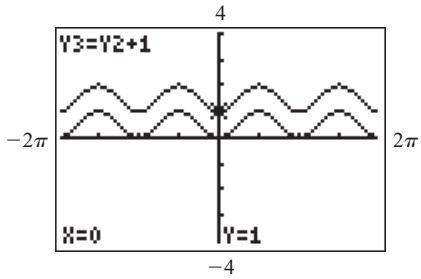
Consider the equation $1 - \cos^2 x = \sin^2 x$. After entering $Y_1 = 1 - \cos(X)^2$ and $Y_2 = \sin(X)^2$, we obtain the graph shown in Figure 7.6 using the calculator's ZOOM **7:ZTrig** feature.

Figure 7.6

Since only one graph appears in this window, it seems that an identity relationship *likely* exists between Y_1 and Y_2. This can be further supported (but still not proven) by entering $Y_3 = Y_2 + 1$ to vertically translate the graph of Y_2 up 1 unit (be sure to deactivate Y_2) and observing the GRAPH (see Figure 7.7). Of course the calculator's **TABLE** feature could also be used on Y_1 and Y_2.

To graphically investigate the equation $\sin(2x) = 2\sin x$, GRAPH $Y_1 = \sin(2X)$ and $Y_2 = 2\sin(X)$ and note the existence of two distinct graphs (Figure 7.8). The resulting graphs confirm our solution to Example 6(a): $\sin(2x) \neq 2\sin x$—even though $\sin(2x) = 2\sin x$ for *integer* multiples of π (the points of intersection). **See Exercises 65 through 68.**

Figure 7.7



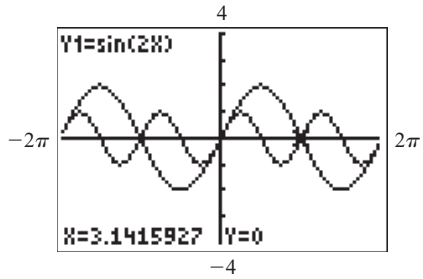


Figure 7.8

☑ **C.** You've just seen how we can use counterexamples and contradictions to show an equation is not an identity

7.2 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. The identities $-\sin x \tan x = \sin(-x)\tan x$ and $\cos(-x)\cot x = \cos x \cot x$ are examples of _____ due to _____.

2. To show an equation is *not an identity,* we must find at least _____ input value where both sides of the equation are defined, but results in a _____ equation.

3. To verify an identity, always begin with the more _____ expression, since it is easier to _____ than to _____.

4. Converting all terms to functions of _____ and _____ may help verify an identity.

5. Discuss/Explain why you must not add, subtract, multiply, or divide both sides of the equation when verifying identities.

6. Discuss/Explain the difference between operating on both sides of an equation (see Exercise 5) and working on each side independently.

▶ DEVELOPING YOUR SKILLS

Verify that the following equations are identities.

7. $(1 + \sin x)[1 + \sin(-x)] = \cos^2 x$

8. $(\sec x + 1)[\sec(-x) - 1] = \tan^2 x$

9. $\sin^2(-x) + \cos^2 x = 1$

10. $1 + \cot^2(-x) = \csc^2 x$

11. $\dfrac{1 - \sin(-x)}{\cos x + \cos(-x)\sin x} = \sec x$

12. $\dfrac{1 + \cos(-x)}{\sin x - \cos x \sin(-x)} = \csc x$

13. $\cos^2 x \tan^2 x = 1 - \cos^2 x$

14. $\sin^2 x \cot^2 x = 1 - \sin^2 x$

15. $\tan x + \cot x = \sec x \csc x$

16. $\cot x \cos x = \csc x - \sin x$

17. $\dfrac{\cos x}{\tan x} = \csc x - \sin x$

18. $\dfrac{\sin x}{\cot x} = \sec x - \cos x$

19. $\dfrac{\sec x}{\cot x + \tan x} = \sin x$

20. $\dfrac{\csc x}{\cot x + \tan x} = \cos x$

21. $\dfrac{\sin x - \csc x}{\csc x} = -\cos^2 x$

22. $\dfrac{\cos x - \sec x}{\sec x} = -\sin^2 x$

23. $\dfrac{1}{\csc x - \sin x} = \tan x \sec x$

24. $\dfrac{1}{\sec x - \cos x} = \cot x \csc x$

25. $\dfrac{\cos \theta}{1 - \sin \theta} = \sec \theta + \tan \theta$

26. $\dfrac{\sin \theta}{1 - \cos \theta} = \csc \theta + \cot \theta$

27. $\dfrac{1 - \sin x}{\cos x} = \dfrac{\cos x}{1 + \sin x}$

28. $\dfrac{1 - \cos x}{\sin x} = \dfrac{\sin x}{1 + \cos x}$

29. $\dfrac{\csc x}{\cos x} - \dfrac{\cos x}{\csc x} = \dfrac{\cot^2 x + \sin^2 x}{\cot x}$

30. $\dfrac{1}{\cos^2 x} + \dfrac{1}{\sin^2 x} = \csc^2 x \sec^2 x$

31. $\dfrac{\sin x}{1 + \sin x} - \dfrac{\sin x}{1 - \sin x} = -2 \tan^2 x$

32. $\dfrac{\cos x}{1 + \cos x} - \dfrac{\cos x}{1 - \cos x} = -2 \cot^2 x$

33. $\dfrac{\cot x}{1 + \csc x} - \dfrac{\cot x}{1 - \csc x} = 2 \sec x$

34. $\dfrac{\tan x}{1 + \sec x} - \dfrac{\tan x}{1 - \sec x} = 2 \csc x$

35. $\dfrac{\sec^2 x}{1 + \cot^2 x} = \tan^2 x$

36. $\dfrac{\csc^2 x}{1 + \tan^2 x} = \cot^2 x$

37. $\sin^2 x (\cot^2 x - \csc^2 x) = -\sin^2 x$

38. $\cos^2 x (\tan^2 x - \sec^2 x) = -\cos^2 x$

39. $\cos x \cot x + \sin x = \csc x$

40. $\sin x \tan x + \cos x = \sec x$

41. $\dfrac{1 + \sin x}{1 - \sin x} = (\tan x + \sec x)^2$

42. $\dfrac{1 - \cos x}{1 + \cos x} = (\csc x - \cot x)^2$

43. $\dfrac{\cos x - \sin x}{1 - \tan x} = \dfrac{\cos x + \sin x}{1 + \tan x}$

44. $\dfrac{1 - \cot x}{1 + \cot x} = \dfrac{\sin x - \cos x}{\sin x + \cos x}$

45. $\dfrac{\tan^2 x - \cot^2 x}{\tan x - \cot x} = \csc x \sec x$

46. $\dfrac{\cot x - \tan x}{\cot^2 x - \tan^2 x} = \sin x \cos x$

47. $\dfrac{\cot x}{\cot x + \tan x} = 1 - \sin^2 x$

48. $\dfrac{\tan x}{\cot x + \tan x} = 1 - \cos^2 x$

49. $\dfrac{\sec^4 x - \tan^4 x}{\sec^2 x + \tan^2 x} = 1$

50. $\dfrac{\csc^4 x - \cot^4 x}{\csc^2 x + \cot^2 x} = 1$

51. $\dfrac{\cos^4 x - \sin^4 x}{\cos^2 x} = 2 - \sec^2 x$

52. $\dfrac{\sin^4 x - \cos^4 x}{\sin^2 x} = 2 - \csc^2 x$

53. $(\sec x + \tan x)^2 = \dfrac{(\sin x + 1)^2}{\cos^2 x}$

54. $(\csc x + \cot x)^2 = \dfrac{(\cos x + 1)^2}{\sin^2 x}$

55. $\dfrac{\cos x}{\sin x} + \dfrac{\sin x}{\cos x} + \dfrac{\csc x}{\sec x} = \dfrac{\sec x + \cos x}{\sin x}$

56. $\dfrac{\cos x}{\sin x} + \dfrac{\sin x}{\cos x} + \dfrac{\sec x}{\csc x} = \dfrac{\csc x + \sin x}{\cos x}$

57. $\dfrac{\sin^4 x - \cos^4 x}{\sin^3 x + \cos^3 x} = \dfrac{\sin x - \cos x}{1 - \sin x \cos x}$

58. $\dfrac{\sin^4 x - \cos^4 x}{\sin^3 x - \cos^3 x} = \dfrac{\sin x + \cos x}{1 + \sin x \cos x}$

Show that the following equations *are not identities.*

59. $\sin\left(\theta + \frac{\pi}{3}\right) = \sin\theta + \sin\left(\frac{\pi}{3}\right)$

60. $\cos\left(\frac{\pi}{4}\right) + \cos\theta = \cos\left(\frac{\pi}{4} + \theta\right)$

61. $\cos(2\theta) = 2\cos\theta$

62. $\tan(2\theta) = 2\tan\theta$

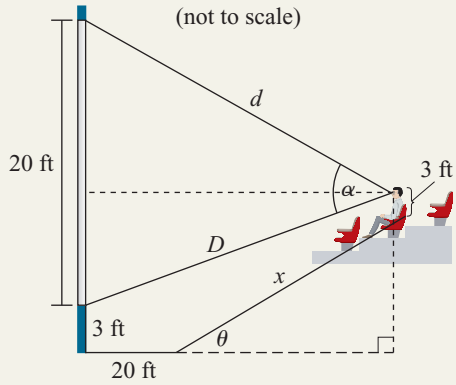
63. $\tan\left(\frac{\theta}{4}\right) = \frac{\tan\theta}{\tan 4}$

64. $\cos^2\theta - \sin^2\theta = -1$

Determine which of the following are not identities by using a calculator to compare the graphs of the left- and right-hand sides of each equation.

65. $\frac{1 - \sin^2\theta}{\cos\theta} = \cos\theta$

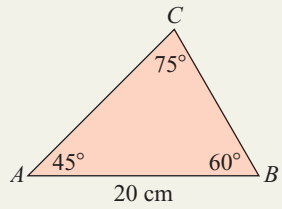
66. $\cos(2x) = 1 - 2\sin^2 x$



67. $\frac{\cos x}{1 + \sin x} = \frac{1 + \sin x}{\cos x}$

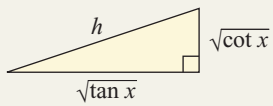
68. $\frac{\cos x}{1 - \sin x} = \sec x - \tan x$

▶ WORKING WITH FORMULAS



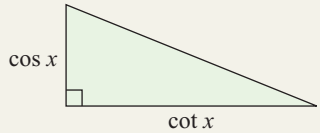
69. Distance to top of movie screen: $d^2 = (20 + x\cos\theta)^2 + (20 - x\sin\theta)^2$

At a theater, the optimum viewing angle depends on a number of factors, like the height of the screen, the incline of the auditorium, the location of a seat, the height of your eyes while seated, and so on. One of the measures needed to find the "best" seat is the distance from your eyes to the top of the screen. For a theater with the dimensions shown, this distance is given by the formula here (x is the diagonal distance from the horizontal floor to your seat). (a) Show the formula is equivalent to $d^2 = 800 + 40x(\cos\theta - \sin\theta) + x^2$. (b) Find the distance d if $\theta = 18°$ and you are sitting in the eighth row with the rows spaced 3 ft apart.



70. The area of triangle ABC: $A = \frac{c^2 \sin A \sin B}{2 \sin C}$

If one side and three angles of a triangle are known, its area can be computed using this formula, where side c is opposite angle C. Find the area of the triangle shown in the diagram.



▶ APPLICATIONS

71. Pythagorean theorem: For the triangle shown, (a) find an expression for the length of the hypotenuse in terms of $\tan x$ and $\cot x$, then determine the length of the hypotenuse when $x = 1.5$ rad. (b) Show the expression you found in part (a) is equivalent to $h = \sqrt{\csc x \sec x}$ and recompute the length of the hypotenuse using this expression. Did the answers match?

72. Pythagorean theorem: For the triangle shown, (a) find an expression for the area of the triangle in terms of $\cot x$ and $\cos x$, then determine its area given $x = \frac{\pi}{6}$. (b) Show the expression you found in part (a) is equivalent to $A = \frac{1}{2}(\csc x - \sin x)$ and recompute the area using this expression. Did the answers match?

Exercise 72

73. Viewing distance: Referring to Exercise 69, find a formula for D—the distance from a patron's eyes to the *bottom* of the movie screen. Simplify the result using a Pythagorean identity, then find the value of D for the same seat described in part (b) of Exercise 69.

74. Viewing angle: Referring to Exercises 69 and 73, once d and D are known, the viewing angle α (the angle subtended by the movie screen and the viewer's eyes) can be found using the formula $\cos\alpha = \dfrac{d^2 + D^2 - 20^2}{2dD}$. Find the value of $\cos\alpha$ for the same seat described in part (b) of Exercise 69.

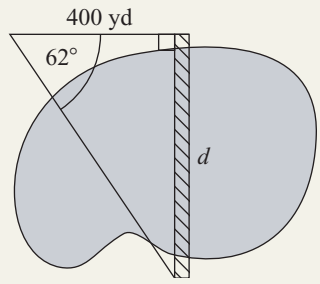
75. Intensity of light: In a study of the luminous intensity of light, the expression $\sin\alpha = \dfrac{I_1\cos\theta}{\sqrt{(I_1\cos\theta)^2 + (I_2\sin\theta)^2}}$ can occur. Simplify the equation for the moment $I_1 = I_2$.

76. Intensity of light: Referring to Exercise 75, find the angle θ given $I_1 = I_2$ and $\alpha = 60°$.

▶ EXTENDING THE CONCEPT

77. Verify the identity $\dfrac{\sin^6 x - \cos^6 x}{\sin^4 x - \cos^4 x} = 1 - \sin^2 x\cos^2 x$.

78. Use factoring to show the equation is an identity: $\sin^4 x + 2\sin^2 x\cos^2 x + \cos^4 x = 1$.



▶ MAINTAINING YOUR SKILLS

79. (4.4) Graph the rational function given. $h(x) = \dfrac{x-1}{x^2-4}$

80. (6.2) Verify that $\left(\dfrac{\sqrt{7}}{4}, \dfrac{3}{4}\right)$ is a point on the unit circle, then state the values of $\sin t$, $\cos t$, and $\tan t$ associated with this point.

81. (6.6) Use an appropriate trig ratio to find the length of the bridge needed to cross the lake shown in the figure.

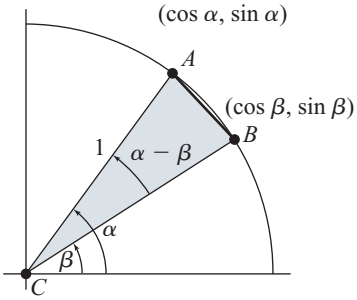
Exercise 82

82. (2.3) Graph using transformations of a toolbox function: $f(x) = -2|x-3| + 6$

7.3 The Sum and Difference Identities

LEARNING OBJECTIVES

In Section 7.3 you will see how we can:



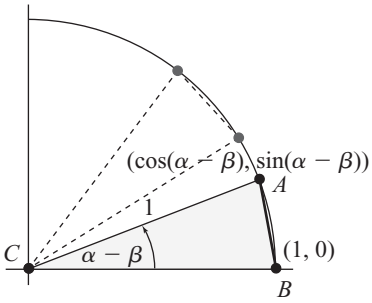
- ❑ **A.** Develop and use sum and difference identities for cosine
- ❑ **B.** Use the cofunction identities to develop the sum and difference identities for sine and tangent
- ❑ **C.** Use the sum and difference identities to verify other identities

The sum and difference formulas for sine and cosine have a long and ancient history. Originally developed to help study the motion of celestial bodies, they were used centuries later to develop more complex concepts, such as the derivatives of the trig functions, complex number theory, and the study of wave motion in different mediums. These identities are also used to find exact results (in radical form) for many nonstandard angles, a result of great importance to the ancient astronomers and still of notable mathematical significance today.

A. The Sum and Difference Identities for Cosine

On the unit circle with center C, consider the point A on the terminal side of angle α, and point B on the terminal side of angle β, as shown in Figure 7.9. Since $r = 1$, the coordinates of A and B are $(\cos\alpha, \sin\alpha)$ and $(\cos\beta, \sin\beta)$, respectively. Using the

Figure 7.9



distance formula, we find that segment $\overline{AB}$ is equal to

$$\begin{aligned}
\overline{AB} &= \sqrt{(\cos\alpha - \cos\beta)^2 + (\sin\alpha - \sin\beta)^2} \\
&= \sqrt{\cos^2\alpha - 2\cos\alpha\cos\beta + \cos^2\beta + \sin^2\alpha - 2\sin\alpha\sin\beta + \sin^2\beta} && \text{binomial squares} \\
&= \sqrt{(\cos^2\alpha + \sin^2\alpha) + (\cos^2\beta + \sin^2\beta) - 2\cos\alpha\cos\beta - 2\sin\alpha\sin\beta} && \text{regroup} \\
&= \sqrt{2 - 2\cos\alpha\cos\beta - 2\sin\alpha\sin\beta} && \cos^2 u + \sin^2 u = 1
\end{aligned}$$

With no loss of generality, we can rotate sector ACB clockwise, until side $\overline{CB}$ coincides with the x-axis. This creates new coordinates of $(1, 0)$ for B, and new coordinates of $(\cos(\alpha - \beta), \sin(\alpha - \beta))$ for A, *but the distance* $\overline{AB}$ *remains unchanged!* (See Figure 7.10.) Recomputing the distance gives

Figure 7.10

$$\begin{aligned}
\overline{AB} &= \sqrt{[\cos(\alpha - \beta) - 1]^2 + [\sin(\alpha - \beta) - 0]^2} \\
&= \sqrt{\cos^2(\alpha - \beta) - 2\cos(\alpha - \beta) + 1 + \sin^2(\alpha - \beta)} \\
&= \sqrt{[\cos^2(\alpha - \beta) + \sin^2(\alpha - \beta)] - 2\cos(\alpha - \beta) + 1} \\
&= \sqrt{2 - 2\cos(\alpha - \beta)}
\end{aligned}$$

Since both expressions represent the same distance, we can set them equal to each other and solve for $\cos(\alpha - \beta)$.

$$\begin{aligned}
\sqrt{2 - 2\cos(\alpha - \beta)} &= \sqrt{2 - 2\cos\alpha\cos\beta - 2\sin\alpha\sin\beta} && \overline{AB} = \overline{AB} \\
2 - 2\cos(\alpha - \beta) &= 2 - 2\cos\alpha\cos\beta - 2\sin\alpha\sin\beta && \text{property of radicals} \\
-2\cos(\alpha - \beta) &= -2\cos\alpha\cos\beta - 2\sin\alpha\sin\beta && \text{subtract 2} \\
\cos(\alpha - \beta) &= \cos\alpha\cos\beta + \sin\alpha\sin\beta && \text{divide both sides by } -2
\end{aligned}$$

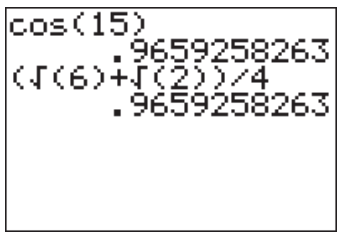
The result is called the **difference identity for cosine.** The **sum identity for cosine** follows immediately, by substituting $-\beta$ for β.

$$\begin{aligned}
\cos(\alpha - \beta) &= \cos\alpha\cos\beta + \sin\alpha\sin\beta && \text{difference identity} \\
\cos(\alpha - [-\beta]) &= \cos\alpha\cos(-\beta) + \sin\alpha\sin(-\beta) && \text{substitute } -\beta \text{ for } \beta \\
\cos(\alpha + \beta) &= \cos\alpha\cos\beta - \sin\alpha\sin\beta && \cos(-\beta) = \cos\beta;\ \sin(-\beta) = -\sin\beta
\end{aligned}$$

The sum and difference identities can be used to find exact values for the trig functions of certain angles (values written in nondecimal form using radicals), simplify expressions, and to establish additional identities.

EXAMPLE 1 ▶ Finding Exact Values for Non-Standard Angles

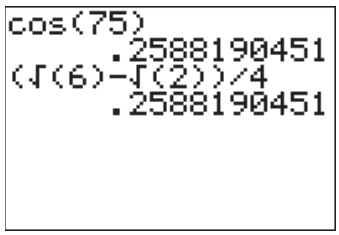
Use the sum and difference identities for cosine to find exact values for



a. $\cos 15° = \cos(45° - 30°)$ **b.** $\cos 75° = \cos(45° + 30°)$

Check results on a calculator in degree (MODE).

Solution ▶ Each involves a direct application of the related identity, and uses special values.



a.
$$\begin{aligned}
\cos(\alpha - \beta) &= \cos\alpha\cos\beta + \sin\alpha\sin\beta && \text{difference identity} \\
\cos(45° - 30°) &= \cos 45°\cos 30° + \sin 45°\sin 30° && \alpha = 45°, \beta = 30° \\
&= \left(\frac{\sqrt{2}}{2}\right)\left(\frac{\sqrt{3}}{2}\right) + \left(\frac{\sqrt{2}}{2}\right)\left(\frac{1}{2}\right) && \text{standard values} \\
\cos 15° &= \frac{\sqrt{6} + \sqrt{2}}{4} && \text{combine terms}
\end{aligned}$$

Figure 7.11

See Figure 7.11.

Figure 7.12

b. $\cos(\alpha + \beta) = \cos\alpha\cos\beta - \sin\alpha\sin\beta$ sum identity

$\cos(45° + 30°) = \cos 45°\cos 30° - \sin 45°\sin 30°$ $\alpha = 45°, \beta = 30°$

$= \left(\frac{\sqrt{2}}{2}\right)\left(\frac{\sqrt{3}}{2}\right) - \left(\frac{\sqrt{2}}{2}\right)\left(\frac{1}{2}\right)$ standard values

$\cos 75° = \frac{\sqrt{6} - \sqrt{2}}{4}$ combine terms

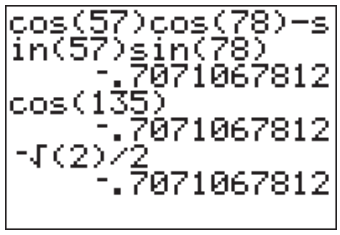
See Figure 7.12.

Now try Exercises 7 through 12 ▶

CAUTION ▶ Be sure you clearly understand how these identities work. In particular, note that $\cos(60° + 30°) \neq \cos 60° + \cos 30° \left(0 \neq \frac{1}{2} + \frac{\sqrt{3}}{2}\right)$ and in general $f(a+b) \neq f(a) + f(b)$.

These identities are listed here using the "$\pm$" and "$\mp$" notation to avoid needless repetition. In their application, use both upper symbols or both lower symbols, with the order depending on whether you're evaluating the cosine of a sum or difference of two angles. As with the other identities, these can be rewritten to form other members of the identity family. One such version is used in Example 2 to consolidate a larger expression.

The Sum and Difference Identities for Cosine



cosine family: $\cos(\alpha \pm \beta) = \cos\alpha\cos\beta \mp \sin\alpha\sin\beta$ functions repeat, signs alternate

$\cos\alpha\cos\beta \mp \sin\alpha\sin\beta = \cos(\alpha \pm \beta)$ can be used to *expand* or *contract*

EXAMPLE 2 ▶ **Using a Sum/Difference Identity to Simplify an Expression**

Write as a single expression in cosine and evaluate: $\cos 57°\cos 78° - \sin 57°\sin 78°$

Solution ▶ Since the functions repeat and are expressed as a difference, we use the sum identity for cosine to rewrite the difference as a single expression.

$\cos\alpha\cos\beta - \sin\alpha\sin\beta = \cos(\alpha + \beta)$ sum identity for cosine

$\cos 57°\cos 78° - \sin 57°\sin 78° = \cos(57° + 78°)$ $\alpha = 57°, \beta = 78°$

$= \cos 135°$ $57° + 78° = 135°$

The expression is equal to $\cos 135° = -\frac{\sqrt{2}}{2}$. See the figure.

Now try Exercises 13 through 16 ▶

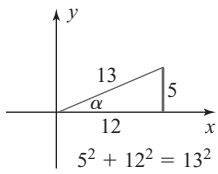
The sum and difference identities can be used to evaluate the cosine of the sum of two angles, even when they are not adjacent or expressed in terms of cosine.

EXAMPLE 3 ▶ **Computing the Cosine of a Sum**

Given $\sin\alpha = \frac{5}{13}$ with the terminal side of α in QI, and $\tan\beta = -\frac{24}{7}$ with the terminal side of β in QII. Compute the value of $\cos(\alpha + \beta)$.

Solution ▶ To use the sum formula we need the value of $\cos\alpha$, $\sin\alpha$, $\cos\beta$, and $\sin\beta$. Using the given information about the quadrants along with the Pythagorean theorem, we draw the triangles shown in Figures 7.13 and 7.14, yielding the values that follow.

Figure 7.13



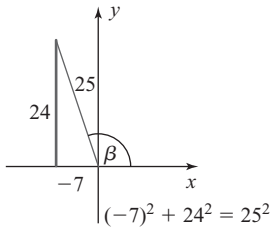


Figure 7.14

$$\cos\alpha = \frac{12}{13}\text{ (QI)},\ \sin\alpha = \frac{5}{13}\text{ (given)},\ \cos\beta = -\frac{7}{25}\text{ (QII)},\ \text{and}\ \sin\beta = \frac{24}{25}\text{ (QII)}$$

Using $\cos(\alpha + \beta) = \cos\alpha\cos\beta - \sin\alpha\sin\beta$ gives this result:

$$\begin{aligned}\cos(\alpha + \beta) &= \left(\frac{12}{13}\right)\left(-\frac{7}{25}\right) - \left(\frac{5}{13}\right)\left(\frac{24}{25}\right)\\ &= -\frac{84}{325} - \frac{120}{325}\\ &= -\frac{204}{325}\end{aligned}$$

Now try Exercises 17 and 18 ▶

To verify the result of Example 3, we can use the inverse trigonometric functions and our knowledge of reference angles to approximate the values of α and β. In the first line of Figure 7.15, we find the QI value of α is approximately 22.62°, and store it in memory location A using STO▸ ALPHA MATH **(A).** Noting the terminal side of β is in QII, we compute its value (≈106.26°) as shown in the second calculation and store it in memory location B. For the final step of the verification, we evaluate cos(A + B) in fractional form and obtain $\frac{-204}{325}$, as in Example 3.

Figure 7.15

```
sin⁻¹(5/13)→A
      22.61986495
180−tan⁻¹(24/7)→B
      106.2602047
cos(A+B)▸Frac
          -204/325
```

☑ **A.** You've just seen how we can develop and use sum and difference identities for cosine

B. The Sum and Difference Identities for Sine and Tangent

The cofunction identities were introduced in Section 6.6, using the complementary angles in a right triangle. In this section we'll *verify* that $\cos\left(\frac{\pi}{2} - \theta\right) = \sin\theta$ and $\sin\left(\frac{\pi}{2} - \theta\right) = \cos\theta$. For the first, we use the difference identity for cosine to obtain

$$\begin{aligned}\cos\left(\frac{\pi}{2} - \theta\right) &= \cos\frac{\pi}{2}\cos\theta + \sin\frac{\pi}{2}\sin\theta\\ &= (0)\cos\theta + (1)\sin\theta\\ &= \sin\theta\end{aligned}$$

For the second, we use $\cos\left(\frac{\pi}{2} - \theta\right) = \sin\theta$, and replace θ with the real number $\frac{\pi}{2} - t$. This gives

$$\cos\left(\frac{\pi}{2} - \theta\right) = \sin\theta \qquad \text{cofunction identity for cosine}$$

$$\cos\left(\frac{\pi}{2} - \left[\frac{\pi}{2} - t\right]\right) = \sin\left(\frac{\pi}{2} - t\right) \qquad \text{replace } \theta \text{ with } \frac{\pi}{2} - t$$

$$\cos t = \sin\left(\frac{\pi}{2} - t\right) \qquad \text{result, note } \left[\frac{\pi}{2} - \left(\frac{\pi}{2} - t\right)\right] = t$$

This establishes the cofunction relationship for sine: $\sin\left(\frac{\pi}{2} - t\right) = \cos t$ for any real number t. Both identities can be written in terms of the real number t. **See Exercises 19 through 24.**

The Cofunction Identities

$$\cos\left(\frac{\pi}{2} - t\right) = \sin t \qquad \sin\left(\frac{\pi}{2} - t\right) = \cos t$$

The sum and difference identities for sine can easily be developed using cofunction identities. Since $\sin t = \cos\left(\frac{\pi}{2} - t\right)$, we need only rename t as the sum $(\alpha + \beta)$ or the difference $(\alpha - \beta)$ and work from there.

$$\sin t = \cos\left(\frac{\pi}{2} - t\right) \qquad \text{cofunction identity}$$

$$\sin(\alpha + \beta) = \cos\left[\frac{\pi}{2} - (\alpha + \beta)\right] \qquad \text{substitute } (\alpha + \beta) \text{ for } t$$

$$= \cos\left[\left(\frac{\pi}{2} - \alpha\right) - \beta\right] \qquad \text{regroup argument}$$

$$= \cos\left(\frac{\pi}{2} - \alpha\right)\cos\beta + \sin\left(\frac{\pi}{2} - \alpha\right)\sin\beta \qquad \text{apply difference identity for cosine}$$

$$\sin(\alpha + \beta) = \sin\alpha\cos\beta + \cos\alpha\sin\beta \qquad \text{result}$$

The difference identity for sine is likewise developed. The sum and difference identities for tangent can be derived using ratio identities and their derivation is left as an exercise **(see Exercise 78).**

The Sum and Difference Identities for Sine and Tangent

sine family:

$$\sin(\alpha \pm \beta) = \sin\alpha\cos\beta \pm \cos\alpha\sin\beta \qquad \text{functions alternate, signs repeat}$$

$$\sin\alpha\cos\beta \pm \cos\alpha\sin\beta = \sin(\alpha \pm \beta) \qquad \text{can be used to } \textit{expand} \text{ or } \textit{contract}$$

tangent family:

$$\tan(\alpha \pm \beta) = \frac{\tan\alpha \pm \tan\beta}{1 \pm \tan\alpha\tan\beta} \qquad \text{signs match original in numerator, signs alternate in denominator}$$

$$\frac{\tan\alpha \pm \tan\beta}{1 \mp \tan\alpha\tan\beta} = \tan(\alpha \pm \beta) \qquad \text{can be used to } \textit{expand} \text{ or } \textit{contract}$$

EXAMPLE 4A ▶ **Simplifying Expressions Using Sum/Difference Identities**

Write as a single expression in sine: $\sin(2t)\cos t + \cos(2t)\sin t$.

Solution ▶ Since the functions in each term alternate and the expression is written as a sum, we use the sum identity for sine:

$$\begin{aligned} \sin\alpha\cos\beta + \cos\alpha\sin\beta &= \sin(\alpha+\beta) && \text{sum identity for sine}\\ \sin(2t)\cos t + \cos(2t)\sin t &= \sin(2t+t) && \text{substitute } 2t \text{ for } \alpha \text{ and } t \text{ for } \beta\\ &= \sin(3t) && \text{simplify}\end{aligned}$$

The expression is equal to $\sin(3t)$.

With $Y_1 = \sin(2X)\cos(X) + \cos(2X)\sin(X)$ and $Y_2 = \sin(3X)$, the **TABLE** feature of a calculator set in radian (MODE) provides strong support for the result of Example 4A (see Figure 7.16).

Figure 7.16

X	Y1	Y2
0	0	0
1	.14112	.14112
2	-.2794	-.2794
3	.41212	.41212
4	-.5366	-.5366
5	.65029	.65029
6	-.751	-.751

Y2=sin(3X)

EXAMPLE 4B ▶ **Simplifying Expressions Using Sum/Difference Identities**

Use the sum or difference identity for tangent to find the exact value of $\tan\dfrac{11\pi}{12}$.

Solution ▶ Since an exact value is requested, $\dfrac{11\pi}{12}$ must be the sum or difference of two standard angles. A casual inspection reveals $\dfrac{11\pi}{12} = \dfrac{2\pi}{3} + \dfrac{\pi}{4}$. This gives

$$\begin{aligned} \tan(\alpha+\beta) &= \frac{\tan\alpha+\tan\beta}{1-\tan\alpha\tan\beta} && \text{sum identity for tangent}\\ \tan\left(\frac{2\pi}{3}+\frac{\pi}{4}\right) &= \frac{\tan\left(\frac{2\pi}{3}\right)+\tan\left(\frac{\pi}{4}\right)}{1-\tan\left(\frac{2\pi}{3}\right)\tan\left(\frac{\pi}{4}\right)} && \alpha=\frac{2\pi}{3},\ \beta=\frac{\pi}{4}\\ &= \frac{-\sqrt{3}+1}{1-(-\sqrt{3})(1)} && \tan\left(\frac{2\pi}{3}\right)=-\sqrt{3},\ \tan\left(\frac{\pi}{4}\right)=1\\ &= \frac{1-\sqrt{3}}{1+\sqrt{3}} && \text{simplify expression}\end{aligned}$$

B. You've just seen how we can use the cofunction identities to develop the sum and difference identities for sine and tangent

Now try Exercises 25 through 54 ▶

C. Verifying Other Identities

Once the sum and difference identities are established, we can simply add these to the tools we use to verify other identities.

EXAMPLE 5 ▶ **Verifying an Identity**

Verify that $\tan\left(\theta-\dfrac{\pi}{4}\right) = \dfrac{\tan\theta-1}{\tan\theta+1}$ is an identity.

Solution ▶ Using a direct application of the difference formula for tangent we obtain

$$\tan\left(\theta - \frac{\pi}{4}\right) = \frac{\tan\theta - \tan\frac{\pi}{4}}{1 + \tan\theta\tan\frac{\pi}{4}} \qquad \alpha = \theta, \beta = \frac{\pi}{4}$$

$$= \frac{\tan\theta - 1}{1 + \tan\theta} = \frac{\tan\theta - 1}{\tan\theta + 1} \qquad \tan\left(\frac{\pi}{4}\right) = 1$$

Now try Exercises 55 through 60 ▶

EXAMPLE 6 ▶ Verifying an Identity

Verify that $\sin(\alpha + \beta)\sin(\alpha - \beta) = \sin^2\alpha - \sin^2\beta$ is an identity.

Solution ▶ Using the sum and difference formulas for sine we obtain

$$\begin{aligned}
\sin(\alpha + \beta)\sin(\alpha - \beta) &= (\sin\alpha\cos\beta + \cos\alpha\sin\beta)(\sin\alpha\cos\beta - \cos\alpha\sin\beta) \\
&= \sin^2\alpha\cos^2\beta - \cos^2\alpha\sin^2\beta && (A + B)(A - B) = A^2 - B^2 \\
&= \sin^2\alpha(1 - \sin^2\beta) - (1 - \sin^2\alpha)\sin^2\beta && \text{use } \cos^2x = 1 - \sin^2x \text{ to write the expression solely in terms of sine} \\
&= \sin^2\alpha - \sin^2\alpha\sin^2\beta - \sin^2\beta + \sin^2\alpha\sin^2\beta && \text{distribute} \\
&= \sin^2\alpha - \sin^2\beta && \text{simplify}
\end{aligned}$$

C. You've just seen how we can use the sum and difference identities to verify other identities

Now try Exercises 61 through 68 ▶

7.3 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. Since $\tan 45° + \tan 60° > 1$, we know $\tan 45° + \tan 60° = \tan 105°$ is ____ since $\tan\theta < 0$ in ____.
2. To find an exact value for $\tan 105°$, use the sum identity for tangent with $\alpha =$ ____ and $\beta =$ ____.
3. For the cosine sum/difference identities, the functions ____ in each term, with the ____ sign between them.
4. For the sine sum/difference identities, the functions ____ in each term, with the ____ sign between them.
5. Discuss/Explain how we know the exact value for $\cos\frac{11\pi}{12} = \cos\left(\frac{2\pi}{3} + \frac{\pi}{4}\right)$ will be negative, prior to applying any identity.
6. Discuss/Explain why $\tan(\alpha - \beta) = \frac{\sin(\alpha - \beta)}{\cos(\beta - \alpha)}$ is an identity, even though the arguments of cosine have been reversed. Then verify the identity.

▶ DEVELOPING YOUR SKILLS

Find the exact value of the expression given using a sum or difference identity. Some simplifications may involve using symmetry and the formulas for negatives. Check results on a calculator.

7. $\cos 105°$ **8.** $\cos 135°$

9. $\cos\left(\frac{7\pi}{12}\right)$ **10.** $\cos\left(-\frac{5\pi}{12}\right)$

Use sum/difference identities to verify that both expressions give the same result. Check results on a calculator.

11. a. $\cos(45° + 30°)$ **b.** $\cos(120° - 45°)$

12. a. $\cos\left(\frac{\pi}{6} - \frac{\pi}{4}\right)$ **b.** $\cos\left(\frac{\pi}{4} - \frac{\pi}{3}\right)$

Rewrite as a single expression in cosine.

13. $\cos(7\theta)\cos(2\theta) + \sin(7\theta)\sin(2\theta)$

14. $\cos\left(\frac{\theta}{3}\right)\cos\left(\frac{\theta}{6}\right) - \sin\left(\frac{\theta}{3}\right)\sin\left(\frac{\theta}{6}\right)$

Find the exact value of the given expressions. Check results on a calculator.

15. $\cos 183° \cos 153° + \sin 183° \sin 153°$

16. $\cos\left(\frac{7\pi}{36}\right)\cos\left(\frac{5\pi}{36}\right) - \sin\left(\frac{7\pi}{36}\right)\sin\left(\frac{5\pi}{36}\right)$

17. For $\sin\alpha = -\frac{4}{5}$ with terminal side of α in QIV and $\tan\beta = -\frac{5}{12}$ with terminal side of β in QII, find $\cos(\alpha + \beta)$.

18. For $\sin\alpha = \frac{112}{113}$ with terminal side of α in QII and $\sec\beta = -\frac{89}{39}$ with terminal side of β in QII, find $\cos(\alpha - \beta)$.

Use a cofunction identity to write an equivalent expression.

19. $\cos 57°$ **20.** $\sin 18°$

21. $\tan\left(\frac{5\pi}{12}\right)$ **22.** $\sec\left(\frac{\pi}{10}\right)$

23. $\sin\left(\frac{\pi}{6} - \theta\right)$ **24.** $\cos\left(\frac{\pi}{3} + \theta\right)$

Rewrite as a single expression.

25. $\sin(3x)\cos(5x) + \cos(3x)\sin(5x)$

26. $\sin\left(\frac{x}{2}\right)\cos\left(\frac{x}{3}\right) - \cos\left(\frac{x}{2}\right)\sin\left(\frac{x}{3}\right)$

27. $\dfrac{\tan(5\theta) - \tan(2\theta)}{1 + \tan(5\theta)\tan(2\theta)}$

28. $\dfrac{\tan\left(\frac{x}{2}\right) + \tan\left(\frac{x}{8}\right)}{1 - \tan\left(\frac{x}{2}\right)\tan\left(\frac{x}{8}\right)}$

Find the exact value of the given expressions.

29. $\sin 137° \cos 47° - \cos 137° \sin 47°$

30. $\sin\left(\frac{11\pi}{24}\right)\cos\left(\frac{5\pi}{24}\right) + \cos\left(\frac{11\pi}{24}\right)\sin\left(\frac{5\pi}{24}\right)$

31. $\dfrac{\tan\left(\frac{11\pi}{21}\right) - \tan\left(\frac{4\pi}{21}\right)}{1 + \tan\left(\frac{11\pi}{21}\right)\tan\left(\frac{4\pi}{21}\right)}$

32. $\dfrac{\tan\left(\frac{3\pi}{20}\right) + \tan\left(\frac{\pi}{10}\right)}{1 - \tan\left(\frac{3\pi}{20}\right)\tan\left(\frac{\pi}{10}\right)}$

33. For $\cos\alpha = -\frac{7}{25}$ with terminal side of α in QII and $\cot\beta = \frac{15}{8}$ with terminal side of β in QIII, find

a. $\sin(\alpha + \beta)$ **b.** $\tan(\alpha + \beta)$

34. For $\csc\alpha = \frac{29}{20}$ with terminal side of α in QI and $\cos\beta = -\frac{12}{37}$ with terminal side of β in QII, find

a. $\sin(\alpha - \beta)$ **b.** $\tan(\alpha - \beta)$

Find the exact value of the expression given using a sum or difference identity. Some simplifications may involve using symmetry and the formulas for negatives.

35. $\sin 105°$ **36.** $\sin(-75°)$

37. $\sin\left(\frac{5\pi}{12}\right)$ **38.** $\sin\left(\frac{11\pi}{12}\right)$

39. $\tan 150°$

40. $\tan\left(\frac{2\pi}{3}\right)$

41. $\tan 75°$

42. $\tan\left(-\frac{\pi}{12}\right)$

Use sum/difference identities to verify that both expressions give the same result.

43. **a.** $\sin(45° - 30°)$ **b.** $\sin(135° - 120°)$

44. **a.** $\sin\left(\frac{\pi}{3} - \frac{\pi}{4}\right)$ **b.** $\sin\left(\frac{\pi}{4} - \frac{\pi}{6}\right)$

45. Find $\sin 255°$ given $150° + 105° = 255°$. See Exercises 7 and 35.

46. Find $\cos\left(\frac{19\pi}{12}\right)$ given $2\pi - \frac{5\pi}{12} = \frac{19\pi}{12}$. See Exercises 10 and 37.

47. Given α and β are acute angles with $\sin\alpha = \frac{12}{13}$ and $\tan\beta = \frac{35}{12}$, find

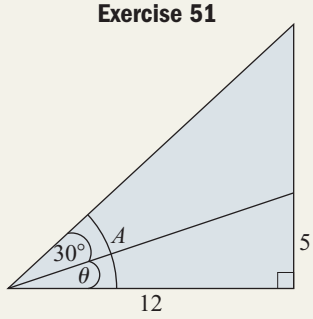
a. $\sin(\alpha + \beta)$ **b.** $\cos(\alpha - \beta)$ **c.** $\tan(\alpha + \beta)$

48. Given α and β are acute angles with $\cos\alpha = \frac{8}{17}$ and $\sec\beta = \frac{25}{7}$, find

a. $\sin(\alpha + \beta)$ **b.** $\cos(\alpha - \beta)$ **c.** $\tan(\alpha + \beta)$

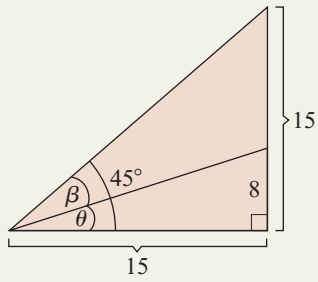
49. Given α and β are obtuse angles with $\sin\alpha = \frac{28}{53}$ and $\cos\beta = -\frac{13}{85}$, find

a. $\sin(\alpha - \beta)$ **b.** $\cos(\alpha + \beta)$ **c.** $\tan(\alpha - \beta)$



50. Given α and β are obtuse angles with $\tan\alpha = -\frac{60}{11}$ and $\sin\beta = \frac{35}{37}$, find

a. $\sin(\alpha - \beta)$ **b.** $\cos(\alpha + \beta)$ **c.** $\tan(\alpha - \beta)$

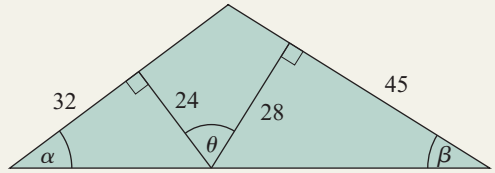


51. Use the diagram indicated to compute the following:

a. $\sin A$ **b.** $\cos A$ **c.** $\tan A$

Exercise 51

Exercise 52

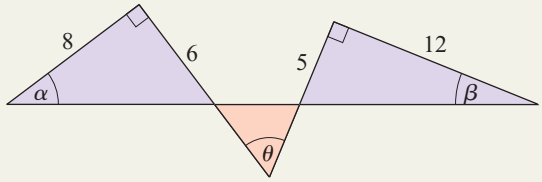


52. Use the diagram indicated to compute the following:

a. $\sin\beta$ **b.** $\cos\beta$ **c.** $\tan\beta$

53. For the figure indicated, show that $\theta = \alpha + \beta$ and compute the following:

a. $\sin\theta$ **b.** $\cos\theta$ **c.** $\tan\theta$



Exercise 53

54. For the figure indicated, show that $\theta = \alpha + \beta$ and compute the following:

a. $\sin\theta$ **b.** $\cos\theta$ **c.** $\tan\theta$

Exercise 54

Verify each identity.

55. $\sin(\pi - \alpha) = \sin\alpha$ **56.** $\cos(\pi - \alpha) = -\cos\alpha$

57. $\cos\left(x + \frac{\pi}{4}\right) = \frac{\sqrt{2}}{2}(\cos x - \sin x)$

58. $\sin\left(x + \frac{\pi}{4}\right) = \frac{\sqrt{2}}{2}(\sin x + \cos x)$

59. $\tan\left(x + \frac{\pi}{4}\right) = \frac{1 + \tan x}{1 - \tan x}$

60. $\tan\left(x - \frac{\pi}{4}\right) = \frac{\tan x - 1}{\tan x + 1}$

61. $\cos(\alpha + \beta) + \cos(\alpha - \beta) = 2\cos\alpha\cos\beta$

62. $\sin(\alpha + \beta) + \sin(\alpha - \beta) = 2\sin\alpha\sin\beta$

63. $\cos(2t) = \cos^2 t - \sin^2 t$

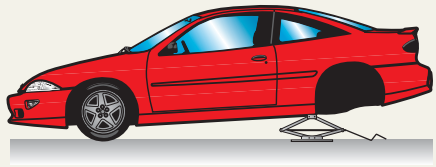
64. $\sin(2t) = 2\sin t\cos t$

65. $\sin(3t) = -4\sin^3 t + 3\sin t$

66. $\cos(3t) = 4\cos^3 t - 3\cos t$

67. Use a difference identity to show

$$\cos\left(x - \frac{\pi}{4}\right) = \frac{\sqrt{2}}{2}(\cos x + \sin x).$$



68. Use sum/difference identities to show

$$\sin\left(x + \frac{\pi}{4}\right) + \sin\left(x - \frac{\pi}{4}\right) = \sqrt{2}\sin x.$$

▶ WORKING WITH FORMULAS

69. Force and equilibrium: $\boldsymbol{F = \frac{Wk}{c}\tan(p - \theta)}$

The force required to maintain equilibrium when a screw jack is used can be modeled by the formula shown, where p is the pitch angle of the screw, W is the weight of the load, θ is the angle of friction, with k and c being constants related to a particular jack. Simplify the formula using the difference formula for tangent given $p = \frac{\pi}{6}$ and $\theta = \frac{\pi}{4}$.

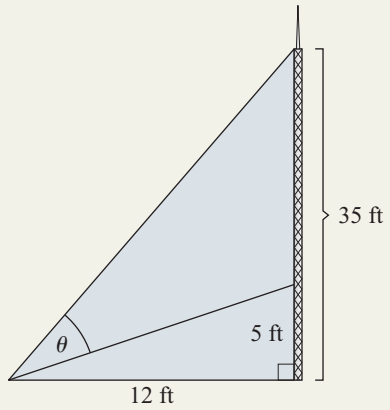
70. Brewster's law of reflection: $\boldsymbol{\tan\theta_p = \frac{n_2}{n_1}}$

Brewster's law of optics states that when unpolarized light strikes a dielectric surface, the transmitted light rays and the reflected light rays are perpendicular to each other. The proof of Brewster's law involves the expression $n_1\sin\theta_p = n_2\sin\left(\frac{\pi}{2} - \theta_p\right)$. Use the difference identity for sine to verify that this expression leads to Brewster's law.

▶ APPLICATIONS

71. AC circuits: In a study of AC circuits, the equation $R = \frac{\cos s\cos t}{\omega C\sin(s + t)}$ sometimes arises. Use a sum identity and algebra to show this equation is equivalent to $R = \frac{1}{\omega C(\tan s + \tan t)}$.

72. Fluid mechanics: In studies of fluid mechanics, the equation $\gamma_1 V_1\sin\alpha = \gamma_2 V_2\sin(\alpha - \beta)$ sometimes arises. Use a difference identity to show that if $\gamma_1 V_1 = \gamma_2 V_2$, the equation is equivalent to $\cos\beta - \cot\alpha\sin\beta = 1$.



73. Art and mathematics: When working in two-point geometric perspective, artists must scale their work to fit on the paper or canvas they are using. In doing so, the equation $\frac{A}{B} = \frac{\tan\theta}{\tan(90° - \theta)}$ arises. Rewrite the expression on the right in terms of sine and cosine, then use the difference identities to show the equation can be rewritten as $\frac{A}{B} = \tan^2\theta$.

74. Traveling waves: If two waves of the same frequency, velocity, and amplitude are traveling along a string in opposite directions, they can be represented by the equations $Y_1 = A\sin(kx - \omega t)$ and $Y_2 = A\sin(kx + \omega t)$. Use the sum and difference formulas for sine to show the result $Y_R = Y_1 + Y_2$ of these waves can be expressed as $Y_R = 2A\sin(kx)\cos(\omega t)$.

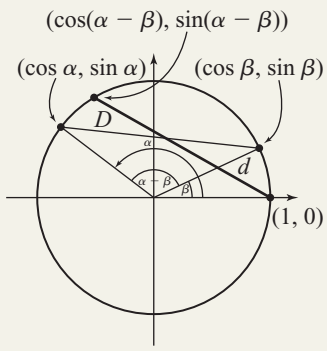
75. Pressure on the eardrum: If a frequency generator is placed a certain distance from the ear, the pressure on the eardrum can be modeled by the function $P_1(t) = A\sin(2\pi ft)$, where f is the frequency and t is the time in seconds. If a second frequency generator with identical settings is placed slightly closer to the ear, its pressure on the eardrum could be represented by $P_2(t) = A\sin(2\pi ft + C)$, where C is a constant. Show that if $C = \frac{\pi}{2}$, the total pressure on the eardrum $[P_1(t) + P_2(t)]$ is $P(t) = A[\sin(2\pi ft) + \cos(2\pi ft)]$.

76. Angle between two cables: Two cables used to steady a radio tower are attached to the tower at heights of 5 ft and 35 ft, with both secured to a stake 12 ft from the tower (see figure). Find the value of $\cos\theta$, where θ is the angle between the upper and lower cables.

Exercise 76

77. Difference quotient: Given $f(x) = \sin x$, show that the difference quotient $\dfrac{f(x+h)-f(x)}{h}$ results in the expression $\sin x\left(\dfrac{\cos h - 1}{h}\right) + \cos x\left(\dfrac{\sin h}{h}\right)$.

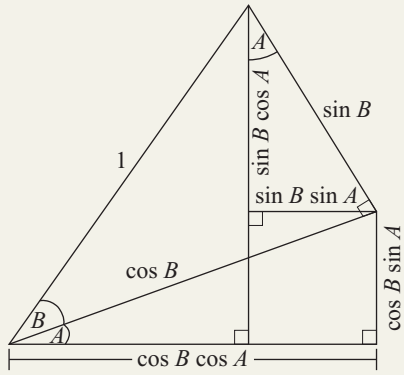
78. Difference identity: Derive the difference identity for tangent using $\tan(\alpha-\beta) = \dfrac{\sin(\alpha-\beta)}{\cos(\alpha-\beta)}$. (*Hint:* After applying the difference identities, divide the numerator and denominator by $\cos\alpha\cos\beta$.)



▶ EXTENDING THE CONCEPT

A family of identities called the *angle reduction formulas* will be of use in our study of complex numbers and other areas. These formulas use the period of a function to reduce large angles to an angle in $[0, 360°)$ or $[0, 2\pi)$ having an equivalent function value: (1) $\cos(t + 2\pi k) = \cos t$; (2) $\sin(t + 2\pi k) = \sin t$. Use the reduction formulas to find values for the following functions (note the formulas can also be expressed in degrees).

79. $\cos 1665°$ **80.** $\cos\left(\dfrac{91\pi}{6}\right)$ **81.** $\sin\left(\dfrac{41\pi}{6}\right)$ **82.** $\sin 2385°$



83. An alternative method of proving the difference formula for cosine uses a unit circle and the fact that equal arcs are subtended by equal chords ($D = d$ in the diagram). Using a combination of algebra, the distance formula, and a Pythagorean identity, show that $\cos(\alpha-\beta) = \cos\alpha\cos\beta + \sin\alpha\sin\beta$ (start by computing D^2 and d^2). Then discuss/explain how the sum identity can be found using the fact that $\beta = -(-\beta)$.

Exercise 83

84. Verify the Pythagorean theorem for each right triangle in the diagram, then discuss/explain how the diagram offers a proof of the sum identities for sine and cosine.

Exercise 84

▶ MAINTAINING YOUR SKILLS

85. **(6.5)** State the period of the functions given:

a. $y = 3\sin\left(\frac{\pi}{8}x - \frac{\pi}{3}\right)$

b. $y = 4\tan\left(2x + \frac{\pi}{4}\right)$

86. **(2.5)** Graph the piecewise-defined function given:

$$f(x) = \begin{cases} 3 & x < -1 \\ x^2 & -1 \le x \le 1 \\ x & x > 1 \end{cases}$$

87. **(6.6)** Clarence the Clown is about to be shot from a circus cannon to a safety net on the other side of the main tent. If the cannon is 30 ft long and must be aimed at 40° for Clarence to hit the net, the end of the cannon must be how high from ground level?

88. **(1.4)** Find the equation of the line parallel to $2x + 5y = -10$, containing the point $(5, -2)$. Write your answer in standard form.

7.4 The Double-Angle, Half-Angle, and Product-to-Sum Identities

LEARNING OBJECTIVES

In Section 7.4 you will see how we can:

- ❑ **A.** Derive and use the double-angle identities for cosine, tangent, and sine
- ❑ **B.** Develop and use the power reduction and half-angle identities
- ❑ **C.** Derive and use the product-to-sum and sum-to-product identities
- ❑ **D.** Solve applications using identities

The derivation of the sum and difference identities in Section 7.3 was a "watershed event" in the study of identities. By making various substitutions, they lead us very naturally to many new identity families, giving us a heightened ability to simplify expressions, solve equations, find exact values, and model real-world phenomena. In fact, many of the identities are applied in very practical ways, as in a study of projectile motion and the conic sections (Chapter 10). In addition, one of the most profound principles discovered in the eighteenth and nineteenth centuries was that electricity, light, and sound could all be studied using sinusoidal waves. These waves often interact with each other, creating the phenomena known as reflection, diffraction, superposition, interference, standing waves, and others. The product-to-sum and sum-to-product identities play a fundamental role in the investigation and study of these phenomena.

A. The Double-Angle Identities

The double-angle identities for sine, cosine, and tangent can all be derived using the related sum identities with two equal angles ($\alpha = \beta$). We'll illustrate the process here for the cosine of twice an angle.

$$\begin{aligned} \cos(\alpha + \beta) &= \cos\alpha\cos\beta - \sin\alpha\sin\beta && \text{sum identity for cosine} \\ \cos(\alpha + \alpha) &= \cos\alpha\cos\alpha - \sin\alpha\sin\alpha && \text{assume } \alpha = \beta \text{ and substitute } \alpha \text{ for } \beta \\ \cos(2\alpha) &= \cos^2\alpha - \sin^2\alpha && \text{simplify—double-angle identity for cosine} \end{aligned}$$

Using the Pythagorean identity $\cos^2\alpha + \sin^2\alpha = 1$, we can easily find two additional members of this family, which are often quite useful. For $\cos^2\alpha = 1 - \sin^2\alpha$ we have

$$\begin{aligned} \cos(2\alpha) &= \cos^2\alpha - \sin^2\alpha && \text{double-angle identity for cosine} \\ &= (1 - \sin^2\alpha) - \sin^2\alpha && \text{substitute } 1 - \sin^2\alpha \text{ for } \cos^2\alpha \\ \cos(2\alpha) &= 1 - 2\sin^2\alpha && \text{double-angle in terms of sine} \end{aligned}$$

Using $\sin^2\alpha = 1 - \cos^2\alpha$ we obtain an additional form:

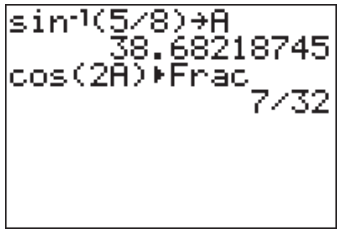
$$\begin{aligned} \cos(2\alpha) &= \cos^2\alpha - \sin^2\alpha && \text{double-angle identity for cosine} \\ &= \cos^2\alpha - (1 - \cos^2\alpha) && \text{substitute } 1 - \cos^2\alpha \text{ for } \sin^2\alpha \\ \cos(2\alpha) &= 2\cos^2\alpha - 1 && \text{double-angle in terms of cosine} \end{aligned}$$

The derivations of $\sin(2\alpha)$ and $\tan(2\alpha)$ are likewise developed and are asked for in **Exercise 105.** The double-angle identities are collected here for your convenience.

The Double-Angle Identities

cosine: $\cos(2\alpha) = \cos^2\alpha - \sin^2\alpha$
$= 1 - 2\sin^2\alpha$
$= 2\cos^2\alpha - 1$

sine: $\sin(2\alpha) = 2\sin\alpha\cos\alpha$



tangent: $\tan(2\alpha) = \dfrac{2\tan\alpha}{1 - \tan^2\alpha}$

EXAMPLE 1 ▶ **Using a Double-Angle Identity to Find Function Values**

Given $\sin\alpha = \frac{5}{8}$, find the value of $\cos(2\alpha)$.

Solution ▶ Using the double-angle identity for cosine interms of sine, we find

$\cos(2\alpha) = 1 - 2\sin^2\alpha$ double-angle in terms of sine
$= 1 - 2\left(\frac{5}{8}\right)^2$ substitute $\frac{5}{8}$ for $\sin\alpha$
$= 1 - \frac{25}{32}$ $2\left(\frac{5}{8}\right)^2 = \frac{25}{32}$
$= \frac{7}{32}$ result

If $\sin\alpha = \frac{5}{8}$, then $\cos(2\alpha) = \frac{7}{32}$. A calculator check is shown in the figure.

Now try Exercises 7 through 20 ▶

Like the fundamental identities, the double-angle identities can be used to verify or develop others. In Example 2, we explore one of many **multiple-angle identities,** verifying that $\cos(3\theta)$ can be rewritten as $4\cos^3\theta - 3\cos\theta$ (in terms of powers of $\cos\theta$).

EXAMPLE 2 ▶ **Verifying a Multiple Angle Identity**

Verify that $\cos(3\theta) = 4\cos^3\theta - 3\cos\theta$ is an identity.

Solution ▶ Use the sum identity for cosine, with $\alpha = 2\theta$ and $\beta = \theta$. Note that our goal is an expression using cosines only, with no multiple angles.

$\cos(\alpha + \beta) = \cos\alpha\cos\beta - \sin\alpha\sin\beta$ sum identity for cosine
$\cos(2\theta + \theta) = \cos(2\theta)\cos\theta - \sin(2\theta)\sin\theta$ substitute 2θ for α and θ for β
$\cos(3\theta) = (2\cos^2\theta - 1)\cos\theta - (2\sin\theta\cos\theta)\sin\theta$ substitute for $\cos(2\theta)$ and $\sin(2\theta)$
$= 2\cos^3\theta - \cos\theta - 2\cos\theta\sin^2\theta$ multiply
$= 2\cos^3\theta - \cos\theta - 2\cos\theta(1 - \cos^2\theta)$ substitute $1 - \cos^2\theta$ for $\sin^2\theta$
$= 2\cos^3\theta - \cos\theta - 2\cos\theta + 2\cos^3\theta$ multiply
$= 4\cos^3\theta - 3\cos\theta$ combine terms

Now try Exercises 21 and 22 ▶

EXAMPLE 3 ▶ **Using a Double-Angle Formula to Find Exact Values**

Find the exact value of $\sin 22.5° \cos 22.5°$.

Solution ▶ A product of sines and cosines having the same argument hints at the double-angle identity for sine. Using $\sin(2\alpha) = 2 \sin \alpha \cos \alpha$ and dividing by 2 gives

$$\sin \alpha \cos \alpha = \frac{\sin(2\alpha)}{2} \qquad \text{double-angle identity for sine}$$

$$\sin 22.5° \cos 22.5° = \frac{\sin[2(22.5°)]}{2} \qquad \text{replace } \alpha \text{ with } 22.5°$$

$$= \frac{\sin 45°}{2} \qquad \text{multiply}$$

$$= \frac{\left(\frac{\sqrt{2}}{2}\right)}{2} = \frac{\sqrt{2}}{4} \qquad \sin 45° = \frac{\sqrt{2}}{2}$$

A. You've just seen how we can derive and use the double-angle identities for cosine, tangent, and sine

Now try Exercises 23 through 30 ▶

B. The Power Reduction and Half-Angle Identities

Expressions having a trigonometric function raised to a power occur quite frequently in various applications. We can rewrite even powers of these trig functions in terms of an expression containing only cosine to the power 1, using what are called the **power reduction identities.** In calculus, this becomes an indispensible tool, making expressions easier to use and evaluate. It can legitimately be argued that the power reduction identities are actually members of the double-angle family, as all three are a direct consequence. To find identities for $\cos^2\alpha$ and $\sin^2\alpha$, we solve the related double-angle identity involving $\cos(2\alpha)$.

$$1 - 2\sin^2\alpha = \cos(2\alpha) \qquad \cos(2\alpha) \text{ in terms of sine}$$

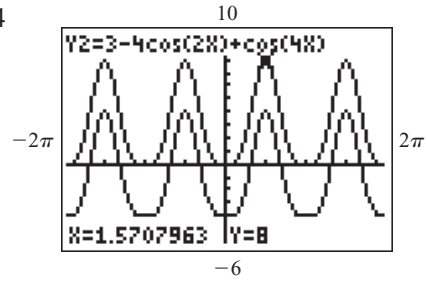
$$-2\sin^2\alpha = \cos(2\alpha) - 1 \qquad \text{subtract 1, then divide by } -2$$

$$\sin^2\alpha = \frac{1 - \cos(2\alpha)}{2} \qquad \text{power reduction identity for sine}$$

Using the same approach for $\cos^2\alpha$ gives $\cos^2\alpha = \frac{1 + \cos(2\alpha)}{2}$. The identity for $\tan^2\alpha$ can be derived from $\tan(2\alpha) = \frac{2\tan\alpha}{1 - \tan^2\alpha}$ **(see Exercise 106),** but in this case it's easier to use the identity $\tan^2\alpha = \frac{\sin^2\alpha}{\cos^2\alpha}$. The result is $\frac{1 - \cos(2\alpha)}{1 + \cos(2\alpha)}$.

The Power Reduction Identities

$$\cos^2\alpha = \frac{1 + \cos(2\alpha)}{2} \qquad \sin^2\alpha = \frac{1 - \cos(2\alpha)}{2} \qquad \tan^2\alpha = \frac{1 - \cos(2\alpha)}{1 + \cos(2\alpha)}$$



EXAMPLE 4 ▶ **Using a Power Reduction Formula**

Write $8\sin^4 x$ in terms of an expression containing only cosines to the power 1 and use the GRAPH feature of a calculator to support your result.

Solution ▶

$$\begin{aligned}
8\sin^4 x &= 8(\sin^2 x)^2 && \text{original expression}\\
&= 8\left[\frac{1-\cos(2x)}{2}\right]^2 && \text{substitute } \frac{1-\cos(2x)}{2} \text{ for } \sin^2 x\\
&= 2[1-2\cos(2x)+\cos^2(2x)] && \text{multiply}\\
&= 2\left[1-2\cos(2x)+\frac{1+\cos(4x)}{2}\right] && \text{substitute } \frac{1+\cos(4x)}{2} \text{ for } \cos^2(2x)\\
&= 2-4\cos(2x)+1+\cos(4x) && \text{multiply}\\
&= 3-4\cos(2x)+\cos(4x) && \text{result}
\end{aligned}$$

To support our result, we enter $Y_1 = 8\sin(X)\text{^}4$ and $Y_2 = 3-4\cos(2X)+\cos(4X)$ in our calculator. Recognizing Y_1 can only take on nonnegative values less than or equal to 8, we set the window as shown in the figure. Anticipating that only one graph will be seen (since Y_1 and Y_2 should be coincident), we can vertically shift Y_2 down 4 units and graph $Y_3 = Y_2 - 4$. The figure then helps support that $8\sin^4 x = 3-4\cos(2x)+\cos(4x)$.

Now try Exercises 31 through 36 ▶

The half-angle identities follow directly from the power reduction identities, using algebra and a simple change of variable. For $\cos^2\alpha = \dfrac{1+\cos(2\alpha)}{2}$, we first take square roots and obtain $\cos\alpha = \pm\sqrt{\dfrac{1+\cos(2\alpha)}{2}}$. Using the substitution $u = 2\alpha$ gives $\alpha = \dfrac{u}{2}$, and making these substitutions results in the half-angle identity for cosine: $\cos\left(\dfrac{u}{2}\right) = \pm\sqrt{\dfrac{1+\cos u}{2}}$, where the radical's sign depends on the quadrant in which $\dfrac{u}{2}$ terminates. Using the same substitution for sine gives $\sin\left(\dfrac{u}{2}\right) = \pm\sqrt{\dfrac{1-\cos u}{2}}$, and for the tangent identity, $\tan\left(\dfrac{u}{2}\right) = \pm\sqrt{\dfrac{1-\cos u}{1+\cos u}}$. In the case of $\tan\left(\dfrac{u}{2}\right)$, we can actually develop identities that are free of radicals by rationalizing the denominator or numerator. We'll illustrate the former, leaving the latter as an exercise **(see Exercise 104).**

$$\begin{aligned}
\tan\left(\frac{u}{2}\right) &= \pm\sqrt{\frac{(1-\cos u)(1-\cos u)}{(1+\cos u)(1-\cos u)}} && \text{multiply by the conjugate}\\
&= \pm\sqrt{\frac{(1-\cos u)^2}{1-\cos^2 u}} && \text{rewrite}\\
&= \pm\sqrt{\frac{(1-\cos u)^2}{\sin^2 u}} && \text{Pythagorean identity}\\
&= \pm\left|\frac{1-\cos u}{\sin u}\right| && \sqrt{x^2} = |x|
\end{aligned}$$

Since $1-\cos u > 0$ and $\sin u$ has the same sign as $\tan\left(\dfrac{u}{2}\right)$ for all u in its domain, the relationship can simply be written $\tan\left(\dfrac{u}{2}\right) = \dfrac{1-\cos u}{\sin u}$.

The Half-Angle Identities

$$\cos\left(\frac{u}{2}\right) = \pm\sqrt{\frac{1+\cos u}{2}} \qquad \sin\left(\frac{u}{2}\right) = \pm\sqrt{\frac{1-\cos u}{2}} \qquad \tan\left(\frac{u}{2}\right) = \pm\sqrt{\frac{1-\cos u}{1+\cos u}}$$

$$\tan\left(\frac{u}{2}\right) = \frac{1-\cos u}{\sin u} \qquad \tan\left(\frac{u}{2}\right) = \frac{\sin u}{1+\cos u}$$

EXAMPLE 5 ▶ **Using Half-Angle Formulas to Find Exact Values**

Use the half-angle identities to find exact values for (a) sin 15° and (b) tan 15°.

Solution ▶ Noting that 15° is one-half the standard angle 30°, we can find each value by applying the respective half-angle identity with $u = 30°$ in Quadrant I.

a. $\sin\left(\frac{30°}{2}\right) = \sqrt{\frac{1-\cos 30°}{2}}$

$$= \sqrt{\frac{1-\frac{\sqrt{3}}{2}}{2}}$$

$$\sin 15° = \frac{\sqrt{2-\sqrt{3}}}{2}$$

b. $\tan\left(\frac{30°}{2}\right) = \frac{1-\cos 30°}{\sin 30°}$

$$\tan 15° = \frac{1-\frac{\sqrt{3}}{2}}{\frac{1}{2}} = 2-\sqrt{3}$$

```
sin(15)
      .2588190451
√(2-√(3))/2
      .2588190451
```

Note the verification of part (a) in the figure. Part (b) can be similarly checked with a calculator in **degree** MODE.

Now try Exercises 37 through 48 ▶

EXAMPLE 6 ▶ **Using Half-Angle Formulas to Find Exact Values**

For $\cos\theta = -\frac{7}{25}$ and θ in QIII, find exact values of $\sin\left(\frac{\theta}{2}\right)$ and $\cos\left(\frac{\theta}{2}\right)$.

Solution ▶ With θ in QIII $\rightarrow \pi < \theta < \frac{3\pi}{2}$, we know $\frac{\theta}{2}$ must be in QII $\rightarrow \frac{\pi}{2} < \frac{\theta}{2} < \frac{3\pi}{4}$ and we choose our signs accordingly: $\sin\left(\frac{\theta}{2}\right) > 0$ and $\cos\left(\frac{\theta}{2}\right) < 0$.

$$\sin\left(\frac{\theta}{2}\right) = \sqrt{\frac{1-\cos\theta}{2}} = \sqrt{\frac{1-\left(-\frac{7}{25}\right)}{2}} = \sqrt{\frac{16}{25}} = \frac{4}{5}$$

$$\cos\left(\frac{\theta}{2}\right) = -\sqrt{\frac{1+\cos\theta}{2}} = -\sqrt{\frac{1+\left(-\frac{7}{25}\right)}{2}} = -\sqrt{\frac{9}{25}} = -\frac{3}{5}$$

Now try Exercises 49 through 64 ▶

☑ **B.** You've just seen how we can develop and use the power reduction and half-angle identities

C. The Product-to-Sum Identities

As mentioned in the introduction, the product-to-sum and sum-to-product identities are of immense importance to the study of any phenomenon that travels in waves, like light and sound. In fact, the tones you hear as you dial a telephone are actually the sum of two sound waves interacting with each other. Each derivation of a product-to-sum identity is very similar **(see Exercise 107),** and we illustrate by deriving the identity for $\cos\alpha\cos\beta$. Beginning with the sum and difference identities for cosine, we have

$$\begin{aligned}
\cos\alpha\cos\beta + \sin\alpha\sin\beta &= \cos(\alpha-\beta) && \text{cosine of a difference}\\
+\ \underline{\cos\alpha\cos\beta - \sin\alpha\sin\beta} &= \underline{\cos(\alpha+\beta)} && \text{cosine of a sum}\\
2\cos\alpha\cos\beta &= \cos(\alpha-\beta)+\cos(\alpha+\beta) && \text{combine equations}\\
\cos\alpha\cos\beta &= \frac{1}{2}[\cos(\alpha-\beta)+\cos(\alpha+\beta)] && \text{divide by 2}
\end{aligned}$$

In addition to wave phenomenon, the identities from this family are very useful in a study of calculus and are listed here.

The Product-to-Sum Identities

$$\cos\alpha\cos\beta = \frac{1}{2}[\cos(\alpha-\beta)+\cos(\alpha+\beta)] \qquad \sin\alpha\sin\beta = \frac{1}{2}[\cos(\alpha-\beta)-\cos(\alpha+\beta)]$$

$$\sin\alpha\cos\beta = \frac{1}{2}[\sin(\alpha+\beta)+\sin(\alpha-\beta)] \qquad \cos\alpha\sin\beta = \frac{1}{2}[\sin(\alpha+\beta)-\sin(\alpha-\beta)]$$

EXAMPLE 7 ▶ Rewriting a Product as an Equivalent Sum Using Identities

Write the product $2\cos(27t)\cos(15t)$ as the sum of two cosine functions.

Solution ▶ This is a direct application of the product-to-sum identity, with $\alpha = 27t$ and $\beta = 15t$.

$$\begin{aligned}
\cos\alpha\cos\beta &= \frac{1}{2}[\cos(\alpha-\beta)+\cos(\alpha+\beta)] && \text{product-to-sum identity}\\
2\cos(27t)\cos(15t) &= 2\left(\frac{1}{2}\right)[\cos(27t-15t)+\cos(27t+15t)] && \text{substitute}\\
&= \cos(12t)+\cos(42t) && \text{result}
\end{aligned}$$

Now try Exercises 65 through 74 ▶

There are times we find it necessary to "work in the other direction," writing a sum of two trig functions as a product. This family of identities can be derived from the product-to-sum identities using a change of variable. We'll illustrate the process for $\sin u + \sin v$. You are asked for the derivation of $\cos u + \cos v$ in **Exercise 108.** To begin, we use $2\alpha = u + v$ and $2\beta = u - v$. This creates the sum $2\alpha + 2\beta = 2u$ and the difference $2\alpha - 2\beta = 2v$, yielding $\alpha + \beta = u$ and $\alpha - \beta = v$, respectively. Dividing the original expressions by 2 gives $\alpha = \frac{u+v}{2}$ and $\beta = \frac{u-v}{2}$, which all together make the derivation a matter of direct substitution. Using these values in any product-to-sum identity gives the related sum-to-product, as shown here.

$$\sin\alpha\cos\beta = \frac{1}{2}[\sin(\alpha+\beta)+\sin(\alpha-\beta)] \quad \text{product-to-sum identity (sum of sines)}$$

$$\sin\left(\frac{u+v}{2}\right)\cos\left(\frac{u-v}{2}\right) = \frac{1}{2}(\sin u+\sin v) \quad \text{substitute } \frac{u+v}{2} \text{ for } \alpha, \frac{u-v}{2} \text{ for } \beta, \text{ substitute } u \text{ for } \alpha+\beta \text{ and } v \text{ for } \alpha-\beta$$

$$2\sin\left(\frac{u+v}{2}\right)\cos\left(\frac{u-v}{2}\right) = \sin u+\sin v \quad \text{multiply by 2}$$

The sum-to-product identities follow.

The Sum-to-Product Identities

$$\cos u+\cos v = 2\cos\left(\frac{u+v}{2}\right)\cos\left(\frac{u-v}{2}\right) \qquad \sin u+\sin v = 2\sin\left(\frac{u+v}{2}\right)\cos\left(\frac{u-v}{2}\right)$$

$$\sin u-\sin v = 2\cos\left(\frac{u+v}{2}\right)\sin\left(\frac{u-v}{2}\right) \qquad \cos u-\cos v = -2\sin\left(\frac{u+v}{2}\right)\sin\left(\frac{u-v}{2}\right)$$

EXAMPLE 8 ▶ Rewriting a Sum as an Equivalent Product Using Identities

Given $y_1 = \sin(12\pi t)$ and $y_2 = \sin(10\pi t)$, express $y_1 + y_2$ as a product of trigonometric functions.

Solution ▶ This is a direct application of the sum-to-product identity $\sin u + \sin v$, with $u = 12\pi t$ and $v = 10\pi t$.

$$\sin u+\sin v = 2\sin\left(\frac{u+v}{2}\right)\cos\left(\frac{u-v}{2}\right) \quad \text{sum-to-product identity}$$

$$\sin(12\pi t)+\sin(10\pi t) = 2\sin\left(\frac{12\pi t+10\pi t}{2}\right)\cos\left(\frac{12\pi t-10\pi t}{2}\right) \quad \text{substitute } 12\pi t \text{ for } u \text{ and } 10\pi t \text{ for } v$$

$$= 2\sin(11\pi t)\cos(\pi t) \quad \text{substitute}$$

Now try Exercises 75 through 84 ▶

C. You've just seen how we can derive and use the product-to-sum and sum-to-product identities

For a mixed variety of identities, **see Exercises 85 through 102.**

D. Applications of Identities

In more advanced mathematics courses, rewriting an expression using identities enables the extension or completion of a task that would otherwise be very difficult (or even impossible). In addition, there are a number of practical applications in the physical sciences.

Projectile Motion

A projectile is any object that is thrown, shot, kicked, dropped, or otherwise given an initial velocity, but lacking a continuing source of propulsion. If air resistance is ignored, the range of the projectile depends only on its initial velocity v and the angle θ at which it is propelled. This phenomenon is modeled by the function

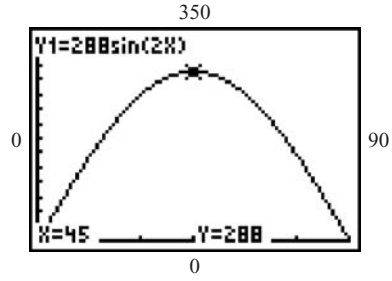
$$r(\theta) = \frac{1}{16}v^2\sin\theta\cos\theta$$

EXAMPLE 9 ▶ **Using Identities to Solve an Application**

a. Use an identity to show $r(\theta) = \frac{1}{16}v^2 \sin\theta\cos\theta$ is equivalent to $r(\theta) = \frac{1}{32}v^2\sin(2\theta)$.

b. If the projectile is thrown with an initial velocity of $v = 96$ ft/sec, how far will it travel if $\theta = 15°$?

c. From the result of part (a), determine what angle θ will give the maximum range for the projectile.



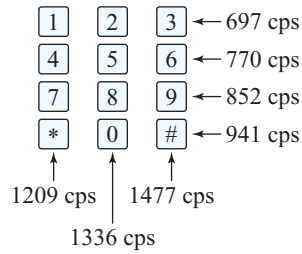
Solution ▶

a. Note that we can use a double-angle identity if we rewrite the coefficient. Writing $\frac{1}{16}$ as $2\left(\frac{1}{32}\right)$ and commuting the factors gives

$$r(\theta) = \left(\frac{1}{32}\right)v^2(2\sin\theta\cos\theta) = \left(\frac{1}{32}\right)v^2\sin(2\theta).$$

b. With $v = 96$ ft/sec and $\theta = 15°$, the formula gives $r(15°) = \left(\frac{1}{32}\right)(96)^2\sin 30°$. Evaluating the result shows the projectile travels a horizontal distance of 144 ft.

c. For any initial velocity v, $r(\theta)$ will be maximized when $\sin(2\theta)$ is a maximum. This occurs when $\sin(2\theta) = 1$, meaning $2\theta = 90°$ and $\theta = 45°$. The maximum range is achieved when the projectile is released at an angle of 45°. For verification we'll assume an initial velocity of 96 ft/sec and enter the function $r(\theta) = \frac{1}{32}(96)^2\sin(2\theta) = 288\sin(2\theta)$ as Y_1. With an amplitude of 288 and results confined to the first quadrant, we set an appropriate window, graph the function, and use the 2nd TRACE **(CALC) 4:maximum** feature. As shown in the figure, the max occurs at $\theta = 45°$.



Now try Exercises 111 and 112 ▶

Sound Waves

Each tone you hear on a touch-tone phone is actually the combination of precisely two sound waves with different frequencies (frequency f is defined as $f = \frac{B}{2\pi}$). This is why the tones you hear sound identical, regardless of what phone you use. The sum-to-product and product-to-sum formulas help us to understand, study, and use sound in very powerful and practical ways, like sending faxes and using other electronic media.

EXAMPLE 10 ▶ **Using an Identity to Solve an Application**

On a touch-tone phone, the sound created by pressing 5 is produced by combining a sound wave with frequency 1336 cycles/sec, with another wave having frequency 770 cycles/sec. Their respective equations are $y_1 = \cos(2\pi\ 1336t)$ and $y_2 = \cos(2\pi\ 770t)$, with the resultant wave being $y = y_1 + y_2$ or $y = \cos(2672\pi t) + \cos(1540\pi t)$. Rewrite this sum as a product.

Solution ▶ This is a direct application of a sum-to-product identity, with $u = 2672\pi t$ and $v = 1540\pi t$. Computing one-half the sum/difference of u and v gives

$$\frac{2672\pi t + 1540\pi t}{2} = 2106\pi t \text{ and } \frac{2672\pi t - 1540\pi t}{2} = 566\pi t.$$

$$\cos u + \cos v = 2\cos\left(\frac{u+v}{2}\right)\cos\left(\frac{u-v}{2}\right) \quad \text{sum-to-product identity}$$

$$\cos(2672\pi t) + \cos(1540\pi t) = 2\cos(2106\pi t)\cos(566\pi t) \quad \text{substitute } 2672\pi t \text{ for } u \text{ and } 1540\pi t \text{ for } v$$

Now try Exercises 113 through 116 ▶

Note we can identify the button pressed when the wave is written as a sum. If we have only the resulting wave (written as a product), the product-to-sum formula must be used to identify which button was pressed.

Additional applications requiring the use of identities can be found in **Exercises 117 through 122.**

☑ **D.** You've just seen how we can solve applications using identities

7.4 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. The double-angle identities can be derived using the _____ identities with $\alpha = \beta$. For $\cos(2\theta)$ we expand $\cos(\alpha + \beta)$ using _____.
2. If θ is in QIII then $180° < \theta < 270°$ and $\frac{\theta}{2}$ must be in _____ since _____ $< \frac{\theta}{2} <$ _____.
3. Multiple-angle identities can be derived using the sum and difference identities. For $\sin(3x)$ use $\sin($_____ + _____$)$.
4. For the half-angle identities the sign preceding the radical depends on the _____ in which $\frac{u}{2}$ _____.
5. Explain/Discuss how the three different identities for $\tan\left(\frac{u}{2}\right)$ are related. Verify that $\frac{1-\cos u}{\sin u} = \frac{\sin u}{1+\cos u}$.
6. In Example 6, we were given $\cos\theta = -\frac{7}{25}$ and θ in QIII. Discuss how the result would differ if we stipulate that θ is in QII instead.

▶ DEVELOPING YOUR SKILLS

Find exact values for $\sin(2\theta)$, $\cos(2\theta)$, and $\tan(2\theta)$ using the information given. Check results on a calculator.

7. $\sin\theta = \frac{5}{13}$; θ in QII
8. $\cos\theta = -\frac{21}{29}$; θ in QII
9. $\cos\theta = -\frac{9}{41}$; θ in QII
10. $\sin\theta = -\frac{63}{65}$; θ in QIII
11. $\tan\theta = \frac{13}{84}$; θ in QIII
12. $\sec\theta = \frac{53}{28}$; θ in QI
13. $\sin\theta = \frac{48}{73}$; $\cos\theta < 0$
14. $\cos\theta = -\frac{8}{17}$; $\tan\theta > 0$
15. $\csc\theta = \frac{5}{3}$; $\sec\theta < 0$
16. $\cot\theta = -\frac{80}{39}$; $\cos\theta > 0$

Find exact values for $\sin\theta$, $\cos\theta$, and $\tan\theta$ using the information given.

17. $\sin(2\theta) = \frac{24}{25}$; 2θ in QII

18. $\sin(2\theta) = -\frac{240}{289}$; 2θ in QIII

19. $\cos(2\theta) = -\frac{41}{841}$; 2θ in QII

20. $\cos(2\theta) = \frac{120}{169}$; 2θ in QIV

21. Verify the following identity:
$\sin(3\theta) = 3\sin\theta - 4\sin^3\theta$

22. Verify the following identity:
$\cos(4\theta) = 8\cos^4\theta - 8\cos^2\theta + 1$

Use a double-angle identity to find exact values for the following expressions.

23. $\cos 75° \sin 75°$

24. $\cos^2 15° - \sin^2 15°$

25. $1 - 2\sin^2\left(\frac{\pi}{8}\right)$

26. $2\cos^2\left(\frac{\pi}{12}\right) - 1$

27. $\frac{2\tan 22.5°}{1 - \tan^2 22.5°}$

28. $\frac{2\tan\left(\frac{\pi}{12}\right)}{1 - \tan^2\left(\frac{\pi}{12}\right)}$

29. Use a double-angle identity to rewrite $9\sin(3x)\cos(3x)$ as a single function.
[*Hint:* $9 = \frac{9}{2}(2)$.]

30. Use a double-angle identity to rewrite $2.5 - 5\sin^2 x$ as a single term.
[*Hint:* Factor out a constant.]

Rewrite in terms of an expression containing only cosines to the power 1. Verify result with a calculator.

31. $\sin^2 x \cos^2 x$

32. $\sin^4 x \cos^2 x$

33. $3\cos^4 x$

34. $\cos^4 x \sin^4 x$

35. $2\sin^6 x$

36. $4\cos^6 x$

Use a half-angle identity to find exact values for $\sin\theta$, $\cos\theta$, and $\tan\theta$ for the given value of θ. Check results on a calculator.

37. $\theta = 22.5°$

38. $\theta = 75°$

39. $\theta = \frac{\pi}{12}$

40. $\theta = \frac{5\pi}{12}$

41. $\theta = 67.5°$

42. $\theta = 112.5°$

43. $\theta = \frac{3\pi}{8}$

44. $\theta = \frac{11\pi}{12}$

Use the results of Exercises 37–40 and a half-angle identity to find the exact value.

45. $\sin 11.25°$

46. $\tan 37.5°$

47. $\sin\left(\frac{\pi}{24}\right)$

48. $\cos\left(\frac{5\pi}{24}\right)$

Use a half-angle identity to rewrite each expression as a single, nonradical function.

49. $\sqrt{\frac{1 + \cos 30°}{2}}$

50. $\sqrt{\frac{1 - \cos 45°}{2}}$

51. $\sqrt{\frac{1 - \cos(4\theta)}{1 + \cos(4\theta)}}$

52. $\sqrt{\frac{1 + \cos(6\theta)}{1 - \cos(6\theta)}}$

53. $\frac{\sin(2x)}{1 + \cos(2x)}$

54. $\frac{1 - \cos(6x)}{\sin(6x)}$

Find exact values for $\sin\left(\frac{\theta}{2}\right)$, $\cos\left(\frac{\theta}{2}\right)$, and $\tan\left(\frac{\theta}{2}\right)$ using the information given.

55. $\sin\theta = \frac{12}{13}$; θ is obtuse

56. $\cos\theta = -\frac{8}{17}$; θ is obtuse

57. $\cos\theta = -\frac{4}{5}$; θ in QII

58. $\sin\theta = -\frac{7}{25}$; θ in QIII

59. $\tan\theta = -\frac{35}{12}$; θ in QII

60. $\sec\theta = -\frac{65}{33}$; θ in QIII

61. $\sin\theta = \frac{15}{113}$; θ is acute

62. $\cos\theta = \frac{48}{73}$; θ is acute

63. $\cot\theta = \frac{21}{20}$; $\pi < \theta < \frac{3\pi}{2}$

64. $\csc\theta = \frac{41}{9}$; $\frac{\pi}{2} < \theta < \pi$

Write each product as a sum using the product-to-sum identities.

65. $\sin(-4\theta)\sin(8\theta)$

66. $\cos(15\alpha)\sin(-3\alpha)$

67. $2\cos\left(\frac{7t}{2}\right)\sin\left(\frac{3t}{2}\right)$

68. $2\sin\left(\frac{5t}{2}\right)\sin\left(\frac{9t}{2}\right)$

69. $2\cos(1979\pi t)\cos(439\pi t)$

70. $2\cos(2150\pi t)\cos(268\pi t)$

Find the exact value using product-to-sum identities.

71. $2\cos 15^\circ \sin 135^\circ$

72. $2\cos 105^\circ \cos 165^\circ$

73. $\sin\left(\frac{7\pi}{8}\right)\cos\left(\frac{\pi}{8}\right)$

74. $\sin\left(\frac{7\pi}{12}\right)\sin\left(-\frac{\pi}{12}\right)$

Write each sum as a product using the sum-to-product identities.

75. $\cos(9h) + \cos(4h)$

76. $\sin(14k) + \sin(41k)$

77. $\sin\left(\frac{11x}{8}\right) - \sin\left(\frac{5x}{8}\right)$

78. $\cos\left(\frac{7x}{6}\right) - \cos\left(\frac{5x}{6}\right)$

79. $\cos(697\pi t) + \cos(1447\pi t)$

80. $\cos(852\pi t) + \cos(1209\pi t)$

Find the exact value using sum-to-product identities.

81. $\cos 75^\circ + \cos 15^\circ$

82. $\cos 285^\circ - \cos 195^\circ$

83. $\sin\left(\frac{17\pi}{12}\right) - \sin\left(\frac{13\pi}{12}\right)$

84. $\sin\left(\frac{11\pi}{12}\right) + \sin\left(\frac{7\pi}{12}\right)$

Verify the following identities.

85. $\dfrac{2\sin x\cos x}{\cos^2 x - \sin^2 x} = \tan(2x)$

86. $\dfrac{1 - 2\sin^2 x}{2\sin x\cos x} = \cot(2x)$

87. $(\sin x + \cos x)^2 = 1 + \sin(2x)$

88. $(\sin^2 x - 1)^2 = \sin^4 x + \cos(2x)$

89. $\cos(8\theta) = \cos^2(4\theta) - \sin^2(4\theta)$

90. $\sin(4x) = 4\sin x\cos x(1 - 2\sin^2 x)$

91. $\dfrac{\cos(2\theta)}{\sin^2\theta} = \cot^2\theta - 1$

92. $\csc^2\theta - 2 = \dfrac{\cos(2\theta)}{\sin^2\theta}$

93. $\tan(2\theta) = \dfrac{2}{\cot\theta - \tan\theta}$

94. $\cot\theta - \tan\theta = \dfrac{2\cos(2\theta)}{\sin(2\theta)}$

95. $\tan x + \cot x = 2\csc(2x)$

96. $\csc(2x) = \dfrac{1}{2}\csc x\sec x$

97. $\cos^2\left(\frac{x}{2}\right) - \sin^2\left(\frac{x}{2}\right) = \cos x$

98. $1 - 2\sin^2\left(\frac{x}{4}\right) = \cos\left(\frac{x}{2}\right)$

99. $1 - \sin^2(2\theta) = 1 - 4\sin^2\theta + 4\sin^4\theta$

100. $2\cos^2\left(\frac{x}{2}\right) - 1 = \cos x$

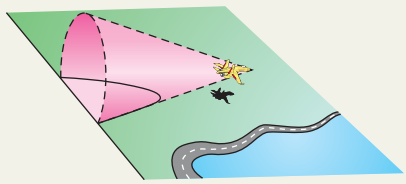
101. $\dfrac{\sin(120\pi t) + \sin(80\pi t)}{\cos(120\pi t) - \cos(80\pi t)} = -\cot(20\pi t)$

102. $\dfrac{\sin m + \sin n}{\cos m + \cos n} = \tan\left(\dfrac{m+n}{2}\right)$

103. Show $\sin^2\alpha + (1 - \cos\alpha)^2 = \left[2\sin\left(\frac{\alpha}{2}\right)\right]^2$.

104. Show that $\tan\left(\frac{u}{2}\right) = \pm\sqrt{\dfrac{1-\cos u}{1+\cos u}}$ is equivalent to $\dfrac{\sin u}{1+\cos u}$ by rationalizing the numerator.

105. Derive the identity for $\sin(2\alpha)$ and $\tan(2\alpha)$ using $\sin(\alpha+\beta)$ and $\tan(\alpha+\beta)$, where $\alpha = \beta$.



106. Derive the identity for $\tan^2(\alpha)$ using $\tan(2\alpha) = \dfrac{2\tan(\alpha)}{1 - \tan^2(\alpha)}$. *Hint:* Solve for $\tan^2\alpha$ and work in terms of sines and cosines.

107. Derive the product-to-sum identity for $\sin\alpha\sin\beta$.

108. Derive the sum-to-product identity for $\cos u + \cos v$.

▶ WORKING WITH FORMULAS

109. Supersonic speeds, the sound barrier, and Mach numbers: $\mathcal{M} = \csc\left(\frac{\theta}{2}\right)$

The speed of sound varies with temperature and altitude. At 32°F, sound travels about 742 mi/hr at sea level. A jet-plane flying faster than the speed of sound (called supersonic speed) has "broken the sound barrier." The plane projects three-dimensional sound waves about the nose of the craft that form the shape of a cone. The cone intersects the Earth along a hyperbolic path, with a sonic boom being heard by anyone along this path. The ratio of the plane's speed to the speed of sound is called its Mach number $\mathcal{M}$, meaning a plane flying at $\mathcal{M} = 3.2$ is traveling 3.2 times the speed of sound. This Mach number can be determined using the formula given here, where θ is the vertex angle of the cone described. For the following exercises, use the formula to find $\mathcal{M}$ or θ as required. For parts (a) and (b), answer in exact form (using a half-angle identity) and approximate form.

a. $\theta = 30°$ **b.** $\theta = 45°$ **c.** $\mathcal{M} = 2$

110. Malus's law: $I = I_0 \cos^2\theta$

When a beam of plane-polarized light with intensity I_0 hits an analyzer, the intensity I of the transmitted beam of light can be found using the formula shown, where θ is the angle formed between the transmission axes of the polarizer and the analyzer. Find the intensity of the beam when $\theta = 15°$ and $I_0 = 300$ candelas (cd). Answer in exact form (using a power reduction identity) and approximate form.

▶ APPLICATIONS

Range of a projectile: Exercises 111 and 112 refer to Example 9. In Example 9, we noted that the range of a projectile was maximized at $\theta = 45°$. If $\theta > 45°$ or $\theta < 45°$, the projectile falls short of its maximum potential distance. In Exercises 111 and 112 assume that the projectile has an initial velocity of 96 ft/sec.

111. Compute how many feet short of maximum the projectile falls if (a) $\theta = 22.5°$ and (b) $\theta = 67.5°$. Answer in both exact and approximate form.

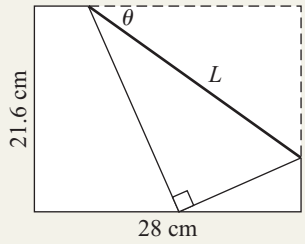
112. Use a calculator to compute how many feet short of maximum the projectile falls if (a) $\theta = 40°$ and $\theta = 50°$ and (b) $\theta = 37.5°$ and $\theta = 52.5°$. Do you see a pattern? Discuss/explain what you notice and experiment with other values to confirm your observations.

Touch-tone phones: The diagram given in Example 10 shows the various frequencies used to create the tones for a touch-tone phone. Use a sum-to-product identity to write the resultant wave when the following numbers are pressed.

113. 3

114. 8

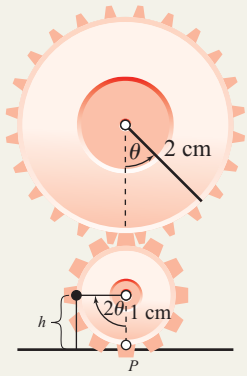
One button is randomly pressed and the resultant wave is modeled by $y(t)$ shown. Use a product-to-sum identity to write the expression as a sum and determine the button pressed.



115. $y(t) = 2\cos(2150\pi t)\cos(268\pi t)$

116. $y(t) = 2\cos(1906\pi t)\cos(512\pi t)$

117. Clock angles: Kirkland City has a large clock atop city hall, with a minute hand that is 3 ft long. Claire and Monica independently attempt to devise a function that will track the distance between the tip of the minute hand at t minutes between the hours, and the tip of the minute hand when it is in the vertical position as shown. Claire finds the function $d(t) = \left|6\sin\left(\frac{\pi t}{60}\right)\right|$, while Monica devises $d(t) = \sqrt{18\left[1 - \cos\left(\frac{\pi t}{30}\right)\right]}$. Use the identities from this section to show the functions are equivalent.



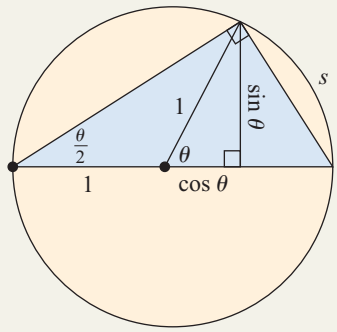
118. Origami: The Japanese art of origami involves the repeated folding of a single piece of paper to create various art forms. When the upper right corner of a rectangular 21.6-cm by 28-cm piece of paper is folded down until the corner is flush with the other side, the length L of the fold is related to the angle θ by $L = \dfrac{10.8}{\sin\theta\cos^2\theta}$.

(a) Show this is equivalent to $L = \dfrac{21.6\sec\theta}{\sin(2\theta)}$,
(b) find the length of the fold if $\theta = 30°$, and
(c) find the angle θ if $L = 28.8$ cm.

119. Machine gears: A machine part involves two gears. The first has a radius of 2 cm and the second a radius of 1 cm, so the smaller gear turns twice as fast as the larger gear. Let θ represent the angle of rotation in the larger gear, measured from a vertical and downward starting position. Let P be a point on the circumference of the smaller gear, starting at the vertical and downward position. Four engineers working on an improved design for this component devise functions that track the height of point P above the horizontal plane shown, for a rotation of $\theta°$ by the larger gear. The functions they develop are:
Engineer A: $f(\theta) = \sin(2\theta - 90°) + 1$;
Engineer B: $g(\theta) = 2\sin^2\theta$;
Engineer C: $k(\theta) = 1 + \sin^2\theta - \cos^2\theta$; and
Engineer D: $h(\theta) = 1 - \cos(2\theta)$. Use any of the identities you've learned so far to show these four functions are equivalent.

120. Working with identities: Compute the value of $\sin 15°$ two ways, first using the half-angle identity for sine, and second using the difference identity for sine. (a) Find a decimal approximation for each to show the results are equivalent and (b) verify algebraically that they are equivalent. (*Hint:* Square both sides.)

121. Working with identities: Compute the value of $\cos 15°$ two ways, first using the half-angle identity for cosine, and second using the difference identity for cosine. (a) Find a decimal approximation for each to show the results are equivalent and (b) verify algebraically that they are equivalent. (*Hint:* Square both sides.)



122. Standing waves: A clapotic (or standing) wave is formed when a wave strikes and reflects off a seawall or other immovable object. Against one particular seawall, the standing wave that forms can be modeled by summing the incoming wave represented by the equation $y_i = 2\sin(1.1x - 0.6t)$ with the outgoing wave represented by the equation $y_o = 2\sin(1.1x + 0.6t)$. Use a sum-to-product identity to express the resulting wave $y = y_i + y_o$ as a product.

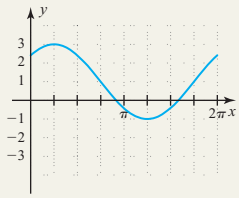
▶ EXTENDING THE CONCEPT

123. Can you find three distinct, real numbers whose sum is equal to their product? A little known fact from trigonometry stipulates that for any triangle, the sum of the tangents of the angles is equal to the products of their tangents. Use a calculator to test this statement, recalling the three angles must sum to 180°. Our website at www.mhhe.com/coburn shows a method that enables you to verify the statement using tangents that are all rational values.

124. A proof without words: From elementary geometry we have the following: (a) an angle inscribed in a semicircle is a right angle; and (b) the measure of an inscribed angle (vertex on the circumference) is one-half the measure of its intercepted arc. Discuss/explain how the unit-circle diagram offers a proof that $\tan\left(\dfrac{x}{2}\right) = \dfrac{\sin x}{1 + \cos x}$. Be detailed and thorough.

Exercise 124

125. Using $\theta = 30°$ and repeatedly applying the half-angle identity for cosine, show that $\cos 3.75°$ is equal to $\dfrac{\sqrt{2 + \sqrt{2 + \sqrt{2 + \sqrt{3}}}}}{2}$. Verify the result using a calculator, then use the patterns noted to write the value of $\cos 1.875°$ in closed form (also verify this result). As θ becomes very small, what appears to be happening to the value of $\cos\theta$?



▶ MAINTAINING YOUR SKILLS

126. **(4.2)** Use the rational roots theorem to find all zeroes of $x^4 + x^3 - 8x^2 - 6x + 12 = 0$.

127. **(6.1)** The hypotenuse of a certain right triangle is twice the shortest side. Solve the triangle.

128. **(6.2)** Verify that $(\frac{16}{65}, \frac{63}{65})$ is on the unit circle, then find $\tan\theta$ and $\sec\theta$ to verify $1 + \tan^2\theta = \sec^2\theta$.

129. **(6.5)** Write the equation of the function graphed in terms of a sine function of the form $y = A\sin(Bx + C) + D$.

MID-CHAPTER CHECK

1. Verify the identity using a multiplication: $\sin x(\csc x - \sin x) = \cos^2 x$

2. Verify the identity by factoring: $\cos^2 x - \cot^2 x = -\cos^2 x \cot^2 x$

3. Verify the identity by combining terms: $\dfrac{2\sin x}{\sec x} - \dfrac{\cos x}{\csc x} = \cos x \sin x$

4. Show the equation given is not an identity. $1 + \sec^2 x = \tan^2 x$

5. Verify each identity.

a. $\dfrac{\sin^3 x + \cos^3 x}{\sin x + \cos x} = 1 - \sin x \cos x$

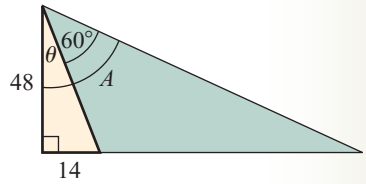
b. $\dfrac{1 + \sec x}{\csc x} - \dfrac{1 + \cos x}{\cot x} = 0$

6. Verify each identity.

a. $\dfrac{\sec^2 x - \tan^2 x}{\sec^2 x} = \cos^2 x$

b. $\dfrac{\cot x - \tan x}{\csc x \sec x} = \cos^2 x - \sin^2 x$

7. Given α and β are obtuse angles with $\sin\alpha = \dfrac{56}{65}$ and $\tan\beta = -\dfrac{80}{39}$, find



a. $\sin(\alpha - \beta)$

b. $\cos(\alpha + \beta)$

c. $\tan(\alpha - \beta)$

8. Use the diagram shown to compute $\sin A$, $\cos A$, and $\tan A$.

Exercise 8

9. Given $\cos\theta = -\dfrac{15}{17}$ and θ in QII, find exact values of $\sin\left(\dfrac{\theta}{2}\right)$ and $\cos\left(\dfrac{\theta}{2}\right)$.

10. Given $\sin\alpha = -\dfrac{7}{25}$ with α in QIII, find the value of $\sin(2\alpha)$, $\cos(2\alpha)$, and $\tan(2\alpha)$.

REINFORCING BASIC CONCEPTS

Identities—Connections and Relationships

It is a well-known fact that information is retained longer and used more effectively when it is organized, sequential, and connected. In this feature, we attempt to do just that with our study of identities. In flowchart form we'll show that the entire range of identities has only two tiers, and that the fundamental identities and the sum and difference identities are really the keys to the entire range of identities. Beginning with the right triangle definition of sine, cosine, and tangent, the **reciprocal identities** and **ratio identities** are more semantic (word related) than mathematical, and the **Pythagorean identities** follow naturally from the properties of right triangles. These form the first tier.

Basic Definitions

$$\sin\theta = \frac{\text{opp}}{\text{hyp}} \qquad \cos\theta = \frac{\text{adj}}{\text{hyp}} \qquad \tan\theta = \frac{\text{opp}}{\text{adj}}$$

Fundamental Identities

defined defined derived

Reciprocal Identities

$$\frac{1}{\sin\theta} = \csc\theta$$
$$\frac{1}{\cos\theta} = \sec\theta$$
$$\frac{1}{\tan\theta} = \cot\theta$$

Ratio Identities

$$\frac{\sin\theta}{\cos\theta} = \tan\theta$$
$$\frac{\cos\theta}{\sin\theta} = \cot\theta$$
$$\frac{\sec\theta}{\csc\theta} = \tan\theta$$

Pythagorean Identities

$$\cos^2\theta + \sin^2\theta = 1$$

$1 + \tan^2\theta = \sec^2\theta$ (divide by $\cos^2\theta$)

$\cot^2\theta + 1 = \csc^2\theta$ (divide by $\sin^2\theta$)

The reciprocal and ratio identities are actually *defined,* while the Pythagorean identities are *derived* from these two families. In addition, the identity $\cos^2\theta + \sin^2\theta = 1$ is the only Pythagorean identity we actually need to memorize; the other two follow by division of $\cos^2\theta$ and $\sin^2\theta$ as indicated.

In virtually the same way, the sum and difference identities for sine and cosine are the only identities that need to be memorized, as all other identities in the second tier flow from these.

Sum/Difference Identities

$$\begin{cases} \cos(\alpha \pm \beta) = \cos\alpha\cos\beta \mp \sin\alpha\sin\beta \\ \sin(\alpha \pm \beta) = \sin\alpha\cos\beta \pm \cos\alpha\sin\beta \end{cases}$$

Double-Angle Identities
use $\alpha = \beta$ in sum identities

$$\sin(2\alpha) = 2\sin\alpha\cos\alpha$$
$$\cos(2\alpha) = \cos^2\alpha - \sin^2\alpha$$

$\cos(2\alpha) = 2\cos^2\alpha - 1$ (use $\sin^2\alpha = 1 - \cos^2\alpha$)

$\cos(2\alpha) = 1 - 2\sin^2\alpha$ (use $\cos^2\alpha = 1 - \sin^2\alpha$)

Power Reduction Identities
solve for $\cos^2\alpha$, $\sin^2\alpha$ in related $\cos(2\alpha)$ identity

$$\cos^2\alpha = \frac{1 + \cos(2\alpha)}{2}$$
$$\sin^2\alpha = \frac{1 - \cos(2\alpha)}{2}$$

Half-Angle Identities
solve for $\cos\alpha$, $\sin\alpha$ and use $\alpha = u/2$ in the power reduction identities

$$\cos\left(\frac{u}{2}\right) = \pm\sqrt{\frac{1 + \cos u}{2}}$$
$$\sin\left(\frac{u}{2}\right) = \pm\sqrt{\frac{1 - \cos u}{2}}$$

Product-to-Sum Identities
combine various sum/difference identities

see Section 7.4

see Section 7.4

Exercise 1: Starting with the identity $\cos^2\alpha + \sin^2\alpha = 1$, derive the other two Pythagorean identities.

Exercise 2: Starting with the identity $\cos(\alpha \pm \beta) = \cos\alpha\cos\beta \mp \sin\alpha\sin\beta$, derive the double-angle identities for cosine.

7.5 The Inverse Trig Functions and Their Applications

LEARNING OBJECTIVES

In Section 7.5 you will see how we can:

- ❑ **A.** Find and graph the inverse sine function and evaluate related expressions
- ❑ **B.** Find and graph the inverse cosine and tangent functions and evaluate related expressions
- ❑ **C.** Apply the definition and notation of inverse trig functions to simplify compositions
- ❑ **D.** Find and graph inverse functions for sec *x*, csc *x*, and cot *x*
- ❑ **E.** Solve applications involving inverse functions

While we usually associate the number π with the features of a circle, it also occurs in some "interesting" places, such as the study of normal (bell) curves, Bessel functions, Stirling's formula, Fourier series, Laplace transforms, and infinite series. In much the same way, the trigonometric functions are surprisingly versatile, finding their way into a study of complex numbers and vectors, the simplification of algebraic expressions, and finding the area under certain curves—applications that are hugely important in a continuing study of mathematics. As you'll see, a study of the inverse trig functions helps support these fascinating applications.

A. The Inverse Sine Function

In Section 5.1 we established that only one-to-one functions have an inverse. All six trig functions fail the horizontal line test and are not one-to-one as given. However, by suitably restricting the domain, a one-to-one function can be defined that makes finding an inverse possible. For the sine function, it seems natural to choose the interval $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$ since it is centrally located and the sine function attains all possible range values in this interval. A graph of $y = \sin x$ is shown in Figure 7.17, with the portion corresponding to this interval colored in red. Note the range is still $[-1, 1]$ (Figure 7.18).

Figure 7.17

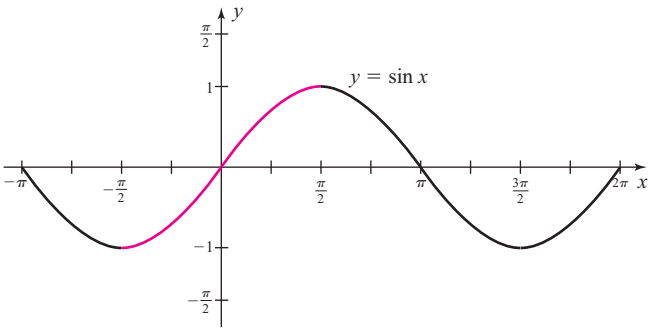


Figure 7.18

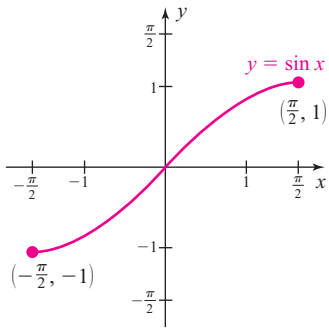

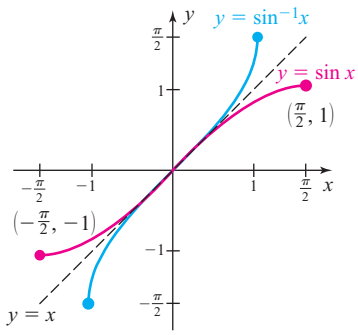

Figure 7.19

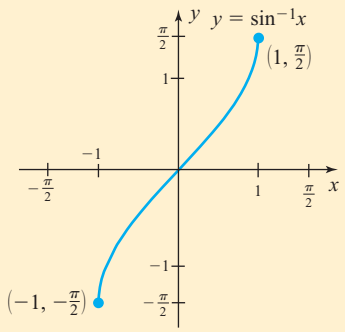
We can obtain an implicit equation for the inverse of $y = \sin x$ by interchanging x- and y-values, obtaining $x = \sin y$. By accepted convention, the *explicit* form of the inverse sine function is written $y = \sin^{-1}x$ or $y = \arcsin x$. Since domain and range values have been interchanged, the domain of $y = \sin^{-1}x$ is $[-1, 1]$ and the range is $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$. The graph of $y = \sin^{-1}x$ can be found by reflecting the portion in red across the line $y = x$ and using the endpoints of the domain and range (see Figure 7.19).



The Inverse Sine Function

For $y = \sin x$ with domain $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$ and range $[-1, 1]$, the inverse sine function is

$$\boldsymbol{y = \sin^{-1}x \text{ or } y = \arcsin x,}$$

with domain $[-1, 1]$ and range $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$.

$$\boldsymbol{y = \sin^{-1}x \text{ if and only if } \sin y = x}$$

From the implicit form $x = \sin y$, we learn to interpret the inverse function as, "y is the number or angle whose sine is x." Learning to read and interpret the explicit form in this way will be helpful.

$$y = \sin^{-1}x \Leftrightarrow x = \sin y \qquad x = \sin y \Leftrightarrow y = \sin^{-1}x$$

EXAMPLE 1 ▶ **Evaluating $y = \sin^{-1}x$ Using Special Values**

Evaluate the inverse sine function for the values given:

a. $y = \sin^{-1}\left(\frac{\sqrt{3}}{2}\right)$ **b.** $y = \arcsin\left(-\frac{1}{2}\right)$ **c.** $y = \sin^{-1}(2)$

Solution ▶ For x in $[-1, 1]$ and y in $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$,

a. $y = \sin^{-1}\left(\frac{\sqrt{3}}{2}\right)$: y is the number or angle whose sine is $\frac{\sqrt{3}}{2}$

$\Rightarrow \sin y = \frac{\sqrt{3}}{2}$, so $\sin^{-1}\left(\frac{\sqrt{3}}{2}\right) = \frac{\pi}{3}$.

b. $y = \arcsin\left(-\frac{1}{2}\right)$: y is the arc or angle whose sine is $-\frac{1}{2}$

$\Rightarrow \sin y = -\frac{1}{2}$, so $\arcsin\left(-\frac{1}{2}\right) = -\frac{\pi}{6}$.

c. $y = \sin^{-1}(2)$: y is the number or angle whose sine is 2

$\Rightarrow \sin y = 2$. Since 2 is not in $[-1, 1]$, $\sin^{-1}(2)$ is undefined.

Now try Exercises 7 through 12 ▶

Table 7.1

x	$\sin x$
$-\frac{\pi}{2}$	-1
$-\frac{\pi}{3}$	$-\frac{\sqrt{3}}{2}$
$-\frac{\pi}{4}$	$-\frac{\sqrt{2}}{2}$
$-\frac{\pi}{6}$	$-\frac{1}{2}$
0	0
$\frac{\pi}{6}$	$\frac{1}{2}$
$\frac{\pi}{4}$	$\frac{\sqrt{2}}{2}$
$\frac{\pi}{3}$	$\frac{\sqrt{3}}{2}$
$\frac{\pi}{2}$	1

In Examples 1(a) and 1(b), note that the equations $\sin y = \frac{\sqrt{3}}{2}$ and $\sin y = -\frac{1}{2}$ each have an infinite number of solutions, but only one solution in $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$.

When x is one of the standard values $\left(0, \frac{1}{2}, \frac{\sqrt{3}}{2}, 1, \text{and so on}\right)$, $y = \sin^{-1}x$ can be evaluated by reading a standard table "in reverse." For $y = \arcsin(-1)$, we locate the number -1 in the right-hand column of Table 7.1, and note the "number or angle whose sine is -1," is $-\frac{\pi}{2}$. If x is between -1 and 1 but is not a standard value, we can use the $\sin^{-1}$ function on a calculator, which is most often the 2nd or INV function for SIN.

EXAMPLE 2 ▶ **Evaluating $y = \sin^{-1}x$ Using a Calculator**

Evaluate each inverse sine function twice. First in radians rounded to four decimal places, then in degrees to the nearest tenth.

a. $y = \sin^{-1}0.8492$ **b.** $y = \arcsin(-0.2317)$

Solution ▶ For x in $[-1, 1]$, we evaluate $y = \sin^{-1}x$.

a. $y = \sin^{-1}0.8492$: With the calculator in radian MODE, use the keystrokes 2nd SIN 0.8492) ENTER. We find $\sin^{-1}(0.8492) \approx 1.0145$ radians. In degree MODE, the same sequence of keystrokes gives $\sin^{-1}(0.8492) \approx 58.1°$ (note that 1.0145 rad $\approx 58.1°$).

WORTHY OF NOTE

The $\sin^{-1}x$ notation for the inverse sine function is a carryover from the $f^{-1}(x)$ notation for a general inverse function, and likewise has nothing to do with the reciprocal of the function. The arcsin x notation derives from our work in radians on the unit circle, where $y = \arcsin x$ can be interpreted as "y is an arc whose sine is x."

b. $y = \arcsin(-0.2317)$: In radian MODE, we find $\sin^{-1}(-0.2317) \approx -0.2338$ rad. In degree MODE, $\sin^{-1}(-0.2317) \approx -13.4°$.

Now try Exercises 13 through 16 ▶

From our work in Section 5.1, we know that if f and g are inverses, $(f \circ g)(x) = x$ and $(g \circ f)(x) = x$. This suggests the following properties.

Inverse Function Properties for Sine

For $f(x) = \sin x$ and $g(x) = \sin^{-1}x$:

$$\textbf{I.}\ (f \circ g)(x) = \sin(\sin^{-1}x) = x \text{ for } x \text{ in } [-1, 1]$$

and

$$\textbf{II.}\ (g \circ f)(x) = \sin^{-1}(\sin x) = x \text{ for } x \text{ in } \left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$$

EXAMPLE 3 ▶ Evaluating Expressions Using Inverse Function Properties

Evaluate each expression and verify the result on a calculator.

a. $\sin\left[\sin^{-1}\left(\frac{1}{2}\right)\right]$ **b.** $\arcsin\left[\sin\left(\frac{\pi}{4}\right)\right]$ **c.** $\sin^{-1}(\sin 150°)$

Solution ▶

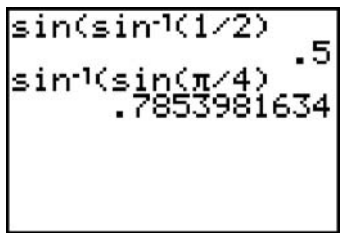
a. $\sin\left[\sin^{-1}\left(\frac{1}{2}\right)\right] = \frac{1}{2}$, since $\frac{1}{2}$ is in $[-1, 1]$ Property I

b. $\arcsin\left[\sin\left(\frac{\pi}{4}\right)\right] = \frac{\pi}{4}$, since $\frac{\pi}{4}$ is in $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$ Property II

c. $\sin^{-1}(\sin 150°) \neq 150°$, since $150°$ is not in $[-90°, 90°]$.

This doesn't mean the expression cannot be evaluated, only that we cannot use Property II. Since $\sin 150° = \sin 30°$, $\sin^{-1}(\sin 150°) = \sin^{-1}(\sin 30°) = 30°$. The calculator verification for each is shown in Figures 7.20 and 7.21. Note $\frac{\pi}{4} \approx 0.7854$.

Figure 7.20
Parts (a) and (b)



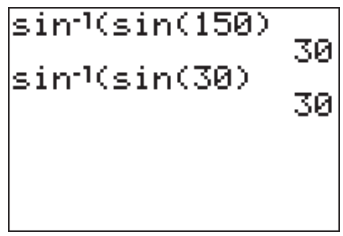


Figure 7.21
Part (c)

Now try Exercises 17 through 24 ▶

The domain and range concepts at play in Example 3(c) can be further explored with the **TABLE** feature of a calculator. Begin by using the **TBLSET** screen (2nd WINDOW) to set TblStart = 90 with ΔTbl = −30. After placing the calculator in **degree** MODE, go to the Y= screen and input $Y_1 = \sin X$, $Y_2 = \sin^{-1}X$, and $Y_3 = Y_2(Y_1)$ (the composition $Y_2 \circ Y_1$). Then disable Y_2 so that only Y_1 and Y_3 will be displayed (Figure 7.22). Note the inputs are standard angles, the outputs in Y_1 are the (expected)

standard values, and the outputs in Y_3 return the original standard angles. Now scroll upward until 180° is at the top of the X column (Figure 7.23), and note that Y_3 continues to return standard angles from the interval $[-90°, 90°]$, including Example 3(c)'s result: $\sin^{-1}(\sin 150°) \neq 150°$. This is a powerful reminder that *the inverse function properties cannot always be used when working with inverse trigonometric functions*.

B. The Inverse Cosine and Inverse Tangent Functions

Like the sine function, the cosine function is not one-to-one and its domain must also be restricted to develop an inverse function. For convenience we choose the interval $x \in [0, \pi]$ since it is again somewhat central and takes on all of its range values in this interval. A graph of the cosine function, with the interval corresponding to this interval shown in red, is given in Figure 7.24. Note the range is still $[-1, 1]$ (Figure 7.25).

Figure 7.24

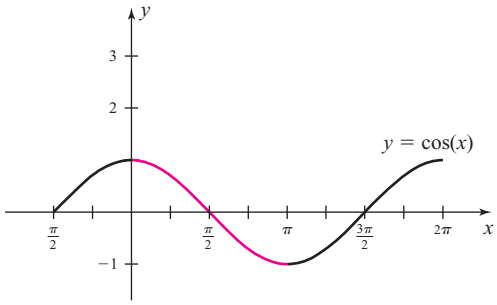

Figure 7.25

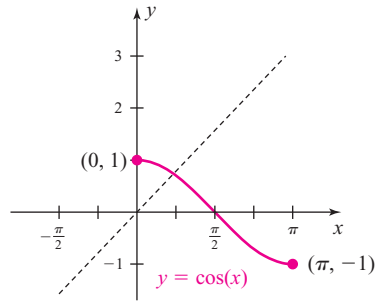

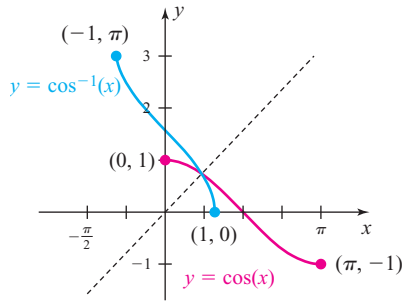

Figure 7.26

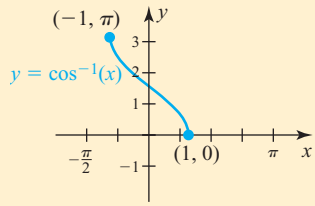
For the implicit equation of inverse cosine, $y = \cos x$ becomes $x = \cos y$, with the corresponding explicit forms being $y = \cos^{-1}x$ or $y = \arccos x$. By reflecting the graph of $y = \cos x$ across the line $y = x$, we obtain the graph of $y = \cos^{-1} x$ shown in Figure 7.26.



The Inverse Cosine Function

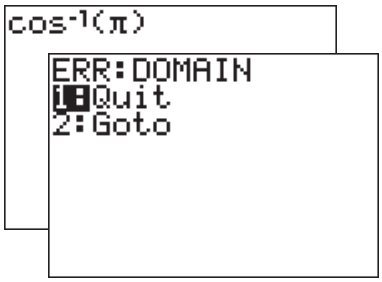
For $y = \cos x$ with domain $[0, \pi]$ and range $[-1, 1]$, the inverse cosine function is

$$y = \cos^{-1}x \text{ or } y = \arccos x$$

with domain $[-1, 1]$ and range $[0, \pi]$.

$$y = \cos^{-1}x \text{ if and only if } \cos y = x$$

EXAMPLE 4 ▶ **Evaluating $y = \cos^{-1}x$ Using Special Values**



Evaluate the inverse cosine for the values given:

a. $y = \cos^{-1}(0)$ **b.** $y = \arccos\left(-\frac{\sqrt{3}}{2}\right)$ **c.** $y = \cos^{-1}(\pi)$

Solution ▶ For x in $[-1, 1]$ and y in $[0, \pi]$,

a. $y = \cos^{-1}(0)$: y is the number or angle whose cosine is $0 \Rightarrow \cos y = 0$.

This shows $\cos^{-1}(0) = \frac{\pi}{2}$.

b. $y = \arccos\left(-\frac{\sqrt{3}}{2}\right)$: y is the arc or angle whose cosine is $-\frac{\sqrt{3}}{2} \Rightarrow \cos y = -\frac{\sqrt{3}}{2}$. This shows $\arccos\left(-\frac{\sqrt{3}}{2}\right) = \frac{5\pi}{6}$.

c. $y = \cos^{-1}(\pi)$: y is the number or angle whose cosine is $\pi \Rightarrow \cos y = \pi$. Since $\pi \notin [-1, 1]$, $\cos^{-1}(\pi)$ is undefined. Attempting to evaluate $\cos^{-1}(\pi)$ on a calculator will produce the error message shown in the figure.

Now try Exercises 25 through 34 ▶

Knowing that $y = \cos x$ and $y = \cos^{-1}x$ are inverse functions enables us to state inverse function properties similar to those for sine.

Inverse Function Properties for Cosine

For $f(x) = \cos x$ and $g(x) = \cos^{-1}x$:

I. $(f \circ g)(x) = \cos(\cos^{-1}x) = x$ for x in $[-1, 1]$

and

II. $(g \circ f)(x) = \cos^{-1}(\cos x) = x$ for x in $[0, \pi]$

EXAMPLE 5 ▶ **Evaluating Expressions Using Inverse Function Properties**

Evaluate each expression.

a. $\cos[\cos^{-1}(0.73)]$ **b.** $\arccos\left[\cos\left(\frac{\pi}{12}\right)\right]$ **c.** $\cos^{-1}\left[\cos\left(\frac{4\pi}{3}\right)\right]$

Solution ▶

a. $\cos[\cos^{-1}(0.73)] = 0.73$, since 0.73 is in $[-1, 1]$ Property I

b. $\arccos\left[\cos\left(\frac{\pi}{12}\right)\right] = \frac{\pi}{12}$, since $\frac{\pi}{12}$ is in $[0, \pi]$ Property II

c. $\cos^{-1}\left[\cos\left(\frac{4\pi}{3}\right)\right] \neq \frac{4\pi}{3}$, since $\frac{4\pi}{3}$ is not in $[0, \pi]$.

This expression cannot be evaluated using Property II. Since

$\cos\left(\frac{4\pi}{3}\right) = \cos\left(\frac{2\pi}{3}\right)$, $\cos^{-1}\left[\cos\left(\frac{4\pi}{3}\right)\right] = \cos^{-1}\left[\cos\left(\frac{2\pi}{3}\right)\right] = \frac{2\pi}{3}$.

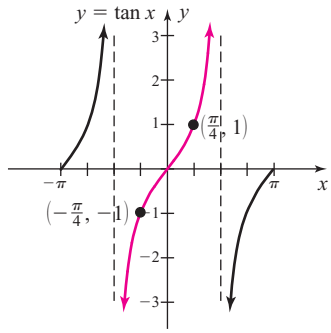
The results can also be verified using a calculator.

Now try Exercises 35 through 42 ▶

For the tangent function, we likewise restrict the domain to obtain a one-to-one function, with the most common choice being $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$. The corresponding range is $\mathbb{R}$. The *implicit* equation for the inverse tangent function is $x = \tan y$ with the explicit forms $y = \tan^{-1}x$ or $y = \arctan x$. With the domain and range interchanged, the domain of $y = \tan^{-1}x$ is $\mathbb{R}$, and the range is $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$. The graph of $y = \tan x$ for x in $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$

is shown in red (Figure 7.27), with the inverse function $y = \tan^{-1} x$ shown in blue (Figure 7.28).

Figure 7.27



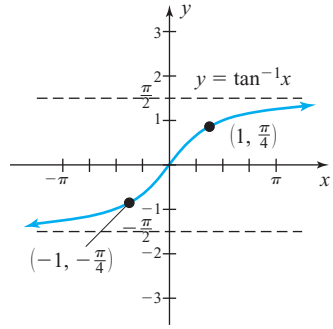


Figure 7.28

The Inverse Tangent Function

For $y = \tan x$ with domain $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ and range $\mathbb{R}$, the inverse tangent function is

$$y = \tan^{-1} x \text{ or } y = \arctan x,$$

with domain $\mathbb{R}$ and range $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$.

$y = \tan^{-1} x$ **if and only if** $\tan y = x$

Inverse Function Properties for Tangent

For $f(x) = \tan x$ and $g(x) = \tan^{-1} x$:

I. $(f \circ g)(x) = \tan(\tan^{-1} x) = x$ for x in $\mathbb{R}$

and

II. $(g \circ f)(x) = \tan^{-1}(\tan x) = x$ for x in $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$.

EXAMPLE 6 ▶ **Evaluating Expressions Involving Inverse Tangent**

Evaluate each expression.

a. $\tan^{-1}(-\sqrt{3})$ **b.** $\arctan[\tan(-0.89)]$

Solution ▶ For x in $\mathbb{R}$ and y in $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$,

a. $\tan^{-1}(-\sqrt{3}) = -\frac{\pi}{3}$, since $\tan\left(-\frac{\pi}{3}\right) = -\sqrt{3}$

b. $\arctan[\tan(-0.89)] = -0.89$, since -0.89 is in $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ Property II

Now try Exercises 43 through 52 ▶

B. You've just seen how we can find and graph the inverse cosine and tangent functions and evaluate related expressions

C. Using the Inverse Trig Functions to Evaluate Compositions

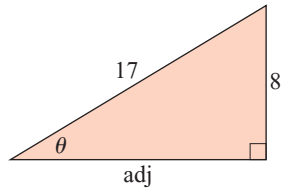
In the context of angle measure, the expression $y = \sin^{-1}\left(-\frac{1}{2}\right)$ represents an angle—the *angle* y whose sine is $-\frac{1}{2}$. It seems natural to ask, "What happens if we take the tangent of this angle?" In other words, what does the expression $\tan\left[\sin^{-1}\left(-\frac{1}{2}\right)\right]$ mean? Similarly, if $y = \cos\left(\frac{\pi}{3}\right)$ represents a real number between -1 and 1, how do we compute $\sin^{-1}\left[\cos\left(\frac{\pi}{3}\right)\right]$? Expressions like these occur in many fields of study.

EXAMPLE 7 ▶ **Simplifying Expressions Involving Inverse Trig Functions**

Simplify each expression:

a. $\tan\left[\arcsin\left(-\frac{1}{2}\right)\right]$ **b.** $\sin^{-1}\left[\cos\left(\frac{\pi}{3}\right)\right]$

Solution ▶



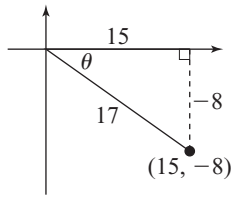
a. In Example 1 we found $\arcsin\left(-\frac{1}{2}\right) = -\frac{\pi}{6}$. Substituting $-\frac{\pi}{6}$ for $\arcsin\left(-\frac{1}{2}\right)$ gives $\tan\left(-\frac{\pi}{6}\right) = -\frac{\sqrt{3}}{3}$, showing $\tan\left[\arcsin\left(-\frac{1}{2}\right)\right] = -\frac{\sqrt{3}}{3}$.

b. For $\sin^{-1}\left[\cos\left(\frac{\pi}{3}\right)\right]$, we begin with the inner function $\cos\left(\frac{\pi}{3}\right) = \frac{1}{2}$. Substituting $\frac{1}{2}$ for $\cos\left(\frac{\pi}{3}\right)$ gives $\sin^{-1}\left(\frac{1}{2}\right)$. With the appropriate checks satisfied we have $\sin^{-1}\left(\frac{1}{2}\right) = \frac{\pi}{6}$, showing $\sin^{-1}\left[\cos\left(\frac{\pi}{3}\right)\right] = \frac{\pi}{6}$.

Now try Exercises 53 through 64 ▶

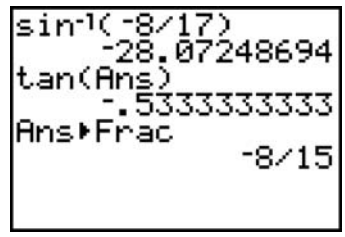
If the argument is not a special value and we need the answer in exact form, we can draw the triangle described by the inner expression using the definition of the trigonometric functions as ratios. In other words, for either y or $\theta = \sin^{-1}\left(\frac{8}{17}\right)$, we draw a triangle with hypotenuse 17 and side 8 opposite θ to model the statement, "an angle whose sine is $\frac{8}{17} = \frac{\text{opp}}{\text{hyp}}$," (see Figure 7.29). Using the Pythagorean theorem, we find the adjacent side is 15 and can now name any of the other trig functions.

Figure 7.29



EXAMPLE 8 ▶ **Using a Diagram to Evaluate an Expression Involving Inverse Trig Functions**

Evaluate the expression $\tan\left[\sin^{-1}\left(-\frac{8}{17}\right)\right]$.

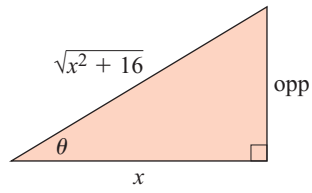


Solution ▶ The expression $\tan\left[\sin^{-1}\left(-\frac{8}{17}\right)\right]$ is equivalent to $\tan\theta$, where $\theta = \sin^{-1}\left(-\frac{8}{17}\right)$ with θ in $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$ (QIV or QI). For $\sin\theta = -\frac{8}{17}$ ($\sin\theta < 0$), θ must be in QIII or QIV. To satisfy both, θ must be in QIV. From Figure 7.30 we note $\tan\theta = -\frac{8}{15}$, showing $\tan\left[\sin^{-1}\left(-\frac{8}{17}\right)\right] = -\frac{8}{15}$.

Figure 7.30

A calculator check is shown in Figure 7.31.

Figure 7.31



Now try Exercises 65 through 72 ▶

These ideas apply even when one side of the triangle is unknown. In other words, we can still draw a triangle for $\theta = \cos^{-1}\left(\frac{x}{\sqrt{x^2+16}}\right)$, since "$\theta$ is an angle whose cosine is $\frac{x}{\sqrt{x^2+16}} = \frac{\text{adj}}{\text{hyp}}$."

EXAMPLE 9 ▶ **Using a Diagram to Evaluate an Expression Involving Inverse Trig Functions**

Evaluate the expression $\tan\left[\cos^{-1}\left(\frac{x}{\sqrt{x^2+16}}\right)\right]$. Assume $x > 0$ and the inverse function is defined for the expression given.

Solution ▶ Rewrite $\tan\left[\cos^{-1}\left(\frac{x}{\sqrt{x^2+16}}\right)\right]$ as $\tan\theta$, where $\theta = \cos^{-1}\left(\frac{x}{\sqrt{x^2+16}}\right)$. Draw a triangle with side x adjacent to θ and a hypotenuse of $\sqrt{x^2+16}$ (see the figure). The Pythagorean theorem gives $x^2 + \text{opp}^2 = (\sqrt{x^2+16})^2$, which leads to $\text{opp}^2 = (x^2+16) - x^2$ giving $\text{opp} = \sqrt{16} = 4$. This shows $\tan\theta = \tan\left[\cos^{-1}\left(\frac{x}{\sqrt{x^2+16}}\right)\right] = \frac{4}{x}$.

Now try Exercises 73 through 76 ▶

C. You've just seen how we can apply the definition and notation of inverse trig functions to simplify compositions

D. The Inverse Functions for Secant, Cosecant, and Cotangent

As with the other functions, we restrict the domains of the secant, cosecant, and cotangent functions to obtain one-to-one functions that are invertible (an inverse can be found). Once again the choice is arbitrary, and because some domains are easier to work with than others, these restrictions are not necessarily used uniformly in subsequent mathematics courses. For $y = \sec x$, we've chosen the "most intuitive" restriction, one that seems more centrally located (nearer the origin). The graph of $y = \sec x$ is reproduced here, along with its inverse function (see Figures 7.32 and 7.33). The domain, range, and graphs of the functions $y = \csc^{-1}x$ and $y = \cot^{-1}x$ are given in Figures 7.34 and 7.35.

Figure 7.32
$y = \sec x$

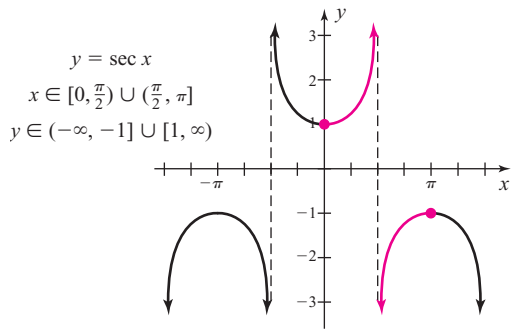


Figure 7.33
$y = \sec^{-1}x$

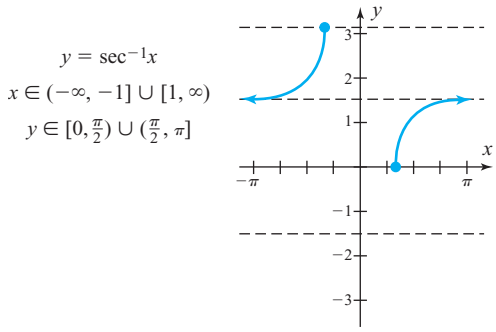

Figure 7.34

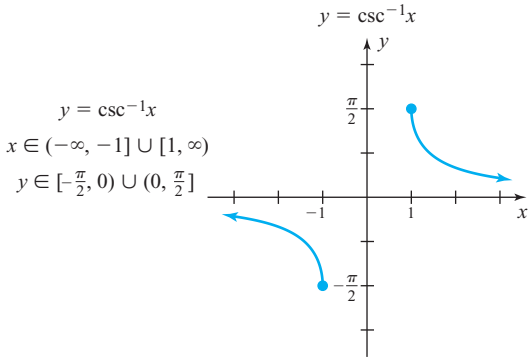

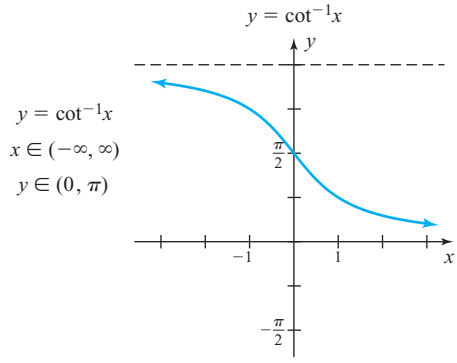

Figure 7.35

The functions $y = \sec^{-1}x$, $y = \csc^{-1}x$, and $y = \cot^{-1}x$ can be evaluated by noting their relationships to $y = \cos^{-1}x$, $y = \sin^{-1}x$, and $y = \tan^{-1}x$, respectively. For $y = \sec^{-1}x$, we have

$$\begin{aligned}
\sec y &= x && \text{definition of inverse function}\\
\frac{1}{\sec y} &= \frac{1}{x} && \text{property of reciprocals}\\
\cos y &= \frac{1}{x} && \text{reciprocal ratio}\\
y &= \cos^{-1}\left(\frac{1}{x}\right) && \text{rewrite using inverse function notation}\\
\sec^{-1}x &= \cos^{-1}\left(\frac{1}{x}\right) && \text{substitute } \sec^{-1}x \text{ for } y
\end{aligned}$$

In other words, to find the value of $y = \sec^{-1}x$, evaluate $y = \cos^{-1}\left(\frac{1}{x}\right)$, $|x| \geq 1$. Similarly, the expression $\csc^{-1}x$ can be evaluated using $\sin^{-1}\left(\frac{1}{x}\right)$, $|x| \geq 1$. The expression $\cot^{-1}x$ can likewise be evaluated using an inverse tangent function: $\cot^{-1}x = \tan^{-1}\left(\frac{1}{x}\right)$.

WORTHY OF NOTE

While the domains of $y = \cot^{-1}x$ and $y = \tan^{-1}x$ both include all real numbers, evaluating $\cot^{-1}x$ using $\tan^{-1}\left(\frac{1}{x}\right)$ involves the restriction $x \neq 0$. To maintain consistency, the equation $\cot^{-1}x = \frac{\pi}{2} - \tan^{-1}x$ is often used. The graph of $y = \frac{\pi}{2} - \tan^{-1}x$ is that of $y = \tan^{-1}x$ reflected across the x-axis and shifted $\frac{\pi}{2}$ units up, with the result identical to the graph of $y = \cot^{-1}x$.

EXAMPLE 10 ▶ **Evaluating an Inverse Trig Function**

Evaluate using a calculator only if necessary:

a. $\sec^{-1}\left(\frac{2}{\sqrt{3}}\right)$ **b.** $\cot^{-1}\left(\frac{\pi}{12}\right)$

Solution ▶

a. From our previous discussion, for $\sec^{-1}\left(\frac{2}{\sqrt{3}}\right)$, we evaluate $\cos^{-1}\left(\frac{\sqrt{3}}{2}\right)$. Since this is a standard value, no calculator is needed and the result is 30°.

b. For $\cot^{-1}\left(\frac{\pi}{12}\right)$, find $\tan^{-1}\left(\frac{12}{\pi}\right)$ on a calculator:

$$\cot^{-1}\left(\frac{\pi}{12}\right) = \tan^{-1}\left(\frac{12}{\pi}\right) \approx 1.3147.$$

Now try Exercises 77 through 86 ▶

A summary of the highlights from this section follows.

Summary of Inverse Function Properties and Compositions

1. For $\sin x$ and $\sin^{-1}x$,
   $\sin(\sin^{-1}x) = x$, for any x in the interval $[-1, 1]$;
   $\sin^{-1}(\sin x) = x$, for any x in the interval $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$
2. For $\cos x$ and $\cos^{-1}x$,
   $\cos(\cos^{-1}x) = x$, for any x in the interval $[-1, 1]$;
   $\cos^{-1}(\cos x) = x$, for any x in the interval $[0, \pi]$
3. For $\tan x$ and $\tan^{-1}x$,
   $\tan(\tan^{-1}x) = x$, for any real number x;
   $\tan^{-1}(\tan x) = x$, for any x in the interval $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$
4. To evaluate $\sec^{-1}x$, use $\cos^{-1}\left(\frac{1}{x}\right)$, $|x| \geq 1$;
   $\csc^{-1}x$, use $\sin^{-1}\left(\frac{1}{x}\right)$, $|x| \geq 1$;
   $\cot^{-1}x$, use $\frac{\pi}{2} - \tan^{-1}x$, for all real numbers x

Our calculators can lend some insight to the varied domain restrictions the inverse trig functions demand, simply by graphing $y = f(g(x))$. The result should yield the identity function $y = x$ for the domain specified. With the calculator in **radian** MODE and a ZOOM **4:ZDecimal** window, compare the graphs of $Y_1 = \sin(\sin^{-1}X)$ and $Y_2 = \sin^{-1}(\sin X)$ shown in Figures 7.36 and 7.37, respectively. A casual observation verifies property 1: $\sin(\sin^{-1}x) = x$ for any x in the interval $[-1, 1]$ and $\sin^{-1}(\sin x) = x$ for any x in the interval $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$. **See Exercises 87 through 90** for verifications of properties 2 and 3.

E. Applications of Inverse Trig Functions

We close this section with one example of the many ways that inverse functions can be applied.

EXAMPLE 11 ▶ **Using Inverse Trig Functions to Find Viewing Angles**

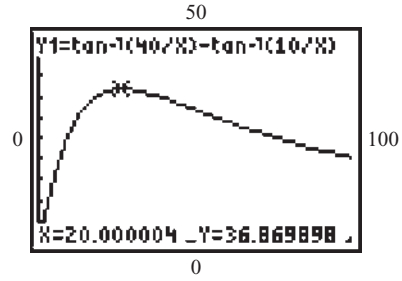
Believe it or not, the drive-in movie theaters that were so popular in the 1950s are making a comeback! If you arrive early, you can park in one of the coveted "center spots," but if you arrive late, you might have to park very close and strain your neck to watch the movie. Surprisingly, the maximum viewing angle (not the most comfortable viewing angle in this case) is actually very close to the front. Assume the base of a 30-ft screen is 10 ft above eye level (see Figure 7.38).

Figure 7.38

a. Use the inverse function concept to find expressions for angle α and angle β.

b. Use the result of part (a) to find an expression for the *viewing angle* θ.

c. Use a calculator to find the viewing angle θ (to tenths of a degree) for distances of 15, 25, 35, and 45 ft, then to determine the distance x (to tenths of a foot) that maximizes the viewing angle.



Solution ▶

a. The side opposite β is 10 ft, and we want to know x — the adjacent side. This suggests we use $\tan\beta = \frac{10}{x}$, giving $\beta = \tan^{-1}\left(\frac{10}{x}\right)$. In the same way, we find that $\alpha = \tan^{-1}\left(\frac{40}{x}\right)$.

b. From the diagram we note that $\theta = \alpha - \beta$, and substituting for α and β directly gives $\theta = \tan^{-1}\left(\frac{40}{x}\right) - \tan^{-1}\left(\frac{10}{x}\right)$.

c. After we enter $Y_1 = \tan^{-1}\left(\frac{40}{X}\right) - \tan^{-1}\left(\frac{10}{X}\right)$, a graphing calculator in degree MODE gives approximate viewing angles of 35.8°, 36.2°, 32.9°, and 29.1°, for $x = 15$, 25, 35, and 45 ft, respectively. From this data, we note the distance x that makes θ a maximum must be between 15 and 35 ft, and using 2nd TRACE **(CALC) 4:maximum** shows θ is a maximum of 36.9° at a distance of 20 ft from the screen (see Figure 7.39).

7.5 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. All six trigonometric functions fail the _____ _____ test and therefore are not _____-to-_____.

2. The two most common ways of writing the inverse function for $y = \sin x$ are _____ and _____.

3. The domain for the inverse sine function is _____ and the range is _____.

4. The domain for the inverse cosine function is _____ and the range is _____.

5. Most calculators do not have a key for evaluating an expression like $\sec^{-1}5$. Explain how it is done using the COS key.

6. Discuss/Explain what is meant by the *implicit form* of an inverse function and the *explicit form.* Give algebraic and trigonometric examples.

▶ DEVELOPING YOUR SKILLS

The tables here show values of sin θ, cos θ, and tan θ for $\theta \in [-180° \text{ to } 210°]$. The restricted domain used to develop the inverse functions is shaded. Use the information from these tables to complete the exercises that follow.

$y = \sin\theta$

θ	$\sin\theta$	θ	$\sin\theta$
$-180°$	0	$30°$	$\frac{1}{2}$
$-150°$	$-\frac{1}{2}$	$60°$	$\frac{\sqrt{3}}{2}$
$-120°$	$-\frac{\sqrt{3}}{2}$	$90°$	1
$-90°$	-1	$120°$	$\frac{\sqrt{3}}{2}$
$-60°$	$-\frac{\sqrt{3}}{2}$	$150°$	$\frac{1}{2}$
$-30°$	$-\frac{1}{2}$	$180°$	0
0	0	$210°$	$-\frac{1}{2}$

$y = \cos\theta$

θ	$\cos\theta$	θ	$\cos\theta$
$-180°$	-1	$30°$	$\frac{\sqrt{3}}{2}$
$-150°$	$-\frac{\sqrt{3}}{2}$	$60°$	$\frac{1}{2}$
$-120°$	$-\frac{1}{2}$	$90°$	0
$-90°$	0	$120°$	$-\frac{1}{2}$
$-60°$	$\frac{1}{2}$	$150°$	$-\frac{\sqrt{3}}{2}$
$-30°$	$\frac{\sqrt{3}}{2}$	$180°$	-1
0	1	$210°$	$-\frac{\sqrt{3}}{2}$

$y = \tan\theta$

θ	$\tan\theta$	θ	$\tan\theta$
$-180°$	0	$30°$	$\frac{\sqrt{3}}{3}$
$-150°$	$\frac{\sqrt{3}}{3}$	$60°$	$\sqrt{3}$
$-120°$	$\sqrt{3}$	$90°$	—
$-90°$	—	$120°$	$-\sqrt{3}$
$-60°$	$-\sqrt{3}$	$150°$	$-\frac{\sqrt{3}}{3}$
$-30°$	$-\frac{\sqrt{3}}{3}$	$180°$	0
0	0	$210°$	$\frac{\sqrt{3}}{3}$

Use the preceding tables to fill in each blank (principal values only).

7.

$\sin 0 = 0$	$\sin^{-1}0 =$ ____
$\sin\left(\frac{\pi}{6}\right) =$ ____	$\arcsin\left(\frac{1}{2}\right) = \frac{\pi}{6}$
$\sin\left(-\frac{5\pi}{6}\right) = -\frac{1}{2}$	$\sin^{-1}\left(-\frac{1}{2}\right) =$ ____
$\sin\left(-\frac{\pi}{2}\right) = -1$	$\sin^{-1}(-1) =$ ____

8.

$\sin 30° = \frac{1}{2}$	$\sin^{-1}\frac{1}{2} =$ ____
$\sin 120° = \frac{\sqrt{3}}{2}$	$\sin^{-1}\left(\frac{\sqrt{3}}{2}\right) =$ ____
$\sin(-60°) = -\frac{\sqrt{3}}{2}$	$\arcsin\left(-\frac{\sqrt{3}}{2}\right) =$ ____
$\sin 180° =$ ____	$\arcsin 0 = 0°$

Evaluate without the aid of calculators or tables, *keeping the domain and range of each function in mind.* Answer in radians.

9. $\sin^{-1}\left(\frac{\sqrt{2}}{2}\right)$

10. $\arcsin\left(\frac{\sqrt{3}}{2}\right)$

11. $\sin^{-1}1$

12. $\arcsin\left(-\frac{1}{2}\right)$

Evaluate using a calculator. Answer in radians to the nearest ten-thousandth *and* in degrees to the nearest tenth.

13. $\arcsin 0.8892$

14. $\arcsin\left(\frac{7}{8}\right)$

15. $\sin^{-1}\left(\frac{1}{\sqrt{7}}\right)$

16. $\sin^{-1}\left(\frac{1-\sqrt{5}}{2}\right)$

Evaluate each expression, *keeping the domain and range of each function in mind.* Check results using a calculator.

17. $\sin\left[\sin^{-1}\left(\frac{\sqrt{2}}{2}\right)\right]$

18. $\sin\left[\arcsin\left(\frac{\sqrt{3}}{2}\right)\right]$

19. $\arcsin\left[\sin\left(\frac{\pi}{3}\right)\right]$

20. $\sin^{-1}(\sin 30°)$

21. $\sin^{-1}(\sin 135°)$

22. $\arcsin\left[\sin\left(\frac{-2\pi}{3}\right)\right]$

23. $\sin(\sin^{-1} 0.8205)$

24. $\sin\left[\arcsin\left(\frac{3}{5}\right)\right]$

Use the tables given prior to Exercise 7 to fill in each blank (principal values only).

25.

$\cos 0 = 1$	$\cos^{-1}1 =$ ____
$\cos\left(\frac{\pi}{6}\right) =$ ____	$\arccos\left(\frac{\sqrt{3}}{2}\right) = \frac{\pi}{6}$
$\cos 120° = -\frac{1}{2}$	$\arccos\left(-\frac{1}{2}\right) =$ ____
$\cos\pi = -1$	$\cos^{-1}(-1) =$ ____

26.

$\cos(-60°) = \frac{1}{2}$	$\cos^{-1}\left(\frac{1}{2}\right) =$ ____
$\cos\left(-\frac{\pi}{6}\right) = \frac{\sqrt{3}}{2}$	$\cos^{-1}\left(\frac{\sqrt{3}}{2}\right) =$ ____
$\cos(-120°) =$ ____	$\arccos\left(-\frac{1}{2}\right) = 120°$
$\cos(2\pi) = 1$	$\cos^{-1}1 =$ ____

Evaluate without the aid of calculators or tables. Answer in radians.

27. $\cos^{-1}\left(\frac{1}{2}\right)$ **28.** $\arccos\left(-\frac{\sqrt{3}}{2}\right)$

29. $\cos^{-1}(-1)$ **30.** $\arccos(0)$

Evaluate using a calculator. Answer in radians to the nearest ten-thousandth, degrees to the nearest tenth.

31. $\arccos 0.1352$ **32.** $\arccos\left(\frac{4}{7}\right)$

33. $\cos^{-1}\left(\frac{\sqrt{5}}{3}\right)$ **34.** $\cos^{-1}\left(\frac{\sqrt{6}-1}{5}\right)$

Evaluate each expression, *keeping the domain and range of each function in mind.* Check results using a calculator.

35. $\arccos\left[\cos\left(\frac{\pi}{4}\right)\right]$ **36.** $\cos^{-1}(\cos 60°)$

37. $\cos(\cos^{-1} 0.5560)$ **38.** $\cos\left[\arccos\left(-\frac{8}{17}\right)\right]$

39. $\cos\left[\cos^{-1}\left(-\frac{\sqrt{2}}{2}\right)\right]$ **40.** $\cos\left[\arccos\left(\frac{\sqrt{3}}{2}\right)\right]$

41. $\cos^{-1}\left[\cos\left(\frac{5\pi}{4}\right)\right]$ **42.** $\arccos(\cos 315.8°)$

Use the tables presented before Exercise 7 to fill in each blank.

43.

$\tan 0 = 0$	$\tan^{-1}0 =$ ____
$\tan\left(-\frac{\pi}{3}\right) =$ ____	$\arctan(-\sqrt{3}) = -\frac{\pi}{3}$
$\tan 30° = \frac{\sqrt{3}}{3}$	$\arctan\left(\frac{\sqrt{3}}{3}\right) =$ ____
$\tan\left(\frac{\pi}{3}\right) =$ ____	$\tan^{-1}(\sqrt{3}) =$ ____

44.

$\tan(-150°) = \frac{\sqrt{3}}{3}$	$\tan^{-1}\left(\frac{\sqrt{3}}{3}\right) =$ ____
$\tan \pi = 0$	$\tan^{-1}0 =$ ____
$\tan 120° = -\sqrt{3}$	$\arctan(-\sqrt{3}) =$ ____
$\tan\left(\frac{\pi}{4}\right) =$ ____	$\arctan 1 = \frac{\pi}{4}$

Evaluate without the aid of calculators or tables.

45. $\tan^{-1}\left(-\frac{\sqrt{3}}{3}\right)$ **46.** $\arctan(-1)$

47. $\arctan(\sqrt{3})$ **48.** $\tan^{-1}0$

Evaluate using a calculator. Answer in radians to the nearest ten-thousandth *and* in degrees to the nearest tenth.

49. $\tan^{-1}(-2.05)$ **50.** $\tan^{-1}(0.3267)$

51. $\arctan\left(\frac{29}{21}\right)$ **52.** $\arctan(-\sqrt{6})$

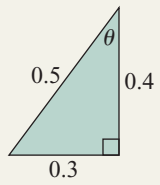
Simplify each expression without using a calculator.

53. $\sin^{-1}\left[\cos\left(\frac{2\pi}{3}\right)\right]$ **54.** $\cos^{-1}\left[\sin\left(-\frac{\pi}{3}\right)\right]$

55. $\tan\left[\arccos\left(\frac{\sqrt{3}}{2}\right)\right]$ **56.** $\sec\left[\arcsin\left(\frac{1}{2}\right)\right]$

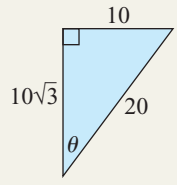
57. $\csc\left[\sin^{-1}\left(\frac{\sqrt{2}}{2}\right)\right]$ **58.** $\cot\left[\cos^{-1}\left(-\frac{1}{2}\right)\right]$

59. $\arccos[\sin(-30°)]$ **60.** $\arcsin(\cos 135°)$



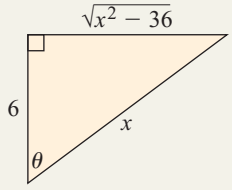
Explain why the following expressions are not defined.

61. $\tan(\sin^{-1}1)$ **62.** $\cot(\arccos 1)$

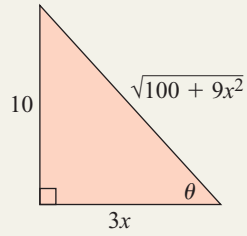


63. $\sin^{-1}\left[\csc\left(\frac{\pi}{4}\right)\right]$ **64.** $\cos^{-1}\left[\sec\left(\frac{2\pi}{3}\right)\right]$

Use the diagrams below to write the value of: (a) sin θ, (b) cos θ, and (c) tan θ.



65.



66.

67.

68.

Evaluate each expression by drawing a right triangle and labeling the sides.

69. $\sin\left[\cos^{-1}\left(-\frac{7}{25}\right)\right]$

70. $\cos\left[\sin^{-1}\left(-\frac{11}{61}\right)\right]$

71. $\sin\left[\tan^{-1}\left(\frac{\sqrt{5}}{2}\right)\right]$

72. $\tan\left[\cos^{-1}\left(\frac{\sqrt{23}}{12}\right)\right]$

73. $\cot\left[\arcsin\left(\frac{3x}{5}\right)\right]$

74. $\tan\left[\operatorname{arcsec}\left(\frac{5}{2x}\right)\right]$

75. $\cos\left[\sin^{-1}\left(\frac{x}{\sqrt{12+x^2}}\right)\right]$

76. $\tan\left[\sec^{-1}\left(\frac{\sqrt{9+x^2}}{x}\right)\right]$

Use the tables given prior to Exercise 7 to help fill in each blank.

77.

$\sec 0 = 1$	$\sec^{-1}1 =$ ____
$\sec\left(\frac{\pi}{3}\right) =$ ____	$\operatorname{arcsec} 2 = \frac{\pi}{3}$
$\sec(-30°) = \frac{2}{\sqrt{3}}$	$\operatorname{arcsec}\left(\frac{2}{\sqrt{3}}\right) =$ ____
$\sec(\pi) =$ ____	$\sec^{-1}(-1) = \pi$

78.

$\sec(-60°) = 2$	$\operatorname{arcsec} 2 =$ ____
$\sec\left(\frac{7\pi}{6}\right) = -\frac{2}{\sqrt{3}}$	$\operatorname{arcsec}\left(-\frac{2}{\sqrt{3}}\right) =$ ____
$\sec(-360°) = 1$	$\operatorname{arcsec} 1 =$ ____
$\sec(60°) =$ ____	$\sec^{-1}2 = 60°$

Evaluate using a calculator in degree MODE only as necessary.

79. arccsc 2

80. $\csc^{-1}\left(-\frac{2}{\sqrt{3}}\right)$

81. $\cot^{-1}\sqrt{3}$

82. $\operatorname{arccot}(-1)$

83. arcsec 5.789

84. $\cot^{-1}\left(-\frac{\sqrt{7}}{2}\right)$

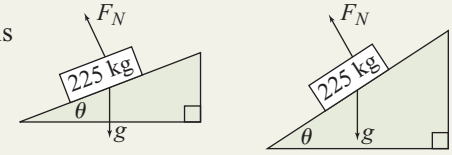
85. $\sec^{-1}\sqrt{7}$

86. arccsc 2.9875

Use the graphing feature of a calculator to determine the interval where the following functions are equivalent to the identity function $y = x$. If necessary, use the TRACE or 2nd TRACE (CALC) features to determine whether or not endpoints should be included.

87. $Y = \cos(\cos^{-1}x)$

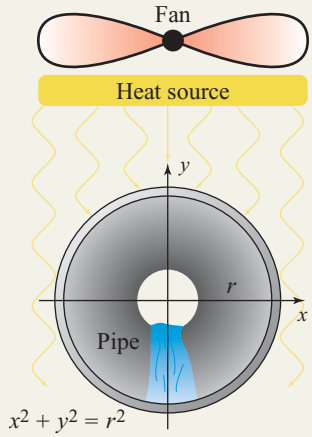
88. $Y = \cos^{-1}(\cos x)$



89. $Y = \tan(\tan^{-1}x)$

90. $Y = \tan^{-1}(\tan x)$

▶ WORKING WITH FORMULAS



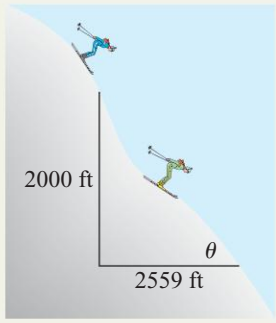
91. The force normal to an object on an inclined plane: $F_N = mg\cos\theta$

When an object is on an inclined plane, the **normal force** is the force acting perpendicular to the plane and away from the force of gravity, and is measured in a unit called **newtons (N).** The magnitude of this force depends on the angle of incline of the plane according to the formula above, where m is the mass of the object in kilograms and g is the force of gravity (9.8 m/sec^2). Given $m = 225$ g, find (a) F_N for $\theta = 15°$ and $\theta = 45°$ and (b) θ for $F_N = 1$ N and $F_N = 2$ N.

92. Heat flow on a cylindrical pipe: $T = (T_0 - T_R)\sin\left(\frac{y}{\sqrt{x^2+y^2}}\right) + T_R;\ y \geq 0$

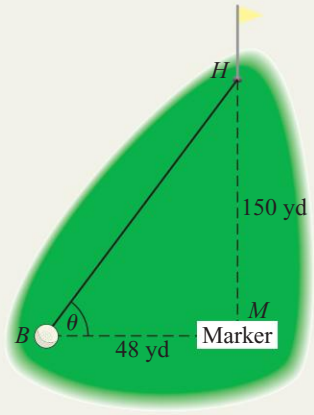
When a circular pipe is exposed to a fan-driven source of heat, the temperature of the air reaching the pipe is greatest at the point nearest to the source (see diagram). As you move around the circumference of the pipe away from the source, the temperature of the air reaching the pipe gradually decreases. One possible model of this phenomenon is given by the formula shown, where T is the temperature of the air at a point (x, y) on the circumference of a pipe with outer radius $r = \sqrt{x^2+y^2}$, T_0 is the temperature of the air at the source, and T_R is the surrounding room temperature. Assuming $T_0 = 220°$F, $T_R = 72°$ and $r = 5$ cm: (a) Find the temperature of the air at the points (0, 5), (3, 4), (4, 3), (4.58, 2), and (4.9, 1). (b) Why is the temperature decreasing for this sequence of points? (c) Simplify the formula using $r = 5$ and use it to find two points on the pipe's circumference where the temperature of the air is 113°.

▶ APPLICATIONS



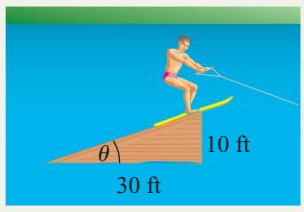
93. Snowcone dimensions: *Made in the Shade Snowcones* sells a colossal size cone that uses a conical cup holding 20 oz of ice and liquid. The cup is 20 cm tall and has a radius of 5.35 cm. Find the angle θ formed by a cross-section of the cup.

Exercise 93



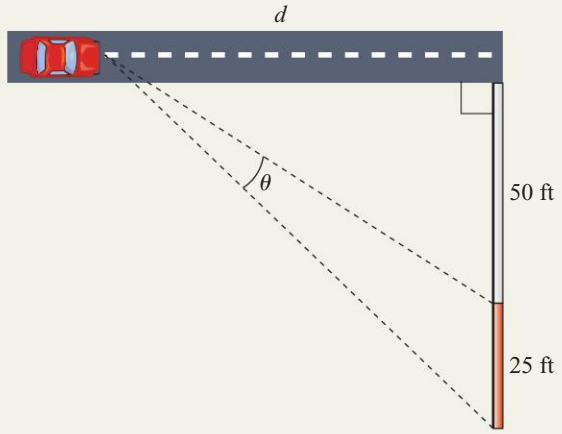
94. Avalanche conditions: Winter avalanches occur for many reasons, one being the slope of the mountain. Avalanches seem to occur most often for slopes between 35° and 60° (snow gradually slides off steeper slopes). The slopes at a local ski resort have an average rise of 2000 ft for each horizontal run of 2559 ft. Is this resort prone to avalanches? Find the angle θ and respond.

Exercise 94



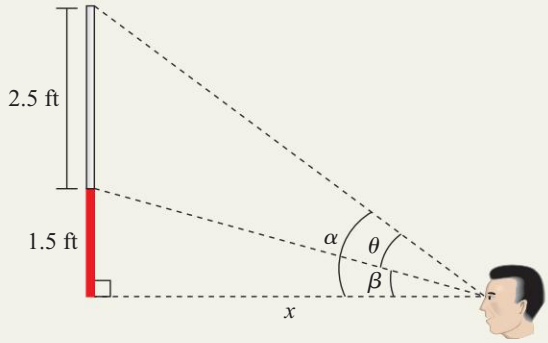
95. Distance to hole: A popular story on the PGA Tour has Gerry Yang, Tiger Woods' teammate at Stanford and occasional caddie, using the Pythagorean theorem to find the distance Tiger needed to reach a particular hole. Suppose you notice a marker in the ground stating that the straight-line distance from the marker to the hole (H) is 150 yd. If your ball B is 48 yd from the marker (M) and angle BMH is a right angle, determine the angle θ and *your* straight-line distance from the hole.

Exercise 95



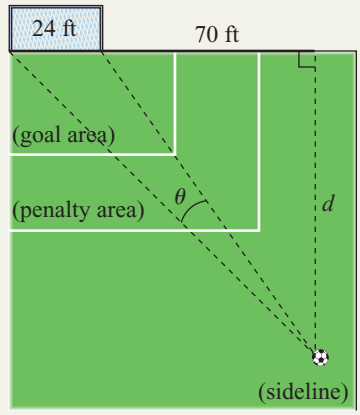
96. Ski jumps: At a waterskiing contest on a large lake, skiers use a ramp rising out of the water that is 30 ft long and 10 ft high at the high end. What angle θ does the ramp make with the lake?

Exercise 96



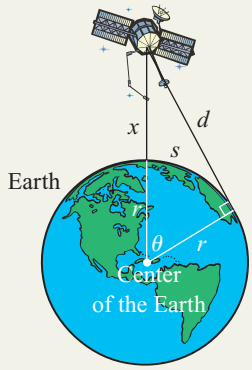
97. Viewing angles for advertising: A 25-ft-wide billboard is erected perpendicular to a straight highway, with the closer edge 50 ft away (see figure). Assume the advertisement on the billboard is most easily read when the viewing angle is 10.5° or more. (a) Use inverse functions to find an expression for the viewing angle θ. (b) Use a calculator to help determine the distance d (to tenths of a foot) for which the viewing angle is greater than 10.5°. (c) What distance d maximizes this viewing angle?

Exercise 97



98. Viewing angles at an art show: At an art show, a painting 2.5 ft in height is hung on a wall so that its base is 1.5 ft above the eye level of an average viewer (see figure). (a) Use inverse functions to find expressions for angles α and β. (b) Use the result to find an expression for the *viewing angle* θ. (c) Use a calculator to help determine the distance x (to tenths of a foot) that maximizes this viewing angle.

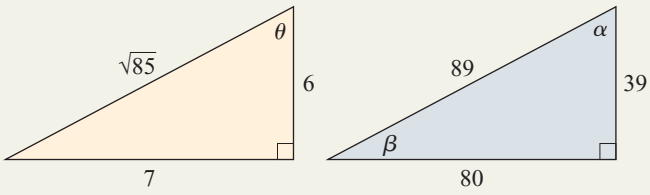
Exercise 98



99. Shooting angles and shots on goal: A soccer player is on a breakaway and is dribbling just inside the right sideline toward the opposing goal (see figure). As the defense closes in, she has just a few seconds to decide when to shoot. (a) Use inverse functions to find an expression for the shooting angle θ. (b) Use a calculator to help determine the distance d (to tenths of a foot) that will maximize the shooting angle for the dimensions shown.

▶ EXTENDING THE CONCEPT

Consider a satellite orbiting at an altitude of x mi above Earth. The distance d from the satellite to the horizon and the length s of the corresponding arc of Earth are shown in the diagram.



100. To find the distance d we use the formula $d = \sqrt{2rx + x^2}$. (a) Show how this formula was developed using the Pythagorean theorem. (b) Find a formula for the angle θ in terms of r and x, then a formula for the arc length s.

101. If Earth has a radius of 3960 mi and the satellite is orbiting at an altitude of 150 mi, (a) what is the measure of angle θ? (b) how much longer is d than s?

▶ MAINTAINING YOUR SKILLS

102. (7.4) Use the triangle given with a double-angle identity to find the exact value of $\sin(2\theta)$.

103. (7.3) Use the triangle given with a sum identity to find the exact value of $\sin(\alpha + \beta)$.

104. (4.6) Solve the inequality $f(x) \leq 0$ using zeroes and end-behavior given $f(x) = x^3 - 9x$.

105. (1.4) In 2000, Space Tourists Inc. sold 28 low-orbit travel packages. By 2005, yearly sales of the low-orbit package had grown to 105. Assuming the growth is linear, (a) find the equation that models this growth ($2000 \rightarrow t = 0$), (b) discuss the meaning of the slope in this context, and (c) use the equation to project the number of packages that were sold in 2010.

7.6 Solving Basic Trig Equations

LEARNING OBJECTIVES

In Section 7.6 you will see how we can:

- ❑ **A.** Use a graph to gain information about principal roots, roots in $[0, 2\pi)$, and roots in $\mathbb{R}$
- ❑ **B.** Use inverse functions to solve trig equations for the principal root
- ❑ **C.** Solve trig equations for roots in $[0, 2\pi)$ or $[0, 360°)$
- ❑ **D.** Solve trig equations for roots in $\mathbb{R}$

In this section, we'll take the elements of basic equation solving and use them to help solve **trig equations,** or equations containing trigonometric functions. All of the algebraic techniques previously used can be applied to these equations, including the properties of equality and all forms of factoring (common terms, difference of squares, etc.). As with polynomial equations, we continue to be concerned with the *number of solutions* as well as with the *solutions themselves,* but there is one major difference. There is no "algebra" that can transform a function like $\sin x = \frac{1}{2}$ into $x = solution$. For that we rely on the inverse trig functions from Section 7.5.

A. The Principal Root, Roots in $[0, 2\pi)$, and Real Roots

In a study of polynomial equations, making a connection between the degree of an equation, its graph, and its possible roots, helped give insights as to the number, location, and nature of the roots. Similarly, keeping graphs of basic trig functions in mind helps you gain information regarding the solution(s) to trig equations. When solving trig equations, we refer to the solution found using $\sin^{-1}$, $\cos^{-1}$, and $\tan^{-1}$ as the **principal root.** You will alternatively be asked to find (1) the principal root, (2) solutions in $[0, 2\pi)$ or $[0°, 360°)$, and (3) solutions from the set of real numbers $\mathbb{R}$. For convenience, graphs of the basic sine, cosine, and tangent functions are repeated in Figures 7.40 through 7.42. Take a mental snapshot of them and keep them close at hand.

Figure 7.40

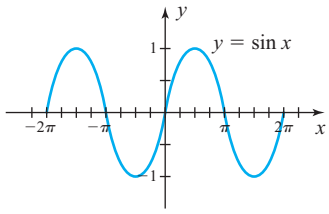


Figure 7.41

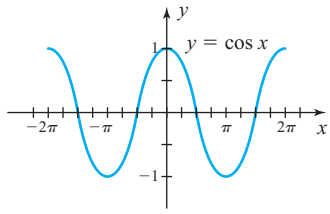

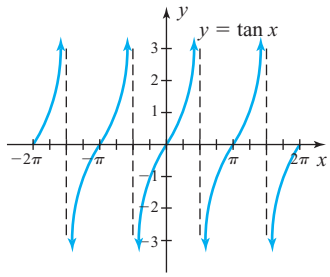

Figure 7.42

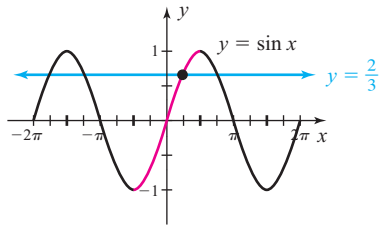
EXAMPLE 1 ▶ **Visualizing Solutions Graphically**



Consider the equation $\sin x = \frac{2}{3}$. Using a graph of $y = \sin x$ and $y = \frac{2}{3}$,

a. state the quadrant of the principal root.

b. state the number of roots in $[0, 2\pi)$ and their quadrants.

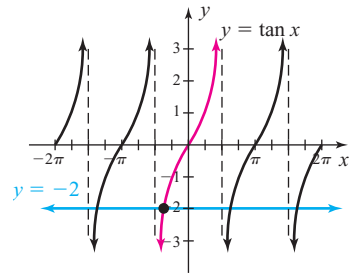
c. comment on the number of real roots.

Solution ▶ We begin by drawing a quick sketch of $y = \sin x$ and $y = \frac{2}{3}$, noting that solutions will occur where the graphs intersect.

a. The sketch shows the principal root occurs between 0 and $\frac{\pi}{2}$ in QI.

b. For $[0, 2\pi)$ we note the graphs intersect twice and there will be two solutions in this interval, one in QI and one in QII.

c. Since the graphs of $y = \sin x$ and $y = \frac{2}{3}$ extend infinitely in both directions, they will intersect an infinite number of times—*but at regular intervals!* Once a root is found, adding integer multiples of 2π (the period of sine) to this root will give the location of additional roots.



WORTHY OF NOTE

Note that we refer to $\left(0, \frac{\pi}{2}\right)$ as Quadrant I or QI, regardless of whether we're discussing the unit circle or the graph of the function. In Example 1(b), the solutions correspond to those found in QI and QII on the unit circle, where $\sin x$ is also positive.

Now try Exercises 7 through 10 ▶

When this process is applied to the equation $\tan x = -2$, the graph shows the principal root occurs between $-\frac{\pi}{2}$ and 0 in QIV (see Figure 7.43). In the interval $[0, 2\pi)$ the graphs intersect twice, in QII and QIV where $\tan x$ is negative (graphically—below the x-axis). As in Example 1, the graphs continue infinitely and will intersect an infinite number of times—*but again at regular intervals!* Once a root is found, adding integer multiples of π (the period of tangent) to this root will give the location of other roots.

Figure 7.43

☑ **A.** You've just seen how we can use a graph to gain information about principal roots, roots in $[0, 2\pi)$, and roots in $\mathbb{R}$

B. Inverse Functions and Principal Roots

To solve equations having a single variable term, the basic goal is to isolate the variable term and apply the inverse function or operation. This is true for algebraic equations like $2x - 1 = 0$, $2\sqrt{x} - 1 = 0$, or $2x^2 - 1 = 0$, and for trig equations like $2 \sin x - 1 = 0$. In each case we would add 1 to both sides, divide by 2, then apply the appropriate inverse. When the inverse trig functions are applied, the result is only the principal root and other solutions may exist depending on the interval under consideration.

EXAMPLE 2 ▶ **Finding Principal Roots**

Find the principal root of $\sqrt{3} \tan x - 1 = 0$.

Solution ▶ We begin by isolating the variable term, then apply the inverse function.

$$\sqrt{3} \tan x - 1 = 0 \qquad \text{given equation}$$

$$\tan x = \frac{1}{\sqrt{3}} \qquad \text{add 1 and divide by } \sqrt{3}$$

$$\tan^{-1}(\tan x) = \tan^{-1}\left(\frac{1}{\sqrt{3}}\right) \qquad \text{apply inverse tangent to both sides}$$

$$x = \frac{\pi}{6} \qquad \text{result (exact form)}$$

Now try Exercises 11 through 28 ▶

☑ **B.** You've just seen how we can use inverse functions to solve trig equations for the principal root

Table 7.2

θ	$\sin\theta$	$\cos\theta$
0	0	1
$\frac{\pi}{6}$	$\frac{1}{2}$	$\frac{\sqrt{3}}{2}$
$\frac{\pi}{4}$	$\frac{\sqrt{2}}{2}$	$\frac{\sqrt{2}}{2}$
$\frac{\pi}{3}$	$\frac{\sqrt{3}}{2}$	$\frac{1}{2}$
$\frac{\pi}{2}$	1	0
$\frac{2\pi}{3}$	$\frac{\sqrt{3}}{2}$	$-\frac{1}{2}$
$\frac{3\pi}{4}$	$\frac{\sqrt{2}}{2}$	$-\frac{\sqrt{2}}{2}$
$\frac{5\pi}{6}$	$\frac{1}{2}$	$-\frac{\sqrt{3}}{2}$
π	0	-1

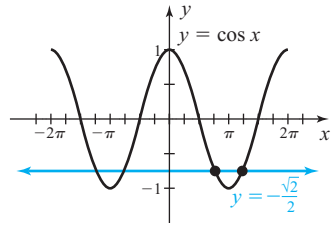
Equations like the one in Example 2 demonstrate the need to be *very* familiar with the functions of special angles. They are frequently used in equations and applications to ensure results don't get so messy they obscure the main ideas. For convenience, the values of $\sin\theta$ and $\cos\theta$ are repeated in Table 7.2 for $\theta \in [0, \pi]$. Using symmetry and the appropriate sign, the table can easily be extended to all values in $[0, 2\pi)$. Using the reciprocal and ratio relationships, values for the other trig functions can also be found.

C. Solving Trig Equations for Roots in $[0, 2\pi)$ or $[0°, 360°)$

To find multiple solutions to a trig equation, we simply take the reference angle of the principal root, and *use this angle to find all solutions* within a specified range. A mental image of the graph still guides us, and the standard table of values (also held in memory) allows for a quick solution to many equations.

EXAMPLE 3 ▶ **Finding Solutions in $[0, 2\pi)$**

For $2\cos\theta + \sqrt{2} = 0$, find all solutions in $[0, 2\pi)$.



Solution ▶ Isolate the variable term, then apply the inverse function.

$$2\cos\theta + \sqrt{2} = 0 \qquad \text{given equation}$$
$$\cos\theta = -\frac{\sqrt{2}}{2} \qquad \text{subtract } \sqrt{2} \text{ and divide by 2}$$
$$\cos^{-1}(\cos\theta) = \cos^{-1}\left(-\frac{\sqrt{2}}{2}\right) \qquad \text{apply inverse cosine to both sides}$$
$$\theta = \frac{3\pi}{4} \qquad \text{result}$$

WORTHY OF NOTE

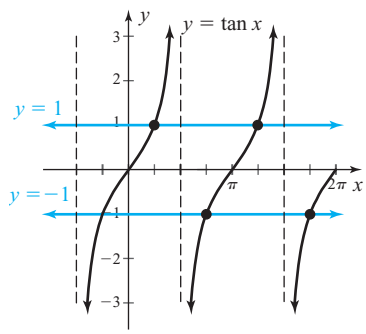
Note how the graph of a trig function displays the information regarding *quadrants*. From the graph of $y = \cos x$ we "read" that cosine is negative in QII and QIII [the lower "hump" of the graph is below the x-axis in $(\pi/2, 3\pi/2)$] and positive in QI and QIV [the graph is above the x-axis in the intervals $(0, \pi/2)$ and $(3\pi/2, 2\pi)$].

With $\frac{3\pi}{4}$ as the principal root, we know $\theta_r = \frac{\pi}{4}$. Since $\cos x$ is negative in QII and QIII, the second solution is $\frac{5\pi}{4}$. The second solution could also have been found from memory, recognition, or symmetry on the unit circle. Our (mental) graph verifies these are the only solutions in $[0, 2\pi)$.

Now try Exercises 29 through 34 ▶

EXAMPLE 4 ▶ **Finding Solutions in $[0, 2\pi)$**

For $\tan^2 x - 1 = 0$, find all solutions in $[0, 2\pi)$.



Solution ▶ As with the other equations having a single variable term, we try to isolate this term or attempt a solution by factoring.

$$\tan^2 x - 1 = 0 \qquad \text{given equation}$$
$$\sqrt{\tan^2 x} = \pm\sqrt{1} \qquad \text{add 1 to both sides and take square roots}$$
$$\tan x = \pm 1 \qquad \text{result}$$

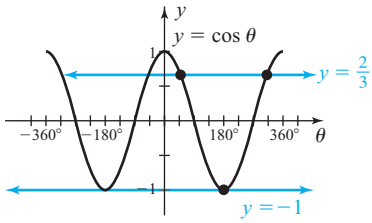
The algebra gives $\tan x = 1$ or $\tan x = -1$ and we solve each equation independently.

$$\tan x = 1 \qquad \tan x = -1$$
$$\tan^{-1}(\tan x) = \tan^{-1}(1) \qquad \tan^{-1}(\tan x) = \tan^{-1}(-1) \qquad \text{apply inverse tangent}$$
$$x = \frac{\pi}{4} \qquad x = -\frac{\pi}{4} \qquad \text{principal roots}$$

Of the principal roots, only $x = \frac{\pi}{4}$ is in the specified interval. With $\tan x$ positive in QI and QIII, a second solution is $\frac{5\pi}{4}$. While $x = -\frac{\pi}{4}$ is not in the interval, we still use it as a reference to identify the angles in QII and QIV (for $\tan x = -1$) and find the solutions $x = \frac{3\pi}{4}$ and $\frac{7\pi}{4}$. The four solutions are $x = \frac{\pi}{4}, \frac{3\pi}{4}, \frac{5\pi}{4}$, and $\frac{7\pi}{4}$, which is supported by the graph shown.

Now try Exercises 35 through 42 ▶

For any trig function that is not equal to a standard value, we can use a calculator to approximate the principal root or leave the result in exact form, and apply the same ideas to this root to find all solutions in the interval.



EXAMPLE 5 ▶ Finding Solutions in [0°, 360°)

Find all solutions in $[0°, 360°)$ for $3\cos^2\theta + \cos\theta - 2 = 0$.

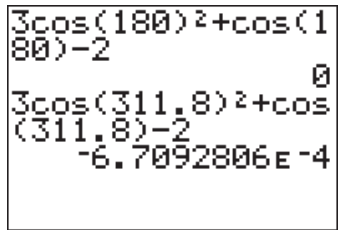
Solution ▶ Use a u-substitution to simplify the equation and help select an appropriate strategy. For $u = \cos\theta$, the equation becomes $3u^2 + u - 2 = 0$ and factoring seems the best approach. The factored form is $(u + 1)(3u - 2) = 0$, with solutions $u = -1$ and $u = \frac{2}{3}$. Re-substituting $\cos\theta$ for u gives

$\cos\theta = -1$	$\cos\theta = \frac{2}{3}$	equations from factored form
$\cos^{-1}(\cos\theta) = \cos^{-1}(-1)$	$\cos^{-1}(\cos\theta) = \cos^{-1}\left(\frac{2}{3}\right)$	apply inverse cosine
$\theta = 180°$	$\theta \approx 48.2°$	principal roots

Figure 7.44

Both principal roots are in the specified interval. The first is quadrantal, the second was found using a calculator and is approximately 48.2°. With $\cos\theta$ positive in QI and QIV, a second solution is $(360 - 48.2)° = 311.8°$. The three solutions seen in Figure 7.44 are 48.2°, 180°, and 311.8° although only $\theta = 180°$ is exact. With the calculator still in **degree** MODE, the solutions $\theta = 180°$ and $\theta \approx 311.8°$ are verified in Figure 7.45. While we may believe the second calculation is not *exactly* zero due to round-off error, a more satisfactory check can be obtained by storing the result of $360 - \cos^{-1}(\frac{2}{3})$ as X, and using $3\cos(X)^2 + \cos(X) - 2$, as shown in Figure 7.46.

Figure 7.45



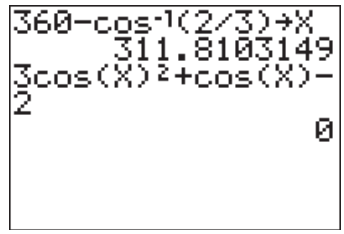


Figure 7.46

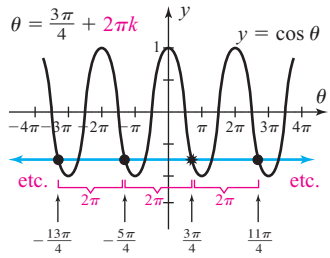
☑ **C.** You've just seen how we can solve trig equations for roots in $[0, 2\pi)$ or $[0, 360°)$

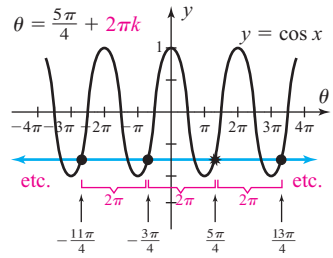
Now try Exercises 43 through 50 ▶

D. Solving Trig Equations for All Real Roots ($\mathbb{R}$)

As we noted, the intersections of a trig function with a horizontal line occur at regular, *predictable* intervals. This makes finding solutions from the set of real numbers a simple matter of extending the solutions we found in $[0, 2\pi)$ or $[0°, 360°)$. To illustrate, consider the solutions to Example 3. For $2\cos\theta + \sqrt{2} = 0$, we found the solutions $\theta = \frac{3\pi}{4}$ and $\theta = \frac{5\pi}{4}$. For solutions in $\mathbb{R}$, we note the "predictable interval" between roots *is identical to the period of the function.* This means all real solutions will be represented by $\theta = \frac{3\pi}{4} + 2\pi k$ and $\theta = \frac{5\pi}{4} + 2\pi k$, $k \in \mathbb{Z}$ (k is an integer). Both are illustrated in Figures 7.47 and 7.48 with the primary solution indicated with a *.

Figure 7.47





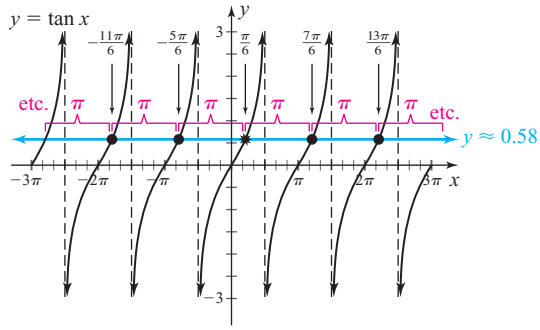


Figure 7.48

EXAMPLE 6 ▶ **Finding Solutions in ℝ**

Find all real solutions to $\sqrt{3}\tan x - 1 = 0$.

Solution ▶ In Example 2 we found the principal root was $x = \frac{\pi}{6}$. Since the tangent function has a period of π, adding integer multiples of π to this root will identify all solutions:

$x = \frac{\pi}{6} + \pi k$, $k \in \mathbb{Z}$, as illustrated here.

Now try Exercises 51 through 56 ▶

These fundamental ideas can be extended to many different situations. When asked to find *all real solutions,* be sure you find all roots in a stipulated interval before naming solutions by applying the period of the function. For instance, $\cos x = 0$ has two solutions in $[0, 2\pi)$ $\left[x = \frac{\pi}{2} \text{ and } x = \frac{3\pi}{2}\right]$, which we can quickly extend to find all real roots. But using $x = \cos^{-1}0$ or a calculator limits us to the single (principal) root $x = \frac{\pi}{2}$, and we'd miss all solutions stemming from $\frac{3\pi}{2}$. Note that solutions involving multiples of an angle (or fractional parts of an angle) should likewise be "handled with care," as in Example 7.

EXAMPLE 7 ▶ **Finding Solutions in ℝ**

Find all real solutions to $2\sin(2x)\cos x - \cos x = 0$.

Solution ▶ Since we have a common factor of $\cos x$, we begin by rewriting the equation as $\cos x[2\sin(2x) - 1] = 0$ and solve using the zero factor property. The resulting equations are $\cos x = 0$ and $2\sin(2x) - 1 = 0 \rightarrow \sin(2x) = \frac{1}{2}$.

$$\cos x = 0 \qquad \sin(2x) = \frac{1}{2} \quad \text{equations from factored form}$$

WORTHY OF NOTE

When solving trig equations that involve arguments other than a single variable, a u-substitution is sometimes used. For Example 7, substituting u for $2x$ gives the equation $\sin u = \frac{1}{2}$, making it "easier to see" that $u = \frac{\pi}{6}$ (since $\frac{1}{2}$ is a special value), and therefore $2x = \frac{\pi}{6}$ and $x = \frac{\pi}{12}$.

In $[0, 2\pi)$, $\cos x = 0$ has solutions $x = \frac{\pi}{2}$ and $x = \frac{3\pi}{2}$, giving $x = \frac{\pi}{2} + 2\pi k$ and $x = \frac{3\pi}{2} + 2\pi k$ as solutions in $\mathbb{R}$. Note these can actually be combined and written as $x = \frac{\pi}{2} + \pi k$, $k \in \mathbb{Z}$. For $\sin(2x) = \frac{1}{2}$ we know that $\sin u$ is positive in QI and QII, and the reference angle for $\sin u = \frac{1}{2}$ is $\frac{\pi}{6}$. This yields the solutions $u = \frac{\pi}{6}$(QI) and $u = \frac{5\pi}{6}$(QII), or in this case $2x = \frac{\pi}{6}$ and $2x = \frac{5\pi}{6}$. Since we seek all real roots, *we first extend each solution by* $2\pi k$ before dividing by 2, otherwise multiple solutions would be overlooked.

$$2x = \frac{\pi}{6} + 2\pi k \qquad 2x = \frac{5\pi}{6} + 2\pi k \qquad \text{solutions from } \sin(2x) = \tfrac{1}{2};\ k \in \mathbb{Z}$$

$$x = \frac{\pi}{12} + \pi k \qquad x = \frac{5\pi}{12} + \pi k \qquad \text{divide by 2}$$

Now try Exercises 57 through 66 ▶

In the process of solving trig equations, we sometimes employ fundamental identities to help simplify an equation, or to make factoring or some other method possible.

EXAMPLE 8 ▶ Solving Trig Equations Using an Identity

Find all real solutions for $\cos(2x) + \sin^2 x - 3\cos x = 1$.

Solution ▶

With a mixture of functions, exponents, and arguments, the equation is almost impossible to solve as it stands. But we can eliminate the sine function using the identity $\cos(2x) = \cos^2 x - \sin^2 x$, leaving a quadratic equation in $\cos x$.

$$\begin{aligned}
\cos(2x) + \sin^2 x - 3\cos x &= 1 && \text{given equation}\\
\cos^2 x - \sin^2 x + \sin^2 x - 3\cos x &= 1 && \text{substitute } \cos^2 x - \sin^2 x \text{ for } \cos(2x)\\
\cos^2 x - 3\cos x &= 1 && \text{combine like terms}\\
\cos^2 x - 3\cos x - 1 &= 0 && \text{subtract 1}
\end{aligned}$$

Let's substitute u for $\cos x$ to give us a simpler view of the equation. This gives $u^2 - 3u - 1 = 0$, which is clearly not factorable over the integers. Using the quadratic formula with $a = 1$, $b = -3$, and $c = -1$ gives

$$\begin{aligned}
u &= \frac{3 \pm \sqrt{(-3)^2 - 4(1)(-1)}}{2(1)} && \text{quadratic formula in } u\\
&= \frac{3 \pm \sqrt{13}}{2} && \text{simplified}
\end{aligned}$$

To four decimal places we have $u \approx 3.3028$ and $u \approx -0.3028$. To answer in terms of the original variable we re-substitute $\cos x$ for u, realizing that $\cos x \approx 3.3028$ has no solution, so solutions in $[0, 2\pi)$ must be provided by $\cos x \approx -0.3028$ and will occur in QII and QIII. The primary solutions are $x = \cos^{-1}(-0.3028) \approx 1.8784$ and $2\pi - 1.8784 \approx 4.4048$ rounded to four decimal places, so all real solutions are given by $x \approx 1.8784 + 2\pi k$ and $x \approx 4.4048 + 2\pi k$.

Now try Exercises 67 through 82 ▶

The **TABLE** feature of a calculator in radian (MODE) can partially (yet convincingly) verify the solutions to Example 8. On the (Y=) screen, enter $Y_1 = 4.4048 + 2\pi X$. This expression is then used in place of X when the left-hand side of the original equation is entered as Y_2 (see Figure 7.49). After using the **TBLSET** screen to set TblStart = 0 and ΔTbl = 1, the keystrokes (2nd) (GRAPH) **(TABLE)** will produce the table shown in Figure 7.50. Note the values in the Y_2 column are all very close to 1 (the right-hand side of the original equation), implying the Y_1 values are solutions.

Figure 7.49

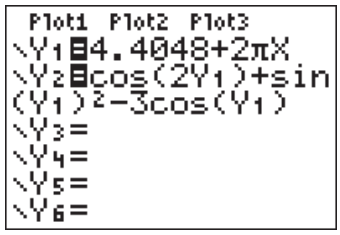

Figure 7.50

X	Y1	Y2

☑ **D.** You've just seen how we can solve trig equations for roots in $\mathbb{R}$

7.6 EXERCISES

▶ CONCEPTS AND VOCABULARY

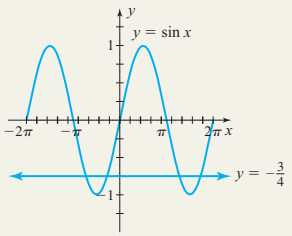
Fill in each blank with the appropriate word or phrase. Carefully reread the section if necessary.

1. For simple equations, a mental graph will tell us the quadrant of the _____ root, the number of roots in _____, and show a pattern for all _____ roots.

2. Solving trig equations is similar to solving algebraic equations, in that we first _____ the variable term, then apply the appropriate _____ function.

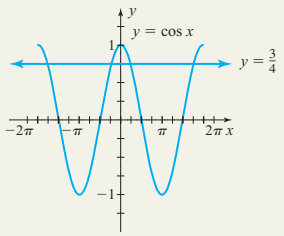
3. For $\sin x = \dfrac{\sqrt{2}}{2}$ the principal root is _____, solutions in $[0, 2\pi)$ are _____ and _____, and an expression for all real roots is _____ and _____; $k \in \mathbb{Z}$.

4. For $\tan x = -1$, the principal root is _____, solutions in $[0, 2\pi)$ are _____ and _____, and an expression for all real roots is _____.



5. Discuss/Explain/Illustrate why $\tan x = \dfrac{3}{4}$ and $\cos x = \dfrac{3}{4}$ have two solutions in $[0, 2\pi)$, even though the period of $y = \tan x$ is π, while the period of $y = \cos x$ is 2π.

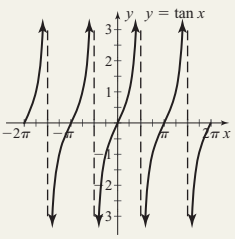
6. The equation $\sin^2 x = \dfrac{1}{2}$ has four solutions in $[0, 2\pi)$. Explain how these solutions can be viewed as the vertices of a square inscribed in the unit circle.



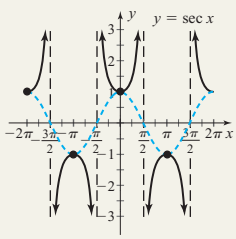
▶ DEVELOPING YOUR SKILLS

7. For the equation $\sin x = -\frac{3}{4}$ and the graphs of $y = \sin x$ and $y = -\frac{3}{4}$ given, state (a) the quadrant of the principal root and (b) the number of roots in $[0, 2\pi)$.

Exercise 7



Exercise 8



8. For the equation $\cos x = \frac{3}{4}$ and the graphs of $y = \cos x$ and $y = \frac{3}{4}$ given, state (a) the quadrant of the principal root and (b) the number of roots in $[0, 2\pi)$.

9. Given the graph $y = \tan x$ shown here, draw the horizontal line $y = -1.5$ and then for $\tan x = -1.5$, state (a) the quadrant of the principal root and (b) the number of roots in $[0, 2\pi)$.

Exercise 9

Exercise 10

10. Given the graph of $y = \sec x$ shown, draw the horizontal line $y = \frac{5}{4}$ and then for $\sec x = \frac{5}{4}$, state (a) the quadrant of the principal root and (b) the number of roots in $[0, 2\pi)$.

11. The table shows θ in multiples of $\frac{\pi}{6}$ between 0 and $\frac{4\pi}{3}$, with the values for $\sin\theta$ given. Complete the table without a calculator or references using your knowledge of the unit circle, the signs of the trig functions in each quadrant, memory/recognition, $\tan\theta = \frac{\sin\theta}{\cos\theta}$, and so on.

Exercise 11

θ	$\sin\theta$	$\cos\theta$	$\tan\theta$
0	0		
$\frac{\pi}{6}$	$\frac{1}{2}$		
$\frac{\pi}{3}$	$\frac{\sqrt{3}}{2}$		
$\frac{\pi}{2}$	1		
$\frac{2\pi}{3}$	$\frac{\sqrt{3}}{2}$		
$\frac{5\pi}{6}$	$\frac{1}{2}$		
π	0		
$\frac{7\pi}{6}$	$-\frac{1}{2}$		
$\frac{4\pi}{3}$	$-\frac{\sqrt{3}}{2}$		

Exercise 12

θ	$\sin\theta$	$\cos\theta$	$\tan\theta$
0		1	
$\frac{\pi}{4}$		$\frac{\sqrt{2}}{2}$	
$\frac{\pi}{2}$		0	
$\frac{3\pi}{4}$		$-\frac{\sqrt{2}}{2}$	
π		-1	
$\frac{5\pi}{4}$		$-\frac{\sqrt{2}}{2}$	
$\frac{3\pi}{2}$		0	
$\frac{7\pi}{4}$		$\frac{\sqrt{2}}{2}$	
2π		1	

12. The table shows θ in multiples of $\frac{\pi}{4}$ between 0 and 2π, with the values for $\cos\theta$ given. Complete the table without a calculator or references using your knowledge of the unit circle, the signs of the trig functions in each quadrant, memory/recognition, $\tan\theta = \frac{\sin\theta}{\cos\theta}$, and so on.

Find the principal root of each equation.

13. $2\cos x = \sqrt{2}$

14. $2\sin x = -1$

15. $-4\sin x = 2\sqrt{2}$

16. $-4\cos x = 2\sqrt{3}$

17. $\sqrt{3}\tan x = 1$

18. $-2\sqrt{3}\tan x = 2$

19. $2\sqrt{3}\sin x = -3$

20. $-3\sqrt{2}\csc x = 6$

21. $-6\cos x = 6$

22. $4\sec x = -8$

23. $\frac{7}{8}\cos x = \frac{7}{16}$

24. $-\frac{5}{3}\sin x = \frac{5}{6}$

25. $2 = 4\sin\theta$

26. $\pi\tan x = 0$

27. $-5\sqrt{3} = 10\cos\theta$

28. $4\sqrt{3} = 4\tan\theta$

Find all solutions in $[0, 2\pi)$.

29. $9\sin x - 3.5 = 1$

30. $6.2\cos x + 4 = 7.1$

31. $8\tan x + 7\sqrt{3} = -\sqrt{3}$

32. $\frac{1}{2}\sec x - \frac{3}{4} = -\frac{7}{4}$

33. $\frac{2}{3}\cot x - \frac{5}{6} = -\frac{3}{2}$

34. $-110 \sin x = -55\sqrt{3}$ **35.** $4 \cos^2 x = 3$

36. $4 \sin^2 x = 1$ **37.** $-7 \tan^2 x = -21$

38. $3 \sec^2 x = 6$ **39.** $-4 \csc^2 x = -8$

40. $6\sqrt{3} \cos^2 x = 3\sqrt{3}$ **41.** $4\sqrt{2} \sin^2 x = 4\sqrt{2}$

42. $\frac{2}{3} \cos^2 x + \frac{5}{6} = \frac{4}{3}$

Solve the following equations by factoring. State all solutions in [0°, 360°). Round to one decimal place if the result is not a standard value.

43. $3 \cos^2\theta + 14 \cos\theta - 5 = 0$

44. $6 \tan^2\theta - 2\sqrt{3} \tan\theta = 0$

45. $2 \cos x \sin x - \cos x = 0$

46. $2 \sin^2 x + 7 \sin x = 4$ **47.** $\sec^2 x - 6 \sec x = 16$

48. $2 \cos^3 x + \cos^2 x = 0$ **49.** $4 \sin^2 x - 1 = 0$

50. $4 \cos^2 x - 3 = 0$

Find all real solutions. Note that identities are not required to solve these exercises.

51. $-2 \sin x = \sqrt{2}$ **52.** $2 \cos x = 1$

53. $-4 \cos x = 2\sqrt{2}$ **54.** $4 \sin x = 2\sqrt{3}$

55. $\sqrt{3} \tan x = -\sqrt{3}$ **56.** $2\sqrt{3} \tan x = 2$

57. $6 \cos(2x) = -3$ **58.** $2 \sin(3x) = -\sqrt{2}$

59. $\sqrt{3} \tan(2x) = -\sqrt{3}$ **60.** $2\sqrt{3} \tan(3x) = 6$

61. $-2\sqrt{3} \cos\left(\frac{1}{3}x\right) = 2\sqrt{3}$

62. $-8 \sin\left(\frac{1}{2}x\right) = -4\sqrt{3}$

63. $\sqrt{2} \cos x \sin(2x) - 3 \cos x = 0$

64. $\sqrt{3} \sin x \tan(2x) - \sin x = 0$

65. $\cos(3x)\csc(2x) - 2 \cos(3x) = 0$

66. $\sqrt{3} \sin(2x) \sec(2x) - 2 \sin(2x) = 0$

Solve each equation using a calculator and inverse trig functions to determine the principal root (not by graphing). Clearly state (a) the principal root and (b) all real roots.

67. $3 \cos x = 1$ **68.** $5 \sin x = -2$

69. $\sqrt{2} \sec x + 3 = 7$ **70.** $\sqrt{3} \csc x + 2 = 11$

71. $\frac{1}{2} \sin(2\theta) = \frac{1}{3}$ **72.** $\frac{2}{5} \cos(2\theta) = \frac{1}{4}$

73. $-5 \cos(2\theta) - 1 = 0$ **74.** $6 \sin(2\theta) - 3 = 2$

Solve the following equations using an identity. State all real solutions in radians using the exact form where possible and rounded to four decimal places if the result is not a standard value.

75. $\cos^2 x - \sin^2 x = \frac{1}{2}$

76. $4 \sin^2 x - 4 \cos^2 x = 2\sqrt{3}$

77. $2 \cos\left(\frac{1}{2}x\right)\cos x - 2 \sin\left(\frac{1}{2}x\right)\sin x = 1$

78. $\sqrt{2} \sin(2x)\cos(3x) + \sqrt{2} \sin(3x)\cos(2x) = 1$

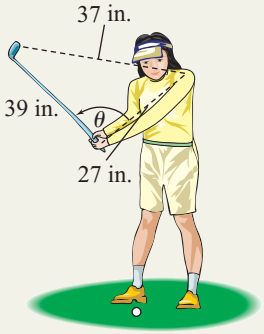
79. $(\cos\theta + \sin\theta)^2 = 1$

80. $(\cos\theta + \sin\theta)^2 = 2$

81. $\cos(2\theta) + 2 \sin^2\theta - 3 \sin\theta = 0$

82. $3 \sin(2\theta) - \cos^2(2\theta) - 1 = 0$

▶ WORKING WITH FORMULAS



83. Range of a projectile: $R = \frac{5}{49} v^2 \sin(2\theta)$

The distance a projectile travels is called its range and is modeled by the formula shown, where R is the range in meters, v is the initial velocity in meters per second, and θ is the angle of release. Two friends are standing 16 m apart playing catch. If the first throw has an initial velocity of 15 m/sec, what *two* angles will ensure the ball travels the 16 m between the friends?

84. Fine-tuning a golf swing: (club head to shoulder)^2 = (club length)^2 + (arm length)^2 − 2 (club length)(arm length)cos θ

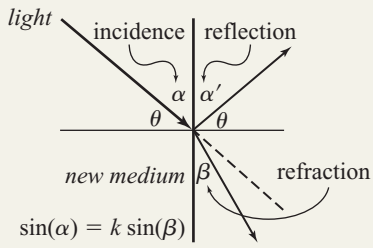
A golf pro is taking specific measurements on a client's swing to help improve her game. If the angle θ is too small, the ball is hit late and "too thin" (you *top the ball*). If θ is too large, the ball is hit early and "too fat" (you *scoop the ball*). Approximate the angle θ formed by the club and the extended (left) arm using the given measurements and formula shown.

Exercise 84

▶ APPLICATIONS

Acceleration due to gravity: When a steel ball is released down an inclined plane, the rate of the ball's acceleration depends on the angle of incline. The acceleration can be approximated by the formula $A(\theta) = 9.8 \sin \theta$, where θ is in degrees and the acceleration is measured in meters per second/per second. To the nearest tenth of a degree,

85. What angle produces an acceleration of 0 m/sec^2 when the ball is released? Explain why this is reasonable.



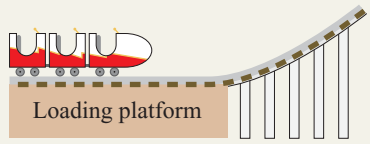
86. What angle produces an acceleration of 9.8 m/sec^2? What does this tell you about the acceleration due to gravity?

87. What angle produces an acceleration of 5 m/sec^2? Will the angle be larger or smaller for an acceleration of 4.5 m/sec^2?

88. Will an angle producing an acceleration of 2.5 m/sec^2 be one-half the angle required for an acceleration of 5 m/sec^2? Explore and discuss.

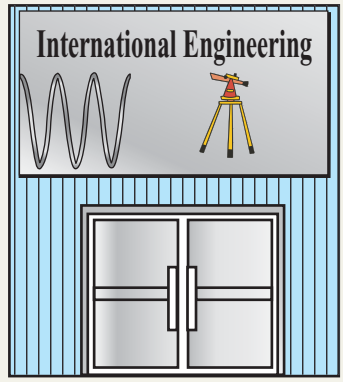
Snell's law states that when a ray of light passes from one medium into another, the sine of the angle of incidence α *varies directly with* the sine of the angle of refraction β (see the figure). This phenomenon is modeled by the formula $\sin \alpha = k \sin \beta$, where k is called the **index of refraction.** Note the angle θ is the angle at which the light strikes the surface, so that $\alpha = 90° - \theta$. Use this information to work Exercises 89 to 92.

Exercises 89 to 92



89. A ray of light passes from air into water, striking the water at an angle of 55°. Find the angle of incidence α and the angle of refraction β, if the index of refraction for water is $k = 1.33$.

90. A ray of light passes from air into a diamond, striking the surface at an angle of 75°. Find the angle of incidence α and the angle of refraction β, if the index of refraction for a diamond is $k = 2.42$.



91. Find the index of refraction for ethyl alcohol if a beam of light strikes the surface of this medium at an angle of 40° and produces an angle of refraction $\beta = 34.3°$. Use this index to find the angle of incidence if a second beam of light created an angle of refraction measuring 15°.

92. Find the index of refraction for rutile (a type of mineral) if a beam of light strikes the surface of this medium at an angle of 30° and produces an angle of refraction $\beta = 18.7°$. Use this index to find the angle of incidence if a second beam of light created an angle of refraction measuring 10°.

93. Roller coaster design: As part of a science fair project, Hadra builds a scale model of a roller coaster using the equation $y = 5 \sin\left(\frac{1}{2}x\right) + 7$, where y is the height of the model in inches and x is the distance from the "loading platform" in inches. (a) How high is the platform? (b) What distances from the platform does the model attain a height of 9.5 in.?

94. Company logo: Part of the logo for an engineering firm was modeled by a cosine function. The logo was then manufactured in steel and installed on the entrance marquee of the home office. The position and size of the logo is modeled by the function $y = 9 \cos x + 15$, where y is the height of the graph above the base of the marquee in inches and x represents the distance from the edge of the marquee. Assume the graph begins flush with the edge. (a) How far above the base is the beginning of the cosine graph? (b) What distances from the edge does the graph attain a height of 19.5 in.?

▶ EXTENDING THE CONCEPT

95. Find all real solutions to $5\cos x - x = -x$ in two ways. First use a calculator with $Y_1 = 5\cos X - X$ and $Y_2 = -X$ to determine the regular intervals between points of intersection. Second, simplify by adding x to both sides, and draw a quick sketch of the result to locate x-intercepts. Explain why both methods give the same result, even though the first presents you with a very different graph.

96. Once the fundamental ideas of solving a given family of equations are understood and practiced, a student usually begins to generalize them—making the numbers or symbols used in the equation irrelevant. (a) Use the inverse sine function to find the principal root of $y = A\sin(Bx - C) + D$, by solving for x in terms of y, A, B, C, and D. (b) Solve the following equation using the techniques addressed in this section, and then using the "formula" from part (a): $5 = 2\sin\left(\frac{1}{2}x + \frac{\pi}{4}\right) + 3$. Do the results agree?

▶ MAINTAINING YOUR SKILLS

97. (3.1) Use a substitution to show that $x = 2 + i$ is a zero of $f(x) = x^2 - 4x + 5$.

98. (3.3) Currently, tickets to productions of the Shakespeare Community Theater cost \$10.00, with an average attendance of 250 people. Due to market research, the theater director believes that for each \$0.50 reduction in price, 25 more people will attend. What ticket price will maximize the theater's revenue? What will the average attendance projected to become at that price?

99. (7.5) Evaluate without using a calculator:

a. $\tan\left[\sin^{-1}\left(-\frac{1}{2}\right)\right]$ **b.** $\sin[\tan^{-1}(-1)]$

100. (6.1) The largest Ferris wheel in the world, located in Yokohama, Japan, has a radius of 50 m. To the nearest hundredth of a meter, how far does a seat on the rim travel as the wheel turns through $\theta = 292.5°$?

7.7 General Trig Equations and Applications

LEARNING OBJECTIVES

In Section 7.7 you will see how we can:

- ❑ **A.** Use additional algebraic techniques to solve trig equations
- ❑ **B.** Solve trig equations using multiple angle, sum and difference, and sum-to-product identities
- ❑ **C.** Solve trig equations using graphing technology
- ❑ **D.** Solve trig equations of the form $A\sin(Bx + C) + D = k$
- ❑ **E.** Use a combination of skills to model and solve a variety of applications

At this point you're likely beginning to understand the true value of trigonometry to the scientific world. Essentially, any phenomenon that is cyclic or periodic is beyond the reach of polynomial (and other) functions, and may require trig for an accurate understanding. And while there is an abundance of trig applications in oceanography, astronomy, meteorology, geology, zoology, and engineering, their value is not limited to the hard sciences. There are also rich applications in business and economics, and a growing number of modern artists are creating works based on attributes of the trig functions. In this section, we try to place some of these applications within your reach, with the Exercise Set offering an appealing variety from many of these fields.

A. Trig Equations and Algebraic Methods

We begin this section with a follow-up to Section 7.6, by introducing trig equations that require slightly more sophisticated methods to work out a solution.

EXAMPLE 1 ▶ **Solving a Trig Equation by Squaring Both Sides**

Find all solutions in $[0, 2\pi)$: $\sec x + \tan x = \sqrt{3}$.

Solution ▶ Our first instinct might be to rewrite the equation in terms of sine and cosine, but that simply leads to a similar equation that still has two different functions $[\sqrt{3}\cos x - \sin x = 1]$. Instead, we *square both sides* and see if the Pythagorean identity $1 + \tan^2 x = \sec^2 x$ will be of use. Prior to squaring, we separate the functions on opposite sides to avoid the mixed term $2 \tan x \sec x$.

$$\begin{aligned} \sec x + \tan x &= \sqrt{3} && \text{given equation} \\ (\sec x)^2 &= (\sqrt{3} - \tan x)^2 && \text{subtract } \tan x \text{ and square} \\ \sec^2 x &= 3 - 2\sqrt{3}\tan x + \tan^2 x && \text{result} \end{aligned}$$

Since $\sec^2 x = 1 + \tan^2 x$, we substitute directly and obtain an equation in tangent alone.

$$\begin{aligned} 1 + \tan^2 x &= 3 - 2\sqrt{3}\tan x + \tan^2 x && \text{substitute } 1 + \tan^2 x \text{ for } \sec^2 x \\ -2 &= -2\sqrt{3}\tan x && \text{simplify} \\ \frac{1}{\sqrt{3}} &= \tan x && \text{solve for } \tan x \end{aligned}$$

$\tan x > 0$ in QI and QIII

The proposed solutions are $x = \frac{\pi}{6}$ [QI] and $\frac{7\pi}{6}$ [QIII]. Since squaring an equation sometimes introduces extraneous roots, both should be checked in the original equation. The check shows only $x = \frac{\pi}{6}$ is a solution.

Now try Exercises 7 through 12 ▶

Here is one additional example that uses a factoring strategy commonly employed when an equation has more than three terms.

EXAMPLE 2 ▶ **Solving a Trig Equation by Factoring**

Find all solutions in $[0°, 360°)$: $8\sin^2\theta\cos\theta - 2\cos\theta - 4\sin^2\theta + 1 = 0$.

Solution ▶ The four terms in the equation share no common factors, so we attempt to factor by grouping. We could factor $2\cos\theta$ from the first two terms but instead elect to group the $\sin^2\theta$ terms and begin there.

$$\begin{aligned} 8\sin^2\theta\cos\theta - 2\cos\theta - 4\sin^2\theta + 1 &= 0 && \text{given equation} \\ (8\sin^2\theta\cos\theta - 4\sin^2\theta) - (2\cos\theta - 1) &= 0 && \text{rearrange and group terms} \\ 4\sin^2\theta(2\cos\theta - 1) - 1(2\cos\theta - 1) &= 0 && \text{remove common factors} \\ (2\cos\theta - 1)(4\sin^2\theta - 1) &= 0 && \text{remove common binomial factors} \end{aligned}$$

Using the zero factor property, we write two equations and solve each independently.

$2\cos\theta - 1 = 0$	$4\sin^2\theta - 1 = 0$	resulting equations
$2\cos\theta = 1$	$\sin^2\theta = \frac{1}{4}$	isolate variable term
$\cos\theta = \frac{1}{2}$	$\sin\theta = \pm\frac{1}{2}$	solve
$\cos\theta > 0$ in QI and QIV	$\sin\theta > 0$ in QI and QII	
$\theta = 60°, 300°$	$\sin\theta < 0$ in QIII and QIV	
	$\theta = 30°, 150°, 210°, 330°$	solutions

Initially factoring $2\cos\theta$ from the first two terms and proceeding from there would have produced the same result.

Now try Exercises 13 through 16 ▶

A. You've just seen how we can use additional algebraic techniques to solve trig equations

B. Solving Trig Equations Using Various Identities

To solve equations effectively, a student should strive to develop *all* of the necessary "tools." Certainly the underlying concepts and graphical connections are of primary importance, as are the related algebraic skills. But to solve *trig* equations effectively we must also have a ready command of commonly used identities. Observe how Example 3 combines a double-angle identity with factoring by grouping.

EXAMPLE 3 ▶ **Using Identities and Algebra to Solve a Trig Equation**

Find all solutions in $[0, 2\pi)$: $3\sin(2x) + 2\sin x - 3\cos x = 1$. Round solutions to four decimal places as necessary.

Solution ▶ Noting that one of the terms involves a double angle, we attempt to replace that term to make factoring a possibility. Using the double identity for sine, we have

$$\begin{aligned} 3(2\sin x\cos x) + 2\sin x - 3\cos x &= 1 && \text{substitute } 2\sin x\cos x \text{ for } \sin(2x)\\ (6\sin x\cos x + 2\sin x) - (3\cos x + 1) &= 0 && \text{set equal zero and group terms}\\ 2\sin x(3\cos x + 1) - 1(3\cos x + 1) &= 0 && \text{factor using } 3\cos x + 1\\ (3\cos x + 1)(2\sin x - 1) &= 0 && \text{common binomial factor} \end{aligned}$$

Use the zero factor property to solve each equation independently.

$$\begin{aligned} 3\cos x + 1 &= 0 & 2\sin x - 1 &= 0 && \text{resulting equations}\\ \cos x &= -\frac{1}{3} & \sin x &= \frac{1}{2} && \text{isolate variable term}\\ \cos x &< 0 \text{ in QII and QIII} & \sin x &> 0 \text{ in QI and QII}\\ x &\approx 1.9106, 4.3726 & x &= \frac{\pi}{6}, \frac{5\pi}{6} && \text{solutions} \end{aligned}$$

Should you prefer the exact form, the solutions from the cosine equation could be written as $x = \cos^{-1}\left(-\frac{1}{3}\right)$ and $x = 2\pi - \cos^{-1}\left(-\frac{1}{3}\right)$.

B. You've just seen how we can solve trig equations using various identities

Now try Exercises 17 through 26 ▶

C. Trig Equations and Graphing Technology

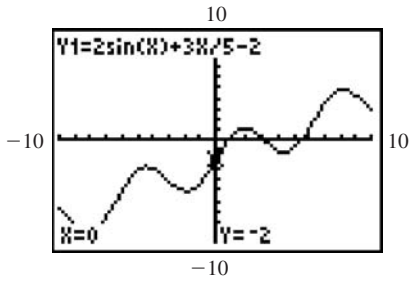
A majority of the trig equations you'll encounter in your studies can be solved using the ideas and methods presented both here and in the previous section. But there are some equations that cannot be solved using standard methods because they mix polynomial functions (linear, quadratic, and so on) that can be solved using algebraic methods, with what are called **transcendental functions** (trigonometric, logarithmic, and so on). By definition, transcendental functions are those that *transcend* the reach of standard algebraic methods. These kinds of equations serve to highlight the value of graphing and calculating technology to today's problem solvers.

EXAMPLE 4 ▶ **Solving Trig Equations Using Technology**

Use a graphing calculator in radian mode to find all real roots of $2 \sin x + \frac{3x}{5} - 2 = 0$. Round solutions to four decimal places.

Solution ▶ When using graphing technology our initial concern is the size of the viewing window. After carefully entering the equation on the Y= screen, we note the term $2 \sin x$ will never be larger than 2 or less than -2 for any real number x. On the other hand, the term $\frac{3x}{5}$ becomes larger for larger values of x, which would seem to cause $2 \sin x + \frac{3x}{5}$ to "grow" as x gets larger. We conclude the standard window is a good place to start, and the resulting graph is shown in Figure 7.51.

Figure 7.51



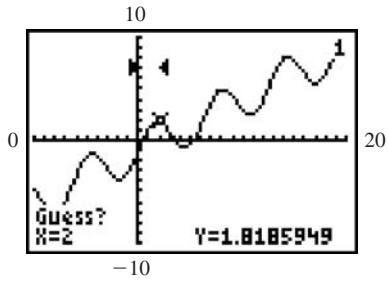


Figure 7.52

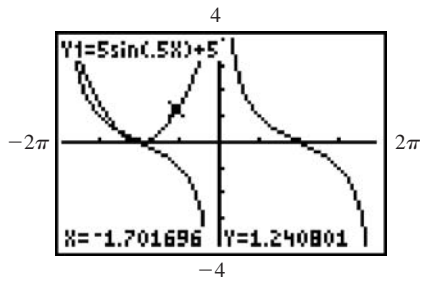

From this screen it appears there are three real roots, but to be sure none are hidden to the right, we extend the Xmax value to 20 (Figure 7.52). Using 2nd TRACE **(CALC) 2:zero,** we follow the prompts and enter a left bound of 0 (a number to the left of the zero) and a right bound of 2 (a number to the right of the zero—see Figure 7.52). The calculator then prompts you for a GUESS, which you can bypass by pressing ENTER. The smallest root is approximately $x \approx 0.8435$. Repeating this sequence we find the other roots are $x \approx 3.0593$ and $x \approx 5.5541$.

Now try Exercises 27 through 32 ▶

Some equations are very difficult to solve analytically, and even with the use of a graphing calculator, a strong combination of analytical skills with technical skills is required to state the solution set. Consider the equation $5 \sin\left(\frac{1}{2}x\right) + 5 = \cot\left(\frac{1}{2}x\right)$ and solutions in $[-2\pi, 2\pi)$. There appears to be no quick analytical solution, and the first attempt at a graphical solution holds some hidden surprises. Enter $Y_1 = 5 \sin\left(\frac{1}{2}X\right) + 5$ and $Y_2 = \frac{1}{\tan(\frac{1}{2}X)}$ on the Y= screen. Pressing ZOOM **7:ZTrig** gives the screen in Figure 7.53, where we note there are at least two and possibly three solutions, depending on how the sine graph intersects the cotangent graph. We are also uncertain as to whether the graphs intersect again between $-\frac{\pi}{2}$ and $\frac{\pi}{2}$. Increasing the maximum Y-value to Ymax $= 8$ shows they do indeed. But once again, are there now three or four solutions? In situations like this it may

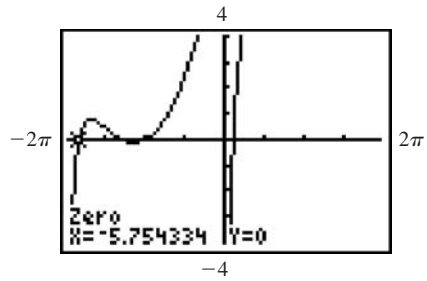

Figure 7.53

☑ **C.** You've just seen how we can solve trig equations using graphing technology

be helpful to use the Zeroes Method for solving graphically. On the Y= screen, disable Y_1 and Y_2 and enter Y_3 as $Y_1 - Y_2$. Pressing ZOOM **7:ZTrig** at this point clearly shows that there are four solutions in this interval (Figure 7.54), which can easily be found using 2nd TRACE **(CALC) 2:zero:** $x \approx -5.7543, -4.0094, -3.1416$, and 0.3390. **See Exercises 33 and 34** for more practice with these ideas.

Figure 7.54

D. Solving Equations of the Form $A \sin(Bx \pm C) \pm D = k$

You may remember equations of this form from Section 6.5. They actually occur quite frequently in the investigation of many natural phenomena and in the modeling of data from a periodic or seasonal context. Solving these equations requires a good combination of algebra skills with the fundamentals of trig.

EXAMPLE 5 ▶ **Solving Equations That Involve Transformations**

Given $f(x) = 160 \sin\left(\frac{\pi}{3}x + \frac{\pi}{3}\right) + 320$ and $x \in [0, 2\pi)$, for what real numbers x is $f(x)$ less than 240?

Algebraic Solution ▶

We reason that to find values where $f(x) < 240$, we should begin by finding values where $f(x) = 240$. The result is

$$160 \sin\left(\frac{\pi}{3}x + \frac{\pi}{3}\right) + 320 = 240 \quad \text{equation}$$

$$\sin\left(\frac{\pi}{3}x + \frac{\pi}{3}\right) = -0.5 \quad \text{subtract 320 and divide by 160; isolate variable term}$$

At this point we elect to use a u-substitution for $\left(\frac{\pi}{3}x + \frac{\pi}{3}\right) = \frac{\pi}{3}(x + 1)$ to obtain a "clearer view."

$$\sin u = -0.5 \quad \text{substitute } u \text{ for } \tfrac{\pi}{3}(x + 1)$$

$\sin u < 0$ in QIII and QIV

$$u = \frac{7\pi}{6} \qquad u = \frac{11\pi}{6} \quad \text{solutions in } u$$

To complete the solution we re-substitute $\frac{\pi}{3}(x + 1)$ for u and solve.

$$\frac{\pi}{3}(x + 1) = \frac{7\pi}{6} \qquad \frac{\pi}{3}(x + 1) = \frac{11\pi}{6} \quad \text{re-substitute } \tfrac{\pi}{3}(x + 1) \text{ for } u$$

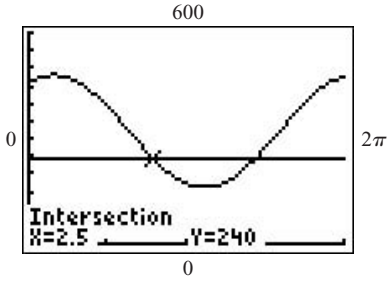
$$x + 1 = \frac{7}{2} \qquad x + 1 = \frac{11}{2} \quad \text{multiply both sides by } \tfrac{3}{\pi}$$

$$x = 2.5 \qquad x = 4.5 \quad \text{solutions}$$

We now know $f(x) = 240$ when $x = 2.5$ and $x = 4.5$ but when will $f(x)$ be *less than* 240? By analyzing the equation, we find the function has period of $P = \frac{2\pi}{\frac{\pi}{3}} = 6$ and is shifted to the left 1 units. This would indicate the graph peaks early in the interval $[0, 2\pi)$ with a "valley" in the interior. We conclude $f(x) < 240$ in the interval $(2.5, 4.5)$.

Graphical Solution ▶ With the calculator in radian MODE, enter $Y_1 = 160 \sin\left(\frac{\pi}{3}X + \frac{\pi}{3}\right) + 320$ and $Y_2 = 240$ on the Y= screen. To set an appropriate window, note the amplitude of Y_1 is 160 and that the graph has been vertically shifted up 320 units. With the x-values ranging from 0 to 2π, the 2nd TRACE **(CALC) 5:intersect** feature determines (2.5, 240) is a point of intersection of the two graphs (see Figure 7.55). In Figure 7.56, we find a second point of intersection is (4.5, 240). Observing that the graph of Y_1 falls below 240 between these two points, we conclude that in the interval $[0, 2\pi)$, $f(x) < 240$ for $x \in (2.5, 4.5)$.

Figure 7.55



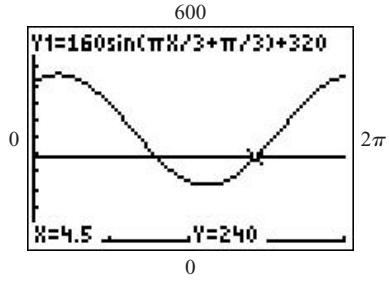


Figure 7.56

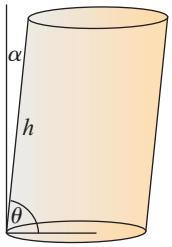


Now try Exercises 35 through 38 ▶

D. You've just seen how we can solve trig equations of the form $A \sin(Bx + C) + D = k$

There is a mixed variety of equation types in **Exercises 39 through 48.**

E. Applications Using Trigonometric Equations

Figure 7.57

Using characteristics of the trig functions, we can often generalize and extend many of the formulas that are familiar to you. For example, the formulas for the volume of a right circular cylinder and a right circular cone are well known, but what about the volume of a nonright figure (see Figure 7.57)? Here, trigonometry provides the answer, as the most general volume formula is $V = V_0 \sin\theta$, where V_0 is a "standard" volume formula and θ is the complement of angle of deflection **(see Exercises 51 and 52).**

As for other applications, consider the following from the environmental sciences. Natural scientists are very interested in the discharge rate of major rivers, as this gives an indication of rainfall over the inland area served by the river. In addition, the discharge rate has a large impact on the freshwater and saltwater zones found at the river's estuary (where it empties into the sea).

EXAMPLE 6 ▶ **Solving an Equation Modeling the Discharge Rate of a River**

For May through November, the discharge rate of the Ganges River (Bangladesh) can be modeled by $D(t) = 16{,}580 \sin\left(\frac{\pi}{3}t - \frac{2\pi}{3}\right) + 17{,}760$ where $t = 1$ represents May 1, and $D(t)$ is the discharge rate in m^3/sec.

Source: Global River Discharge Database Project; www.rivdis.sr.unh.edu.

a. What is the discharge rate in mid-October?

b. For what months (within this interval) is the discharge rate over 26,050 m^3/sec?

Solution ▶

a. To find the discharge rate in mid-October we simply evaluate the function at $t = 6.5$:

$$D(t) = 16{,}580 \sin\left(\frac{\pi}{3}t - \frac{2\pi}{3}\right) + 17{,}760 \qquad \text{given function}$$

$$D(6.5) = 16{,}580 \sin\left[\frac{\pi}{3}(6.5) - \frac{2\pi}{3}\right] + 17{,}760 \qquad \text{substitute 6.5 for } t$$

$$= 1180 \qquad \text{compute result on a calculator}$$

In mid-October the discharge rate is 1180 m^3/sec.

b. We first find when the rate is *equal* to 26,050 m^3/sec: $D(t) = 26{,}050$.

$$26{,}050 = 16{,}580 \sin\left(\frac{\pi}{3}t - \frac{2\pi}{3}\right) + 17{,}760 \qquad \text{substitute 26,050 for } D(t)$$

$$0.5 = \sin\left(\frac{\pi}{3}t - \frac{2\pi}{3}\right) \qquad \text{subtract 17,760; divide by 16,580}$$

Using a u-substitution for $\left(\frac{\pi}{3}t - \frac{2\pi}{3}\right)$ we obtain the equation

$$0.5 = \sin u$$

$\sin u > 0$ in QI and QII

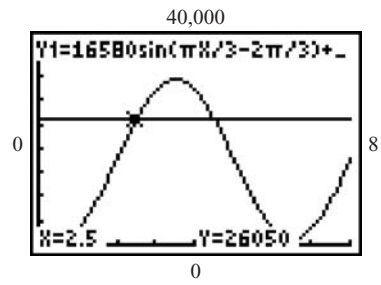
$$u = \frac{\pi}{6} \qquad u = \frac{5\pi}{6} \qquad \text{solutions in } u$$

To complete the solution we re-substitute $\frac{\pi}{3}t - \frac{2\pi}{3} = \frac{\pi}{3}(t - 2)$ for u and solve.

$$\frac{\pi}{3}(t-2) = \frac{\pi}{6} \qquad \frac{\pi}{3}(t-2) = \frac{5\pi}{6} \qquad \text{re-substitute } \frac{\pi}{3}(t-2) \text{ for } u$$

$$t - 2 = 0.5 \qquad t - 2 = 2.5 \qquad \text{multiply both sides by } \frac{3}{\pi}$$

$$t = 2.5 \qquad t = 4.5 \qquad \text{solutions}$$



The Ganges River will have a flow rate of over 26,050 m^3/sec between mid-June (2.5) and mid-August (4.5).

Now try Exercises 53 through 56 ▶

To obtain a graphical solution to Example 6(b), enter $Y_1 = 16{,}580 \sin\left(\frac{\pi}{3}X - \frac{2\pi}{3}\right) + 17{,}760$ on the Y= screen, then $Y_2 = 26{,}050$. Set the window as shown in Figure 7.58 and locate the points of intersection. The graphs verify that in the interval [1, 8], $D(t) > 26{,}050$ for $t \in (2.5, 4.5)$.

There is a variety of additional exercises in the Exercise Set. **See Exercises 57 through 64.**

Figure 7.58

7.7 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. The three Pythagorean identities are _____, _____, and _____.
2. One strategy to solve equations with four terms and no common factors is _____ by _____.
3. When an equation contains two functions from a Pythagorean identity, sometimes _____ both sides will lead to a solution.
4. To combine two sine or cosine terms with different arguments, we can use the _____ to _____ formulas.
5. Regarding Example 4, discuss/explain the relationship between the line $y = \frac{3}{5}x - 2$ and the graph shown in Figure 7.52.
6. Regarding Example 6, discuss/explain how to determine the months of the year the discharge rate is *under* 26,050 m^3/sec, using the solution set given.

▶ DEVELOPING YOUR SKILLS

Solve each equation in $[0, 2\pi)$ using the method indicated. Round nonstandard values to four decimal places.

- **Squaring both sides**

7. $\sin x + \cos x = \frac{\sqrt{6}}{2}$
8. $\cot x - \csc x = \sqrt{3}$
9. $\tan x - \sec x = -1$
10. $\sin x + \cos x = \sqrt{2}$
11. $\cos x + \sin x = \frac{4}{3}$
12. $\sec x + \tan x = 2$

- **Factor by grouping**

13. $\cot x \csc x - 2\cot x - \csc x + 2 = 0$
14. $4\sin x \cos x - 2\sqrt{3}\sin x - 2\cos x + \sqrt{3} = 0$
15. $3\tan^2 x \cos x - 3\cos x + 2 = 2\tan^2 x$
16. $4\sqrt{3}\sin^2 x \sec x - \sqrt{3}\sec x + 2 = 8\sin^2 x$

- **Using identities**

17. $\frac{1 + \cot^2 x}{\cot^2 x} = 2$
18. $\frac{1 + \tan^2 x}{\tan^2 x} = \frac{4}{3}$
19. $3\cos(2x) + 7\sin x - 5 = 0$
20. $3\cos(2x) - \cos x + 1 = 0$
21. $2\sin^2\left(\frac{x}{2}\right) - 3\cos\left(\frac{x}{2}\right) = 0$
22. $2\cos^2\left(\frac{x}{3}\right) + 3\sin\left(\frac{x}{3}\right) - 3 = 0$
23. $\cos(3x) + \cos(5x)\cos(2x) + \sin(5x)\sin(2x) - 1 = 0$
24. $\sin(7x)\cos(4x) + \sin(5x) - \cos(7x)\sin(4x) + \cos x = 0$
25. $\sec^4 x - 2\sec^2 x \tan^2 x + \tan^4 x = \tan^2 x$
26. $\tan^4 x - 2\sec^2 x \tan^2 x + \sec^4 x = \cot^2 x$

Find all roots in $[0, 2\pi)$ using a graphing calculator. State answers in radians rounded to four decimal places.

27. $5\cos x - x = 3$
28. $3\sin x + x = 4$
29. $\cos^2(2x) + x = 3$
30. $\sin^2(2x) + 2x = 1$
31. $x^2 + \sin(2x) = 1$
32. $\cos(2x) - x^2 = -5$
33. $(1 + \sin x)^2 + \cos(2x) = 4\cos x(1 + \sin x)$
34. $4\sin x = 2\cos^2\left(\frac{x}{2}\right)$

State the period P of each function and find all solutions in $[0, P)$. Round to four decimal places as needed.

35. $250 \sin\left(\frac{\pi}{6}x + \frac{\pi}{3}\right) - 125 = 0$

36. $-75\sqrt{2} \sec\left(\frac{\pi}{4}x + \frac{\pi}{6}\right) + 150 = 0$

37. $1235 \cos\left(\frac{\pi}{12}x - \frac{\pi}{4}\right) + 772 = 1750$

38. $-0.075 \sin\left(\frac{\pi}{2}x + \frac{\pi}{3}\right) - 0.023 = -0.068$

Solve each equation in $[0, 2\pi)$ using any appropriate method. Round nonstandard values to four decimal places.

39. $\cos x - \sin x = \frac{\sqrt{2}}{2}$

40. $5 \sec^2 x - 2 \tan x - 8 = 0$

41. $\frac{1 - \cos^2 x}{\tan^2 x} = \frac{\sqrt{3}}{2}$

42. $5 \csc^2 x - 5 \cot x - 5 = 0$

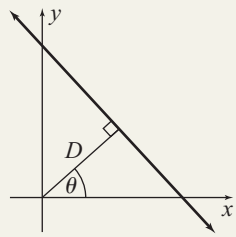
43. $\csc x + \cot x = 1$

44. $\frac{1 - \sin^2 x}{\cot^2 x} = \frac{\sqrt{2}}{2}$

45. $\sec x \cos\left(\frac{\pi}{2} - x\right) = -1$

46. $\sin\left(\frac{\pi}{2} - x\right)\csc x = \sqrt{3}$

47. $\sec^2 x \tan\left(\frac{\pi}{2} - x\right) = 4$



48. $2 \tan\left(\frac{\pi}{2} - x\right)\sin^2 x = \frac{\sqrt{3}}{2}$

▶ WORKING WITH FORMULAS

49. The equation of a line in trigonometric form: $y = \frac{D - x\cos\theta}{\sin\theta}$

The trigonometric form of a linear equation is given by the formula shown, where D is the perpendicular distance from the origin to the line and θ is the angle between the perpendicular segment and the x-axis. For each pair of perpendicular lines given, (a) find the point (a, b) of their intersection; (b) compute the distance $D = \sqrt{a^2 + b^2}$ and the angle $\theta = \tan^{-1}\left(\frac{b}{a}\right)$, and give the equation of the line L_1 in trigonometric form; and (c) use the GRAPH or the **TABLE** feature of a graphing calculator to verify that both equations name the same line.

Exercise 49

I. $L_1: y = -x + 5$ $\quad L_2: y = x$

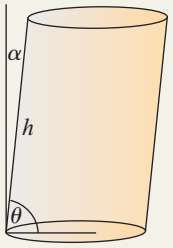
II. $L_1: y = -\frac{1}{2}x + 5$ $\quad L_2: y = 2x$

III. $L_1: y = -\frac{\sqrt{3}}{3}x + \frac{4\sqrt{3}}{3}$ $\quad L_2: y = \sqrt{3}x$

50. Rewriting $y = a\cos x + b\sin x$ as a single function: $y = k\sin(x + \theta)$

Linear terms of sine and cosine can be rewritten as a single function using the formula shown, where $k = \sqrt{a^2 + b^2}$ and $\theta = \sin^{-1}\left(\frac{a}{k}\right)$. Rewrite the equations given using these relationships and verify they are equivalent using the GRAPH or the **TABLE** feature of a graphing calculator:

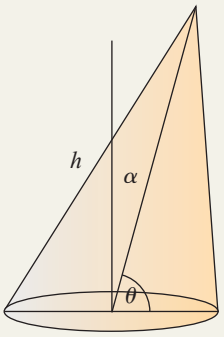
a. $y = 2\cos x + 2\sqrt{3}\sin x$



b. $y = 4\cos x + 3\sin x$

The ability to rewrite a trigonometric equation in simpler form has a tremendous number of applications in graphing, equation solving, working with identities, and solving applications.

▶ APPLICATIONS



51. Volume of a cylinder: The volume of a cylinder is given by the formula $V = \pi r^2 h \sin\theta$, where r is the radius and h is the height of the cylinder, and θ is the indicated complement of the angle of deflection α. Note that when $\theta = \frac{\pi}{2}$, the formula becomes that of a right circular cylinder (if $\theta \neq \frac{\pi}{2}$, then h is called the *slant height or lateral height* of the cylinder). An old farm silo is built in the form of a right circular cylinder with a radius of 10 ft and a height of 25 ft. After an earthquake, the silo became tilted with an angle of deflection $\alpha = 5°$. (a) Find the volume of the silo before the earthquake. (b) Find the volume of the silo after the earthquake. (c) What angle θ is required to bring the original volume of the silo down 2%?

Exercise 51

52. Volume of a cone: The volume of a cone is given by the formula $V = \frac{1}{3}\pi r^2 h \sin\theta$, where r is the radius and h is the height of the cone, and θ is the indicated complement of the angle of deflection α. Note that when $\theta = \frac{\pi}{2}$, the formula becomes that of a right circular cone (if $\theta \neq \frac{\pi}{2}$, then h is called the *slant height or lateral height* of the cone). As part of a sculpture exhibit, an artist is constructing three such structures each with a radius of 2 m and a slant height of 3 m. (a) Find the volume of the sculptures if the angle of deflection is $\alpha = 15°$. (b) What angle θ was used if the volume of each sculpture is 12 m^3?

Exercise 52

53. River discharge rate: For June through February, the discharge rate of the La Corcovada River (Venezuela) can be modeled by the function $D(t) = 36\sin\left(\frac{\pi}{4}t - \frac{9}{4}\right) + 44$, where t represents the months of the year with $t = 1$ corresponding to June, and $D(t)$ is the discharge rate in cubic meters per second. (a) What is the discharge rate in mid-September ($t = 4.5$)? (b) For what months of the year is the discharge rate over 50 m^3/sec?

Source: Global River Discharge Database Project; www.rivdis.sr.unh.edu.

54. River discharge rate: For February through June, the average monthly discharge of the Point Wolfe River (Canada) can be modeled by the function $D(t) = 4.6\sin\left(\frac{\pi}{2}t + 3\right) + 7.4$, where t represents the months of the year with $t = 1$ corresponding to February, and $D(t)$ is the discharge rate in cubic meters/second. (a) What is the discharge rate in mid-March ($t = 2.5$)? (b) For what months of the year is the discharge rate less than 7.5 m^3/sec?

Source: Global River Discharge Database Project; www.rivdis.sr.unh.edu.

55. Seasonal sales: Hank's Heating Oil is a very seasonal enterprise, with sales in the winter far exceeding sales in the summer. Monthly sales for the company can be modeled by $S(x) = 1600\cos\left(\frac{\pi}{6}x - \frac{\pi}{12}\right) + 5100$, where $S(x)$ is the average sales in month x ($x = 1 \rightarrow$ January). (a) What is the average sales amount for July? (b) For what months of the year are sales less than \$4000?

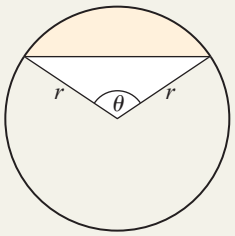
56. Seasonal income: As a roofing company employee, Mark's income fluctuates with the seasons and the availability of work. For the past several years his average monthly income could be approximated by the function $I(m) = 2100\sin\left(\frac{\pi}{6}m - \frac{\pi}{2}\right) + 3520$, where $I(m)$ represents income in month m ($m = 1 \rightarrow$ January). (a) What is Mark's average monthly income in October? (b) For what months of the year is his average monthly income over \$4500?

57. Seasonal ice thickness: The average thickness of the ice covering an arctic lake can be modeled by the function $T(x) = 9\cos\left(\frac{\pi}{6}x\right) + 15$, where $T(x)$ is the average thickness in month x ($x = 1 \rightarrow$ January). (a) How thick is the ice in mid-March? (b) For what months of the year is the ice at most 10.5 in. thick?

58. Seasonal temperatures: The function $T(x) = 19\sin\left(\frac{\pi}{6}x - \frac{\pi}{2}\right) + 53$ models the average monthly temperature of the water in a mountain stream, where $T(x)$ is the temperature (°F) of the water in month x ($x = 1 \rightarrow$ January). (a) What is the temperature of the water in October? (b) What two months are most likely to give a temperature reading of 62°F? (c) For what months of the year is the temperature below 50°F?

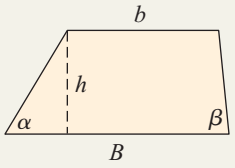
59. Coffee sales: Coffee sales fluctuate with the weather, with a great deal more coffee sold in the winter than in the summer. For Joe's Diner, assume the function $G(x) = 21\cos\left(\frac{2\pi}{365}x + \frac{\pi}{2}\right) + 29$ models daily coffee sales (for non-leap years), where $G(x)$ is the number of gallons sold and x represents the days of the year ($x = 1 \rightarrow$ January 1). (a) How many gallons are projected to be sold on March 21? (b) For what days of the year are more than 40 gal of coffee sold?

60. Park attendance: Attendance at a popular state park varies with the weather, with a great deal more visitors coming in during the summer months. Assume daily attendance at the park can be modeled by the function $V(x) = 437\cos\left(\frac{2\pi}{365}x - \pi\right) + 545$ (for non-leap years), where $V(x)$ gives the number of visitors on day x ($x = 1 \rightarrow$ January 1). (a) Approximately how many people visited the park on November 1 ($11 \times 30.5 = 335.5$)? (b) For what days of the year are there more than 900 visitors?



61. Exercise routine: As part of his yearly physical, Manu Tuiosamoa's heart rate is closely monitored during a 12-min, cardiovascular exercise routine. His heart rate in beats per minute (bpm) is modeled by the function $B(x) = 58\cos\left(\frac{\pi}{6}x + \pi\right) + 126$ where x represents the duration of the workout in minutes. (a) What was his resting heart rate? (b) What was his heart rate 5 min into the workout? (c) At what times during the workout was his heart rate over 170 bpm?

62. Exercise routine: As part of her workout routine, Sara Lee programs her treadmill to begin at a slight initial grade (angle of incline), gradually increase to a maximum grade, then gradually decrease back to the original grade. For the duration of her workout, the grade is modeled by the function $G(x) = 3\cos\left(\frac{\pi}{5}x - \pi\right) + 4$, where $G(x)$ is the percent grade x minutes after the workout has begun. (a) What is the initial grade for her workout? (b) What is the grade at $x = 4$ min? (c) At $G(x) = 4.9\%$, how long has she been working out? (d) What is the duration of the treadmill workout?

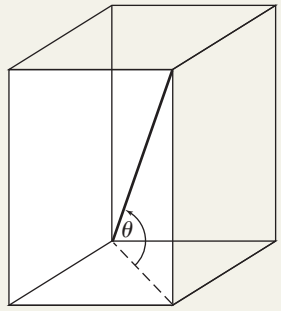


Geometry applications: Solve Exercises 63 and 64 graphically using a calculator. For Exercise 63, give θ in radians rounded to four decimal places. For Exercise 64, answer in degrees to the nearest tenth of a degree.

63. The area of a circular segment (the shaded portion shown) is given by the formula $A = \frac{1}{2}r^2(\theta - \sin\theta)$, where θ is in radians. If the circle has a radius of 10 cm, find the angle θ that gives an area of 12 cm^2.

Exercise 64

64. The perimeter of a trapezoid with parallel sides B and b, altitude h, and base angles α and β is given by the formula $P = B + b + h(\csc\alpha + \csc\beta)$. If $b = 30$ m, $B = 40$ m, $h = 10$ m, and $\alpha = 45°$, find the angle β that gives a perimeter of 105 m.



▶ EXTENDING THE CONCEPT

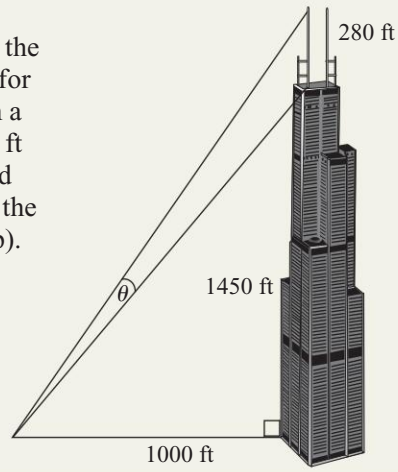
65. As we saw in Chapter 6, cosine is the cofunction of sine and each can be expressed in terms of the other: $\cos\left(\frac{\pi}{2} - \theta\right) = \sin\theta$ and $\sin\left(\frac{\pi}{2} - \theta\right) = \cos\theta$. This implies that either function can be used to model the phenomenon described in this section by adjusting the phase shift. By experimentation, (a) find a model using cosine that will produce results identical to the sine function in Exercise 58 and (b) find a model using sine that will produce results identical to the cosine function in Exercise 59.

66. Use multiple identities to find all real solutions for the equation given: $\sin(5x) + \sin(2x)\cos x + \cos(2x)\sin x = 0$.

67. A rectangular parallelepiped with square ends has 12 edges and six surfaces. If the sum of all edges is 176 cm and the total surface area is 1288 cm^2, find (a) the length of the diagonal of the parallelepiped (shown in bold) and (b) the angle the diagonal makes with the base (two answers are possible).

Exercise 67

▶ MAINTAINING YOUR SKILLS



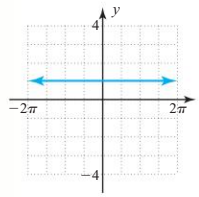
68. **(6.7)** Find the values of all six trig functions of an angle, given $P(-51, 68)$ is on its terminal side.

69. **(4.3)** Sketch the graph of f by locating its zeroes and using end-behavior: $f(x) = x^4 - 3x^3 + 4x$.

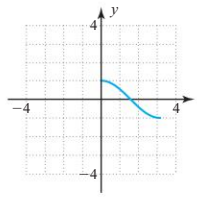
70. **(5.3)** Use a calculator and the change-of-base formula to find the value of $\log_5 279$.

71. **(6.6)** The Willis Tower (formerly known as the Sears Tower) in Chicago, Illinois, remains one of the tallest structures in the world. The top of the roof reaches 1450 ft above the street below and the antenna extends an additional 280 ft into the air. Find the viewing angle θ for the antenna from a distance of 1000 ft (the angle formed from the base of the antenna to its top).

Exercise 71

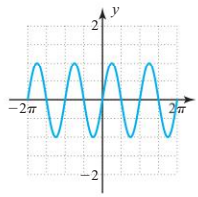


MAKING CONNECTIONS

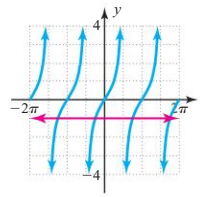


Making Connections: Graphically, Symbolically, Numerically, and Verbally

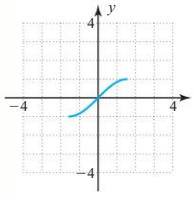
Eight graphs A through H are given. Match the characteristics shown in 1 through 16 to one of the eight graphs.



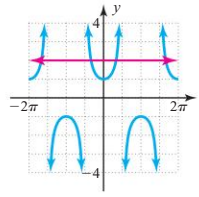
(a)



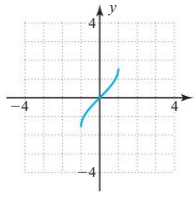
(b)



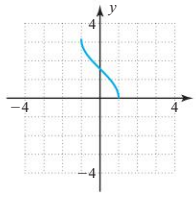
(c)



(d)



(e)



(f)

(g)

(h)

1. ____ $f(t) = \cos t, t \in [0, \pi]$

2. ____ $\tan t = -1$

3. ____ $f(t) = \sin t, t \in \left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$

4. ____ $y = \arcsin t$

5. ____ $\sec t = 2$

6. ____ $\sin(2t)$

7. ____ $x = \cos y$

8. ____ $\left(\frac{\pi}{6}, \frac{\sqrt{3}}{2}\right)$ is on the graph

9. ____ $f\left(\frac{1}{2}\right) = \frac{\pi}{6}$

10. ____ $f(t) = \cos^{-1} t$

11. ____ $2 \sin t \cos t$

12. ____ $t = -\frac{5\pi}{4}, -\frac{\pi}{4}, \frac{3\pi}{4}, \frac{7\pi}{4}$

13. ____ $t = -\frac{5\pi}{3}, -\frac{\pi}{3}, \frac{\pi}{3}, \frac{5\pi}{3}$

14. ____ $f\left(\frac{1}{2}\right) = \frac{\pi}{3}$

15. ____ $x = \sin y$

16. ____ $y = \cos^2 t + \sin^2 t$

SUMMARY AND CONCEPT REVIEW

SECTION 7.1 Fundamental Identities and Families of Identities

KEY CONCEPTS

- The fundamental identities include the *reciprocal, ratio,* and *Pythagorean identities.*
- A given identity can algebraically be rewritten to obtain other identities in an identity "family."
- Standard algebraic skills like distribution, factoring, combining terms, and special products play an important role in working with identities.
- The pattern $\frac{A}{B} \pm \frac{C}{D} = \frac{AD \pm BC}{BD}$ gives an efficient method for combining rational terms.
- Using fundamental identities, a given trig function can be expressed in terms of any other trig function.
- Once the value of a given trig function is known, the value of the other five can be uniquely determined using fundamental identities, *if the quadrant of the terminal side is known*.

EXERCISES

Verify using the method specified and fundamental identities.

1. multiplication

$\sin x(\csc x - \sin x) = \cos^2 x$

2. factoring

$\dfrac{\tan^2 x \csc x + \csc x}{\sec^2 x} = \csc x$

3. special product

$\dfrac{(\sec x - \tan x)(\sec x + \tan x)}{\csc x} = \sin x$

4. combine terms using $\boldsymbol{\frac{A}{B} \pm \frac{C}{D} = \frac{AD \pm BC}{BD}}$

$\dfrac{\sec^2 x}{\csc x} - \sin x = \dfrac{\tan^2 x}{\csc x}$

Find the value of all six trigonometric functions using the information given.

5. $\cos\theta = -\frac{12}{37}$; θ in QIII

6. $\sec\theta = \frac{25}{23}$; θ in QIV

SECTION 7.2 More on Verifying Identities

KEY CONCEPTS

- The sine and tangent functions are odd functions, while cosine is even.
- The steps used to verify an identity must be reversible.
- If two expressions are equal, one may be substituted for the other and the result will be equivalent.
- To verify an identity we mold, change, substitute, and rewrite one side until we "match" the other side.
- Verifying identities often involves a combination of algebraic skills with the fundamental trig identities. A collection and summary of the *Guidelines for Verifying Identities* can be found on page 662.
- To show an equation is not an identity, find any one value where the expressions are defined but the equation is false, or graph both functions on a calculator to see if the graphs are identical.

EXERCISES

Verify that each equation is an identity.

7. $\dfrac{\csc^2 x(1 - \cos^2 x)}{\tan^2 x} = \cot^2 x$

8. $\dfrac{\cot x}{\sec x} - \dfrac{\csc x}{\tan x} = \cot x(\cos x - \csc x)$

9. $\dfrac{\sin^4 x - \cos^4 x}{\sin x \cos x} = \tan x - \cot x$

10. $\dfrac{(\sin x + \cos x)^2}{\sin x \cos x} = \csc x \sec x + 2$

SECTION 7.3 The Sum and Difference Identities

KEY CONCEPTS

The sum and difference identities can be used to

- Find exact values for nonstandard angles that are a sum or difference of two standard angles.
- Verify the cofunction identities and to rewrite a given function in terms of its cofunction.
- Find coterminal angles in $[0°, 360°)$ for very large angles (the angle reduction formulas).
- Evaluate the difference quotient for $\sin x$, $\cos x$, and $\tan x$.
- Rewrite a sum as a single expression: $\cos\alpha\cos\beta + \sin\alpha\sin\beta = \cos(\alpha - \beta)$.

The sum and difference identities for sine and cosine can be remembered by noting

- For $\cos(\alpha \pm \beta)$, the function repeats and the signs alternate: $\cos(\alpha \pm \beta) = \cos\alpha\cos\beta \mp \sin\alpha\sin\beta$
- For $\sin(\alpha \pm \beta)$ the signs repeat and the functions alternate: $\sin(\alpha \pm \beta) = \sin\alpha\cos\beta \pm \cos\alpha\sin\beta$

EXERCISES

Find exact values for the following expressions using sum and difference formulas.

11. a. $\cos 75°$ **b.** $\tan\left(\frac{\pi}{12}\right)$ **12. a.** $\tan 15°$ **b.** $\sin\left(-\frac{\pi}{12}\right)$

Evaluate exactly using sum and difference formulas.

13. a. $\cos 109°\cos 71° - \sin 109°\sin 71°$ **b.** $\sin 139°\cos 19° - \cos 139°\sin 19°$

Rewrite as a single expression using sum and difference formulas.

14. a. $\cos(3x)\cos(-2x) - \sin(3x)\sin(-2x)$ **b.** $\sin\left(\frac{x}{4}\right)\cos\left(\frac{3x}{8}\right) + \cos\left(\frac{x}{4}\right)\sin\left(\frac{3x}{8}\right)$

Evaluate exactly using sum and difference formulas, by reducing the angle to an angle in $[0, 360°)$ or $[0, 2\pi)$.

15. a. $\cos 1170°$ **b.** $\sin\left(\frac{57\pi}{4}\right)$

Use a cofunction identity to write an equivalent expression for the one given.

16. a. $\cos\left(\frac{x}{8}\right)$ **b.** $\sin\left(x - \frac{\pi}{12}\right)$

17. Verify that both expressions yield the same result using sum and difference formulas: $\tan 15° = \tan(45° - 30°)$ and $\tan 15° = \tan(135° - 120°)$.

18. Use sum and difference formulas to verify the following identity.

$$\cos\left(x + \frac{\pi}{6}\right) + \cos\left(x - \frac{\pi}{6}\right) = \sqrt{3}\cos x$$

SECTION 7.4 The Double-Angle, Half-Angle, and Product-to-Sum Identities

KEY CONCEPTS

- When multiple angle identities (identities involving $n\theta$) are used to find exact values, the terminal side of θ must be determined so the appropriate sign can be used.
- The power reduction identities for $\cos^2 x$ and $\sin^2 x$ are closely related to the double-angle identities, and can be derived directly from $\cos(2x) = 2\cos^2 x - 1$ and $\cos(2x) = 1 - 2\sin^2 x$.
- The half-angle identities can be developed from the power reduction identities by using a change of variable and taking square roots. The sign is then chosen based on the quadrant of the half angle.
- The product-to-sum and sum-to-product identities can be derived using the sum and difference formulas, and have important applications in many areas of science.

EXERCISES

Find exact values for $\sin(2\theta)$, $\cos(2\theta)$, and $\tan(2\theta)$ using the information given.

19. a. $\cos\theta = \frac{13}{85}$; θ in QIV **b.** $\csc\theta = -\frac{29}{20}$; θ in QIII

Find exact values for $\sin\theta$, $\cos\theta$, and $\tan\theta$ using the information given.

20. a. $\cos(2\theta) = -\frac{41}{841}$; θ in QII **b.** $\sin(2\theta) = -\frac{336}{625}$; θ in QII

Find exact values using the appropriate double-angle identity.

21. a. $\cos^2 22.5° - \sin^2 22.5°$ **b.** $1 - 2\sin^2\left(\frac{\pi}{12}\right)$

Find exact values for $\sin\theta$ and $\cos\theta$ using the appropriate half-angle identity.

22. a. $\theta = 67.5°$ **b.** $\theta = \frac{5\pi}{8}$

Find exact values for $\sin\left(\frac{\theta}{2}\right)$ and $\cos\left(\frac{\theta}{2}\right)$ using the given information.

23. a. $\cos\theta = \frac{24}{25}$; $0° < \theta < 360°$; θ in QIV **b.** $\csc\theta = -\frac{65}{33}$; $-90° < \theta < 0$; θ in QIV

24. Verify the equation is an identity.
$$\frac{\cos(3\alpha) - \cos\alpha}{\cos(3\alpha) + \cos\alpha} = \frac{2\tan^2\alpha}{\sec^2\alpha - 2}$$

25. Solve using a sum-to-product formula.
$\cos(3x) + \cos x = 0$

26. The area of an isosceles triangle (two equal sides) is given by the formula $A = x^2\sin\left(\frac{\theta}{2}\right)\cos\left(\frac{\theta}{2}\right)$, where the equal sides have length x and the vertex angle measures $\theta°$. (a) Use this formula and the half-angle identities to find the area of an isosceles triangle with vertex angle $\theta = 30°$ and equal sides of 12 cm. (b) Use substitution and a double-angle identity to verify that $x^2\sin\left(\frac{\theta}{2}\right)\cos\left(\frac{\theta}{2}\right) = \frac{1}{2}x^2\sin\theta$, then recompute the triangle's area. Do the results match?

SECTION 7.5 The Inverse Trig Functions and Their Applications

KEY CONCEPTS

- In order to create one-to-one functions, the domains of $y = \sin t$, $y = \cos t$, and $y = \tan t$ are restricted as follows: (a) $y = \sin t$, $t \in \left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$; (b) $y = \cos t$, $t \in [0, \pi]$; and (c) $y = \tan t$; $t \in \left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$.
- For $y = \sin x$, the inverse function is given implicitly as $x = \sin y$ and explicitly as $y = \sin^{-1}x$ or $y = \arcsin x$.
- The expression $y = \sin^{-1}x$ is read, "y is the angle or real number whose sine is x." The other inverse functions are similarly read/understood.
- For $y = \cos x$, the inverse function is given implicitly as $x = \cos y$ and explicitly as $y = \cos^{-1}x$ or $y = \arccos x$.
- For $y = \tan x$, the inverse function is given implicitly as $x = \tan y$ and explicitly as $y = \tan^{-1}x$ or $y = \arctan x$.
- The domains of $y = \sec t$, $y = \csc t$, and $y = \cot t$ are likewise restricted to create one-to-one functions: (a) $y = \sec t$; $t \in \left[0, \frac{\pi}{2}\right) \cup \left(\frac{\pi}{2}, \pi\right]$; (b) $y = \csc t$, $t \in \left[-\frac{\pi}{2}, 0\right) \cup \left(0, \frac{\pi}{2}\right]$; and (c) $y = \cot t$, $t \in (0, \pi)$.
- In some applications, inverse functions occur in a composition with other trig functions, with the expression best evaluated by drawing a diagram using the ratio definition of the trig functions.

- To evaluate $y = \sec^{-1}t$, we use $y = \cos^{-1}\left(\frac{1}{t}\right)$; for $y = \cot^{-1}t$, use $\tan^{-1}\left(\frac{1}{t}\right)$; and so on.
- Trigonometric substitutions can be used to simplify certain algebraic expressions.

EXERCISES

Evaluate without the aid of calculators or tables. State answers in both radians and degrees in exact form.

27. $y = \sin^{-1}\left(\frac{\sqrt{2}}{2}\right)$ **28.** $y = \csc^{-1}2$ **29.** $y = \arccos\left(-\frac{\sqrt{3}}{2}\right)$

Evaluate the following using a calculator. Answer in radians to the nearest ten-thousandth *and* in degrees to the nearest tenth. Some may be undefined.

30. $y = \tan^{-1}4.3165$ **31.** $y = \sin^{-1}0.8892$ **32.** $f(x) = \arccos\left(\frac{7}{8}\right)$

Evaluate the following without the aid of a calculator, *keeping the domain and range of each function in mind*. Some may be undefined.

33. $\left[\sin\left[\sin^{-1}\left(\frac{1}{2}\right)\right]\right]$ **34.** $\operatorname{arcsec}\left[\sec\left(\frac{\pi}{4}\right)\right]$ **35.** $\cos(\cos^{-1}2)$

Evaluate the following using a calculator. Some may be undefined.

36. $\sin^{-1}(\sin 1.0245)$ **37.** $\arccos[\cos(-60°)]$ **38.** $\cot^{-1}\left[\cot\left(\frac{11\pi}{4}\right)\right]$

Evaluate each expression by drawing a right triangle and labeling the sides.

39. $\sin\left[\cos^{-1}\left(\frac{12}{37}\right)\right]$ **40.** $\tan\left[\operatorname{arcsec}\left(\frac{7}{3x}\right)\right]$ **41.** $\cot\left[\sin^{-1}\left(\frac{x}{\sqrt{81 + x^2}}\right)\right]$

Use an inverse function to solve the following equations for θ in terms of x.

42. $x = 5\cos\theta$ **43.** $7\sqrt{3}\sec\theta = x$ **44.** $x = 4\sin\left(\theta - \frac{\pi}{6}\right)$

SECTION 7.6 Solving Basic Trig Equations

KEY CONCEPTS

- When solving trig equations, we often consider either the principal root, roots in $[0, 2\pi)$, or all real roots.
- Keeping the graph of each function in mind helps to determine the desired solution set.
- After isolating the trigonometric term containing the variable, we solve by applying the appropriate inverse function, realizing the result is only the principal root.
- Once the principal root is found, roots in $[0, 2\pi)$ or all real roots can be found using reference angles and the period of the function under consideration.
- Trig identities can be used to obtain an equation that can be solved by factoring or other solution methods.

EXERCISES

Solve each equation without the aid of a calculator (all solutions are standard values). Clearly state (a) the principal root; (b) all solutions in the interval $[0, 2\pi)$; and (c) all real roots.

45. $2\sin x = \sqrt{2}$ **46.** $3\sec x = -6$ **47.** $8\tan x + 7\sqrt{3} = -\sqrt{3}$

Solve using a calculator and the inverse trig functions (not by graphing). Clearly state (a) the principal root; (b) solutions in $[0, 2\pi)$; and (c) all real roots. Answer in radians to the nearest ten-thousandth as needed.

48. $9\cos x = 4$ **49.** $\frac{2}{5}\sin(2\theta) = \frac{1}{4}$ **50.** $\sqrt{2}\csc x + 3 = 7$

SECTION 7.7 General Trig Equations and Applications

KEY CONCEPTS

- In addition to the basic solution methods from Section 7.6, additional strategies include squaring both sides, factoring by grouping, and using the full range of identities to simplify an equation.
- Many applications result in equations of the form $A\sin(Bx + C) + D = k$. To solve, isolate the factor $\sin(Bx + C)$ (subtract D and divide by A), then apply the inverse function.
- Once the principal root is found, roots in $[0, 2\pi)$ or all real roots can be found using reference angles and the period of the function under consideration.

EXERCISES

Find solutions in $[0, 2\pi)$ using the method indicated. Round nonstandard values to four decimal places.

51. squaring both sides

$$\sin x + \cos x = \frac{\sqrt{6}}{2}$$

52. using identities

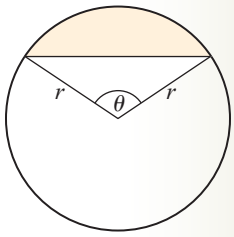
$$3\cos(2x) + 7\sin x - 5 = 0$$

53. factor by grouping

$$4\sin x\cos x - 2\sqrt{3}\sin x - 2\cos x + \sqrt{3} = 0$$

54. using any appropriate method

$$\csc x + \cot x = 1$$



State the period P of each function and find all solutions in $[0, P)$. Round to four decimal places as needed.

55. $-750\sin\left(\frac{\pi}{6}x + \frac{\pi}{2}\right) + 120 = 0$

56. $80\cos\left(\frac{\pi}{3}x + \frac{\pi}{4}\right) - 40\sqrt{2} = 0$

57. The revenue earned by Waipahu Joe's Tanning Lotions fluctuates with the seasons, with a great deal more lotion sold in the summer than in the winter. The function $R(x) = 15\sin\left(\frac{\pi}{6}x - \frac{\pi}{2}\right) + 30$ models the monthly sales of lotion nationwide, where $R(x)$ is the revenue in thousands of dollars and x represents the months of the year ($x = 1 \rightarrow$ Jan). (a) How much revenue is projected for July? (b) For what months of the year does revenue exceed \$37,000?

58. The area of a circular segment (the shaded portion shown in the diagram) is given by the formula $A = \frac{1}{2}r^2(\theta - \sin\theta)$, where θ is in radians. If the circle has a radius of 10 cm, find the angle θ that gives an area of 12 cm^2.

PRACTICE TEST

Verify each identity using fundamental identities and the method specified.

1. special products

$$\frac{(\csc x - \cot x)(\csc x + \cot x)}{\sec x} = \cos x$$

2. factoring $\frac{\sin^3 x - \cos^3 x}{1 + \cos x\sin x} = \sin x - \cos x$

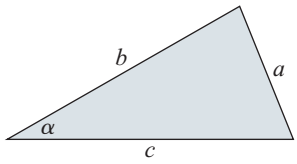
3. Find the value of all six trigonometric functions given $\cos\theta = \frac{48}{73}$; θ in QIV

4. Find the exact value of $\tan 15°$ using a sum or difference formula.

5. Rewrite as a single expression and evaluate: $\cos 81°\cos 36° + \sin 81°\sin 36°$

6. Evaluate $\cos 1935°$ exactly using an angle reduction formula.

7. Use sum and difference formulas to verify



$$\sin\left(x + \frac{\pi}{4}\right) - \sin\left(x - \frac{\pi}{4}\right) = \sqrt{2}\cos x.$$

8. Find exact values for $\sin\theta$, $\cos\theta$, and $\tan\theta$ given $\cos(2\theta) = -\frac{161}{289}$; θ in QI.

9. Use a double-angle identity to evaluate $2\cos^2 75° - 1$.

10. Find exact values for $\sin\left(\frac{\theta}{2}\right)$ and $\cos\left(\frac{\theta}{2}\right)$ given $\tan\theta = \frac{12}{35}$; θ in QI.

11. The area of a triangle is given geometrically as $A = \frac{1}{2}$ base · height. The trigonometric formula for the triangle's area is $A = \frac{1}{2}bc\sin\alpha$, where α is the angle formed by the sides b and c. In a certain triangle, $b = 8$, $c = 10$, and $\alpha = 22.5°$. Use the formula for A given here and a half-angle identity to find the area of the triangle in exact form.

12. The equation $Ax^2 + Bxy + Cy^2 = 0$ can be written in an alternative form that makes it easier to graph. This is done by eliminating the mixed xy-term using the relation $\tan(2\theta) = \frac{B}{A - C}$ to find θ. We can then find values for $\sin\theta$ and $\cos\theta$, which are used in a conversion formula. Find $\sin\theta$ and $\cos\theta$ for $17x^2 + 5\sqrt{3}xy + 2y^2 = 0$, assuming 2θ in QI.

13. Evaluate without the aid of calculators or tables.

a. $y = \tan^{-1}\left(\frac{1}{\sqrt{3}}\right)$ **b.** $y = \sin\left[\sin^{-1}\left(\frac{1}{2}\right)\right]$

c. $y = \arccos(\cos 30°)$

14. Evaluate the following. Use a calculator for part (a), give exact answers for part (b), and find the value of the expression in part (c) without using a calculator. Some may be undefined.

a. $y = \sin^{-1}0.7528$ **b.** $y = \arctan(\tan 78.5°)$

c. $y = \sec^{-1}\left[\sec\left(\frac{7\pi}{24}\right)\right]$

Evaluate the expressions by drawing a right triangle and labeling the sides.

15. $\cos\left[\tan^{-1}\left(\frac{56}{33}\right)\right]$

16. $\cot\left[\cos^{-1}\left(\frac{x}{\sqrt{25 + x^2}}\right)\right]$

17. Solve without the aid of a calculator (all solutions are standard values). Clearly state (a) the principal root, (b) all solutions in the interval $[0, 2\pi)$, and (c) all real roots.

I. $8\cos x = -4\sqrt{2}$ **II.** $\sqrt{3}\sec x + 2 = 4$

18. Solve each equation using a calculator and inverse trig functions to find the principal root (not by graphing). Then state (a) the principal root, (b) all solutions in the interval $[0, 2\pi)$, and (c) all real roots.

I. $\frac{2}{3}\sin(2x) = \frac{1}{4}$ **II.** $-3\cos(2x) - 0.8 = 0$

19. Use a graphing calculator to solve the equations in the indicated interval. State answers in radians rounded to the nearest ten-thousandth.

a. $3\cos(2x - 1) = \sin x$; $x \in [-\pi, \pi]$

b. $2\sqrt{x} - 1 = 3\cos^2 x$; $x \in [0, 2\pi)$

20. Solve the following equations for $x \in [0, 2\pi)$ using a combination of identities and/or factoring. State solutions in radians using the exact form where possible.

a. $2\sin x\sin(2x) + \sin(2x) = 0$

b. $(\cos x + \sin x)^2 = \frac{1}{2}$

Solve each equation in $[0, 2\pi)$ by squaring both sides, factoring, using identities, or by using any appropriate method. Round nonstandard values to four decimal places.

21. $3\sin(2x) + \cos x = 0$

22. $\frac{2}{3}\sin\left(2x - \frac{\pi}{6}\right) + \frac{3}{2} = \frac{5}{6}$

23. The revenue for Otake's Mower Repair is very seasonal, with business in the summer months far exceeding business in the winter months. Monthly revenue for the company can be modeled by the function $R(x) = 7.5\cos\left(\frac{\pi}{6}x + \frac{4\pi}{3}\right) + 12.5$, where $R(x)$ is the average revenue (in thousands of dollars) for month x ($x = 1 \rightarrow$ Jan). (a) What is the average revenue for September? (b) For what months of the year is revenue at least \$12,500?

24. The lowest temperature on record for the even months of the year are given in the table for the city of Denver, Colorado. The equation $y = 35.223\sin(0.576x - 2.589) + 6$ is a fairly accurate model for this data. Use the equation to estimate the record low temperatures for the odd numbered months.

Month (Jan → 1)	Low Temp. (°F)
2	−30
4	−2
6	30
8	41
10	3
12	−25

25. Write the product as a sum using a product-to-sum identity: $2\cos(1979\pi t)\cos(439\pi t)$.

CALCULATOR EXPLORATION AND DISCOVERY

Seeing the Beats as the Beats Go On

When two sound waves of slightly different frequencies are combined, the resultant wave varies periodically in amplitude over time. These amplitude pulsations are called **beats.** In this *Exploration and Discovery,* we'll look at ways to "see" the beats more clearly on a graphing calculator, by representing sound waves very simplistically as $Y_1 = \cos(mX)$ and $Y_2 = \cos(nX)$ and noting a relationship between m, n, and the number of beats in $[0, 2\pi]$. Using a sum-to-product formula, we can represent the resultant wave as a single term. For $Y_1 = \cos(12X)$ and $Y_2 = \cos(8X)$ the result is

$$Y_3 = \cos(12X) + \cos(8X) = 2\cos\left(\frac{12X + 8X}{2}\right)\cos\left(\frac{12X - 8X}{2}\right)$$
$$= 2\cos(10X)\cos(2X)$$

The window used and resulting graph are shown in Figures 7.59 and 7.60, and it appears that "silence" occurs four times in this interval—where the graph of the combined waves is tangent to (bounces off of) the x-axis. This indicates a total of four beats. Note the number of beats is equal to the difference $m - n$: $12 - 8 = 4$. Further experimentation will show this is not a coincidence, and this enables us to construct two additional functions that will *frame these pulsations* and make them easier to see. Since the maximum amplitude of the resulting wave is 2, we use functions of the form $\pm 2\cos\left(\frac{k}{2}x\right)$ to construct the frame, where k is the number of beats in the interval ($m - n = k$). For $Y_1 = \cos(12X)$ and $Y_2 = \cos(8X)$, we have $\frac{k}{2} = \frac{12 - 8}{2} = 2$ and the functions we use will be $Y_4 = 2\cos(2X)$ and $Y_5 = -2\cos(2X)$ as shown in Figure 7.61. The result is shown in Figure 7.62, where the frame clearly shows the four beats or more precisely, the four moments of silence.

Figure 7.59

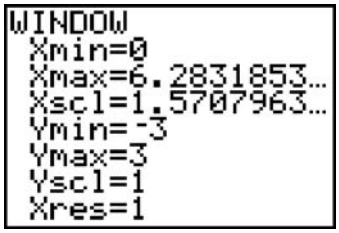

Figure 7.60

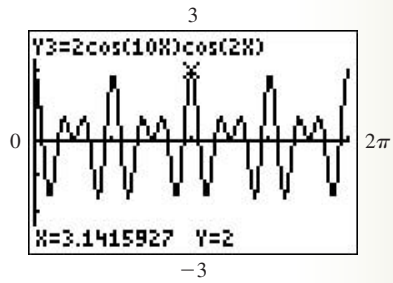

Figure 7.61

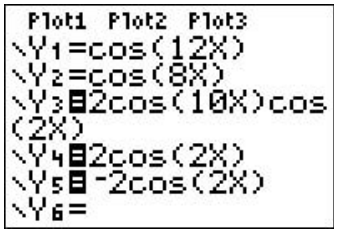

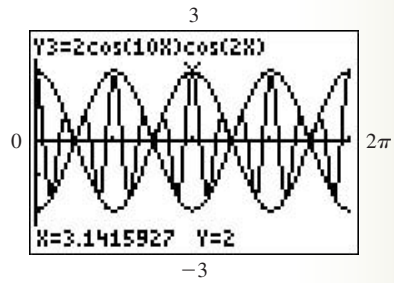

Figure 7.62

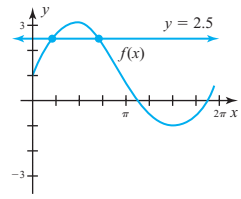
For each exercise, (a) express the sum $Y_1 + Y_2$ as a product, (b) graph Y_R on a graphing calculator for $x \in [0, 2\pi]$ and identify the number of beats in this interval, and (c) determine what value of k in $\pm 2\cos\left(\frac{k}{2}x\right)$ would be used to frame the resultant Y_R, then enter these as Y_4 and Y_5 to check the result.

Exercise 1: $Y_1 = \cos(14X)$; $Y_2 = \cos(8X)$

Exercise 2: $Y_1 = \cos(12X)$; $Y_2 = \cos(9X)$

Exercise 3: $Y_1 = \cos(14X)$; $Y_2 = \cos(6X)$

Exercise 4: $Y_1 = \cos(11X)$; $Y_2 = \cos(10X)$



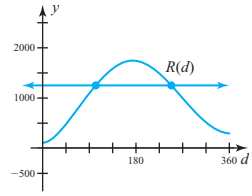
STRENGTHENING CORE SKILLS

Trigonometric Equations and Inequalities

The ability to draw a quick graph of the trigonometric functions is a tremendous help in understanding equations and inequalities. A basic sketch can help reveal the number of solutions in $[0, 2\pi)$ and the quadrant of each solution. For nonstandard angles, the value given by the inverse function can then be used as a basis for stating the solution set for all real numbers. We'll illustrate the process using a few simple examples, then generalize our observations to solve

more realistic applications. Consider the function $f(x) = 2\sin x + 1$, a sine wave with amplitude 2, and a vertical translation of $+1$. To find intervals in $[0, 2\pi)$ where $f(x) > 2.5$, we reason that f has a maximum of $2(1) + 1 = 3$ and a minimum of $2(-1) + 1 = -1$, since $-1 \le \sin x \le 1$. With no phase shift and a standard period of 2π, we can easily draw a quick sketch of f by vertically translating x-intercepts and max/min points 1 unit up. After drawing the line $y = 2.5$ (see Figure 7.63), it appears there are two intersections in the interval, one in QI and one in QII. More importantly, it is clear that $f(x) > 2.5$ *between these two solutions.* Substituting 2.5 for $f(x)$ in $f(x) = 2\sin x + 1$, we solve for $\sin x$ to obtain $\sin x = 0.75$, which we use to state the solution in exact form: $f(x) > 2.5$ for $x \in (\sin^{-1} 0.75, \pi - \sin^{-1} 0.75)$. In approximate form the solution interval is $x \in (0.85, 2.29)$. If the function involves a horizontal shift, the graphical analysis will reveal which intervals should be chosen to satisfy the given inequality.

Figure 7.63



The basic ideas remain the same regardless of the complexity of the equation, and we illustrate by studying the function $R(d) = 750\sin\left(\frac{2\pi}{365}d - \frac{\pi}{2}\right) + 950$ and the inequality $R(d) > 1250$. Remember—our current goal is not a supremely accurate graph, just a sketch that will guide us to the solution using the inverse functions and the correct quadrants. Perhaps that greatest challenge is recalling that when $B \neq 1$, the horizontal shift is $-\frac{C}{B}$, but other than this a fairly accurate sketch can quickly be obtained.

Illustration 1 ▶ Given $R(d) = 750\sin\left(\frac{2\pi}{365}d - \frac{\pi}{2}\right) + 950$, find intervals in $[0, 365]$ where $R(d) > 1250$.

Solution ▶ This is a sine wave with a period of 365 (days), an amplitude of 750, shifted $-\frac{C}{B} = 91.25$ units to the right and 950 units up. The maximum value will be 1700 and the minimum value will be 200. For convenience, scale the axes from 0 to 360 (as though the period were 360 days), and plot the x-intercepts and maximum/minimum values for a standard sine wave with amplitude 750 (by scaling the axes). Then shift these points about 90 units in the positive direction (to the right), and 950 units up, again using a scale that makes this convenient (see Figure 7.64). This sketch along with the graph of $y = 1250$ is sufficient to show that solutions to $R(d) = 1250$ occur early in the second quarter and late in the third quarter, with solutions to $R(d) > 1250$ occurring *between* these solutions. For $R(d) = 750\sin\left(\frac{2\pi}{365}d - \frac{\pi}{2}\right) + 950$, we substitute 1250 for $R(d)$ and isolate the sine function, obtaining $\sin\left(\frac{2\pi}{365}d - \frac{\pi}{2}\right) = 0.4$, which leads to exact form solutions of $d = \left(\sin^{-1}0.4 + \frac{\pi}{2}\right)\left(\frac{365}{2\pi}\right)$ and $d = \left(\pi - \sin^{-1}0.4 + \frac{\pi}{2}\right)\left(\frac{365}{2\pi}\right)$. In approximate form the solution interval is $x \in [115, 250]$.

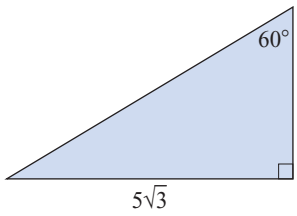
Figure 7.64

Practice with these ideas by finding solutions to the following inequalities in the intervals specified.

Exercise 1: $f(x) = 3\sin x + 2; f(x) > 3.7; x \in [0, 2\pi)$

Exercise 2: $g(x) = 4\sin\left(x - \frac{\pi}{3}\right) - 1; g(x) \le -2; x \in [0, 2\pi)$

Exercise 3: $h(x) = 125\sin\left(\frac{\pi}{6}x - \frac{\pi}{2}\right) + 175; h(x) \le 150; x \in [0, 12)$



Exercise 4: $f(x) = 15{,}750\sin\left(\frac{2\pi}{360}x - \frac{\pi}{4}\right) + 19{,}250; f(x) > 25{,}250; x \in [0, 360)$

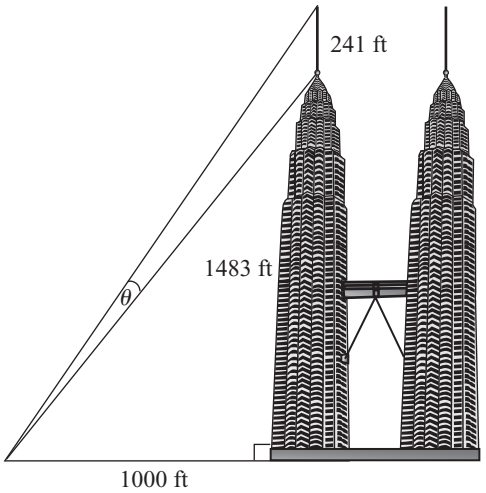
CUMULATIVE REVIEW CHAPTERS 1–7

1. Find $f(\theta)$ for all six trig functions, given $P(-13, 84)$ is on the terminal side with θ in QII.

2. Find the lengths of the missing sides.

Exercise 2

3. Verify that $x = 2 + \sqrt{3}$ is a zero of $g(x) = x^2 - 4x + 1$.



4. Determine the domain of $r(x) = \sqrt{9 - x^2}$. Answer in interval notation.

5. Standing 5 mi (26,400 ft) from the base of Mount Logan (Yukon) the angle of elevation to the summit is 36° 56′. How much taller is Mount McKinley (Alaska) which stands at 20,320 ft high?

6. Use the *Guidelines for Graphing Polynomial Functions* to sketch the graph of $f(x) = x^3 + 3x^2 - 4$.

7. Use the *Guidelines for Graphing Rational Functions* to sketch the graph of $h(x) = \dfrac{x - 1}{x^2 - 4}$

8. The Petronas Towers in Malaysia are two of the tallest structures in the world. The top of the roof reaches 1483 ft above the street below and the stainless steel pinnacles extend an additional 241 ft into the air (see figure). Find the viewing angle θ for the pinnacles from a distance of 1000 ft (the angle formed from the base of the antennae to its top).

9. A wheel with radius 45 cm is turning at 5 revolutions per second. Find the linear velocity of a point on the rim in kilometers per hour, rounded to the nearest hundredth.

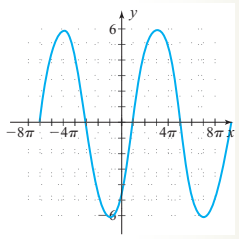
10. Solve for x: $2(x - 3)^{\frac{3}{4}} + 1 = 55$.

11. Solve for x: $-3\left|x - \dfrac{1}{2}\right| + 5 \geq -10$

12. Earth has a radius of 3960 mi. Tokyo, Japan, is located at 35.4° N latitude, very near the 139° E latitude line. Adelaide, Australia, is at 34.6° S latitude, and also very near 139° E latitude. How many miles separate the two cities?

13. Since 1970, sulphur dioxide emissions in the United States have been decreasing at a nearly linear rate. In 1970, about 31 million tons were emitted into the atmosphere. In 2000, the amount had decreased to approximately 16 million tons. (a) Find a linear equation that models sulphur dioxide emissions. (b) Discuss the meaning of the slope ratio in this context. (c) Use the equation model to estimate the emissions in 1985 and 2010.
Source: 2004 Statistical Abstract of the United States, Table 360.

14. List the three Pythagorean identities and three identities equivalent to $\cos(2\theta)$.



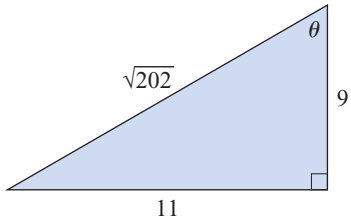
15. For $f(x) = 325\cos\left(\dfrac{\pi}{6}x - \dfrac{\pi}{2}\right) + 168$, what values of x in $[0, 2\pi)$ satisfy $f(x) > 330.5$?

16. Write as a single logarithmic expression in simplest form: $\log(x^2 - 9) + \log(x + 1) - \log(x^2 - 2x - 3)$.

17. After doing some market research, the manager of a sporting goods store finds that when a four-pack of premium tennis balls are priced at \$9 per pack, 20 packs per day are sold. For each decrease of \$0.25, 1 additional pack per day will be sold. Find the price at which four-packs of tennis balls should be sold in order to maximize the store's revenue on this item.

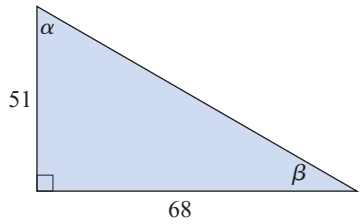
18. Write the equation of the function whose graph is given, in terms of a sine function.

Exercise 18



19. Verify that the following is an identity: $\dfrac{\cos x + 1}{\tan^2 x} = \dfrac{\cos x}{\sec x - 1}$

20. Given the zeroes of $f(x) = x^4 - 18x^2 + 32$ are $x = \pm 4$ and $x = \pm\sqrt{2}$, estimate the following:



a. the domain of the function

b. intervals where $f(x) > 0$ and $f(x) \leq 0$

21. Use the triangle shown to find the exact value of $\sin(2\theta)$.

22. Use the triangle shown to find the exact value of $\sin(\alpha + \beta)$.

23. The amount of waste product released by a manufacturing company varies according to its production schedule, which is much heavier during the summer months and lighter in the winter. Waste product amount reaches a maximum of 32.5 tons in the month of July, and falls to a minimum of 21.7 tons in January ($t = 1$). (a) Use this information to build a sinusoidal equation that models the amount of waste produced each month. (b) During what months of the year does output exceed 30 tons?

24. At what interest rate will \$2500 grow to \$3500 if it's left on deposit for 6 yr and interest is compounded continuously?

25. Identify each geometric formula:

a. $y = \pi r^2 h$ **b.** $y = LWH$

c. $y = 2\pi r$ **d.** $y = \frac{1}{2}bh$

Exercises 26 through 30 require the use of a graphing calculator.

26. Use the GRAPH and **TABLE** features of a calculator to support the validity of the identity $2\cos(1.7x) = \sec(0.9x)\cos(0.8x) + \sec(0.9x)\cos(2.6x)$. Then convert all functions to sines and cosines, rewrite the identity, and verify this new identity using a sum-to-product identity.

27. On a graphing calculator, the graph of $r(x) = \dfrac{1.5x^2 - 0.9x - 2.4}{0.5x^3 - 0.8x^2 + x - 1.6}$ appears to be continuous. However, Descartes' rule of signs tells us the denominator must have at least one real zero. Since the graph does not appear to have any vertical asymptotes, (a) what does this tell you about $r(x)$? (b) Use the **TABLE** feature of a calculator with **ΔTbl = 0.1** to help determine the x-coordinate of this discontinuity.

28. Solve the following equation graphically. Round your answer to two decimal places.

$\cos^{-1}x = \tan x$

29. Use the intersection-of-graphs method to solve the inequality $\sin x \geq \cos x$, for $x \in [0, 2\pi)$. Answer using exact values.

30. The range of a certain projectile is modeled by the function $r(\theta) = \dfrac{625}{4}\sin\theta\cos\theta$, where θ is the angle at launch and $r(\theta)$ is in feet. (a) Rewrite the function using a double angle formula, (b) determine the maximum range of the projectile, and (c) determine the launch angle that results in this maximum range.

In calculus, as in college algebra, we often encounter expressions that are difficult to use in their given form, and so attempt to write the expression in an alternative form more suitable to the task at hand. Often, we see algebra and trigonometry working together to achieve this goal.

Simplifying Expressions Using a Trigonometric Substitution

For instance, it is difficult to apply certain concepts from calculus to the equation $y = \dfrac{x}{\sqrt{9 - x^2}}$, and we attempt to rewrite the expression using a trig substitution and a Pythagorean identity. When doing so, we're careful to ensure the substitution used represents a one-to-one function, and that it maintains the integrity of the domain.

EXAMPLE 1 ▶ **Simplifying Algebraic Expressions Using Trigonometry**

Simplify $y = \dfrac{x}{\sqrt{9 - x^2}}$ using the substitution $x = 3 \sin \theta$ for $-\dfrac{\pi}{2} < \theta < \dfrac{\pi}{2}$, then verify that the result is equivalent to the original function.

Solution ▶

$$y = \frac{3 \sin \theta}{\sqrt{9 - (3 \sin \theta)^2}}$$ substitute $3 \sin \theta$ for x

$$= \frac{3 \sin \theta}{\sqrt{9 - 9 \sin^2 \theta}} = \frac{3 \sin \theta}{\sqrt{9(1 - \sin^2 \theta)}}$$ $(3 \sin \theta)^2 = 9 \sin^2 \theta$; factor

$$= \frac{3 \sin \theta}{\sqrt{9 \cos^2 \theta}}$$ substitute $\cos^2 \theta$ for $1 - \sin^2 \theta$

$$= \frac{3 \sin \theta}{3 \cos \theta}$$ $\sqrt{9 \cos^2 \theta} = 3 \cos \theta$ since $-\dfrac{\pi}{2} \le \theta \le \dfrac{\pi}{2}$

$$= \tan \theta$$ result

Check ▶ Using the notation for inverse functions, we can rewrite $y = \tan \theta$ as a function of x and use a calculator to compare it with the original function. For $x = 3 \sin \theta$ we obtain $\dfrac{x}{3} = \sin \theta$ or $\theta = \sin^{-1}\left(\dfrac{x}{3}\right)$. Substituting $\sin^{-1}\left(\dfrac{x}{3}\right)$ for θ in $y = \tan \theta$ gives $y = \tan\left[\sin^{-1}\left(\dfrac{x}{3}\right)\right]$. With the calculator in radian MODE, enter $Y_1 = \dfrac{X}{\sqrt{9 - X^2}}$ and $Y_2 = \tan\left[\sin^{-1}\left(\dfrac{X}{3}\right)\right]$ on the Y= screen. Using TblStart $= -3$ (due to the domain), the resulting table seems to indicate that the functions are indeed equivalent (see the figure).

Now try Exercises 1 through 6 ▶

Trigonometric Identities and Equations

While the tools of calculus are very powerful, it is the application of rudimentary concepts that makes them work. Earlier, we saw how basic algebra skills were needed to simplify expressions that resulted from applications of calculus. Here we illustrate the use of basic trigonometric skills combined with basic algebra skills to achieve the same end.

EXAMPLE 2 ▶ Finding Maximum and Minimum Values

Using the tools of calculus, it can be shown that the maximum and/or minimum values of $f(\theta) = \dfrac{1 + \cot\theta}{\csc\theta}$ will occur at the zero(s) of the function

$$f(\theta) = \frac{\csc\theta(-\csc^2\theta) - (1 + \cot\theta)(-\csc\theta\cot\theta)}{\csc^2\theta}.$$

Simplify the right-hand side and use the result to find the location of any maximum or minimum values that occur in the interval $[0, 2\pi)$.

Solution ▶ Begin by simplifying the numerator.

$$\begin{aligned} f(\theta) &= \frac{\csc\theta(-\csc^2\theta) - (-\csc\theta\cot\theta - \csc\theta\cot^2\theta)}{\csc^2\theta} && \text{distribute} \\ &= \frac{-\csc^3\theta + \csc\theta\cot\theta + \csc\theta\cot^2\theta}{\csc^2\theta} && \text{simplify} \\ &= \frac{\csc\theta(\cot^2\theta + \cot\theta - \csc^2\theta)}{\csc^2\theta} && \text{factor, commute terms} \\ &= \frac{(\csc^2\theta - 1) + \cot\theta - \csc^2\theta}{\csc\theta} = \frac{\cot\theta - 1}{\csc\theta} && \text{simplify, substitute } \csc^2\theta - 1 \text{ for } \cot^2\theta\text{; result} \end{aligned}$$

This shows that $f(\theta) = 0$ when $\cot\theta = 1$, or when $\theta = \dfrac{\pi}{4} + \pi k$, $k \in \mathbb{Z}$. In the interval $[0, 2\pi)$, this gives $\theta = \dfrac{\pi}{4}$ and $\dfrac{5\pi}{4}$. The function f has a maximum value of $\sqrt{2}$ at $\dfrac{\pi}{4}$, with a minimum value of $-\sqrt{2}$ at $\dfrac{5\pi}{4}$.

Now try Exercises 7 through 10 ▶

Connections to Calculus Exercises

For the functions given, (a) use the substitution indicated to find an equivalent function of θ, (b) rewrite the resulting function in terms of x using an inverse trig function, and (c) use the TABLE feature of a graphing calculator to verify the two functions are equivalent for $x \neq 0$.

1. $y = \dfrac{\sqrt{169 + x^2}}{x}$; $x = 13\tan\theta$, $\theta \in \left(-\dfrac{\pi}{2}, \dfrac{\pi}{2}\right)$

2. $y = \dfrac{\sqrt{144 - x^2}}{x}$; $x = 12\sin\theta$, $\theta \in \left(-\dfrac{\pi}{2}, \dfrac{\pi}{2}\right)$

Rewrite the following expressions using the substitution indicated.

3. $\dfrac{x^2}{\sqrt{16 - x^2}}$; $x = 4\sin\theta$

5. $\dfrac{x}{\sqrt{9 + x^2}}$; $x = 3\tan\theta$

4. $\dfrac{\sqrt{81 - x^2}}{x}$; $x = 9\sin\theta$

6. $\dfrac{8}{(x^2 - 4)^{\frac{3}{2}}}$; $x = 2\sec\theta$

Using the tools of calculus, it can be shown that for each function $f(x)$ given, the zeroes of $f'(x)$ give the location of any maximum and/or minimum values. Find the location of these values in the interval $[0, 2\pi)$, using trig identities as needed to solve $f'(x) = 0$. Verify solutions using a graphing calculator.

7. $f(x) = \dfrac{1 + \cos x}{\sec x}$;

$f'(x) = \dfrac{\sec x(-\sin x) - (1 + \cos x)\sec x\tan x}{\sec^2 x}$

8. $f(x) = \sin x\tan x$;

$f'(x) = \sin x\sec^2 x + \tan x\cos x$

9. $f(x) = 2\sin x\cos x$;

$f'(x) = 2\sin x(-\sin x) + 2\cos x\cos x$

10. $f(x) = \dfrac{\cos x}{2 + \sin x}$;

$f'(x) = \dfrac{(2 + \sin x)(-\sin x) - \cos x\cos x}{(2 + \sin x)^2}$

CHAPTER CONNECTIONS

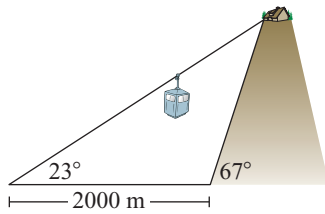
When an airline pilot charts a course, it's not as simple as pointing the airplane in the right direction. Wind currents must be taken into consideration, and compensated for by additional thrust or a change of heading that will help equalize the force of the wind and keep the plane flying in the desired direction. The effect of these forces working together can be modeled using a carefully drawn *vector diagram*, and with the aid of trigonometry, a pilot can easily determine any adjustments in navigation needed.

▶ This application appears as Exercise 85 in Section 8.3.

Connections to Calculus

As with other forms of problem solving, drawing an accurate sketch or diagram of the relationships involved has a large impact on our ability to understand vector applications and other applications of trigonometry. This is certainly no less true in a calculus course and is the subject of the Chapter 8 *Connections to Calculus.*

8.1 Oblique Triangles and the Law of Sines



LEARNING OBJECTIVES

In Section 8.1 you will see how we can:

- ❑ **A.** Develop the law of sines and use it to solve ASA and AAS triangles
- ❑ **B.** Solve SSA triangles (the ambiguous case) using the law of sines
- ❑ **C.** Use the law of sines to solve applications

Many applications of trigonometry involve **oblique triangles,** or triangles that do not have a 90° angle. For example, suppose a trolley carries passengers from ground level up to a mountain chateau, as shown in Figure 8.1. Assuming the cable could be held taut, what is its approximate length? Can we also determine the slant height of the mountain? To answer questions like these, we'll develop techniques that enable us to solve acute and obtuse triangles using fundamental trigonometric relationships.

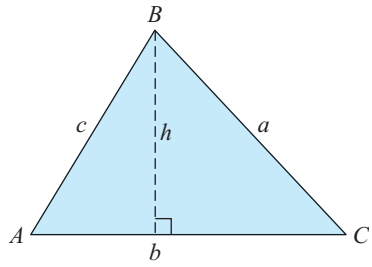


Figure 8.1

A. The Law of Sines and Unique Solutions

Consider the oblique triangle ABC pictured in Figure 8.2. Since it is not a right triangle, it seems the trigonometric ratios studied earlier cannot be applied. But if we draw the altitude h (from vertex B), two right triangles are formed that *share a common side*. By applying the sine ratio to angles A and C, we can develop a relationship that will help us solve the triangle.

Figure 8.2

WORTHY OF NOTE

As with right triangles, solving an oblique triangle involves determining the lengths of all three sides and the measures of all three angles.

For $\angle A$ we have $\sin A = \dfrac{h}{c}$ or $h = c \sin A$. For $\angle C$ we have $\sin C = \dfrac{h}{a}$ or $h = a \sin C$. Since both products are equal to h, the transitive property gives $c \sin A = a \sin C$ and we have

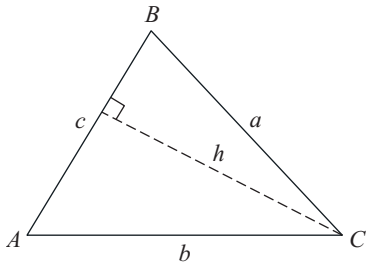
$$c \sin A = a \sin C \quad \text{since } h = h$$

$$\frac{c \sin A}{ac} = \frac{a \sin C}{ac} \quad \text{divide by } ac$$

$$\frac{\sin A}{a} = \frac{\sin C}{c} \quad \text{simplify}$$

Using the same triangle and the altitude drawn from C (Figure 8.3), we note a similar relationship involving angles A and B: $\sin A = \dfrac{h}{b}$ or $h = b \sin A$, and $\sin B = \dfrac{h}{a}$ or $h = a \sin B$. As before, we can then write $\dfrac{\sin A}{a} = \dfrac{\sin B}{b}$. If $\angle A$ is obtuse, the altitude h actually falls outside the triangle, as shown in Figure 8.4. In this case, consider that $\sin(180° - \alpha) = \sin \alpha$ from the difference formula for sines (Exercise 55, Section 7.3). In the figure we note $\sin(180° - \alpha) = \dfrac{h}{c} = \sin \alpha$, yielding $h = c \sin \alpha$ and the

Figure 8.3



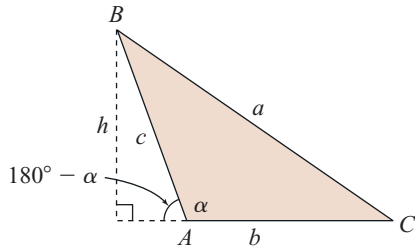


Figure 8.4

preceding relationship can now be stated using any pair of angles and corresponding sides. The result is called the **law of sines,** which is usually stated by combining the three possible proportions.

The Law of Sines

For any triangle ABC, the ratio of the sine of an angle to the side opposite that angle is constant:

$$\frac{\sin A}{a} = \frac{\sin B}{b} = \frac{\sin C}{c}$$

WORTHY OF NOTE

The case where three angles are known (AAA) is not considered since we then have a family of similar triangles, with infinitely many solutions.

As a proportional relationship, the law requires that we have three parts in order to solve for the fourth. This suggests the following possibilities:

1. two angles and an included side (ASA)
2. two angles and a side opposite one of these angles (AAS)
3. two sides and an angle opposite one of these sides (SSA)
4. two sides and an included angle (SAS)
5. three sides (SSS)

Each of these possibilities is diagrammed in Figures 8.5 through 8.9.

WORTHY OF NOTE

When working with triangles, keeping these basic properties in mind will prevent errors and assist in their solution:

1. The angles must sum to 180°.
2. The combined length of any two sides must exceed the length of the third side.
3. Longer sides will be opposite larger angles.
4. The sine of an angle cannot be greater than 1.
5. For $y \in (0, 1)$, the equation $y = \sin\theta$ has two solutions in (0°, 180°) that are supplements.

Figure 8.5

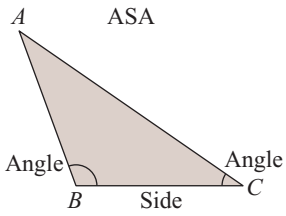

Figure 8.6

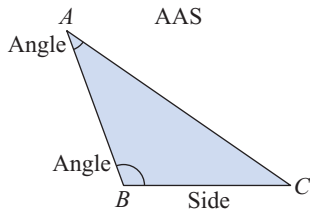

Figure 8.7

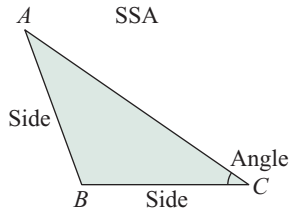

Figure 8.8

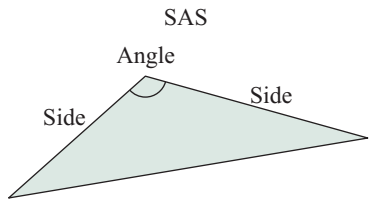

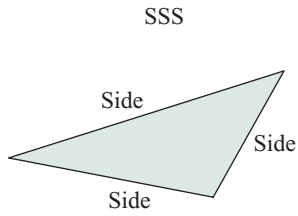

Figure 8.9

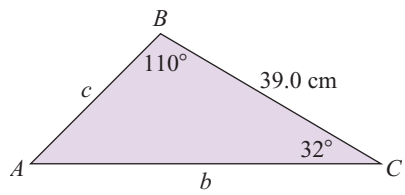


Since applying the law of sines requires we have a given side opposite a known angle, it cannot be used in the case of SAS or SSS triangles. These require the law of cosines, which we will develop in Section 8.2. In the case of ASA and AAS triangles, a unique triangle is formed since the measure of the third angle is fixed by the two given angles (they must sum to 180°) and the remaining sides must be of fixed length.

EXAMPLE 1 ▶ Solving a Triangle Using the Law of Sines

Solve the triangle shown in Figure 8.10 and state your answer using a table. Use a calculator to verify your solution.

Figure 8.10

Solution ▶ This is *not* a right triangle, so the standard ratios cannot be used. Since $\angle B$ and $\angle C$ are given, we know $\angle A = 180° - (110° + 32°) = 38°$. With $\angle A$ and side a, we have

$$\frac{\sin A}{a} = \frac{\sin B}{b} \qquad \text{law of sines applied to } \angle A \text{ and } \angle B$$

$$\frac{\sin 38°}{39} = \frac{\sin 110°}{b} \qquad \text{substitute given values}$$

$$b \sin 38° = 39 \sin 110° \qquad \text{multiply by } 39b$$

$$b = \frac{39 \sin 110°}{\sin 38°} \qquad \text{divide by } \sin 38°$$

$$b \approx 59.5 \qquad \text{result}$$

WORTHY OF NOTE

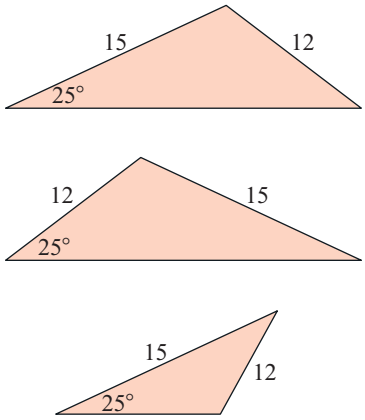
Although not a definitive check, always review the solution table to ensure the shortest side is opposite the smallest angle, the longest side is opposite the largest angle, and so on. If this is not the case, you should go back and check your work.

Repeating this procedure using $\frac{\sin A}{a} = \frac{\sin C}{c}$ shows side $c \approx 33.6$ cm. In table form we have

Angles	Sides (cm)
$A = 38°$	$\boldsymbol{a = 39.0}$
$\boldsymbol{B = 110°}$	$b \approx 59.5$
$\boldsymbol{C = 32°}$	$c \approx 33.6$

Check ▶ Begin by comparing the table entries to the measures of the original triangle. In this case, we have correctly recorded that $B = 110°$, $C = 32°$, and $a = 39.0$. Using the law of sines and a calculator in degree MODE will help to verify the remaining calculations (see Figure 8.11). Note the results are very close (agreeing to four decimal places), with the discrepancies attributed to the rounded values used.

Figure 8.11



```
sin(38)/39.0

sin(32)/33.6
     .0157714067
```

A. You've just seen how we can develop the law of sines and use it to solve ASA and AAS triangles

Now try Exercises 7 through 24 ▶

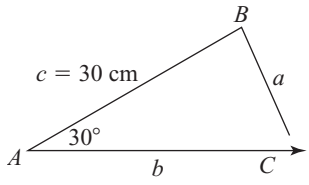
B. Solving SSA Triangles—The Ambiguous Case

Figure 8.12

To understand the concept of unique and nonunique solutions regarding the law of sines, consider an instructor who asks a large group of students to draw a triangle with sides of 15 and 12 units, and a nonincluded 25° angle. Unavoidably, three different solutions will be offered (see Figure 8.12). For the SSA case, there is some doubt as to the number of solutions possible, or whether a solution even exists.

To further understand why, consider a triangle with side $c = 30$ cm, $\angle A = 30°$, and side a opposite the 30° angle (Figure 8.13—note the length of side b is yet to be determined). From our work with 30-60-90 triangles, we know if $a = 15$ cm, it is exactly the length needed to form a right triangle (Figure 8.14).

Figure 8.13



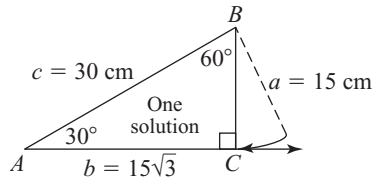


Figure 8.14

By varying the length of side a, we note three other possibilities. If side $a < 15$ cm, no triangle is possible since a is too short to contact side b (Figure 8.15), while if 15 cm < side $a < 30$ cm, two triangles are possible since side a can then intersect side b at two locations, C_1 and C_2 (Figure 8.16).

Figure 8.15

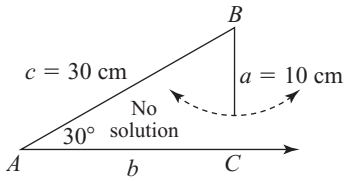

Figure 8.16

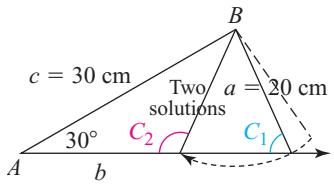

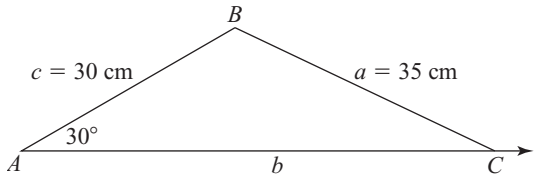

Figure 8.17

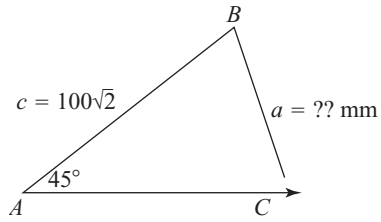
For future use, note that when two triangles are possible, angles C_1 and C_2 must be supplements since an isosceles triangle is formed. Finally, if side $a > 30$ cm, it will intersect side b only once, forming the obtuse triangle shown in Figure 8.17, where we've assumed $a = 35$ cm. Since the final solution is in doubt until we do further work, the SSA case is called the **ambiguous case** of the law of sines.

EXAMPLE 2 ▶ **Analyzing the Ambiguous Case of the Law of Sines**

Given triangle ABC (Figure 8.18) with $\angle A = 45°$ and side $c = 100\sqrt{2}$ mm,



a. What length for side a will produce a right triangle where $\angle C = 90°$?

b. How many triangles can be formed if side $a = 97$ mm?

c. If side $a = 120$ mm, how many triangles can be formed?

d. If side $a = 145$ mm, how many triangles can be formed?

Figure 8.18

Solution ▶

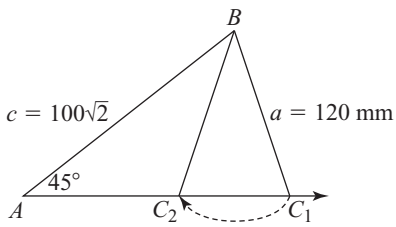
a. Recognizing the sides of a 45-45-90 triangle are in proportion according to $1x{:}1x{:}\sqrt{2}x$, side a must be 100 mm for a right triangle to be formed.

b. If $a = 97$ mm, it will be too short to contact side b and no triangle is possible.

c. As shown in Figure 8.19, if $a = 120$ mm, it will contact side b in two distinct places and two triangles are possible.

d. If $a = 145$ mm, it will contact side b only once, since it is longer than side c and will "miss" intersecting side b a second time as it pivots around B (see Figure 8.20). One triangle is possible.

Figure 8.19



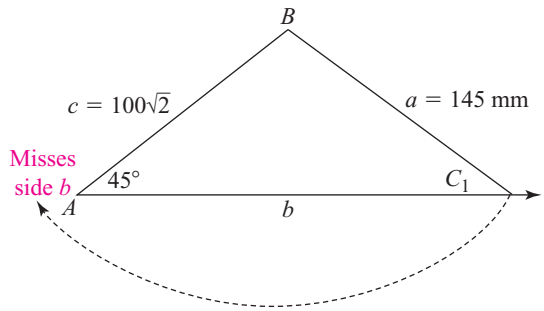


Figure 8.20

Now try Exercises 25 and 26 ▶

The **TABLE** feature of a calculator can help increase our understanding of the ambiguous case. Consider triangle ABC from Example 2. Using the law of sines, we have the following sequence:

$$\frac{\sin C}{100\sqrt{2}} = \frac{\sin 45°}{a} \qquad \text{law of sines}$$

$$\sin C = \frac{\frac{\sqrt{2}}{2}(100\sqrt{2})}{a} \qquad \sin 45° = \frac{\sqrt{2}}{2}\text{, multiply by } 100\sqrt{2}$$

$$\sin C = \frac{100}{a} \qquad \text{simplify}$$

$$C = \sin^{-1}\left(\frac{100}{a}\right) \qquad \text{apply } \sin^{-1}$$

We can enter this expression for $\angle C$ as Y_1 on the Y= screen and then use the **TABLE** feature to evaluate the expression *for different lengths of side a*. If two triangles are possible, C_1 and C_2 must be complements (see comment on top of page 749) and the expression shown for Y_2 in Figure 8.21 gives the second value for $\angle C$. To investigate possibilities for side a, set **TblStart = 97** with **ΔTbl = 1**. Pressing 2nd GRAPH **(TABLE)** produces the results shown in Figure 8.22. Note that when $a = 100$, $C = 90°$ and a right triangle is formed, confirming the solution of Example 2(a). When $a < 100$ as in part (b), $\frac{100}{a}$ is greater than 1 and the table generates an ERROR message, verifying that no triangle can be formed. To investigate part (d), scroll through the table until the screen shown in Figure 8.23 appears and note that when $a = 145$, the second possibility for $\angle C$ would be near 136.4°. Since $\angle A + \angle C \approx 45° + 136.4° = 181.4°$ is already greater than 180° (*without even taking* $\angle B$ *into account*), this second value of $\angle C$ must be discarded. Only one triangle is possible.

Figure 8.21

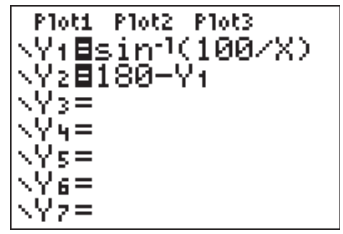

Figure 8.22

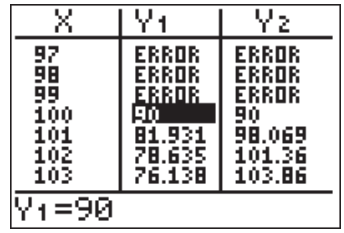

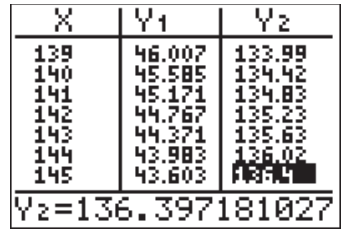

Figure 8.23

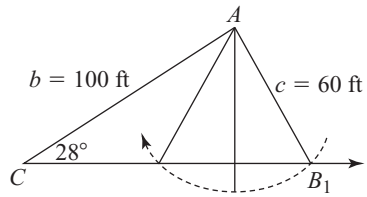


For an even better understanding of the SSA (ambiguous) case, scaled drawings can initially be used along with a metric ruler and protractor. Begin with a horizontal line segment of undetermined length to represent the third (unknown) side, and use the protractor to draw the given angle on either the left or right side of this segment (we chose the left). Then use the metric ruler to draw an adjacent side of appropriate length, *choosing a scale that enables a complete diagram*. For instance, if the given sides are 3 ft and 5 ft, use 3 cm and 5 cm instead (1 cm = 1 ft). If the sides are 80 mi and 120 mi, use 8 cm and 12 cm (1 cm = 10 mi), and so on. Once the adjacent side is drawn, start at the free endpoint and draw a vertical segment to represent the remaining side. A careful sketch will often indicate whether none, one, or two triangles are possible (see the *Reinforcing Basic Concepts* feature on page 786).

EXAMPLE 3 ▶ **Solving the Ambiguous Case of the Law of Sines**

Solve the triangle with side $b = 100$ ft, side $c = 60$ ft, and $\angle C = 28.0°$.

Solution ▶ Two sides and an angle opposite are given (SSA), and we draw a diagram to help determine the possibilities. Draw the horizontal segment of some length and use a protractor to mark $\angle C = 28°$. Then draw a segment 10 cm long (to represent $b = 100$ ft) as the adjacent side of the angle, with a vertical segment 6 cm long from the free end of b (to represent $c = 60$ ft). It seems apparent that side c will intersect the horizontal side in two places (see Figure 8.24), and two triangles are possible. We apply the law of sines to solve the first triangle, whose features we'll note with a subscript of 1.

Figure 8.24

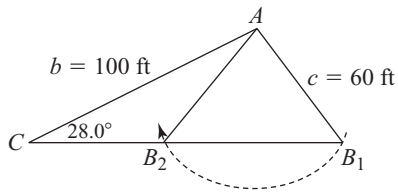
$$\frac{\sin B_1}{b} = \frac{\sin C}{c} \quad \text{law of sines}$$

$$\frac{\sin B_1}{100} = \frac{\sin 28°}{60} \quad \text{substitute}$$

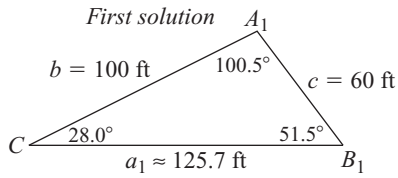
$$\sin B_1 = \frac{5}{3}\sin 28° \quad \text{solve for } \sin B_1$$

$$B_1 \approx 51.5° \quad \text{apply arcsine}$$

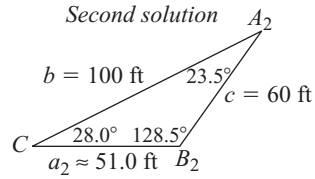
WORTHY OF NOTE



In Example 3, we found $\angle B_2$ using the property that states the angles must be supplements (see the isosceles triangle comment on top of page 749). We could also view $\angle B_1$ as a QI reference angle, which also gives a QII solution of $(180 - 51.5)° = 128.5°$.



Since $\angle B_1 + \angle B_2 = 180°$, we know $\angle B_2 \approx 128.5°$. These values give 100.5° and 23.5° as the measures of $\angle A_1$ and $\angle A_2$, respectively. By once again applying the law of sines to each triangle, we find side $a_1 \approx 125.7$ ft and $a_2 \approx 51.0$ ft. See Figure 8.25.



Angles	Sides (ft)
$A_1 \approx 100.5°$	$a_1 \approx 125.7$
$B_1 \approx 51.5°$	$b = 100$
$C = 28°$	$c = 60$

Angles	Sides (ft)
$A_2 \approx 23.5°$	$a_2 \approx 51.0$
$B_2 \approx 128.5°$	$b = 100$
$C = 28°$	$c = 60$

Figure 8.25

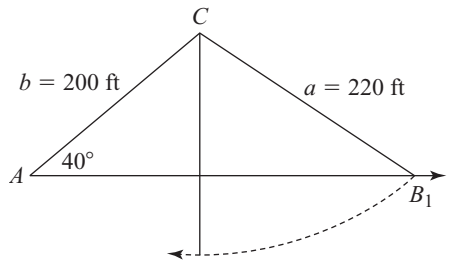
Now try Exercises 27 through 32 ▶

Admittedly, the scaled drawing approach has some drawbacks—it takes time to draw the diagrams and is of little use if the situation is a close call. It does, however, offer a deeper understanding of the subtleties involved in solving the SSA case. Instead of a scaled drawing, we can use a simple sketch *as a guide,* while keeping in mind the properties mentioned in the *Worthy of Note* on page 747.

EXAMPLE 4 ▶ **Solving the Ambiguous Case of the Law of Sines**

Solve the triangle with side $a = 220$ ft, side $b = 200$ ft, and $\angle A = 40°$.

Solution ▶ The information given is again SSA, and we apply the law of sines with this in mind.



$$\frac{\sin A}{a} = \frac{\sin B}{b} \quad \text{law of sines}$$

$$\frac{\sin 40°}{220} = \frac{\sin B}{200} \quad \text{substitute}$$

$$\sin B = \frac{200 \sin 40°}{220} \quad \text{solve for sin } B$$

$$B_1 = \sin^{-1}\left(\frac{200 \sin 40°}{220}\right) \quad \text{apply arcsine}$$

$$B_1 \approx 35.8° \quad \text{calculator result}$$

This is the solution from Quadrant I. The QII solution is about $(180 - 35.8)° = 144.2°$. At this point our solution tables have this form:

Angles	Sides (ft)
$A = 40°$	$a = 220$
$B_1 \approx 35.8°$	$b = 200$
$C_1 =$	$c_1 =$

Angles	Sides (ft)
$A = 40°$	$a = 220$
$B_2 \approx 144.2°$	$b = 200$
$C_2 =$	$c_2 =$

It seems reasonable to once again find the remaining angles and finish by reapplying the law of sines, but observe that the sum of the two angles from the second solution *already exceeds 180°*: $40° + 144.2° = 184.2°$! This means no second solution is possible (side a is too long). We find that $C_1 \approx 104.2°$, and applying the law of sines gives a value of $c_1 \approx 331.7$ ft.

Now try Exercises 33 through 44 ▶

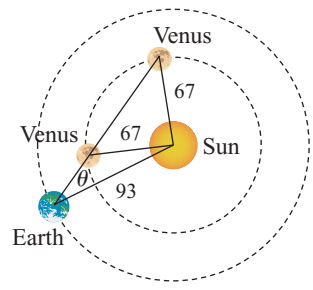
☑ **B.** You've just seen how we can solve SSA triangles (the ambiguous case) using the law of sines

C. Applications of the Law of Sines

As "ambiguous" as it is, the ambiguous case has a number of applications in engineering, astronomy, physics, and other areas. Here is an example from astronomy.

EXAMPLE 5 ▶ **Solving an Application of the Ambiguous Case—Planetary Distance**

The planet Venus can be seen from Earth with the naked eye, but as the diagram indicates, the position of Venus is uncertain (we are unable to tell if Venus is in the near position or the far position). Given Earth is 93 million miles from the Sun and Venus is 67 million miles from the Sun, determine the closest and farthest possible distances that separate the planets in this alignment. Assume a viewing angle of $\theta \approx 18°$ and that the orbits of both planets are roughly circular.



Solution ▶ A close look at the information and diagram shows a SSA case. Begin by applying the law of sines where $E \rightarrow$ Earth, $V \rightarrow$ Venus, and $S \rightarrow$ Sun.

$$\frac{\sin E}{e} = \frac{\sin V}{v} \quad \text{law of sines}$$

$$\frac{\sin 18°}{67} = \frac{\sin V}{93} \quad \text{substitute given values}$$

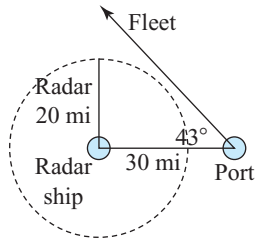
$$\sin V = \frac{93 \sin 18°}{67} \quad \text{solve for sin } V$$

$$V \approx 25.4° \quad \text{apply arcsine}$$

This is the angle V_1 formed when Venus is farthest away. The angle V_2 at the closer distance is $180° - 25.4° = 154.6°$. At this point, our solution tables have this form:

Angles	Sides (10^6 mi)
$E = 18°$	$e = 67$
$V_1 \approx 25.4°$	$v = 93$
$S_1 =$	$s_1 =$

Angles	Sides (10^6 mi)
$E = 18°$	$e = 67$
$V_2 = 154.6°$	$v = 93$
$S_2 =$	$s_2 =$



For S_1 and S_2 we have $S_1 \approx 180° - (18° + 25.4°) = 136.6°$ (larger angle) and $S_2 \approx 180° - (18° + 154.6°) = 7.4°$ (smaller angle). Reapplying the law of sines for s_1 shows the farther distance between the planets is about 149 million miles. Solving for s_2 shows that the closer distance is approximately 28 million miles.

Now try Exercises 47 and 48 ▶

EXAMPLE 6 ▶ Solving an Application of the Ambiguous Case—Radar Detection

As shown in Figure 8.26, a radar ship is 30 mi off shore when a large fleet of ships leaves port at an angle of 43°.

Figure 8.26

a. If the maximum range of the ship's radar is 20 mi, will the departing fleet be detected?

b. If the maximum range of the ship's radar is 25 mi, how far from port is the fleet when it is first detected?

Solution ▶

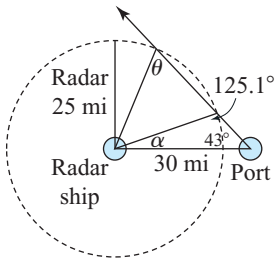
a. This is again the SSA (ambiguous) case. Applying the law of sines gives

$$\frac{\sin 43°}{20} = \frac{\sin \theta}{30} \quad \text{law of sines}$$

$$\sin \theta = \frac{30 \sin 43°}{20} \quad \text{solve for } \sin \theta$$

$$\sin \theta \approx 1.02299754 \quad \text{result}$$

No triangle is possible and the departing fleet will not be detected.



b. If the radar has a range of 25 mi, the radar beam will intersect the course of the fleet in two places.

$$\frac{\sin 43°}{25} = \frac{\sin \theta}{30} \quad \text{law of sines}$$

$$\sin \theta = \frac{30 \sin 43°}{25} \quad \text{solve for } \sin \theta$$

$$\theta \approx 54.9° \quad \text{apply arcsine}$$

Figure 8.27

This is the acute angle θ related to the *farthest point* from port at which the fleet could be detected (see Figure 8.27). For the second triangle, we have $180° - 54.9° = 125.1°$ (the obtuse angle) giving a measure of $180° - (125.1° + 43°) = 11.9°$ for angle α. For d as the side opposite α we have

$$\frac{\sin 43°}{25} = \frac{\sin 11.9°}{d} \quad \text{law of sines}$$

$$d = \frac{25 \sin 11.9°}{\sin 43°} \quad \text{solve for } d$$

$$\approx 7.6 \quad \text{simplify}$$

This shows the fleet is first detected about 7.6 mi from port.

C. You've just seen how we can use the law of sines to solve applications

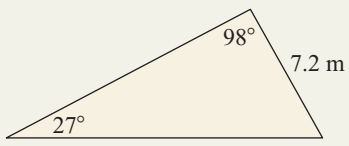
Now try Exercises 49 and 50 ▶

There are a number of additional, interesting applications in the Exercise Set **(see Exercises 51 through 66).**

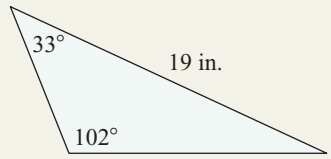
8.1 EXERCISES

▶ CONCEPTS AND VOCABULARY

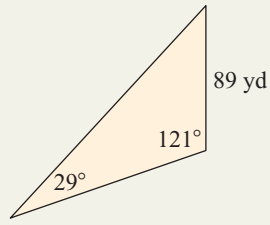
Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.



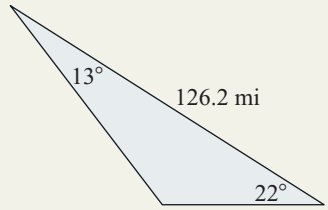
1. For the law of sines, if two sides and an angle opposite one side are given, this is referred to as the _____ case, since the solution is in doubt until further work.
2. Two inviolate properties of a triangle that can be used to help solve the ambiguous case are: (a) the angles must sum to _____ and (b) no sine ratio can exceed _____.
3. For positive $k < 1$, the equation $\sin\theta = k$ has two solutions, one in Quadrant _____ and the other in Quadrant _____.
4. After a triangle is solved, you should always check to ensure that the _____ side is opposite the _____ angle.
5. In your own words, explain why the AAS case results in a unique solution while the SSA case does not. Give supporting diagrams.
6. Explain why no triangle is possible in each case:
   a. $A = 34°, B = 73°, C = 52°, a = 14', b = 22', c = 18'$
   b. $A = 42°, B = 57°, C = 81°, a = 7'', b = 9'', c = 22''$



▶ DEVELOPING YOUR SKILLS

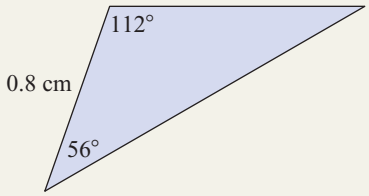


Solve each of the following equations for the unknown part (if possible). Round sides to the nearest hundredth and degrees to the nearest tenth.



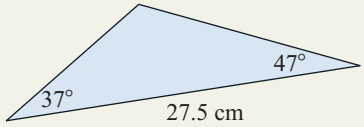
7. $\dfrac{\sin 32°}{15} = \dfrac{\sin 18.5°}{a}$
8. $\dfrac{\sin 52°}{b} = \dfrac{\sin 30°}{12}$
9. $\dfrac{\sin 63°}{21.9} = \dfrac{\sin C}{18.6}$
10. $\dfrac{\sin B}{3.14} = \dfrac{\sin 105°}{6.28}$
11. $\dfrac{\sin C}{48.5} = \dfrac{\sin 19°}{43.2}$
12. $\dfrac{\sin 38°}{125} = \dfrac{\sin B}{190}$

Solve each triangle using the law of sines. If the law of sines cannot be used, state why. Draw and label a triangle or label the triangle given before you begin. Use a calculator to verify your results.



13. side $a = 75$ cm, $\angle A = 38°$, $\angle B = 47°$
14. side $b = 385$ m, $\angle B = 47°$, $\angle A = 108°$
15. side $b = 10\sqrt{3}$ in., $\angle A = 30°$, $\angle B = 60°$
16. 

17. 



18. 

19. $\angle A = 45°$, $\angle B = 45°$, side $c = 15\sqrt{2}$ mi
20. $\angle A = 20.4°$, side $c = 12.9$ mi, $\angle B = 63.4°$
21. $\angle B = 103.4°$, side $a = 42.7$ km, $\angle C = 19.6°$
22. 

23.

24.

Answer each question and justify your response using a diagram, but do not solve.

25. Given $\triangle ABC$ with $\angle A = 30°$ and side $c = 20$ cm, (a) what length for side a will produce a right triangle? (b) How many triangles can be formed if side $a = 8$ cm? (c) If side $a = 12$ cm, how many triangles can be formed? (d) If side $a = 25$ cm, how many triangles can be formed?

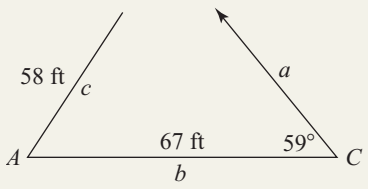
26. Given $\triangle ABC$ with $\angle A = 60°$ and side $c = 6\sqrt{3}$ m, (a) what length for side a will produce a right triangle? (b) How many triangles can be formed if side $a = 8$ m? (c) If side $a = 10$ m, how many triangles can be formed? (d) If side $a = 15$ m, how many triangles can be formed?

Solve using the law of sines and a scaled drawing. If two triangles exist, solve both completely.

27. side $b = 385$ m
$\angle B = 67°$
side $a = 490$ m

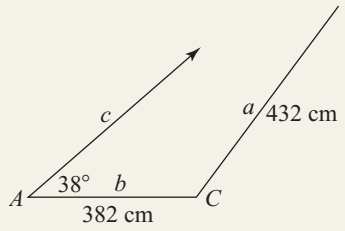
28. side $a = 36.5$ yd
$\angle B = 67°$
side $b = 12.9$ yd

29. side $c = 25.8$ mi
$\angle A = 30°$
side $a = 12.9$ mi



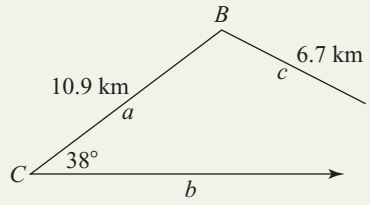
30. side $c = 10\sqrt{3}$ in.
$\angle A = 60°$
side $a = 15$ in.

31. side $c = 58$ mi
$\angle C = 59°$
side $b = 67$ mi

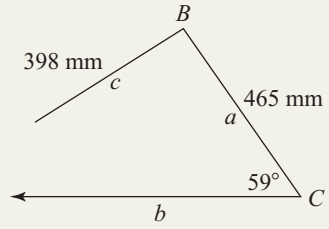


32. side $b = 24.9$ km
$\angle B = 45°$
side $a = 32.8$ km

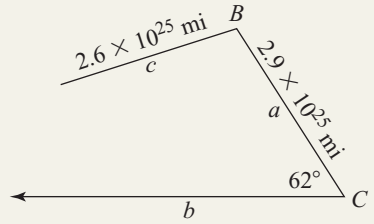
Use the law of sines to determine if no triangle, one triangle, or two triangles can be formed from the diagrams given (diagrams *may not be to scale*), then solve. If two solutions exist, solve both completely. Note the arrowhead marks the side of undetermined length.



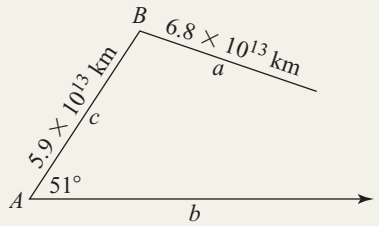
33.



34.



35.



36.

37.

38.

For Exercises 39 to 44, assume the law of sines is being applied to solve a triangle. Solve for the unknown angle (if possible), then determine if a second angle ($0° < \theta < 180°$) exists that also satisfies the proportion.

39. $\dfrac{\sin A}{12} = \dfrac{\sin 48°}{27}$

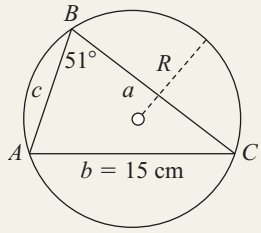
40. $\dfrac{\sin 60°}{32} = \dfrac{\sin B}{9}$

41. $\dfrac{\sin 57°}{35.6} = \dfrac{\sin C}{40.2}$

42. $\dfrac{\sin B}{5.2} = \dfrac{\sin 65°}{4.9}$

43. $\dfrac{\sin A}{280} = \dfrac{\sin 15°}{52}$

44. $\dfrac{\sin 29°}{121} = \dfrac{\sin B}{321}$

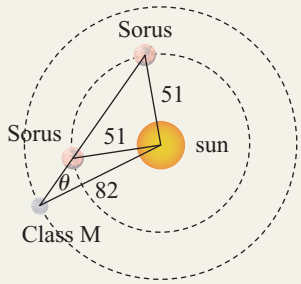


▶ WORKING WITH FORMULAS

45. Triple angle formula for sine: $\sin(3\theta) = 3\sin\theta - 4\sin^3\theta$

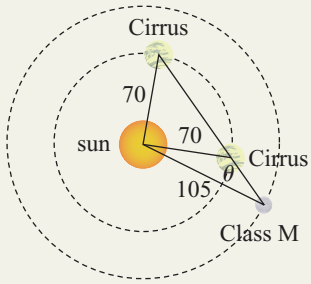
Most students are familiar with the double-angle formula for sine: $\sin(2\theta) = 2\sin\theta\cos\theta$. The triple-angle formula for sine is given here. Use the formula to find an exact value for sin 135°, then verify the result using a reference angle.

46. Radius of a circumscribed circle: $R = \dfrac{b}{2\sin B}$



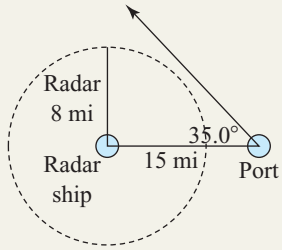
Given $\triangle ABC$ is circumscribed by a circle of radius R, the radius of the circle can be found using the formula shown, where side b is opposite angle B. Find the radius of the circle shown.

▶ APPLICATIONS



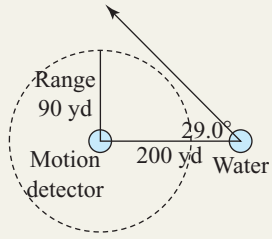
47. Planetary distances: In a solar system that parallels our own, the planet Sorus can be seen from a Class M planet with the naked eye, but as the diagram indicates, the position of Sorus is uncertain. Assume the orbits of both planets are roughly circular and that the viewing angle θ is about 20°. If the Class M planet is 82 million miles from its sun and Sorus is 51 million miles from this sun, determine the closest and farthest possible distances that separate the planets in this alignment.

Exercise 47

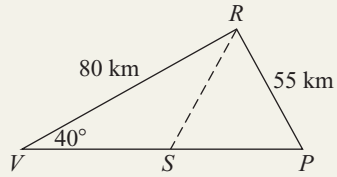


48. Planetary distances: In a solar system that parallels our own, the planet Cirrus can be seen from a Class M planet with the naked eye, but as the diagram indicates, the position of Cirrus is uncertain. Assume the orbits of both planets are roughly circular and that the viewing angle θ is about 15°. If the Class M planet is 105 million miles from its sun and Cirrus is 70 million miles from this sun, determine the closest and farthest possible distances that separate the planets in this alignment.

Exercise 48

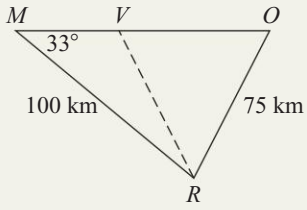


49. Radar detection: A radar ship is 15.0 mi off shore from a major port when a large fleet of ships leaves the port at the 35.0° angle shown. (a) If the maximum range of the ship's radar is 8.0 mi, will the departing fleet be detected? (b) If the maximum range of the ship's radar is 12 mi, how far from port is the fleet when it is first detected?



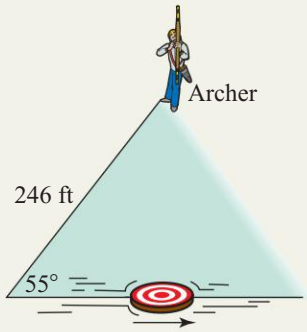
50. Motion detection: To notify environmentalists of the presence of big game, motion detectors are installed 200 yd from a watering hole. A pride of lions has just visited the hole and is leaving the area at the 29.0° angle shown. (a) If the maximum range of the motion detector is 90 yd, will the pride be detected? (b) If the maximum range of the motion detector is 120 yd, how far from the watering hole is the pride when first detected?

Exercise 50



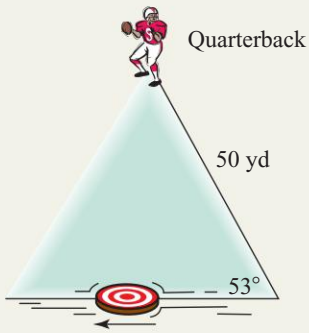
51. Distance between cities: The cities of *V*an Gogh, *R*embrandt, *P*issarro, and *S*eurat are situated as shown in the diagram. Assume that triangle *RSP* is isosceles and use the law of sines to find the distance between *V*an Gogh and *S*eurat, and between *V*an Gogh and *P*issarro.

Exercise 51



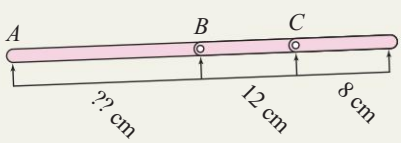
52. Distance between cities: The cities of ***M***ozart, ***R***ossini, ***O***ffenbach, and ***V***erdi are situated as shown in the diagram. Assume that triangle *ROV* is isosceles and use the law of sines to find the distance between *M*ozart and *V*erdi, and between *M*ozart and *O*ffenbach.

Exercise 52

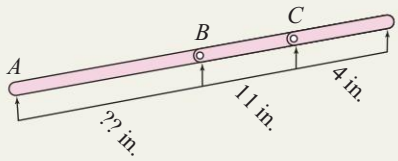


53. Distance to target: To practice for a competition, an archer stands as shown in the diagram and attempts to hit a moving target. (a) If the archer has a maximum effective range of about 180 ft, can the target be hit? (b) What is the shortest range the archer can have and still hit the target? (c) If the archer's range is 215 ft and the target is moving at 10 ft/sec, how many seconds is the target within range?

Exercise 53

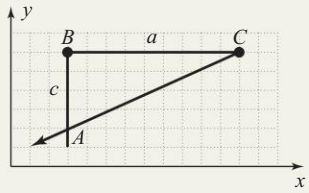


54. Distance to target: As part of an All-Star competition, a quarterback stands as shown in the diagram and attempts to hit a moving target with a football. (a) If the quarterback has a maximum effective range of about 35 yd, can the target be hit? (b) What is the shortest range the quarterback can have and still hit the target? (c) If the quarterback's range is 45 yd and the target is moving at 5 yd/sec, how many seconds is the target within range?

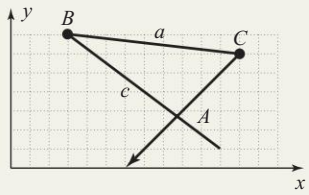


In Exercises 55 and 56, three rods are attached via pivot joints so the rods can be manipulated to form a triangle. How many triangles can be formed if angle *B* must measure 26°? If one triangle, solve it. If two, solve both. Diagrams are not drawn to scale.

55.

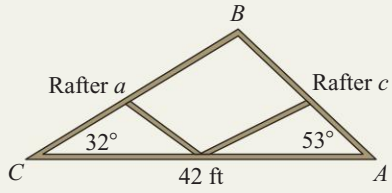


56.

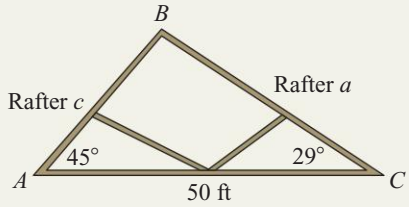


In the diagrams given, the measure of angle *C* and the lengths of sides *a* and *c* are fixed. Side *c* can be rotated at pivot point *B*. Solve any triangles that can be formed. (*Hint:* Begin by using the grid to find lengths *a* and *c*, then find angle *C*.)

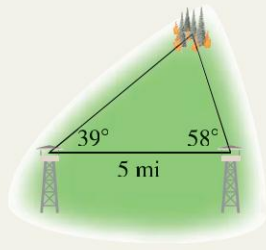
57.



58.

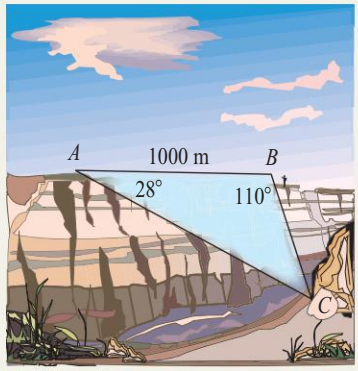


Length of a rafter: Determine the length of both roof rafters in the diagrams given.

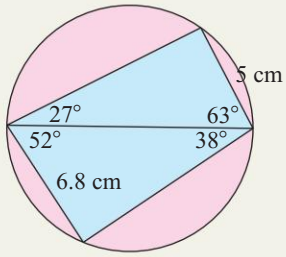


59.

60.



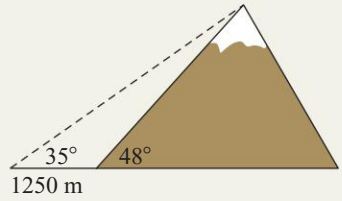
61. Distance to a fire: In Yellowstone Park, a fire is spotted by park rangers stationed in two towers that are known to be 5 mi apart. Using the line between them as a baseline, tower A reports the fire is at an angle of 39°, while tower B reports an angle of 58°. How far is the fire from the closer tower?



62. Width of a canyon: To find the distance across Waimea Canyon (on the island of Kauai), a surveyor marks a 1000-m baseline along the southern rim. Using a transit, she sights on a large rock formation on the north rim, and finds the angles indicated. How wide is the canyon from point B to point C?

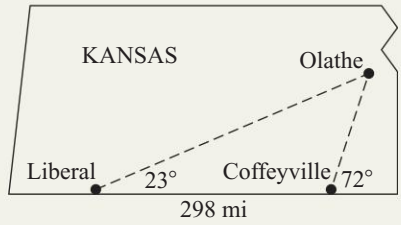
Exercise 62

63. Circumscribed triangles: A triangle is circumscribed within the upper semicircle drawn in the figure. Use the law of sines to solve the triangle given the measures shown. What is the diameter of the circle? What do you notice about the triangle?



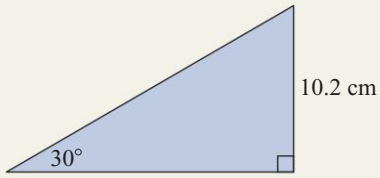
Exercises 63 and 64

64. Circumscribed triangles: A triangle is circumscribed within the lower semicircle shown. Use the law of sines to solve the triangle given the measures shown. How long is the longer chord? What do you notice about the triangle?



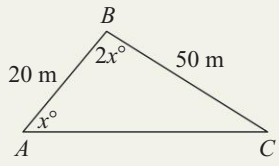
65. Height of a mountain: Approaching from the west, a group of hikers notes the angle of elevation to the summit of a steep mountain is 35° at a distance of 1250 meters. Arriving at the base of the mountain, they estimate this side of the mountain has an average slope of 48°. (a) Find the slant height of the mountain's west side. (b) Find the slant height of the east side of the mountain, if the east side has an average slope of 65°. (c) How tall is the mountain?

Exercise 65



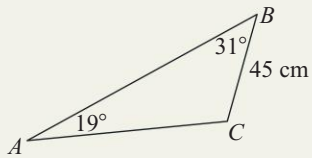
66. Distance on a map: Coffeyville and Liberal, Kansas, lie along the state's southern border and are roughly 298 mi apart. Olathe, Kansas, is very near the state's eastern border at an angle of 23° with Liberal and 72° with Coffeyville (using the southern border as one side of the angle). (a) Compute the distance between these cities. (b) What is the shortest (straight line) distance from Olathe to the southern border of Kansas?

Exercise 66



▶ EXTENDING THE CONCEPT

67. Solve the triangle shown in three ways—first by using the law of sines, second using right triangle trigonometry, and third using the standard 30-60-90 triangle. Was one method "easier" than the others? Use these connections to express the irrational number $\sqrt{3}$ as a quotient of two trigonometric functions of an angle. Can you find a similar expression for $\sqrt{2}$?



68. Use the law of sines and any needed identities to solve the triangle shown.

69. Similar to the law of sines, there is a *law of tangents*. The law says for any triangle ABC,

$$\frac{a+b}{a-b} = \frac{\tan\left[\frac{1}{2}(A+B)\right]}{\tan\left[\frac{1}{2}(A-B)\right]}.$$

Use the law of tangents to solve the triangle shown.

70. A UFO is sighted on a direct line between the towns of Batesville and Cave City, sitting stationary in the sky. The towns are 13 mi apart as the crow flies. A student in Batesville calls a friend in Cave City and both take measurements of the angle of elevation: 35° from Batesville and 42° from Cave City. Suddenly the UFO zips across the sky at a level altitude heading directly for Cave City, then stops and hovers long enough for an additional measurement from Batesville: 24°. If the UFO was in motion for 1.2 sec, at what average speed (in mph) did it travel?

▶ MAINTAINING YOUR SKILLS

71. (7.7) Find all solutions to the equation $2 \sin x = \cos(2x)$

72. (7.2) Prove the given identity: $\tan^2 x - \sin^2 x = \tan^2 x \sin^2 x$

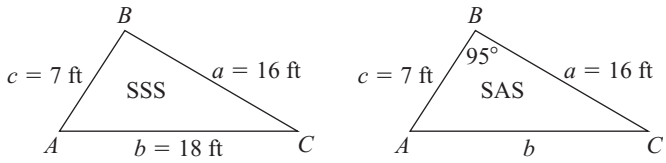
73. (4.2) Write a real polynomial equation with smallest degree possible, having the solutions $x = 2, x = -1$, and $x = 1 + 2i$.

74. (1.4) Given the points $(-5, -3)$ and $(4, 2)$, find (a) the equation of the line containing these points and (b) the distance between these points.

8.2 The Law of Cosines; the Area of a Triangle

LEARNING OBJECTIVES

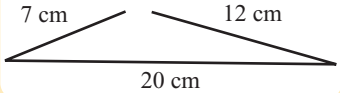
In Section 8.2 you will see how we can:



- ❑ **A.** Apply the law of cosines when two sides and an included angle are known (SAS)
- ❑ **B.** Apply the law of cosines when three sides are known (SSS)
- ❑ **C.** Solve applications using the law of cosines
- ❑ **D.** Use trigonometry to find the area of a triangle

The distance formula $d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$ is traditionally developed by placing two arbitrary points on a rectangular coordinate system and using the Pythagorean theorem. The relationship known as the *law of cosines* is developed in much the same way, but this time by using *three* arbitrary points (the vertices of a triangle). After giving the location of one vertex in trigonometric form, we obtain a formula that enables us to solve SSS and SAS triangles, which cannot be solved using the law of sines alone.

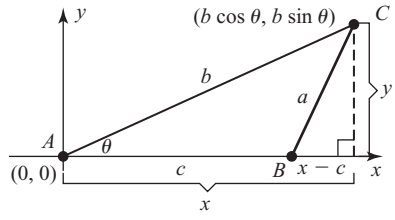
A. The Law of Cosines and SAS Triangles



In situations where all three sides are known (but no angles), the law of sines cannot be applied. The same is true when two sides and the angle between them are known, since we must have an angle opposite one of the sides. In these two cases, side-side-side (**SSS**) and side-angle-side (**SAS**), we use the **law of cosines** (Figure 8.28).

Figure 8.28
Law of sines cannot be applied.

WORTHY OF NOTE



Keep in mind that the sum of any two sides of a triangle must be greater than the remaining side. For example, if $a = 7$, $B = 20$, and $C = 12$, no triangle is possible (see the figure).

To solve these cases, it's evident we need additional insight on the unknown angles. Consider a general triangle ABC on the rectangular coordinate system conveniently placed with vertex A at the origin, side c along the x-axis, and the vertex C at some point (x, y) in QI (Figure 8.29).

Note $\cos\theta = \dfrac{x}{b}$ giving $x = b\cos\theta$, and $\sin\theta = \dfrac{y}{b}$

Figure 8.29

or $y = b \sin \theta$. This means we can write the point (x, y) as $(b \cos \theta, b \sin \theta)$ as shown, and use the Pythagorean theorem with side $x - c$ to find the length of side a of the exterior, right triangle. It follows that

$$\begin{aligned}
a^2 &= (x - c)^2 + y^2 && \text{Pythagorean theorem}\\
&= (b\cos\theta - c)^2 + (b\sin\theta)^2 && \text{substitute } b\cos\theta \text{ for } x \text{ and } b\sin\theta \text{ for } y\\
&= b^2\cos^2\theta - 2bc\cos\theta + c^2 + b^2\sin^2\theta && \text{square binomial, square term}\\
&= b^2\cos^2\theta + b^2\sin^2\theta + c^2 - 2bc\cos\theta && \text{rearrange terms}\\
&= b^2(\cos^2\theta + \sin^2\theta) + c^2 - 2bc\cos\theta && \text{factor out } b^2\\
&= b^2 + c^2 - 2bc\cos\theta && \text{substitute 1 for } \cos^2\theta + \sin^2\theta
\end{aligned}$$

We now have a formula relating all three sides and an included angle. Since the naming of the angles is purely arbitrary, the formula can be used in any of the three forms shown. For the derivation of the formula where $\angle B$ is acute, **see Exercise 60.**

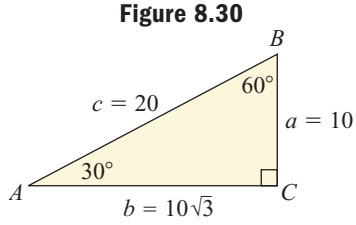
The Law of Cosines

For any triangle ABC and corresponding sides a, b, and c,

$$a^2 = b^2 + c^2 - 2bc\cos A$$
$$b^2 = a^2 + c^2 - 2ac\cos B$$
$$c^2 = a^2 + b^2 - 2ab\cos C$$

Note the relationship between the squared side and indicated angle.

In words, the law of cosines says that the square of any side is equal to the sums of the squares of the other two sides, minus twice their product times the cosine of the included angle. It is interesting to note that if the included angle is 90°, the formula reduces to the Pythagorean theorem since $\cos 90° = 0$.



EXAMPLE 1 ▶ **Verifying the Law of Cosines**

For the triangle shown in Figure 8.30, verify:

a. $c^2 = a^2 + b^2 - 2ab\cos C$

b. $b^2 = a^2 + c^2 - 2ac\cos B$

Figure 8.30

Solution ▶ Note the included angle C is a right angle.

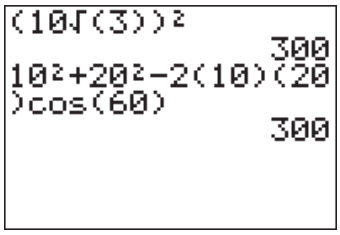
a. $c^2 = a^2 + b^2 - 2ab\cos C$

$20^2 = 10^2 + (10\sqrt{3})^2 - 2(10)(10\sqrt{3})\cos 90°$

$400 = 100 + 300 - 0$

$= 400$ ✓

b. $b^2 = a^2 + c^2 - 2ac\cos B$



$(10\sqrt{3})^2 = 10^2 + 20^2 - 2(10)(20)\cos 60°$

$300 = 100 + 400 - 400\left(\frac{1}{2}\right)$

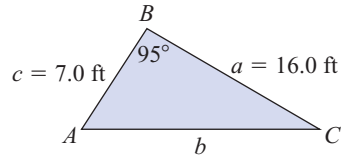
$= 500 - 200$

$= 300$ ✓

Figure 8.31

A calculator check of part (b) is shown in Figure 8.31.

Now try Exercises 7 through 14 ▶



CAUTION ▶ When evaluating the law of cosines, a common error is to combine the coefficient of $\cos\theta$ with the squared terms (the terms shown in blue): $a^2 = b^2 + c^2 - 2bc \cos A$. Be sure to use the correct order of operations when simplifying the expression.

Once additional information about the triangle is known, the law of sines can be used to complete the solution.

EXAMPLE 2 ▶ **Solving a Triangle Using the Law of Cosines—SAS**

Solve the triangle shown in Figure 8.32. Write the solution in table form. Verify your answer with a calculator.

Figure 8.32

Solution ▶ The given information is SAS. Apply the law of cosines with respect to side b and $\angle B$:

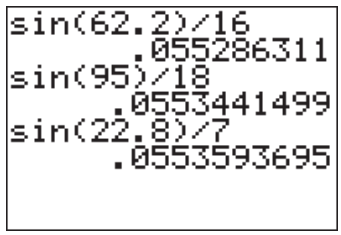
$$b^2 = a^2 + c^2 - 2ac\cos B \qquad \text{law of cosines with respect to } b$$
$$b^2 = (16)^2 + (7)^2 - 2(16)(7)\cos 95° \qquad \text{substitute known values}$$
$$\approx 324.522886 \qquad \text{simplify}$$
$$b \approx 18.0 \qquad \sqrt{324.522886} \approx 18.0$$

WORTHY OF NOTE

After using the law of cosines, we often use the law of sines to complete a solution. With a little foresight, we can avoid the ambiguous case—since the ambiguous case occurs only if θ *could be* obtuse (the largest angle of the triangle). After calculating the third side of a SAS triangle using the law of cosines, use the law of sines to find the smallest angle, since it cannot be obtuse.

We now have side b opposite $\angle B$, and complete the solution using the law of sines, selecting the smaller angle to avoid the ambiguous case (we *could* apply the law of cosines again, if we chose).

$$\frac{\sin C}{c} = \frac{\sin B}{b} \qquad \text{law of sines applied to } \angle C \text{ and } \angle B$$
$$\frac{\sin C}{7} \approx \frac{\sin 95°}{18} \qquad \text{substitute given values}$$
$$\sin C \approx 7 \cdot \frac{\sin 95°}{18} \qquad \text{solve for sin } C$$
$$C \approx \sin^{-1}\left(\frac{7 \sin 95°}{18}\right) \qquad \text{apply } \sin^{-1}$$
$$\approx 22.8° \qquad \text{result}$$



For the remaining angle, $\angle A$:

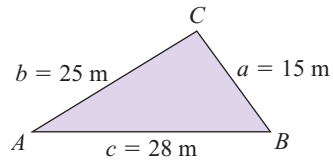
$$180° - (95° + 22.8°) = 62.2°$$

The finished solution is shown in the table (given information is in bold), and a verification (employing the law of sines) is shown in Figure 8.33. As in Section 8.1, the differences beyond the third decimal place are attributed to round-off error.

Angles	Sides (ft)
$A \approx 62.2°$	$\boldsymbol{a = 16.0}$
$\boldsymbol{B = 95.0°}$	$b \approx 18.0$
$C \approx 22.8°$	$\boldsymbol{c = 7.0}$

Figure 8.33

A. You've just seen how we can apply the law of cosines when two sides and an included angle are known (SAS)



Now try Exercises 15 through 26 ▶

B. The Law of Cosines and SSS Triangles

When three sides of a triangle are given, we use the law of cosines to find any one of the three angles. As a good practice, we first find the *largest* angle, or the angle opposite the largest side. This will ensure that the remaining two angles are acute, avoiding the ambiguous case if the law of sines is used to complete the solution.

EXAMPLE 3 ▶ **Solving a Triangle Using the Law of Cosines—SSS**

Solve the triangle shown. Write the solution in table form, with angles rounded to tenths of a degree.

Solution ▶ The information is given as SSS. Since side c is the longest side, we apply the law of cosines with respect to side c and $\angle C$:

$$\begin{aligned} c^2 &= a^2 + b^2 - 2ab\cos C && \text{law of cosines with respect to } c \\ 28^2 &= (15)^2 + (25)^2 - 2(15)(25)\cos C && \text{substitute known values} \\ 784 &= 850 - 750\cos C && \text{simplify} \\ -66 &= -750\cos C && \text{isolate variable term} \\ 0.088 &= \cos C && \text{divide} \\ \cos^{-1}0.088 &= C && \text{solve for } C \\ 85.0^\circ &\approx C && \text{result} \end{aligned}$$

We now have $\angle C$ opposite side c and finish up using the law of sines.

$$\begin{aligned} \frac{\sin A}{a} &= \frac{\sin C}{c} && \text{law of sines applied to } \angle A \text{ and } \angle C \\ \frac{\sin A}{15} &\approx \frac{\sin 85^\circ}{28} && \text{substitute given values} \\ \sin A &\approx 15 \cdot \frac{\sin 85^\circ}{28} && \text{solve for } \sin A \\ &\approx 0.5336757311 && \text{simplify} \\ A &\approx \sin^{-1}0.5336757311 && \text{solve for } A \\ &\approx 32.3^\circ && \text{result} \end{aligned}$$

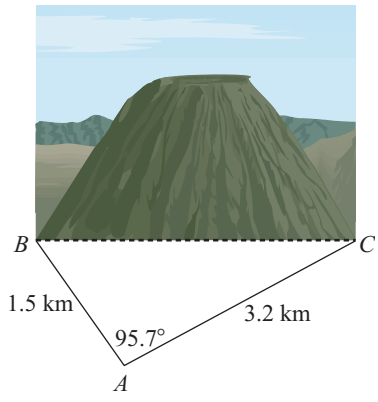
The remaining angle must be acute and we compute it directly.

$$\angle B\text{: } 180^\circ - (85^\circ + 32.3^\circ) = 62.7^\circ$$

The finished solution is shown in the table, with the information originally given shown in bold.

Angles	Sides (m)
$A \approx 32.3^\circ$	$\boldsymbol{a = 15}$
$B \approx 62.7^\circ$	$\boldsymbol{b = 25}$
$C \approx 85^\circ$	$\boldsymbol{c = 28}$

B. You've just seen how we can apply the law of cosines when three sides are known (SSS)



Now try Exercises 27 through 34 ▶

C. Applications Using the Law of Cosines

As with the law of sines, the law of cosines has a large number of applications from very diverse fields including geometry, navigation, surveying, and astronomy.

EXAMPLE 4 ▶ **Solving an Application of the Law of Cosines—Geological Surveys**

A vulcanologist needs to measure the distance across the base of an active volcano. Distance AB is measured at 1.5 km, while distance AC is 3.2 km. Using a theodolite (a sighting instrument used by surveyors), angle BAC is found to be 95.7°. What is the distance across the base?

Solution ▶ The information is given as SAS. To find the distance BC across the base of the volcano, we apply the law of cosines with respect to side a and $\angle A$.

$$\begin{aligned} a^2 &= b^2 + c^2 - 2bc\cos A && \text{law of cosines with respect to } a \\ &= (1.5)^2 + (3.2)^2 - 2(1.5)(3.2)\cos 95.7^\circ && \text{substitute known values} \\ &\approx 13.44347 && \text{simplify} \\ a &\approx 3.7 && \text{solve for } a \end{aligned}$$

The volcano is approximately 3.7 km wide at its base.

Now try Exercises 37 through 40 ▶

☑ **C.** You've just seen how we can solve applications using the law of cosines

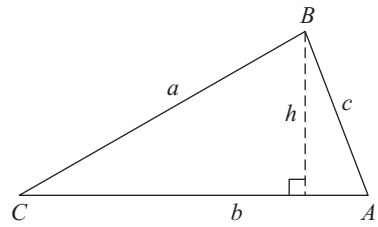
Recall from Section 6.6 that the *bearings* used by surveyors are stated as a number of degrees East or West from a due North or South orientation. *Headings* provide the same information, but are more commonly used in aerial and nautical navigation. They are stated simply as an *amount of rotation* from due north, in the clockwise direction ($0^\circ \le \theta < 360^\circ$). For instance, the bearing N 25° W and a heading of 335° would indicate the same direction or course. **See Exercises 41 through 44.** A variety of additional applications of the law of cosines can be found in **Exercises 45 through 52.**

D. Trigonometry and the Area of a Triangle

While you're likely familiar with the most common formula for a triangle's area, $\mathcal{A} = \frac{1}{2}bh$, there are actually over 20 formulas for computing this area. Many involve basic trigonometric ideas, and we'll use some of these ideas to develop three additional formulas here.

For $\mathcal{A} = \frac{1}{2}bh$, recall that b represents the length of a designated base, and h represents the length of the altitude drawn to that base (see Figure 8.34). If the height h is unknown, but sides a and b with angle C between them are known, h can be found using $\sin C = \dfrac{h}{a}$, giving $h = a\sin C$. Figure 8.35 indicates the same result is obtained if C is obtuse, since $\sin(180^\circ - C) = \sin C$. Substituting $a\sin C$ for h in the formula $\mathcal{A} = \frac{1}{2}bh$ gives $\mathcal{A} = \frac{1}{2}ba\sin C$, or $\mathcal{A} = \frac{1}{2}ab\sin C$ in more common form. Since naming the angles in a triangle is arbitrary, the formulas $\mathcal{A} = \frac{1}{2}bc\sin A$ and $\mathcal{A} = \frac{1}{2}ac\sin B$ can likewise be obtained.

Figure 8.34



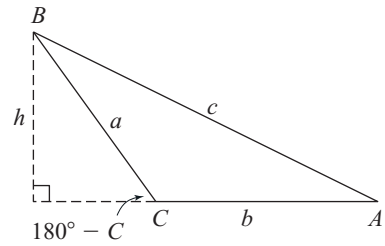


Figure 8.35

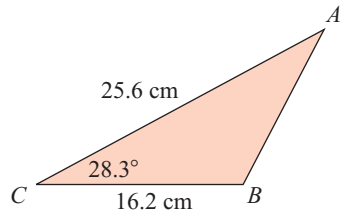


Area Given Two Sides and an Included Angle (SAS)

1. $\mathcal{A} = \dfrac{1}{2}ab\sin C$ **2.** $\mathcal{A} = \dfrac{1}{2}bc\sin A$ **3.** $\mathcal{A} = \dfrac{1}{2}ac\sin B$

In words, the formulas say the area of a triangle is equal to one-half the product of two sides times the sine of the angle between them.

EXAMPLE 5 ▶ **Finding the Area of a Nonright Triangle**

Find the area of $\triangle ABC$, if $a = 16.2$ cm, $b = 25.6$ cm, and $C = 28.3°$.

Solution ▶ Since sides a and b and angle C are given, we apply the first formula.

$$\mathcal{A} = \frac{1}{2}ab \sin C \qquad \text{area formula}$$

$$= \frac{1}{2}(16.2)(25.6) \sin 28.3° \qquad \text{substitute 16.2 for } a\text{, 25.6 for } b\text{, and 28.3° for } C$$

$$\approx 98.3 \text{ cm}^2 \qquad \text{result}$$

The area of this triangle is approximately 98.3 cm^2.

Now try Exercises 53 and 54 ▶

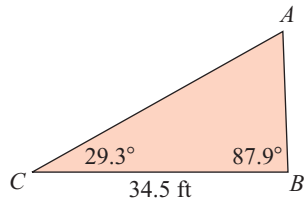
Using these formulas, a second formula type requiring two angles and one side (AAS or ASA) can be developed. Solving for b in $\mathcal{A} = \frac{1}{2}bc \sin A$ gives $b = \frac{2\mathcal{A}}{c \sin A}$. Likewise, solving for a in $\mathcal{A} = \frac{1}{2}ac \sin B$ yields $a = \frac{2\mathcal{A}}{c \sin B}$. Substituting these for b and a in $\mathcal{A} = \frac{1}{2}ab \sin C$ gives

$$\mathcal{A} = \frac{1}{2} \cdot a \cdot b \cdot \sin C \qquad \text{given formula}$$

$$2\mathcal{A} = \frac{2\mathcal{A}}{c \sin B} \cdot \frac{2\mathcal{A}}{c \sin A} \cdot \sin C \qquad \text{substitute } \frac{2\mathcal{A}}{c \sin B} \text{ for } a\text{, } \frac{2\mathcal{A}}{c \sin A} \text{ for } b\text{; multiply by 2}$$

$$c^2 \sin A \cdot \sin B = 2\mathcal{A} \cdot \sin C \qquad \text{multiply by } c \sin A \cdot c \sin B\text{; divide by } 2\mathcal{A}$$

$$\frac{c^2 \sin A \sin B}{2 \sin C} = \mathcal{A} \qquad \text{solve for } \mathcal{A}$$



As with the previous formula, versions relying on side a or side b can also be found.

Area Given Two Angles and Any Side (AAS/ASA)

1. $\mathcal{A} = \dfrac{c^2 \cdot \sin A \cdot \sin B}{2 \sin C}$ **2.** $\mathcal{A} = \dfrac{a^2 \cdot \sin B \cdot \sin C}{2 \sin A}$ **3.** $\mathcal{A} = \dfrac{b^2 \cdot \sin A \cdot \sin C}{2 \sin B}$

EXAMPLE 6 ▶ **Finding the Area of a Nonright Triangle**

Find the area of $\triangle ABC$ if $a = 34.5$ ft, $B = 87.9°$, and $C = 29.3°$.

Solution ▶ Since side a is given, we apply the second version of the formula. First we find the measure of angle A, then make the appropriate substitutions:

$$A = 180° - (87.9° + 29.3°) = 62.8°$$

$$\mathcal{A} = \frac{a^2 \sin B \sin C}{2 \sin A} \qquad \text{area formula—side } a$$

$$= \frac{(34.5)^2 \sin 87.9° \sin 29.3°}{2 \sin 62.8°} \qquad \text{substitute 34.5 for } a\text{, 87.9° for } B\text{, 29.3° for } C\text{, and 62.8° for } A$$

$$\approx 327.2 \text{ ft}^2 \qquad \text{simplify}$$

The area of this triangle is approximately 327.2 ft^2.

Now try Exercises 55 and 56 ▶

Our final formula for a triangle's area is a useful addition to the other two, as it requires only the lengths of the three sides. The development of the formula requires only a Pythagorean identity and solving for the angle C in the law of cosines, as follows.

$$\begin{aligned} a^2 + b^2 - 2ab\cos C &= c^2 && \text{law of cosines} \\ a^2 + b^2 - c^2 &= 2ab\cos C && \text{add } 2ab\cos C\text{, subtract } c^2 \\ \frac{a^2 + b^2 - c^2}{2ab} &= \cos C && \text{divide by } 2ab \end{aligned}$$

Beginning with our first area formula, we then have

$$\begin{aligned} \mathcal{A} &= \frac{1}{2}ab\sin C && \text{previous area formula} \\ &= \frac{1}{2}ab\sqrt{1 - \cos^2 C} && \sin^2 C + \cos^2 C = 1 \to \sin C = \sqrt{1 - \cos^2 C} \\ &= \frac{1}{2}ab\sqrt{1 - \left(\frac{a^2 + b^2 - c^2}{2ab}\right)^2} && \text{substitute } \frac{a^2 + b^2 - c^2}{2ab} \text{ for } \cos C \end{aligned}$$

We can now find the area of any triangle given its three sides. While the formula certainly serves this purpose, it is not so easy to use. By working algebraically and using the perimeter of the triangle, we can derive a more elegant version.

$$\begin{aligned} \mathcal{A}^2 &= \frac{1}{4}a^2b^2\left[1 - \left(\frac{a^2 + b^2 - c^2}{2ab}\right)^2\right] && \text{square both sides} \\ &= \frac{1}{4}a^2b^2\left[1 + \left(\frac{a^2 + b^2 - c^2}{2ab}\right)\right]\left[1 - \left(\frac{a^2 + b^2 - c^2}{2ab}\right)\right] && \text{factor as a difference of squares} \\ &= \frac{1}{4}a^2b^2\left[\frac{2ab + a^2 + b^2 - c^2}{2ab}\right]\left[\frac{2ab - a^2 - b^2 + c^2}{2ab}\right] && 1 = \frac{2ab}{2ab}\text{; combine terms} \\ &= \frac{1}{4}\left[\frac{(a^2 + 2ab + b^2) - c^2}{2}\right]\left[\frac{-(a^2 - 2ab + b^2) + c^2}{2}\right] && \text{rewrite/regroup numerator; cancel } a^2b^2 \\ &= \frac{1}{16}[(a + b)^2 - c^2][c^2 - (a - b)^2] && \text{factor (binomial squares)} \\ &= \frac{1}{16}(a + b + c)(a + b - c)(c + a - b)(c - a + b) && \text{factor (difference of squares)} \end{aligned}$$

For the perimeter $a + b + c = p$, we note the following relationships (subtract $2c$, $2b$, and $2a$ respectively, from both sides):

$$a + b - c = p - 2c \qquad c + a - b = p - 2b \qquad c - a + b = p - 2a$$

and making the appropriate substitutions gives

$$\mathcal{A}^2 = \frac{1}{16}p(p - 2c)(p - 2b)(p - 2a) \quad \text{substitute}$$

While this would provide a usable formula for the area in terms of the perimeter, we can refine it further using the *semi*perimeter $s = \dfrac{a + b + c}{2} = \dfrac{p}{2}$. Since $\dfrac{1}{16} = \left(\dfrac{1}{2}\right)^4$, we can write the expression as

$$\begin{aligned} \mathcal{A}^2 &= \frac{p}{2}\left(\frac{p - 2c}{2}\right)\left(\frac{p - 2b}{2}\right)\left(\frac{p - 2a}{2}\right) && \text{rewrite expression} \\ &= \frac{p}{2}\left(\frac{p}{2} - c\right)\left(\frac{p}{2} - b\right)\left(\frac{p}{2} - a\right) && \text{simplify} \\ &= s(s - c)(s - b)(s - a) && \text{substitute } s \text{ for } \frac{p}{2} \end{aligned}$$

Taking the square root of each side produces what is known as **Heron's formula.**

$$\mathcal{A} = \sqrt{s(s-a)(s-b)(s-c)} \quad \text{Heron's formula}$$

Heron's Formula

Given $\triangle ABC$ with sides a, b, and c and semiperimeter $s = \dfrac{a+b+c}{2}$, the area of the triangle is

$$\mathcal{A} = \sqrt{s(s-a)(s-b)(s-c)}$$

EXAMPLE 7 ▶ **Solving an Application of Heron's Formula—Construction Planning**

A New York City developer wants to build condominiums on the triangular lot formed by Greenwich, Watts, and Canal Streets. How many square meters does the developer have to work with if the frontage along each street is approximately 34.1 m, 43.5 m, and 62.4 m, respectively?

Solution ▶ The perimeter of the lot is $p = 34.1 + 43.5 + 62.4 = 140$ m, so $s = 70$ m. By direct substitution we obtain

$$\begin{aligned}
\mathcal{A} &= \sqrt{s(s-a)(s-b)(s-c)} && \text{Heron's formula}\\
&= \sqrt{70(70-34.1)(70-43.5)(70-62.4)} && \text{substitute known values}\\
&= \sqrt{70(35.9)(26.5)(7.6)} && \text{simplify}\\
&= \sqrt{506{,}118.2} && \text{multiply}\\
&\approx 711.4 && \text{result}
\end{aligned}$$

The developer has about 711.4 m^2 of land to work with.

A calculator verification is shown in the figure, where the keystrokes STO▸ ALPHA LN were used to store the semiperimeter in memory location S. This greatly simplifies the use of Heron's formula, which is then used to verify the preceding calculations.

```
(34.1+43.5+62.4)
/2→S
                70
√(S(S-34.1)(S-43
.5)(S-62.4))
      711.4198479
```

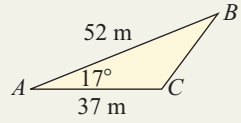
D. You've just seen how we can use trigonometry to find the area of a triangle

Now try Exercises 57 and 58 ▶

For a derivation of Heron's formula that does not depend on trigonometry, see Appendix B.

8.2 EXERCISES

▶ CONCEPTS AND VOCABULARY



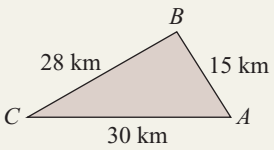
Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. When the information given is SSS or SAS, the law of _____ is used to solve the triangle.

2. Fill in the blank so that the law of cosines is complete: $c^2 = a^2 + b^2 -$ _____ $\cos C$.

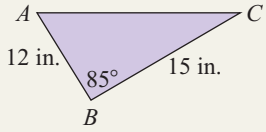
3. If the law of cosines is applied to a right triangle, the result is the same as the _____ theorem, since $\cos 90° = 0$.

4. Write out which version of the law of cosines you would use to begin solving the triangle shown: _____



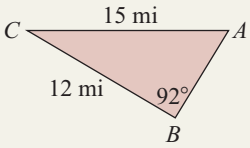
5. Solve the triangle in Exercise 2 using only the law of cosines, then by using the law of cosines followed by the law of sines. Which method was more efficient?

6. Begin with $a^2 = b^2 + c^2 - 2bc\cos A$ and write $\cos A$ in terms of a, b, and c (solve for $\cos A$). Why must $b^2 + c^2 - a^2 < 2bc$ hold in order for a solution to exist?

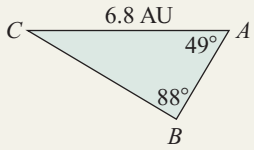


▶ DEVELOPING YOUR SKILLS

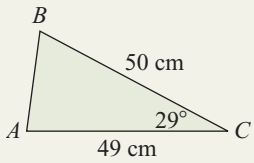
Determine whether the law of cosines can be used to begin the solution process for each triangle.



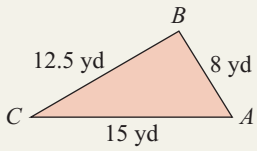
7.



8.

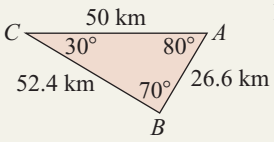


9.

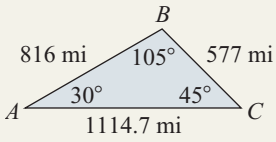


10.

11.



12.



For each triangle, verify all three forms of the law of cosines.

13.

14.

Solve each of the following equations for the unknown part.

15. $4^2 = 5^2 + 6^2 - 2(5)(6)\cos B$

16. $12.9^2 = 15.2^2 + 9.8^2 - 2(15.2)(9.8)\cos C$

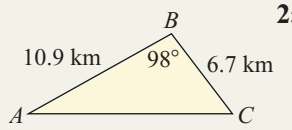
17. $a^2 = 9^2 + 7^2 - 2(9)(7)\cos 52°$

18. $b^2 = 3.9^2 + 9.5^2 - 2(3.9)(9.5)\cos 30°$

19. $10^2 = 12^2 + 15^2 - 2(12)(15)\cos A$

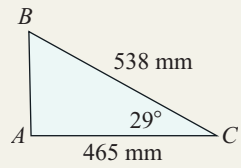
20. $202^2 = 182^2 + 98^2 - 2(182)(98)\cos B$

Solve each triangle using the law of cosines. Use a calculator to verify your results.



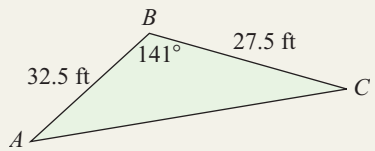
21. side $a = 75$ cm
$\angle C = 38°$
side $b = 32$ cm

22. side $b = 385$ m
$\angle C = 67°$
side $a = 490$ m



23. side $c = 25.8$ mi
$\angle B = 30°$
side $a = 12.9$ mi

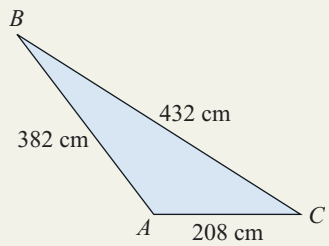
Solve using the law of cosines (if possible). Label each triangle appropriately before you begin. Use a calculator to verify your results.



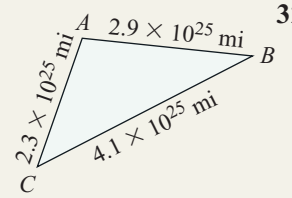
24.

25.

26.

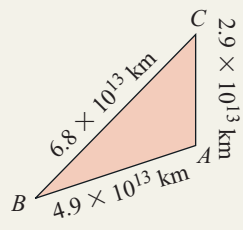


27. side $c = 10\sqrt{3}$ in.
side $b = 6\sqrt{3}$ in.
side $a = 15\sqrt{3}$ in.



28. side $a = 282$ ft
side $b = 129$ ft
side $c = 300$ ft

29. side $a = 32.8$ km
side $b = 24.9$ km
side $c = 12.4$ km

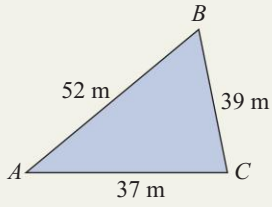


30.

31.

32.

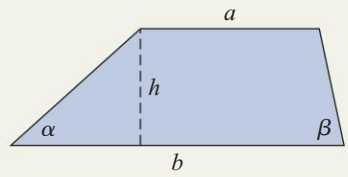
33. side $a = 12\sqrt{3}$ yd
side $b = 12.9$ yd
side $c = 9.2$ yd



34. side $a = 36.5$ AU
side $b = 12.9$ AU
side $c = 22$ AU

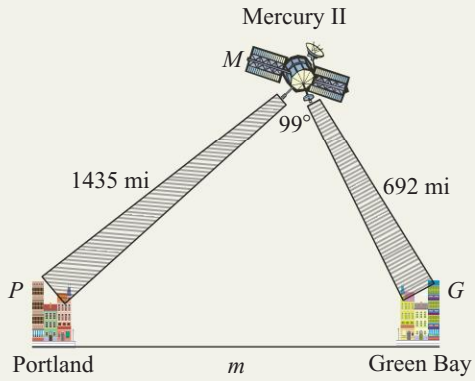
▶ WORKING WITH FORMULAS

35. Alternative form for the law of cosines:



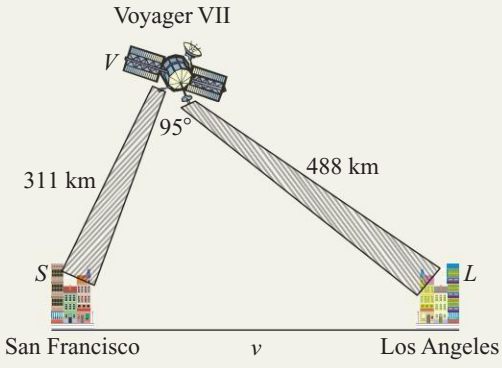
$$\cos A = \frac{b^2 + c^2 - a^2}{2bc}$$

By solving the law of cosines for the cosine of the angle, the formula can be written as shown. Derive this formula (solve for $\cos\theta$), beginning from $a^2 = b^2 + c^2 - 2bc\cos A$, then use this form to begin the solution of the triangle given.

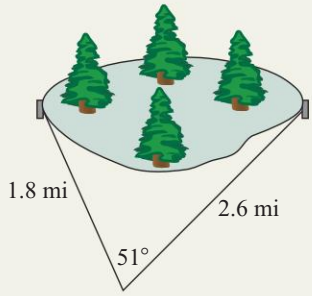


36. The perimeter of a trapezoid:
$P = a + b + h(\csc\alpha + \csc\beta)$

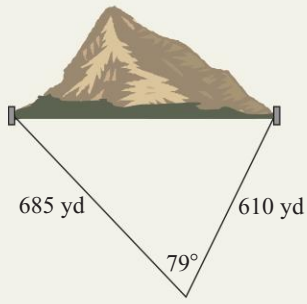
The perimeter of a trapezoid can be found using the formula shown, where a and b represent the lengths of the parallel sides, h is the height of the trapezoid, and α and β are the base angles. Find the perimeter of Trapezoid Park (to the nearest foot) if $a = 5000$ ft, $b = 7500$ ft, and $h = 2000$ ft, with base angles $\alpha = 42°$ and $\beta = 78°$.



▶ APPLICATIONS

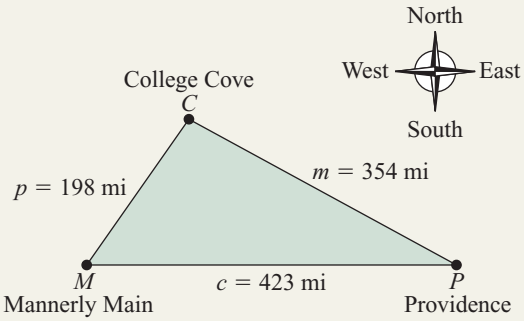


37. Distance between cities: The satellite Mercury II measures its distance from Portland and from Green Bay using radio waves as shown. Using an on-board sighting device, the satellite determines that $\angle M$ is 99°. How many miles is it from Portland to Green Bay?

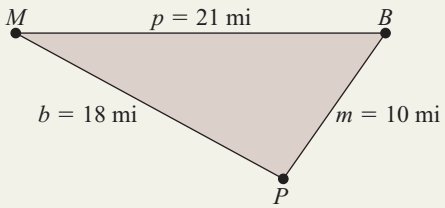


38. Distance between cities: Voyager VII measures its distance from Los Angeles and from San Francisco using radio waves as shown. Using an onboard sighting device, the satellite determines $\angle V$ is 95°. How many kilometers separate Los Angeles and San Francisco?

39. Runway length: Surveyors are measuring a large, marshy area outside of the city as part of a feasibility study for the construction of a new airport. Using a theodolite and the markers shown gives the information indicated. If the main runway must be at least 11,000 ft long, and environmental concerns are satisfied, can the airport be constructed at this site (recall that 1 mi = 5280 ft)?



40. Tunnel length: An engineering firm decides to bid on a proposed tunnel through Harvest Mountain. In order to find the tunnel's length, the measurements shown are taken. (a) How long will the tunnel be? (b) Due to previous tunneling experience, the firm estimates a cost of $5000 per foot for boring through this type of rock and constructing the tunnel according to required specifications. If management insists on a 25% profit, what will be their minimum bid to the nearest hundred?

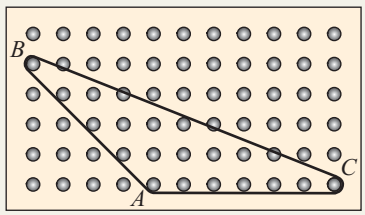


41. Trip planning: A business executive is going to fly the corporate jet from Providence to College Cove. She calculates the distances shown using a map, with Mannerly Main for reference since it is due west of Providence. What is the measure of angle P? What heading should she set for this trip?

Exercise 41

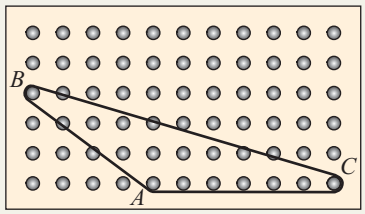
42. Trip planning: A troop of Scouts is planning a hike from ***M***ontgomery to ***P***attonville. They calculate the distances shown using a map, using ***B***radleyton for reference since it is due east of ***M***ontgomery. What is the measure of angle M? What heading should they set for this trip?

Exercise 42



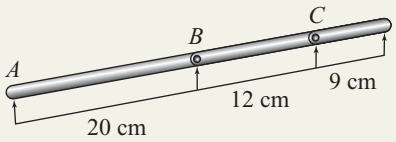
43. Aerial distance: Two planes leave Los Angeles International Airport at the same time. One travels due west (at heading 270°) with a cruising speed of 450 mph, going to Tokyo, Japan, with a group that seeks tranquility at the foot of Mount Fuji. The other travels at heading 225° with a cruising speed of 425 mph, going to Brisbane, Australia, with a group seeking adventure in the Great Outback. Approximate the distance between the planes after 5 hr of flight.

44. Nautical distance: Two ships leave Honolulu Harbor at the same time. One travels 15 knots (nautical miles per hour) at heading 150°, and is going to the Marquesas Islands (*Crosby, Stills, and Nash*). The other travels 12 knots at heading 200°, and is going to the Samoan Islands (*Samoa, le galu a tu*). How far apart are the two ships after 10 hr?



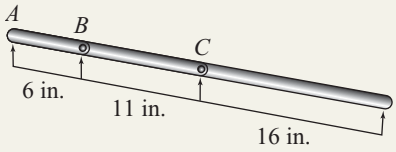
45. Geoboard geometry: A rubber band is placed on a geoboard (a board with all pegs 1 cm apart) as shown. Approximate the perimeter of the triangle formed by the rubber band *and* the angle formed at each vertex. (*Hint:* Use a standard triangle to find $\angle A$ and length $\overline{AB}$.)

Exercise 45



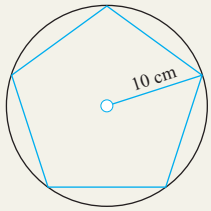
46. Geoboard geometry: A rubber band is placed on a geoboard as shown. Approximate the perimeter of the triangle formed by the rubber band *and* the angle formed at each vertex. (*Hint:* Use a Pythagorean triple, then find angle A.)

Exercise 46



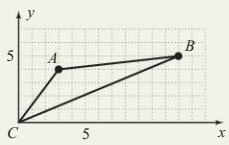
In Exercises 47 and 48, three rods are attached via pivot joints so the rods can be manipulated to form a triangle. Find the three angles of the triangle formed.

47.

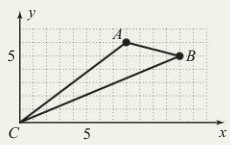


48.

49. Pentagon perimeter: Find the approximate perimeter of a regular *pentagon* that is circumscribed by a circle with radius $r = 10$ cm.



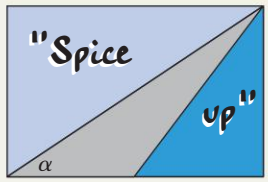
Exercise 49



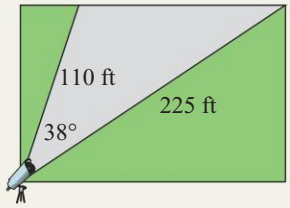
50. Hexagon perimeter: Find the perimeter of a regular *hexagon* that is circumscribed by a circle with radius $r = 15$ cm.

Solve the following triangles. Give exact values for the sides and round angles to the nearest tenth. (*Hint:* Use Pythagorean triples.)

51.

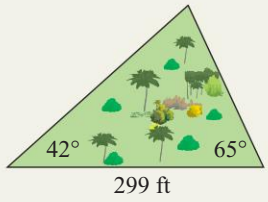


52.



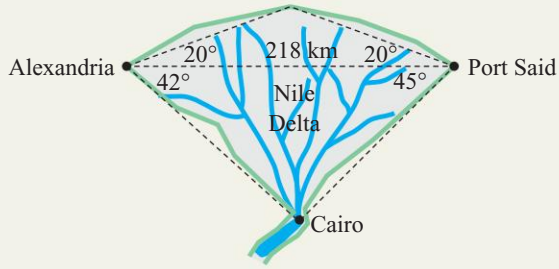
53. Billboard design: Creative Designs iNc. has designed a flashy, new billboard for one of its clients. Using a rectangular highway billboard measuring 20 ft by 30 ft, the primary advertising area is a triangle formed using the diagonal of the billboard as one side, and one-half the base as another (see figure). Use the dimensions given to find the angle α formed at the corner, then compute the area of the triangle using two sides and this included angle.

Exercise 53



54. Area caught by surveillance camera: A stationary surveillance camera is set up to monitor activity in the parking lot of a shopping mall. If the camera has a 38° field of vision, how many square feet of the parking lot can it tape using the dimensions given?

Exercise 54

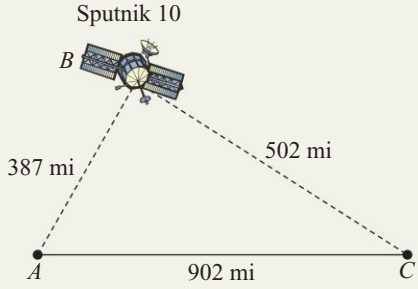


55. Pricing for undeveloped lots: Undeveloped land in a popular resort area is selling for $3,000,000/acre. Given the dimensions of the lot shown, (a) find what percent of a full acre is being purchased (to the nearest whole percent), and (b) compute the cost of the lot. Recall that 1 acre = 43,560 ft^2.

Exercise 55

56. Area of the Nile River Delta: The Nile River Delta is one of the world's largest. The delta begins slightly upriver from the Egyptian capitol (Cairo) and stretches along the Mediterranean from Alexandria in the west to Port Said in the east (over 240 km). Approximate the area of this rich agricultural region using the two triangles shown.

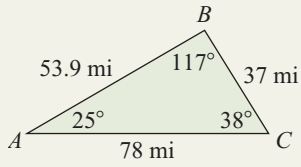
57. Area of the Yukon Territory: The Yukon Territory in northwest Canada is roughly triangular in shape with sides of 1289 km, 1063 km, and 922 km. What is the approximate area covered by this territory?



58. Alternate method for computing area: Referring to Exercise 53, since the dimensions of the billboard are known, all three sides of the triangle can actually be determined. Find the length of the sides rounded to the nearest whole, then use Heron's formula to find the area of the triangle. How close was your answer to that in Exercise 53?

▶ EXTENDING THE CONCEPT

59. No matter how hard I try, I cannot solve the triangle shown. Why?



Exercise 59

60. In Figure 8.29 (page 759), note that if the x-coordinate of vertex B is greater than the x-coordinate of vertex C, $\angle B$ becomes acute, and $\angle C$ obtuse. How does this change the relationship between x and c? Verify the law of cosines remains unchanged.

61. For the triangle shown, verify that $c = b\cos A + a\cos B$, then use two different forms of the law of cosines to show this relationship holds for *any* triangle ABC.

Exercise 61

62. Most students are familiar with this double-angle formula for cosine: $\cos(2\theta) = \cos^2\theta - \sin^2\theta$. The *triple* angle formula for cosine is $\cos(3\theta) = 4\cos^3\theta - 3\cos\theta$. Use the formula to find an exact value for cos 135°. Show that you get the same result as when using a reference angle.

▶ MAINTAINING YOUR SKILLS

63. **(5.4)** Write the expression as a single term in simplest form: $2\log_2 4 + 2\log_2 3 - 2\log_2 6$.

64. **(6.2)** State exact forms for each of the following: $\sin\left(\frac{\pi}{6}\right)$, $\cos\left(\frac{7\pi}{6}\right)$, and $\tan\left(\frac{\pi}{3}\right)$.

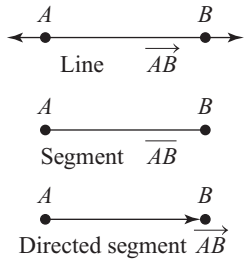
65. **(6.7)** Use fundamental identities to find the values of all six trig functions that satisfy the conditions. $\sin x = -\frac{5}{13}$ and $\cos x > 0$

66. **(4.2)** Use synthetic division to show $f(-2) > 0$ for $f(x) = -x^4 - x^3 + 7x^2 + x - 6$.

8.3 Vectors and Vector Diagrams

LEARNING OBJECTIVES

In Section 8.3 you will see how we can:



- ❑ **A.** Represent a vector quantity geometrically
- ❑ **B.** Represent a vector quantity graphically
- ❑ **C.** Perform defined operations on vectors
- ❑ **D.** Represent a vector quantity algebraically and find unit vectors
- ❑ **E.** Use vector diagrams to solve applications

The study of vectors is closely connected to the study of force, motion, velocity, and other related phenomena. Vectors enable us to quantify certain characteristics of these phenomena and to physically represent their magnitude and direction with a simple model (quantify: to assign a relative numeric value for purposes of study and comparison). While very uncomplicated, this model turns out to be a powerful mathematical tool.

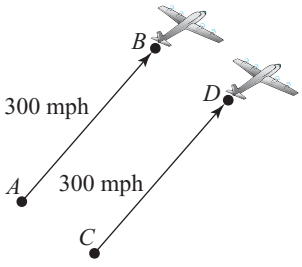
A. The Notation and Geometry of Vectors

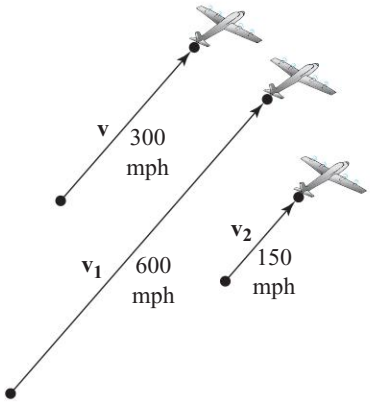
Measurements involving time, area, volume, energy, and temperature are called **scalar measurements** or **scalar quantities** because each can be adequately described by their magnitude alone and the appropriate unit or "scale." The related real number is simply called a **scalar.** Concepts that require more than a single quantity to describe their attributes are called **vector quantities.** Examples might include force, velocity, and displacement, which require knowing a magnitude *and* direction to describe them completely.

Figure 8.36

To begin our study, consider two identical airplanes flying at 300 mph, on parallel courses and in the same direction. Although we don't know how far apart they are, what direction they're flying, or if one is "ahead" of the other, we can still model, "300 mph on parallel courses," using **directed line segments** (Figure 8.36). Drawing these segments parallel with the arrowheads pointing the same way models the direction of flight, while drawing segments the *same length* indicates the velocities are equal (Figure 8.37). The directed segment used to represent a vector quantity is simply called a **vector.** In this case the length of the vector models the **magnitude** of the velocity, while the arrowhead indicates the **direction** of travel. The origin of the segment is called the **initial point,** with the arrowhead pointing to the **terminal point.** These are labeled using capital letters as shown in Figure 8.37 and we call this a *geometric representation* of the vectors.

Figure 8.37





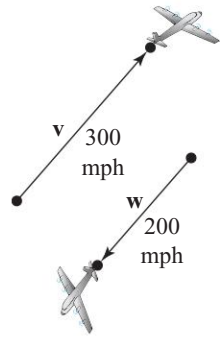


Figure 8.38

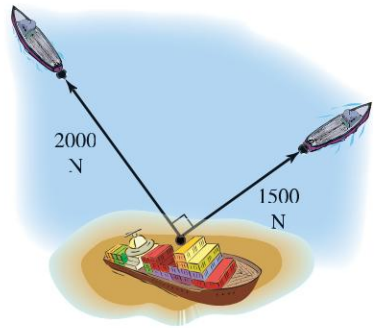
Vectors can be named using the initial and terminal points that define them (initial point first) as in $\overrightarrow{AB}$ and $\overrightarrow{CD}$, or using a bold, lowercase letter with the favorites being **v** (first letter of the word vector) and **u.** Other lowercase, bold letters can be used, and subscripted vector names ($\mathbf{v}_1$, $\mathbf{v}_2$, $\mathbf{v}_3$, . . .) are also common. Two **vectors are equal** if they have the same magnitude and direction. For $\mathbf{u} = \overrightarrow{AB}$ and $\mathbf{v} = \overrightarrow{CD}$, we can say $\mathbf{u} = \mathbf{v}$ or $\overrightarrow{AB} = \overrightarrow{CD}$ since both airplanes are flying at the same speed and in the same direction (Figure 8.37).

Based on these conventions, it seems reasonable to represent an airplane flying at 600 mph with a vector that is twice as long as **u** or **v,** and one flying at 150 mph with a vector that is half as long. If all planes are flying in the same direction on parallel courses, we can represent them geometrically as shown in Figure 8.38, and state that $\mathbf{v_1} = 2\mathbf{v}$, $\mathbf{v_2} = \frac{1}{2}\mathbf{v}$, and $\mathbf{v_1} = 4\mathbf{v_2}$. The multiplication of a vector by a constant is called **scalar multiplication,** since the product changes only the scale or size of the vector and not its direction.

Figure 8.39

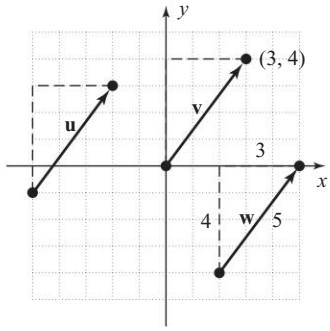


Finally, consider the airplane represented by vector **w**, flying at 200 mph on a parallel course *but in the opposite direction* (Figure 8.39). In this case, the directed segment will be $\frac{200}{300} = \frac{2}{3}$ as long as **v** and point in the opposite or "negative" direction. In perspective we can now state: $\mathbf{w} = -\frac{2}{3}\mathbf{v}$, $\mathbf{w} = -\frac{1}{3}\mathbf{v_1}$, $\mathbf{w} = -\frac{4}{3}\mathbf{v_2}$, or any equivalent form of these equations.

EXAMPLE 1 ▶ **Using Geometric Vectors to Model Forces Acting on a Point**

Two tugboats are attempting to free a barge that is stuck on a sand bar. One is pulling with a force of 2000 newtons (N) in a certain direction, the other is pulling with a force of 1500 N in a direction that is *perpendicular to the first.* Represent the situation geometrically using vectors.

Solution ▶ We could once again draw a vector of arbitrary length and let it represent the 2000-N force applied by the first tugboat. For better perspective, we can actually use a ruler and choose a convenient length, say 6 cm. We then represent the pulling force of the second tug with a vector that is $\frac{1500}{2000} = \frac{3}{4}$ as long (4.5 cm), drawn at a 90° angle with relation to the first. Note that many correct solutions are possible, depending on the direction of the first vector drawn.



A. You've just seen how we can represent a vector quantity geometrically

Now try Exercises 7 through 12 ▶

B. Vectors and the Rectangular Coordinate System

Figure 8.40

Representing vectors geometrically (with a directed line segment) is fine for simple comparisons, but many applications involve numerous vectors acting on a single point or changes in a vector quantity over time. For these situations, a graphical representation in the coordinate plane helps to analyze this interaction. The only question is *where* to place the vector on the grid, and the answer is . . . it really doesn't matter. Consider the three vectors shown in Figure 8.40. From the initial point of each, counting four units in the vertical direction, then three units in the horizontal direction, puts us at the terminal point. This shows the vectors are all 5 units long (since a 3-4-5 triangle is formed) and are all parallel (since slopes are equal: $\frac{\Delta y}{\Delta x} = \frac{4}{3}$). In other words, they are **equivalent vectors.**

Since a vector's location is unimportant, we can replace any given vector with one whose initial point is (0, 0). This unique and equivalent vector is called the **position vector.**

Position Vectors

For a vector **v** with initial point (x_1, y_1) and terminal point (x_2, y_2), the position vector for **v** is

$$\mathbf{v} = \langle x_2 - x_1, y_2 - y_1 \rangle,$$

an equivalent vector with initial point (0, 0) and terminal point $(x_2 - x_1, y_2, -y_1)$.

WORTHY OF NOTE

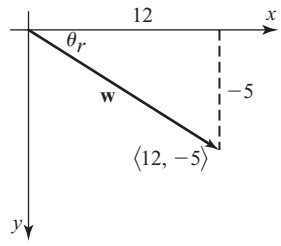
For vector **u**, the initial and terminal points are (−5, −1) and (−2, 3), respectively, yielding the position vector $\langle -2 - (-5), 3 - (-1) \rangle = \langle 3, 4 \rangle$ as noted.

For instance, the initial and terminal points of vector **w** in Figure 8.40 are (2, −4) and (5, 0), respectively, with (5 − 2, 0 − (−4)) = (3, 4). Since (3, 4) is also the terminal point of **v** (whose initial point is at the origin), **v** is the position vector for **u** and **w.** This observation also indicates that every geometric vector in the *xy*-plane corresponds to a unique ordered pair of real numbers (*a*, *b*), with *a* as the **horizontal component** and *b* as the **vertical component** of the vector. As indicated, we denote the vector in **component form** as $\langle a, b \rangle$, using the new notation to prevent confusing vector $\langle a, b \rangle$ with the ordered pair (*a*, *b*). Finally, while each of the vectors in Figure 8.40 has a component form of $\langle 3, 4 \rangle$, the horizontal and vertical components can be read directly only from $\mathbf{v} = \langle 3, 4 \rangle$, giving it a distinct advantage.

EXAMPLE 2 ▶ Verifying the Components of a Position Vector

Vector $\mathbf{w} = \langle 12, -5 \rangle$ has initial point (−4, 3).

a. Find the coordinates of the terminal point.



b. Verify the position vector for **w** is $\langle 12, -5 \rangle$ and find its length.

c. Use the **DRAW** feature of a calculator to graph **w** and its position vector.

Solution ▶

a. Since **w** has a horizontal component of 12 and a vertical component of −5, we add 12 to the *x*-coordinate and −5 to the *y*-coordinate of the initial point. This gives a terminal point of (−4 + 12, 3 + (−5)) = (8, −2).

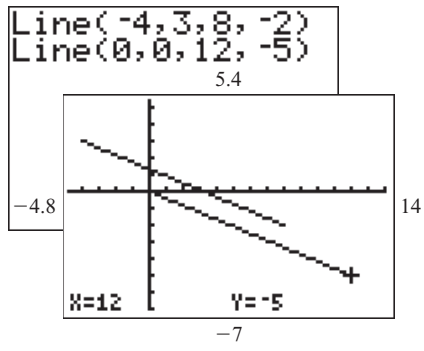


Figure 8.41

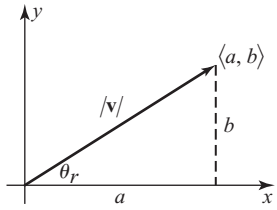
b. To verify, we use the initial and terminal points to compute $\langle x_2 - x_1, y_2 - y_1 \rangle$, giving a position vector of $\langle 8 - (-4), -2 - 3 \rangle = \langle 12, -5 \rangle$. To find its length we can use either the Pythagorean theorem or simply note that a 5-12-13 Pythagorean triple is formed (see Figure 8.41). Vector **w** has a length of 13 units.



c. Most graphing calculators have a feature that can actually draw a vector in the plane, in the form of a line segment that begins and ends at specified points. It's a good practice to first delete any equations in the Y= screen, use the keystrokes 2nd PRGM 1 ENTER to clear any old drawings that may exist, and set an appropriate window before entering the vector. From the home screen, the keystrokes 2nd PRGM **(DRAW) 2:Line(−4, 3, 8, −2)** ENTER will draw the vector **w** from (−4, 3) (the first two entries of the argument), to the point (8, −2). Returning to the home screen and drawing the position vector for **w** will produce the screen shown in Figure 8.42. Note these two vectors appear to have the same magnitude and direction, as expected.

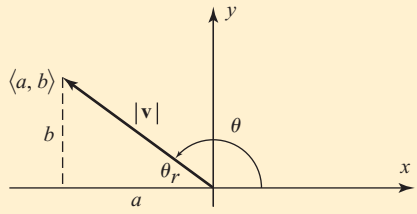
Figure 8.42

Now try Exercises 13 through 20 ▶

Figure 8.43

For the remainder of this section, vector $\mathbf{v} = \langle a, b \rangle$ will refer to the unique position vector for all those equivalent to **v.** Upon considering the graph of $\langle a, b \rangle$ (shown in QI for convenience in Figure 8.43), several things are immediately evident. The length or **magnitude** of the vector, which is denoted $|\mathbf{v}|$, can be determined using the Pythagorean theorem: $|\mathbf{v}| = \sqrt{a^2 + b^2}$. In addition, basic trigonometry shows the horizontal component can be found using $\cos\theta = \dfrac{a}{|\mathbf{v}|}$ or $a = |\mathbf{v}|\cos\theta$, with the vertical component being $\sin\theta = \dfrac{b}{|\mathbf{v}|}$ or $b = |\mathbf{v}|\sin\theta$. Finally, we note the angle θ can be determined using $\tan\theta = \dfrac{b}{a}$, or $\theta_r = \tan^{-1}\left|\dfrac{b}{a}\right|$ and the quadrant of **v**.

Vector Components in Trig Form



For a position vector $\mathbf{v} = \langle a, b \rangle$ and angle θ, we have . . .

horizontal component: $a = |\mathbf{v}|\cos\theta$

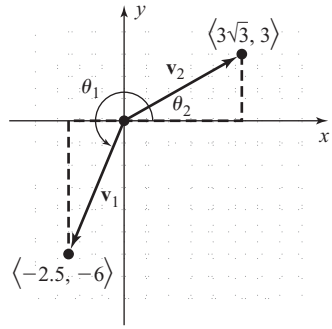
vertical component: $b = |\mathbf{v}|\sin\theta$,

where $\theta_r = \tan^{-1}\left|\dfrac{b}{a}\right|$

and $|\mathbf{v}| = \sqrt{a^2 + b^2}$

The ability to model characteristics of a vector using these equations is a huge benefit to solving applications, since we must often work out solutions using only the partial information given.

EXAMPLE 3 ▶ Finding the Magnitude and Direction Angle of a Vector



For $\mathbf{v}_1 = \langle -2.5, -6 \rangle$ and $\mathbf{v}_2 = \langle 3\sqrt{3}, 3 \rangle$,

a. Graph each vector and name the quadrant where it is located.

b. Find their magnitudes.

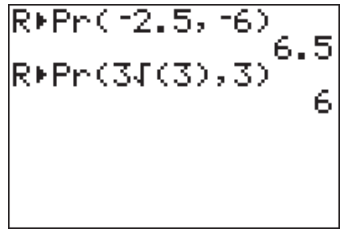
c. Find the angle θ for each vector (round to tenths of a degree as needed).

Figure 8.44

Solution ▶

a. The graphs of $\mathbf{v}_1$ and $\mathbf{v}_2$ are shown in Figure 8.44. Using the signs of each coordinate, we note that $\mathbf{v}_1$ is in QIII, and $\mathbf{v}_2$ is in QI.

b. ▼ **Algebraic Solution**



$$\begin{aligned} |\mathbf{v}_1| &= \sqrt{(-2.5)^2 + (-6)^2} \\ &= \sqrt{6.25 + 36} \\ &= \sqrt{42.25} \\ &= 6.5 \end{aligned}$$

$$\begin{aligned} |\mathbf{v}_2| &= \sqrt{(3\sqrt{3})^2 + (3)^2} \\ &= \sqrt{27 + 9} \\ &= \sqrt{36} \\ &= 6 \end{aligned}$$

▼ **Graphical Solution**

The 2nd APPS **(ANGLE) 5:R▶Pr(** command (introduced in Section 6.7) can be used to find the magnitude of any position vector, as shown in Figure 8.45.

Figure 8.45

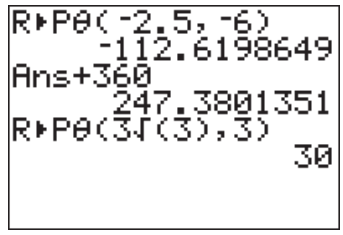
c. ▼ Algebraic Solution

For $\mathbf{v}_1$: $\theta_r = \tan^{-1}\left|\dfrac{-6}{-2.5}\right|$

$= \tan^{-1}(2.4) \approx 67.4°$

In QIII, $\theta_1 \approx 247.4°$.

For $\mathbf{v}_2$: $\theta_r = \tan^{-1}\left|\dfrac{3}{3\sqrt{3}}\right|$



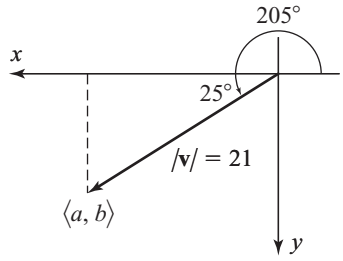
$= \tan^{-1}\left(\dfrac{\sqrt{3}}{3}\right) = 30°$

In QI, $\theta_2 = 30°$.

▼ Graphical Solution

Similarly, the 2nd APPS **(ANGLE) 6:R▶Pθ(** command (also from Section 6.7) can be used to find the angle θ for any position vector. Note in Figure 8.46, this feature returns a negative angle for $\mathbf{v}_1$. Adding 360° in the second entry reveals this angle is coterminal with our algebraic result.

Figure 8.46



Now try Exercises 21 through 24 ▶

EXAMPLE 4 ▶ Finding the Horizontal and Vertical Components of a Vector

The vector $\mathbf{v} = \langle a, b\rangle$ is in QIII, has a magnitude of $|\mathbf{v}| = 21$, and forms an angle of 25° with the negative x-axis (Figure 8.47). Find the horizontal and vertical components of the vector, rounded to tenths.

Figure 8.47

Solution ▶ Begin by graphing the vector and setting up the equations for its components. For $\theta_r = 25°$, $\theta = 205°$.

For the horizontal component:

$a = |\mathbf{v}|\cos\theta$

$= 21\cos 205°$

≈ -19.0

For the vertical component:

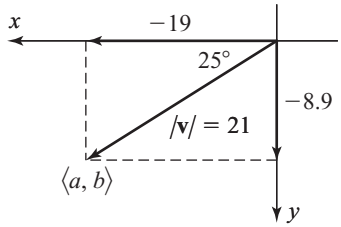
$b = |\mathbf{v}|\sin\theta$

$= 21\sin 205°$

≈ -8.9

With $\mathbf{v}$ in QIII, its component form is approximately $\langle -19, -8.9\rangle$. See Figure 8.48. As a check, we use the **R▶Pr** and **R▶Pθ** features of a calculator as shown in Figure 8.49 ✓.

Figure 8.48



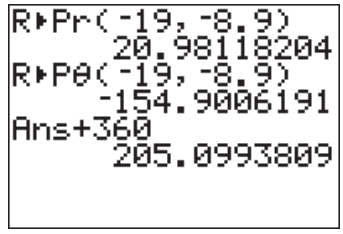


Figure 8.49

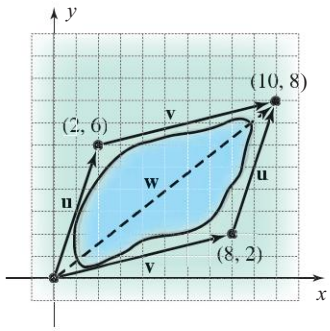

☑ **B.** You've just seen how we can represent a vector quantity graphically

Now try Exercises 25 through 30 ▶

C. Operations on Vectors and Vector Properties

Figure 8.50

The arithmetic operations defined for vectors have a close-knit graphical representation. Consider a local park having a large pond with pathways around both sides, so that a park visitor can enjoy the view from either side. Suppose $\mathbf{v} = \langle 8, 2\rangle$ is the position vector representing a person who decides to turn to the right at the pond, while $\mathbf{u} = \langle 2, 6\rangle$ represents a person who decides to first turn left. At (8, 2) the first person changes direction and walks to (10, 8) on the other side of the pond, while the second person arrives at (2, 6) and turns to head for (10, 8) as well. This is shown graphically in Figure 8.50 and demonstrates that (1) a parallelogram is formed (opposite sides equal and parallel), (2) the path taken is unimportant relative to the destination, and (3) the coordinates of the destination represent the *sum of corresponding coordinates* from the terminal points of **u** and **v:** $(2, 6) + (8, 2) = (2 + 8, 6 + 2) = (10, 8)$. In other words, the result of adding **u** and **v** gives the new position vector $\mathbf{u} + \mathbf{v} = \mathbf{w}$, called the **resultant** or the **resultant vector.** Note the resultant vector is a diagonal of the parallelogram formed. Geometrically or graphically, the addition of vectors can be viewed as a "tail-to-tip" combination of one with another, by shifting one vector (without changing its direction) so that its tail (initial point) is at the tip (terminal point) of the other vector. This is illustrated in Figures 8.51 through 8.53.

Figure 8.51
Given vectors u and v

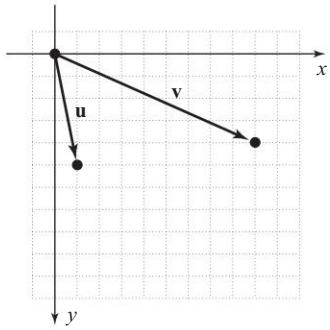

Figure 8.52
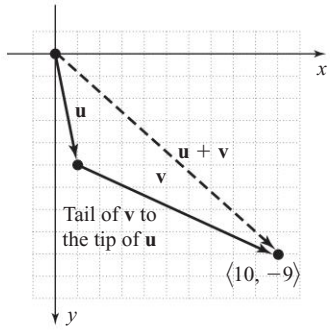
Shift vector v



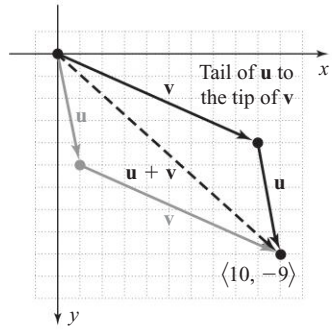


Figure 8.53
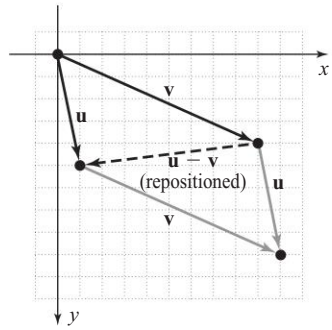
Shift vector u



WORTHY OF NOTE

The geometry of vector subtraction is a key part of resolving a vector into perpendicular components that are nonquadrantal. Applications of this concept are wide ranging, and include thrust and drag forces, tension and stress limits in a cable, and others.

The subtraction of vectors can be understood as either $\mathbf{u} - \mathbf{v}$ or $\mathbf{u} + (-\mathbf{v})$. Since the location of a vector is unimportant relative to the information it carries, vector subtraction can be interpreted as the *tip-to-tip diagonal* of the parallelogram from vector addition. In Figures 8.51 to 8.53, assume $\mathbf{u} = \langle 1, -5\rangle$ and $\mathbf{v} = \langle 9, -4\rangle$. Then $\mathbf{u} - \mathbf{v} = \langle 1, -5\rangle - \langle 9, -4\rangle = \langle 1 - 9, -5 + 4\rangle$ giving the position vector $\langle -8, -1\rangle$. By repositioning this vector with its tail at the tip of **v,** we note the new vector points directly at **u,** forming the diagonal (see Figure 8.54). Scalar multiplication of vectors also has a graphical representation that corresponds to the geometric description given earlier.

Figure 8.54

Operations on Vectors

Given vectors $\mathbf{u} = \langle a, b\rangle$, $\mathbf{v} = \langle c, d\rangle$, and a scalar k,

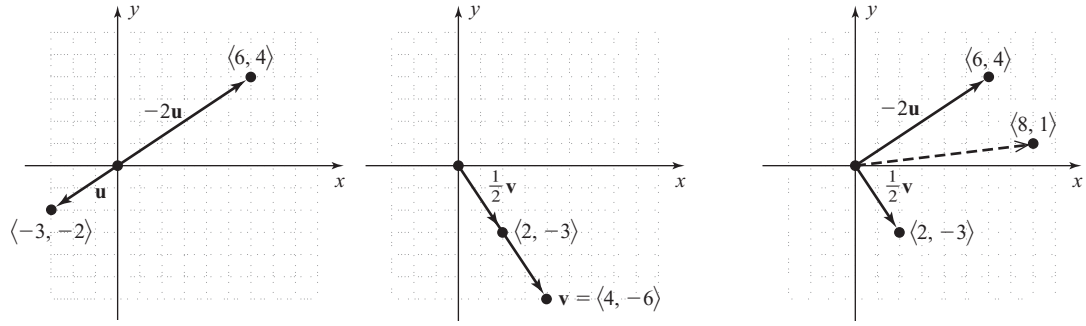
1. $\mathbf{u} + \mathbf{v} = \langle a + c, b + d\rangle$
2. $\mathbf{u} - \mathbf{v} = \langle a - c, b - d\rangle$
3. $k\mathbf{u} = \langle ka, kb\rangle$ for $k \in \mathbb{R}$

If $k > 0$, the new vector points in the same direction as **u.**
If $k < 0$, the new vector points in the opposite direction as **u.**

EXAMPLE 5 ▶ Representing Operations on Vectors Graphically

Given $\mathbf{u} = \langle -3, -2\rangle$ and $\mathbf{v} = \langle 4, -6\rangle$ compute each of the following and represent the result graphically:

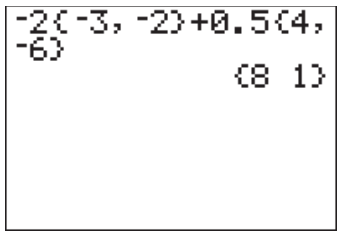
a. $-2\mathbf{u}$ **b.** $\frac{1}{2}\mathbf{v}$ **c.** $-2\mathbf{u} + \frac{1}{2}\mathbf{v}$



Note the relationship between part (c) and parts (a) and (b).

Solution ▶

a. $-2\mathbf{u} = -2\langle -3, -2\rangle = \langle 6, 4\rangle$



b. $\frac{1}{2}\mathbf{v} = \frac{1}{2}\langle 4, -6\rangle = \langle 2, -3\rangle$

c. $-2\mathbf{u} + \frac{1}{2}\mathbf{v} = \langle 6, 4\rangle + \langle 2, -3\rangle = \langle 8, 1\rangle$

Now try Exercises 31 through 48 ▶

Figure 8.55

Most graphing calculators have built-in features that can be used to perform arithmetic operations on vectors. Essentially, we use left and right braces "{" and "}" to denote the vector, instead of "⟨" and "⟩", respectively. In Figure 8.55, the computation from Example 5(c) is verified using this feature (recall the braces are accessed using the 2nd (({) and 2nd) (}) keys).

The properties that guide operations on vectors closely resemble the familiar properties of real numbers. Note we define the zero vector $\mathbf{0} = \langle 0, 0\rangle$ as one having no magnitude or direction.

Properties of Vectors

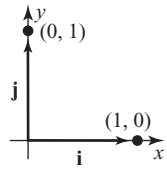
For vector quantities $\mathbf{u}$, $\mathbf{v}$, and $\mathbf{w}$ and real numbers c and k,

1. $1\mathbf{u} = \mathbf{u}$
2. $0\mathbf{u} = \mathbf{0} = k\mathbf{0}$
3. $\mathbf{u} + \mathbf{v} = \mathbf{v} + \mathbf{u}$
4. $\mathbf{u} - \mathbf{v} = \mathbf{u} + (-\mathbf{v})$
5. $(\mathbf{u} + \mathbf{v}) + \mathbf{w} = \mathbf{u} + (\mathbf{v} + \mathbf{w})$
6. $(ck)\mathbf{u} = c(k\mathbf{u}) = k(c\mathbf{u})$
7. $\mathbf{u} + \mathbf{0} = \mathbf{u}$
8. $\mathbf{u} + (-\mathbf{u}) = \mathbf{0}$
9. $k(\mathbf{u} + \mathbf{v}) = k\mathbf{u} + k\mathbf{v}$
10. $(c + k)\mathbf{u} = c\mathbf{u} + k\mathbf{u}$

Proof of Property 3

For $\mathbf{u} = \langle a, b\rangle$ and $\mathbf{v} = \langle c, d\rangle$, we have

$$\begin{aligned}
\mathbf{u} + \mathbf{v} &= \langle a, b\rangle + \langle c, d\rangle && \text{sum of } \mathbf{u} \text{ and } \mathbf{v}\\
&= \langle a + c, b + d\rangle && \text{vector addition}\\
&= \langle c + a, d + b\rangle && \text{commutative property}\\
&= \langle c, d\rangle + \langle a, b\rangle && \text{vector addition}\\
&= \mathbf{v} + \mathbf{u} && \text{result}
\end{aligned}$$



Proofs of the other properties are similarly derived **(see Exercises 89 through 97).**

☑ **C.** You've just seen how we can perform defined operations on vectors

D. Algebraic Vectors, Unit Vectors, and i, j Form

While the bold, small case **v** and the $\langle a, b\rangle$ notation for vectors has served us well, we now introduce an alternative form that is somewhat better suited to the **algebra of vectors,** and is used extensively in some of the physical sciences. Consider the vector $\langle 1, 0\rangle$, a vector 1 unit in length extending along the x-axis. It is called the **horizontal unit vector** and given the special designation **i** (not to be confused with the imaginary unit $i = \sqrt{-1}$). Likewise, the vector $\langle 0, 1\rangle$ is called the **vertical unit vector** and given the designation **j** (see Figure 8.56). Using scalar multiplication, the unit vector along the negative x-axis is $-\mathbf{i}$ and along the negative y-axis is $-\mathbf{j}$. Similarly, the vector $4\mathbf{i}$ represents a position vector 4 units long along the x-axis, and $-5\mathbf{j}$ represents a position vector 5 units long along the negative y-axis. Using these conventions, any nonquadrantal vector $\langle a, b\rangle$ can be written as a **linear combination** of **i** and **j,** with a and b expressed as multiples of **i** and **j,** respectively: $a\mathbf{i} + b\mathbf{j}$. These ideas can easily be generalized and applied to any vector.

Figure 8.56

WORTHY OF NOTE

Earlier we stated, "Two vectors are equal if they have the same magnitude and direction." Note that this means two vectors are equal if *their components are equal*.

Algebraic Vectors and i, j Form

For the unit vectors $\mathbf{i} = \langle 1, 0\rangle$ and $\mathbf{j} = \langle 0, 1\rangle$, any arbitrary vector $\mathbf{v} = \langle a, b\rangle$ can be written as a linear combination of **i** and **j**:

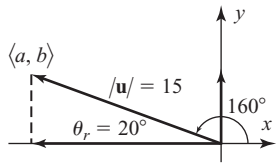
$$\mathbf{v} = a\mathbf{i} + b\mathbf{j}$$

Graphically, **v** is being expressed as the resultant of a vector sum.

EXAMPLE 6 ▶ **Finding the Horizontal and Vertical Components of Algebraic Vectors**

Vector **u** is in QII, has a magnitude of 15, and makes an angle of 20° with the negative x-axis.

a. Graph the vector.



b. Find the horizontal and vertical components (round to one decimal place) then write **u** in component form.

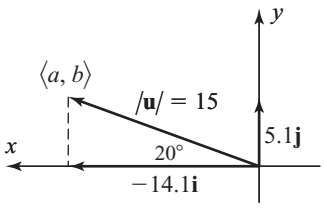
c. Write **u** in terms of **i** and **j**.

Solution ▶

a. The vector is graphed in Figure 8.57.

Figure 8.57

b. **Horizontal Component**



$$a = |\mathbf{v}|\cos\theta$$
$$= 15\cos 160°$$
$$\approx -14.1$$

Vertical Component

$$b = |\mathbf{v}|\sin\theta$$
$$= 15\sin 160°$$
$$\approx 5.1$$

With the vector in QII, $\mathbf{u} \approx \langle -14.1, 5.1\rangle$ in component form.

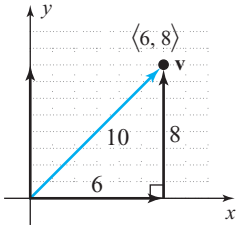


Figure 8.58

c. In terms of **i** and **j** we have $\mathbf{u} \approx -14.1\mathbf{i} + 5.1\mathbf{j}$. See Figure 8.58.

Now try Exercises 49 through 62 ▶

Figure 8.59

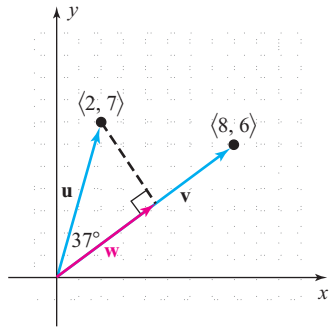
Some applications require that we find a nonhorizontal, nonvertical vector one unit in length, having the same direction as a given vector **v**. To understand how this is done, consider vector $\mathbf{v} = \langle 6, 8\rangle$. Using the Pythagorean theorem we find $|\mathbf{v}| = 10$, and can form a 6-8-10 triangle using the horizontal and vertical components (Figure 8.59). Knowing that similar triangles have sides that are proportional, we can find a unit vector in the same direction as **v** by dividing all three sides by 10, giving a triangle with sides $\frac{3}{5}$, $\frac{4}{5}$, and 1. The new vector "**u**" (along the hypotenuse) indeed points in the same direction since we have merely shortened **v**, and is a unit vector since $\left(\frac{3}{5}\right)^2 + \left(\frac{4}{5}\right)^2 \to \frac{9}{25} + \frac{16}{25} = 1$.

In retrospect, we have divided the components of vector $\mathbf{v}$ by its magnitude $|\mathbf{v}|$ (or multiplied components by the reciprocal of $|\mathbf{v}|$) to obtain the desired unit vector: $\frac{\mathbf{v}}{|\mathbf{v}|} = \frac{\langle 6, 8\rangle}{10} = \left\langle \frac{6}{10}, \frac{8}{10} \right\rangle = \left\langle \frac{3}{5}, \frac{4}{5} \right\rangle$. In general we have the following:

Unit Vectors

For any nonzero vector $\mathbf{v} = \langle a, b\rangle = a\mathbf{i} + b\mathbf{j}$, the vector

$$\mathbf{u} = \frac{\mathbf{v}}{|\mathbf{v}|} = \frac{a}{\sqrt{a^2 + b^2}}\mathbf{i} + \frac{b}{\sqrt{a^2 + b^2}}\mathbf{j}$$



is a unit vector in the same direction as $\mathbf{v}$.

You are asked to verify this relationship in **Exercise 100.** In summary, for vector $\mathbf{v} = 6\mathbf{i} + 8\mathbf{j}$, we find $|\mathbf{v}| = \sqrt{6^2 + 8^2} = 10$, so the unit vector pointing in the same direction is $\frac{\mathbf{v}}{|\mathbf{v}|} = \frac{3}{5}\mathbf{i} + \frac{4}{5}\mathbf{j}$. **See Exercises 63 through 74.**

EXAMPLE 7 ▶ **Using Unit Vectors to Find Coincident Vectors**

Vectors $\mathbf{u}$ and $\mathbf{v}$ form the 37° angle illustrated in the figure. Find the vector $\mathbf{w}$ (in red), which points in the same direction as $\mathbf{v}$ (is coincident with $\mathbf{v}$) and forms the base of the right triangle shown.

Solution ▶ Using the Pythagorean theorem we find $|\mathbf{u}| \approx 7.3$ and $|\mathbf{v}| = 10$. Using the cosine of 37° the magnitude of $\mathbf{w}$ is then $|\mathbf{w}| \approx 7.3 \cos 37°$ or about 5.8. To ensure that $\mathbf{w}$ will point in the same direction as $\mathbf{v}$, we simply multiply the 5.8 magnitude by the unit vector for $\mathbf{v}$: $|\mathbf{w}|\frac{\mathbf{v}}{|\mathbf{v}|} \approx (5.8)\frac{\langle 8, 6\rangle}{10} = (5.8)\langle 0.8, 0.6\rangle$, and we find that $\mathbf{w} \approx \langle 4.6, 3.5\rangle$. As a check we use the Pythagorean theorem: $\sqrt{4.6^2 + 3.5^2} = \sqrt{33.41} \approx 5.8$.

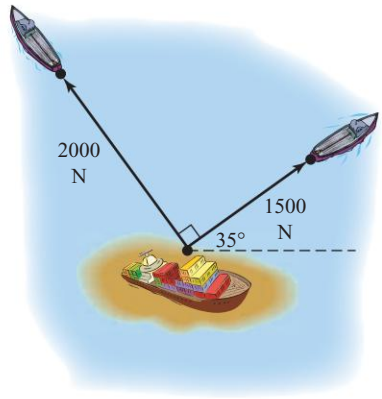
WORTHY OF NOTE

In this context, $\mathbf{w}$ is called the projection of $\mathbf{u}$ on $\mathbf{v}$, an idea applied more extensively in Section 8.4.

Now try Exercises 75 through 78 ▶

☑ **D.** You've just seen how we can represent a vector quantity algebraically and find unit vectors

E. Vector Diagrams and Vector Applications



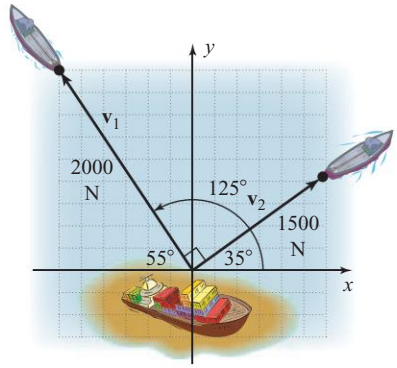
Applications of vectors are virtually unlimited, with many of these in the applied sciences. Here we'll look at two applications that are an extension of our work in this section. In Section 8.4 we'll see how vectors can be applied in a number of other creative and useful ways.

In Example 1, two tugboats were pulling on a barge to dislodge it from a sand bar, with the pulling force of each represented by a vector. Using our knowledge of vector components, vector addition, and **resultant forces** (a force exerted along the resultant), we can now determine the direction and magnitude of the resultant force if we know the angle formed by one of the vector forces and the barge.

EXAMPLE 8 ▶ Solving an Application of Vectors—Force Vectors Acting on a Barge

Two tugboats are attempting to free a barge that is stuck on a sand bar, and are exerting the forces shown in Figure 8.60. Find the magnitude and direction of the resultant force.

Figure 8.60



Solution ▶ Begin by orienting the diagram on a coordinate grid (see Figure 8.61). Since the angle between the vectors is 90°, we know the acute angle formed by the left-hand tugboat and the x-axis is 55°. With this information, we can write each vector in "**i**, **j**" form and add the vectors to find the resultant.

For vector $\mathbf{v}_1$ (in QII):

Horizontal Component	Vertical Component
$a = \lvert\mathbf{v}_1\rvert\cos\theta$	$b = \lvert\mathbf{v}_1\rvert\sin\theta$
$= 2000\cos 125°$	$= 2000\sin 125°$
≈ -1147	≈ 1638

$$\mathbf{v}_1 \approx -1147\mathbf{i} + 1638\mathbf{j}.$$

Figure 8.61

For vector $\mathbf{v}_2$ (in QI):

Horizontal Component	Vertical Component
$a = \lvert\mathbf{v}_2\rvert\cos\theta$	$b = \lvert\mathbf{v}_2\rvert\sin\theta$
$= 1500\cos 35°$	$= 1500\sin 35°$
≈ 1229	≈ 860

$$\mathbf{v}_2 \approx 1229\mathbf{i} + 860\mathbf{j}.$$

This gives a resultant of $\mathbf{v}_1 + \mathbf{v}_2 \approx (-1147\mathbf{i} + 1638\mathbf{j}) + (1229\mathbf{i} + 860\mathbf{j}) = 82\mathbf{i} + 2498\mathbf{j}$, with magnitude $\lvert\mathbf{v}_1 + \mathbf{v}_2\rvert \approx \sqrt{82^2 + 2498^2} \approx 2499$ N. To find the direction of the force, we have $\theta_r = \tan^{-1}\left\lvert\dfrac{2498}{82}\right\rvert$, or about 88°.

Now try Exercises 81 and 82 ▶

It's worth noting that a single tugboat pulling at 88° with a force of 2499 N would have the same effect as the two tugs in the original diagram. In other words, the resultant vector $82\mathbf{i} + 2498\mathbf{j}$ truly represents the "result" of the two forces.

Knowing that the location of a vector is unimportant enables us to model and solve a great number of seemingly unrelated applications. Although the final example concerns aviation, headings, and crosswinds, the solution process has a striking similarity to the "tugboat" example just discussed. In navigation, headings involve a single angle, which is understood to be the amount of rotation from due north in the clockwise direction. Several headings are illustrated in Figures 8.62 through 8.65.

Figure 8.62

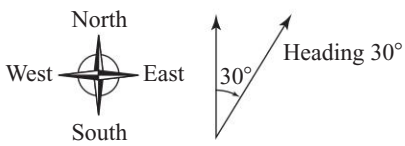


Figure 8.63

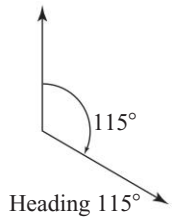

Figure 8.64

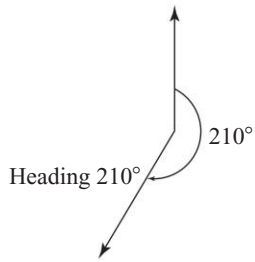

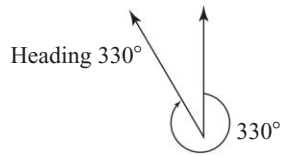

Figure 8.65

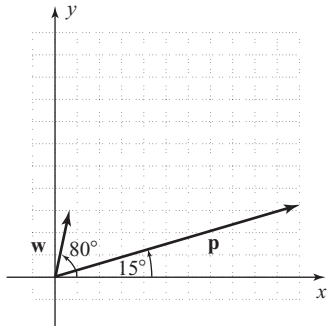
In order to keep an airplane on course, the captain must consider the direction and speed of any wind currents, since the plane's true course (relative to the ground) will be affected. Both the plane and the wind can be represented by vectors, with the plane's true course being the resultant vector.



EXAMPLE 9 ▶ **Solving an Application of Vectors—Airplane Navigation**

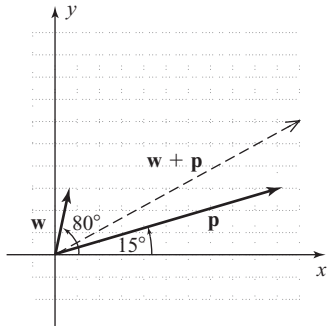
An airplane is flying at 240 mph, heading 75°, when it suddenly encounters a strong, 60 mph wind blowing *from* the southwest, heading 10°. What is the actual course and speed of the plane (relative to the ground) as it flies through this wind?

Solution ▶

Begin by drawing a vector **p** to represent the speed and direction of the airplane (Figure 8.66). Since the heading is 75°, the angle between the vector and the x-axis must be 15°. For convenience (and because location is unimportant) we draw it as a position vector. Note the vector **w** representing the wind will be $\frac{60}{240} = \frac{1}{4}$ as long, and can also be drawn as a position vector—with an acute 80° angle. To find the resultant, we first find the components of each vector, then add. For vector **w** (in QI):

Figure 8.66

Horizontal Component	Vertical Component
$a = \|\mathbf{w}\|\cos\theta$	$b = \|\mathbf{w}\|\sin\theta$
$= 60\cos 80°$	$= 60\sin 80°$
≈ 10.4	≈ 59.1



$$\mathbf{w} \approx 10.4\mathbf{i} + 59.1\mathbf{j}.$$

For vector **p** (in QI):

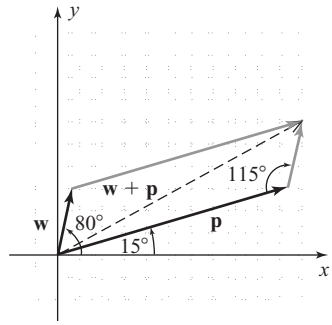
Horizontal Component	Vertical Component
$a = \|\mathbf{p}\|\cos\theta$	$b = \|\mathbf{p}\|\sin\theta$
$= 240\cos 15°$	$= 240\sin 15°$
$= 231.8$	≈ 62.1

$$\mathbf{p} \approx 231.8\mathbf{i} + 62.1\mathbf{j}.$$

Figure 8.67

The resultant is $\mathbf{w} + \mathbf{p} \approx (10.4\mathbf{i} + 59.1\mathbf{j}) + (231.8\mathbf{i} + 62.1\mathbf{j}) = 242.2\mathbf{i} + 121.2\mathbf{j}$, with magnitude $|\mathbf{w} + \mathbf{p}| \approx \sqrt{(242.2)^2 + (121.2)^2} \approx 270.8$ mph (see Figure 8.67).

To find the heading of the plane relative to the ground we use $\theta_r = \tan^{-1}\left|\frac{121.2}{242.2}\right|$, which shows $\theta_r \approx 26.6°$. The plane is flying on a course heading of approximately $90° - 26.6° = 63.4°$ at a speed of about 270.8 mph relative to the ground. Note the airplane has actually "increased speed" due to the wind.



Now try Exercises 83 through 86 ▶

WORTHY OF NOTE

Be aware that using the rounded values of intermediate calculations may cause slight variations in the final result. In Example 9, if we calculate $\mathbf{w} + \mathbf{p} = (60\cos 80° + 240\cos 15°)\mathbf{i} + (60\sin 80° + 240\sin 15°)\mathbf{j}$, then find $|\mathbf{w} + \mathbf{p}|$, the result is actually closer to 270.9 mph.

Applications like those in Examples 8 and 9 can also be solved using what is called the **parallelogram method,** which takes its name from the tail-to-tip vector addition noted earlier (See Figure 8.68). The resultant will be a diagonal of the parallelogram, whose magnitude can be found using the law of cosines. For Example 9, we note the parallelogram has two acute angles of $(80 - 15)° = 65°$, and since the adjacent angles must sum to 180°, the obtuse angles must be 115°. Using the law of cosines,

Figure 8.68

$$\begin{aligned} |\mathbf{w}+\mathbf{p}|^2 &= |\mathbf{p}|^2+|\mathbf{w}|^2-2|\mathbf{p}||\mathbf{w}|\cos 115^\circ && \text{law of cosines}\\ &= 240^2+60^2-2(240)(60)\cos 115^\circ && \text{substitute 240 for } |\mathbf{p}|,\ 60 \text{ for } |\mathbf{w}|\\ &= 73{,}371.40594 && \text{compute result}\\ |\mathbf{w}+\mathbf{p}| &\approx 270.9 && \text{take square roots} \end{aligned}$$

Note this answer is slightly more accurate, since there was no rounding until the final stage.

E. You've just seen how we can use vector diagrams to solve applications

8.3 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. Measurements that can be described using a single number are called _____ quantities.
2. _____ quantities require more than a single number to describe their attributes. Examples are force, velocity, and displacement.
3. To represent a vector quantity geometrically we use a _____ _____ segment.
4. Two vectors are equal if they have the same _____ and _____.
5. Discuss/Explain the geometric interpretation of vector addition. Give several examples and illustrations.
6. Describe the process of finding a resultant vector given the magnitude and direction of two arbitrary vectors **u** and **v.** Follow up with an example.

▶ DEVELOPING YOUR SKILLS

Draw the comparative geometric vectors indicated.

7. Three oceanic research vessels are traveling on parallel courses in the same direction, mapping the ocean floor. One ship is traveling at 12 knots (nautical miles per hour), one at 9 knots, and the third at 6 knots.
8. As part of family reunion activities, the Williams Clan is at a bowling alley and using three lanes. Being amateurs they all roll the ball straight on, aiming for the 1 pin. Grand Dad in Lane 1 rolls his ball at 50 ft/sec. Papa in Lane 2 lets it rip at 60 ft/sec, while Junior in Lane 3 can muster only 30 ft/sec.
9. Vector $\mathbf{v}_1$ is a geometric vector representing a boat traveling at 20 knots. Vectors $\mathbf{v}_2$, $\mathbf{v}_3$, and $\mathbf{v}_4$ are geometric vectors representing boats traveling at 10 knots, 15 knots, and 25 knots, respectively. Draw these vectors given that $\mathbf{v}_2$ and $\mathbf{v}_3$ are traveling the same direction and parallel to $\mathbf{v}_1$, while $\mathbf{v}_4$ is traveling in the opposite direction and parallel to $\mathbf{v}_1$.
10. Vector $\mathbf{F}_1$ is a geometric vector representing a force of 50 N. Vectors $\mathbf{F}_2$, $\mathbf{F}_3$, and $\mathbf{F}_4$ are geometric vectors representing forces of 25 N, 35 N, and 65 N, respectively. Draw these vectors given that $\mathbf{F}_2$ and $\mathbf{F}_3$ are applied in the same direction and parallel to $\mathbf{F}_1$, while $\mathbf{F}_4$ is applied in the opposite direction and parallel to $\mathbf{F}_1$.

Represent each situation described using geometric vectors.

11. Two tractors are pulling at a stump in an effort to clear land for more crops. The Massey-Ferguson is pulling with a force of 250 N, while the John Deere is pulling with a force of 210 N. The chains attached to the stump and each tractor form a 25° angle.
12. In an effort to get their mule up and plowing again, Jackson and Rupert are pulling on ropes attached to the mule's harness. Jackson pulls with 200 lb of force, while Rupert, who is really upset, pulls with 220 lb of force. The angle between their ropes is 16°.

Draw the vector v indicated, then graph the equivalent position vector. Verify your work by using the DRAW feature of a calculator to graph both vectors.

13. initial point $(-3, 2)$; terminal point $(4, 5)$

14. initial point $(-4, -4)$; terminal point $(2, 3)$

15. initial point $(5, -3)$; terminal point $(-1, 2)$

16. initial point $(1, 4)$; terminal point $(-2, 2)$

For each vector $\mathbf{v} = \langle a, b \rangle$ and initial point (x, y) given, find the coordinates of the terminal point and the length of the vector.

17. $\mathbf{v} = \langle 7, 2 \rangle$; initial point $(-2, -3)$

18. $\mathbf{v} = \langle -6, 1 \rangle$; initial point $(5, -2)$

19. $\mathbf{v} = \langle -3, -5 \rangle$; initial point $(2, 6)$

20. $\mathbf{v} = \langle 8, -2 \rangle$; initial point $(-3, -5)$

For each position vector given, (a) graph the vector and name the quadrant, (b) compute its magnitude, and (c) find the acute angle θ formed by the vector and the nearest x-axis. Use the R▶Pr and R▶Pθ features of a calculator to verify your results for parts (b) and (c).

21. $\langle 8, 3 \rangle$ **22.** $\langle -7, 6 \rangle$

23. $\langle -2, -5 \rangle$ **24.** $\langle 8, -6 \rangle$

For Exercises 25 through 30, the magnitude of a vector is given, along with the quadrant of the terminal point and the angle it makes with the nearest x-axis. Find the horizontal and vertical components of each vector and write the result in component form.

25. $|\mathbf{v}| = 12$; $\theta_r = 25°$; QII

26. $|\mathbf{u}| = 25$; $\theta_r = 32°$; QIII

27. $|\mathbf{w}| = 140.5$; $\theta_r = 41°$; QIV

28. $|\mathbf{p}| = 15$; $\theta_r = 65°$; QI

29. $|\mathbf{q}| = 10$; $\theta_r = 15°$; QIII

30. $|\mathbf{r}| = 4.75$; $\theta_r = 62°$; QII

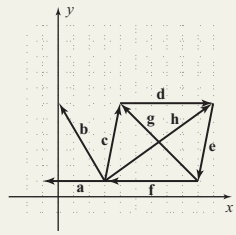
For each pair of vectors u and v given, compute (a) through (d) and illustrate the indicated operations graphically.

a. $\mathbf{u} + \mathbf{v}$ **b.** $\mathbf{u} - \mathbf{v}$

c. $2\mathbf{u} + 1.5\mathbf{v}$ **d.** $\mathbf{u} - 2\mathbf{v}$

31. $\mathbf{u} = \langle 2, 3 \rangle$; $\mathbf{v} = \langle -3, 6 \rangle$

32. $\mathbf{u} = \langle -3, -4 \rangle$; $\mathbf{v} = \langle 0, 5 \rangle$



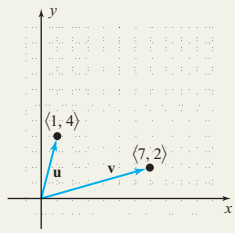
33. $\mathbf{u} = \langle 7, -2 \rangle$; $\mathbf{v} = \langle 1, 6 \rangle$

34. $\mathbf{u} = \langle -5, -3 \rangle$; $\mathbf{v} = \langle 6, -4 \rangle$

35. $\mathbf{u} = \langle -4, 2 \rangle$; $\mathbf{v} = \langle 1, 4 \rangle$

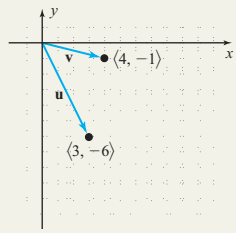
36. $\mathbf{u} = \langle 7, 3 \rangle$; $\mathbf{v} = \langle -7, 3 \rangle$

Use the graphs of vectors a, b, c, d, e, f, g, and h given to determine if the following statements are true or false.



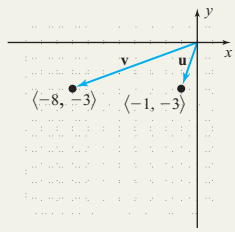
37. $\mathbf{a} + \mathbf{c} = \mathbf{b}$ **38.** $\mathbf{f} - \mathbf{e} = \mathbf{g}$

39. $\mathbf{c} + \mathbf{f} = \mathbf{h}$ **40.** $\mathbf{b} + \mathbf{h} = \mathbf{c}$

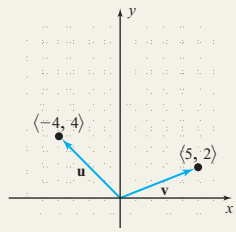


41. $\mathbf{d} - \mathbf{e} = \mathbf{h}$ **42.** $\mathbf{d} + \mathbf{f} = \mathbf{0}$

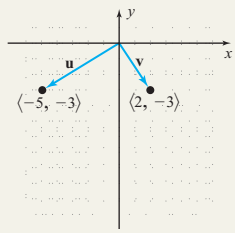
For the vectors u and v shown, compute u + v and u − v and represent each result graphically.



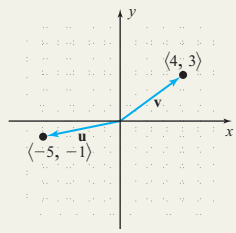
43.



44.



45.



46.

47.

48.

Graph each vector and write it as a linear combination of i and j. Then compute its magnitude.

49. $\mathbf{u} = \langle 8, 15 \rangle$ **50.** $\mathbf{v} = \langle -5, 12 \rangle$

51. $\mathbf{p} = \langle -3.2, -5.7 \rangle$ **52.** $\mathbf{q} = \langle 7.5, -3.4 \rangle$

For each vector here, θ_r represents the acute angle formed by the vector and the x-axis. (a) Graph each vector, (b) find the horizontal and vertical components and write the vector in component form, and (c) write the vector in i, j form. Round to the nearest tenth.

53. $\mathbf{v}$ in QIII, $|\mathbf{v}| = 12$, $\theta_r = 16°$

54. $\mathbf{u}$ in QII, $|\mathbf{u}| = 10.5$, $\theta_r = 25°$

55. $\mathbf{w}$ in QI, $|\mathbf{w}| = 9.5$, $\theta_r = 74.5°$

56. $\mathbf{v}$ in QIV, $|\mathbf{v}| = 20$, $\theta_r = 32.6°$

For vectors $\mathbf{v}_1$ and $\mathbf{v}_2$ given, compute the vector sums (a) through (d) and find the magnitude and direction of each resultant.

a. $\mathbf{v}_1 + \mathbf{v}_2 = \mathbf{p}$ **b.** $\mathbf{v}_1 - \mathbf{v}_2 = \mathbf{q}$

c. $2\mathbf{v}_1 + 1.5\mathbf{v}_2 = \mathbf{r}$ **d.** $\mathbf{v}_1 - 2\mathbf{v}_2 = \mathbf{s}$

57. $\mathbf{v}_1 = 2\mathbf{i} - 3\mathbf{j}$; $\mathbf{v}_2 = -4\mathbf{i} + 5\mathbf{j}$

58. $\mathbf{v}_1 = 7.8\mathbf{i} + 4.2\mathbf{j}$; $\mathbf{v}_2 = 5\mathbf{j}$

59. $\mathbf{v}_1 = 5\sqrt{2}\mathbf{i} + 7\mathbf{j}$; $\mathbf{v}_2 = -3\sqrt{2}\mathbf{i} - 5\mathbf{j}$

60. $\mathbf{v}_1 = 6.8\mathbf{i} - 9\mathbf{j}$; $\mathbf{v}_2 = -4\mathbf{i} + 9\mathbf{j}$

61. $\mathbf{v}_1 = 12\mathbf{i} + 4\mathbf{j}$; $\mathbf{v}_2 = -4\mathbf{i}$

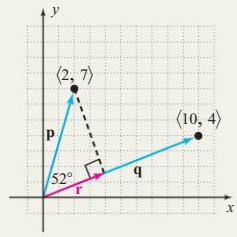
62. $\mathbf{v}_1 = 2\sqrt{3}\mathbf{i} - 6\mathbf{j}$; $\mathbf{v}_2 = -4\sqrt{3}\mathbf{i} + 2\mathbf{j}$

Find a unit vector pointing in the same direction as the vector given. Verify that a unit vector was found.

63. $\mathbf{u} = \langle 7, 24 \rangle$ **64.** $\mathbf{v} = \langle -15, 36 \rangle$

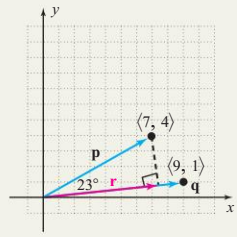
65. $\mathbf{p} = \langle -20, 21 \rangle$ **66.** $\mathbf{q} = \langle 12, -35 \rangle$

67. $20\mathbf{i} - 21\mathbf{j}$ **68.** $-4\mathbf{i} - 7.5\mathbf{j}$



69. $3.5\mathbf{i} + 12\mathbf{j}$ **70.** $-9.6\mathbf{i} + 18\mathbf{j}$

71. $\mathbf{v}_1 = \langle 13, 3 \rangle$ **72.** $\mathbf{v}_2 = \langle -4, 7 \rangle$



73. $6\mathbf{i} + 11\mathbf{j}$ **74.** $-2.5\mathbf{i} + 7.2\mathbf{j}$

Vectors p and q form the angle indicated in each diagram. Find the vector r that points in the same direction as q and forms the base of the right triangle shown.

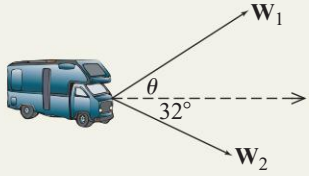
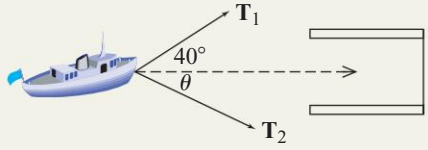
▶ WORKING WITH FORMULAS



The magnitude of a vector in three dimensions: $|\mathbf{v}| = \sqrt{a^2 + b^2 + c^2}$

79. The magnitude of a vector in three dimensional space is given by the formula shown, where the components of the position vector $\mathbf{v}$ are $\langle a, b, c \rangle$. Find the magnitude of $\mathbf{v}$ if $\mathbf{v} = \langle 5, 9, 10 \rangle$.



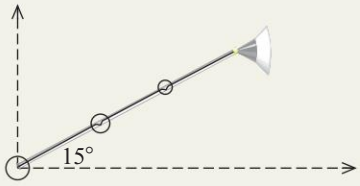
80. Find a cardboard box of any size and carefully measure its length, width, and height. Then use the given formula to find the magnitude of the box's diagonal. Verify your calculation by direct measurement.

▶ APPLICATIONS

81. Tow forces: A large van has careened off of the road into a ditch, and two tow trucks are attempting to winch it out. The cable from the first winch exerts a force of 900 lb, while the cable from the second exerts a force of 700 lb. Determine the angle θ for the first tow truck that will bring the van directly out of the ditch and along the line indicated.

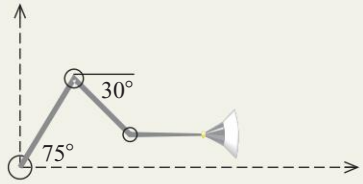
82. Tow forces: Two tugboats are pulling a large ship into dry dock. The first is pulling with a force of 1250 N and the second with a force of 1750 N. Determine the angle θ for the second tugboat that will keep the ship moving straight forward and into the dock.

83. Projectile components: An arrow is shot into the air at an angle of 37° with an initial velocity of 100 ft/sec. Compute the horizontal and vertical components of the representative vector.



84. Projectile components: A football is punted (kicked) into the air at an angle of 42° with an initial velocity of 20 m/sec. Compute the horizontal and vertical components of the representative vector.

85. Headings and cross-winds: An airplane is flying at 250 mph on a heading of 75°. There is a strong 35 mph wind blowing from the southwest on a heading of 10°. What is the true course and speed of the plane (relative to the ground)?



86. Headings and currents: A cruise ship is traveling at 16 knots on a heading of 300°. There is a strong water current flowing at 6 knots from the northwest on a heading of 120°. What is the true course and speed of the cruise ship?

The lights used in a dentist's office are multijointed so they can be configured in multiple ways to accommodate various needs. As a simple model, consider such a light that has the three joints, as illustrated. The first segment has a length of 45 cm, the second is 40 cm in length, and the third is 35 cm.

87. If the joints of the light are positioned so a straight line is formed and the angle made with the horizontal is 15°, determine the approximate coordinates of the joint nearest the light.

88. If the first segment is rotated 75° above horizontal, the second segment −30° (below the horizontal), and the third segment is parallel to the horizontal, determine the approximate coordinates of the joint nearest the light.

▶ EXTENDING THE CONCEPT

For the arbitrary vectors $\mathbf{u} = \langle a, b\rangle$, $\mathbf{v} = \langle c, d\rangle$, and $\mathbf{w} = \langle e, f\rangle$ and the scalars c and k, prove the following vector properties using the properties of real numbers.

89. $1\mathbf{u} = \mathbf{u}$

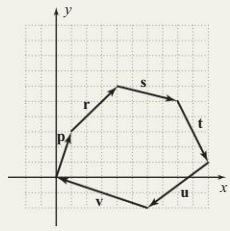
90. $0\mathbf{u} = \mathbf{0} = k\mathbf{0}$

91. $\mathbf{u} - \mathbf{v} = \mathbf{u} + (-\mathbf{v})$

92. $(\mathbf{u} + \mathbf{v}) + \mathbf{w} = \mathbf{u} + (\mathbf{v} + \mathbf{w})$

93. $(ck)\mathbf{u} = c(k\mathbf{u}) = k(c\mathbf{u})$

94. $\mathbf{u} + \mathbf{0} = \mathbf{u}$



95. $\mathbf{u} + (-\mathbf{u}) = \mathbf{0}$

96. $k(\mathbf{u} + \mathbf{v}) = k\mathbf{u} + k\mathbf{v}$

97. $(c + k)\mathbf{u} = c\mathbf{u} + k\mathbf{u}$

98. Consider an airplane flying at 200 mph at a heading of 45°. Compute the groundspeed of the plane under the following conditions. A strong, 40-mph wind is blowing (a) in the same direction; (b) in the direction of due north (0°); (c) in the direction heading 315°; (d) in the direction heading 270°; and (e) in the direction heading 225°. What did you notice about the groundspeed for (a) and (b)? Explain why the plane's speed is greater than 200 mph for (a) and (b), but less than 200 mph for the others.

99. Show that the sum of the vectors given, which form the sides of a closed polygon, is the zero vector. Assume all vectors have integer coordinates and each tick mark is 1 unit.

100. Verify that for $\mathbf{v} = a\mathbf{i} + b\mathbf{j}$ and $|\mathbf{v}| = \sqrt{a^2 + b^2}$, $\dfrac{\mathbf{v}}{|\mathbf{v}|} = 1$.

(*Hint:* Create the vector $\mathbf{u} = \dfrac{\mathbf{v}}{|\mathbf{v}|}$ and find its magnitude.)

101. Referring to Exercises 87 and 88, suppose the dentist needed the pivot joint at the light (the furthest joint from the wall) to be at (80, 20) for a certain patient or procedure. Find at least one set of "joint angles" that will make this possible.

▶ MAINTAINING YOUR SKILLS

102. **(7.1)** Derive the other two common versions of the Pythagorean identities, given $\cos^2 x + \sin^2 x = 1$.

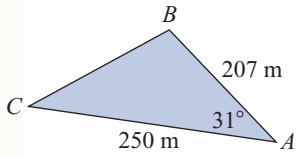
103. **(2.4/5.3)** Evaluate each expression for $x = 3$ (if possible):

a. $y = \ln(2x - 7)$ **b.** $y = \dfrac{5}{x - 3}$

c. $y = \sqrt{\dfrac{1}{3}x - 5}$

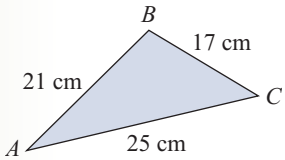
104. **(7.5)** Evaluate the expression $\csc\left[\tan^{-1}\left(\dfrac{55}{48}\right)\right]$ by drawing a representative triangle.

105. **(4.3)** Graph the function $g(x) = x^3 - 7x$ and find its zeroes.



MID-CHAPTER CHECK

1. Beginning with $\dfrac{\sin A}{a} = \dfrac{\sin B}{b}$, solve for $\sin B$.

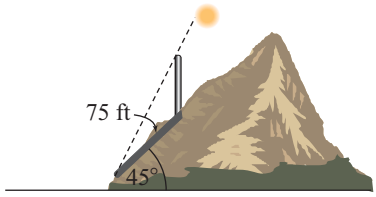


2. Given $b^2 = a^2 + c^2 - 2ac \cos B$, solve for $\cos B$.

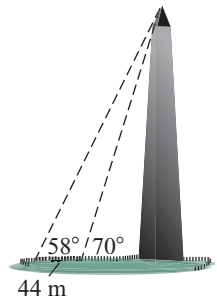
Solve the triangles shown below using any appropriate method. Use a calculator to verify your results.

3.

4.

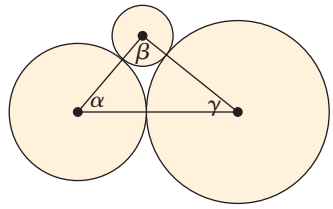


Solve the triangles described below using the law of sines. If more than one triangle exists, solve both.

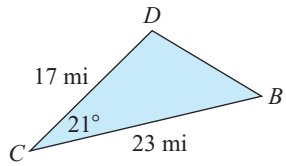


5. $A = 44°$, $a = 2.1$ km, $c = 2.8$ km

6. $C = 27°$, $a = 70$ yd, $c = 100$ yd



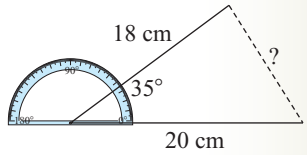
7. A large highway sign is erected on a steep hillside that is inclined 45° from the horizontal. At 9:00 A.M. the sign casts a 75 ft shadow. Find the height of the sign if the angle of elevation (measured from a horizontal line) from the tip of the shadow to the top of the sign is 65°.



8. Modeled after an Egyptian obelisk, the Washington Monument (Washington, D.C.) is one of the tallest masonry buildings in the world. Find the height of the monument given the measurements shown (see the figure).

9. The circles shown here have radii of 4 cm, 9 cm, and 12 cm, and are tangent to each other. Find the angles formed by the line segments joining their centers.

10. On her delivery route, Judy drives 23 mi to ***C***olumbus, then 17 mi to ***D***rake, then back home to ***B***alboa. Use the diagram given to find the distance from ***D***rake to ***B***alboa.



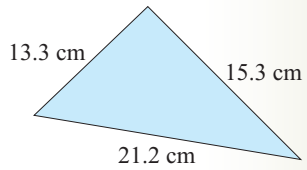
REINFORCING BASIC CONCEPTS

Scaled Drawings and the Laws of Sine and Cosine

In mathematics, there are few things as satisfying as the tactile verification of a concept or computation. In this *Reinforcing Basic Concepts,* we'll use scaled drawings to verify the relationships stated by the law of sines and the law of cosines. First, gather a blank sheet of paper, a ruler marked in centimeters/millimeters, and a protractor.

When working with scale models, always measure and mark as carefully as possible. The greater the care, the better the results. For the first illustration (see Figure 8.69), we'll draw a 20-cm horizontal line segment near the bottom of the paper, then use the left endpoint to mark off a 35° angle. Draw the second side a length of 18 cm. Our first goal is to compute the length of the side needed to complete the triangle, then verify our computation by measurement. Since the current "triangle" is SAS, we use the law of cosines. Label the 35° as $\angle A$, the top vertex as $\angle B$, and the right endpoint as $\angle C$.

Figure 8.69



$$\begin{aligned} a^2 &= b^2 + c^2 - 2bc\cos A && \text{law of cosines with respect to } a \\ &= (20)^2 + (18)^2 - 2(20)(18)\cos 35° && \text{substitute known values} \\ &\approx 724 - 589.8 && \text{simplify (round to tenths)} \\ &= 134.2 && \text{combine terms} \\ a &\approx 11.6 && \text{solve for } a \end{aligned}$$

The computed length of side a is 11.6 cm, and if you took great care in drawing your diagram, you'll find the missing side is indeed very close to this length.

Exercise 1: Finish solving the triangle above using the law of sines. Once you've computed $\angle B$ and $\angle C$, measure these angles from the diagram using your protractor. How close was the computed measure to the actual measure?

For the second illustration (see Figure 8.70), draw *any arbitrary triangle* on a separate blank sheet, noting that the larger the triangle, the easier it is to measure the angles. After you've drawn it, measure the length of each side to the nearest millimeter (our triangle turned out to be 21.2 cm × 13.3 cm × 15.3 cm). Now use the law of cosines to find one angle, then the law of sines to solve the triangle. The computations for our triangle gave angles of 95.4°, 45.9°, and 38.7°. What angles did your computations give? Finally, use your protractor to measure the angles of the triangle you drew. With careful drawings, the measured results are often remarkably accurate!

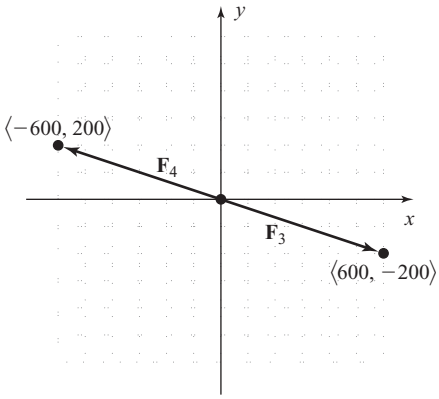
Figure 8.70

Exercise 2: Using sides of 18 cm and 15 cm, draw a 35° angle, a 50° angle, and a 70° angle, then complete each triangle by connecting the endpoints. Use the law of cosines to compute the length of this third side, then actually measure each one. Was the actual length close to the computed length?

8.4 Vector Applications and the Dot Product

LEARNING OBJECTIVES

In Section 8.4 you will see how we can:



- ❑ **A.** Use vectors to investigate forces in equilibrium
- ❑ **B.** Find the components of one vector along another
- ❑ **C.** Solve applications involving work
- ❑ **D.** Compute dot products and the angle between two vectors
- ❑ **E.** Find the projection of one vector along another and resolve a vector into orthogonal components
- ❑ **F.** Use vectors to develop an equation for nonvertical projectile motion and solve related applications

In Section 8.3 we introduced the concept of a vector, with its geometric, graphical, and algebraic representations. We also looked at operations on vectors and employed vector diagrams to solve basic applications. In this section we introduce additional ideas that enable us to solve a variety of new applications, while laying a strong foundation for future studies.

A. Vectors and Equilibrium

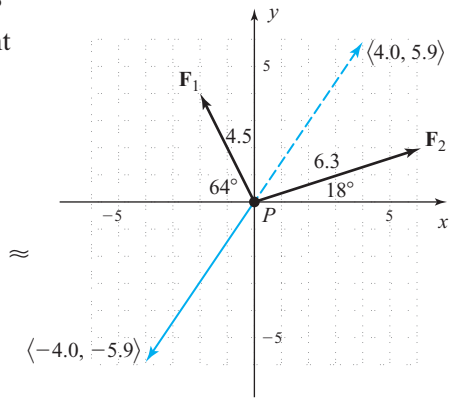
Much like the intuitive meaning of the word, vector forces are in **equilibrium** when they "counterbalance" each other. The simplest example is two vector forces of equal magnitude acting on the same point but in opposite directions. Similar to a tug-of-war with both sides equally matched, no one wins. If vector $\mathbf{F}_1$ has a magnitude of 500 lb in the positive direction, $\mathbf{F}_1 = \langle 500, 0\rangle$ would need vector $\mathbf{F}_2 = \langle -500, 0\rangle$ to counter it. If the forces are nonquadrantal, we intuitively sense the components must still sum to zero, and that $\mathbf{F}_3 = \langle 600, -200\rangle$ would need $\mathbf{F}_4 = \langle -600, 200\rangle$ for equilibrium to occur (see Figure 8.71). In other

Figure 8.71

$\mathbf{F}_3 + \mathbf{F}_4 = \langle -600, 200\rangle + \langle 600, -200\rangle$
$= \langle 0, 0\rangle = \mathbf{0}$

words, two vectors are in equilibrium when their sum is the zero vector **0.** If the forces have unequal magnitudes or do not pull in opposite directions, recall a resultant vector $\mathbf{F} = \mathbf{F}_a + \mathbf{F}_b$ can be found that represents the combined force. Equilibrium will then occur by adding the vector $-1(\mathbf{F})$ and this vector is sometimes called the **equilibriant.**

These ideas can be extended to include any number of vector forces acting on the same point. In general, we have the following:



Vectors and Equilibrium

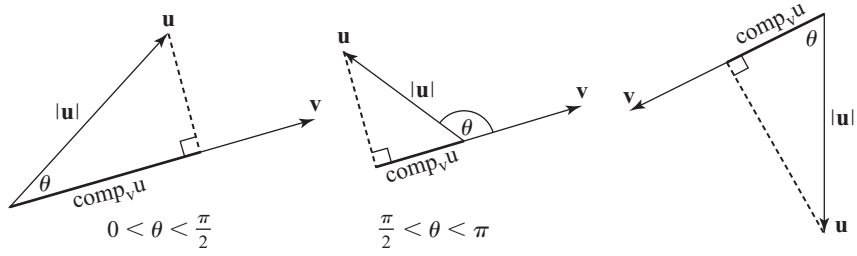
Given vectors $\mathbf{F}_1, \mathbf{F}_2, \ldots, \mathbf{F}_n$ acting on a point P,

1. The resultant vector is $\mathbf{F} = \mathbf{F}_1 + \mathbf{F}_2 + \cdots + \mathbf{F}_n$.
2. Equilibrium for these forces requires the vector $-1\mathbf{F}$, where $\mathbf{F} + (-1\mathbf{F}) = \mathbf{0}$.

EXAMPLE 1 ▶ Finding the Equilibriant for Vector Forces

Two force vectors $\mathbf{F}_1$ and $\mathbf{F}_2$ act on the point P as shown. Find a force $\mathbf{F}_3$ so equilibrium will occur, and sketch it on the grid.

Solution ▶ Begin by finding the horizontal and vertical components of each vector. For $\mathbf{F}_1$ we have $\langle 4.5\cos 116°, 4.5\sin 116°\rangle \approx \langle -2.0, 4.0\rangle$, and for $\mathbf{F}_2$ we have $\langle 6.3\cos 18°, 6.3\sin 18°\rangle \approx \langle 6.0, 1.9\rangle$. The resultant vector is $\mathbf{F} = \mathbf{F}_1 + \mathbf{F}_2 = \langle 4.0, 5.9\rangle$, meaning equilibrium will occur by applying the force $-1\mathbf{F} = \langle -4.0, -5.9\rangle$ (see figure).



Now try Exercises 7 through 20 ▶

A. You've just seen how we can use vectors to investigate forces in equilibrium

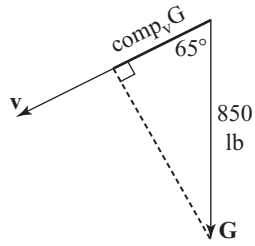
B. The Component of u along v: $\text{comp}_\mathbf{v}\mathbf{u}$

As in Example 1, many simple applications involve position vectors where the angle and horizontal/vertical components are known or can easily be found. In these situations, the components are often quadrantal, that is, they lie along the x- and y-axes and meet at a right angle. Many other applications require us to find components of a vector that are nonquadrantal, with one of the components parallel to, or lying along a second vector. Given vectors **u** and **v,** as shown in Figure 8.72, we symbolize the component of **u** that lies along **v** as $\text{comp}_\mathbf{v}\mathbf{u}$, noting its value is simply $|\mathbf{u}|\cos\theta$ since $\cos\theta = \dfrac{\text{adj}}{\text{hyp}} = \dfrac{\text{comp}_\mathbf{v}\mathbf{u}}{|\mathbf{u}|}$. As the diagrams further indicate, $\text{comp}_\mathbf{v}\mathbf{u} = |\mathbf{u}|\cos\theta$

Figure 8.72

regardless of how the vectors are oriented. Note that even when the components of a vector are not parallel to the x- or y-axes, they are still **orthogonal** (meet at a 90° angle).

It is important to note that $\text{comp}_{\mathbf{v}}\mathbf{u}$ is a *scalar quantity* (not a vector), giving only the magnitude of this component (the **vector projection** of **u** along **v** is studied later in this section). From these developments we make the following observations regarding the angle θ at which vectors **u** and **v** meet:



Vectors and the Component of u Along v

Given vectors **u** and **v,** which meet at an angle θ,

1. $\text{comp}_{\mathbf{v}}\mathbf{u} = |\mathbf{u}|\cos\theta$.
2. If $0° < \theta < 90°$, $\text{comp}_{\mathbf{v}}\mathbf{u} > 0$; if $90° < \theta < 180°$, $\text{comp}_{\mathbf{v}}\mathbf{u} < 0$.
3. If $\theta = 0°$, **u** and **v** have the same direction and $\text{comp}_{\mathbf{v}}\mathbf{u} = |\mathbf{u}|$.
4. If $\theta = 90°$, **u** and **v** are orthogonal and $\text{comp}_{\mathbf{v}}\mathbf{u} = 0$.
5. If $\theta = 180°$, **u** and **v** have opposite directions and $\text{comp}_{\mathbf{v}}\mathbf{u} = -|\mathbf{u}|$.

EXAMPLE 2 ▶ **Finding the Component of Vector G Along Vector v**

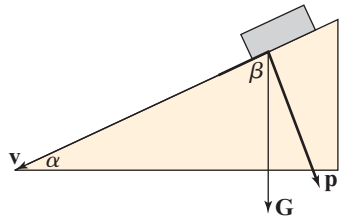
Given the vectors **G** and **v** with $|\mathbf{G}| = 850$ lb as shown in the figure, find $\text{comp}_{\mathbf{v}}\mathbf{G}$.

Solution ▶ Using $|\mathbf{G}|\cos\theta = \text{comp}_{\mathbf{v}}\mathbf{G}$ we have $850\cos 65° \approx 359$ lb. The component of **G** along **v** is about 359 pounds.

Now try Exercises 21 through 26 ▶

One interesting application of equilibrium and $\text{comp}_{\mathbf{v}}\mathbf{u}$ involves the force of gravity acting on an object placed on a ramp or an inclined plane. The greater the incline, the greater the tendency of the object to slide down the plane (for this study, we assume there is no friction between the object and the plane). While the force of gravity continues to pull straight downward (represented by the vector **G** in Figure 8.73), **G** is now the resultant of a force acting parallel to the plane along vector **v** (causing the object to slide) and a force acting perpendicular to the plane along vector **p** (causing the object to press against the plane). If we knew the component of **G** along **v** (indicated by the shorter, bold segment), we would know the force required to keep the object stationary as the two forces must be opposites. For instance, Figure 8.74 shows an 850-lb object sitting on a ramp with a 25° incline. Note that since **G** forms a right angle with the base of the incline, angle β must be complementary to 25° and measures 65°. Since the location of a vector doesn't change its characteristics, vector **p** can be repositioned (from directly under the object) to a location that forms the right triangle shown. The force required to keep the object from sliding down the incline is now seen to be $\text{comp}_{\mathbf{v}}\mathbf{G}$, and you may recognize the result as the same diagram from Example 2, where we calculated that the force required was about 359 lb.

Figure 8.73



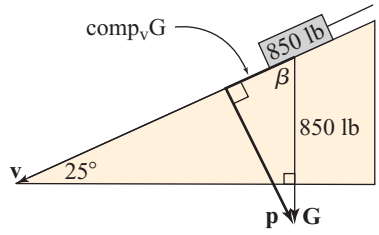


Figure 8.74

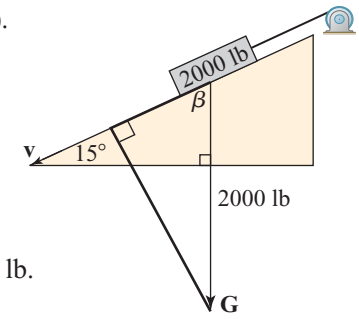


EXAMPLE 3 ▶ **Finding Components of Force for an Object on a Ramp**

A winch is being used to haul a 2000-lb block of granite up a ramp that is inclined at 15° (Figure 8.75).

a. If the winch has a maximum tow rating of 500 lb, will it be successful?

b. Use the **TABLE** feature of a calculator to determine the heaviest block this winch can successfully pull up the incline.

Figure 8.75

Solution ▶

a. We again need the component of **G** along the inclined plane: $\text{comp}_{\mathbf{v}}\mathbf{G} = 2000 \cos 75° \approx 518$ lb. Since the capacity of the winch is exceeded, the attempt will likely not be successful.

b. Begin by entering X cos 75° as Y_1 on the Y= screen. In part (a) we found that 2000 lb exceeded the capacity of this winch, so we set up a **TABLE** to begin at 2000 with **ΔTbl = −1**, essentially decreasing the weight in 1-lb increments until we find a weight less than or equal to the winch's 500-lb capacity. After scrolling down to the screen shown in Figure 8.76, we find the winch can successfully haul a 1931-lb block up the ramp.

Figure 8.76

X	Y_1
1937	501.33
1936	501.07
1935	500.81
1934	500.56
1933	500.3
1932	500.04
1931	[illegible]

$Y_1 = 499.779576093$

B. You've just seen how we can find the components of one vector along another

Now try Exercises 27 through 30 ▶

C. Vector Applications Involving Work

In common, everyday usage, **work** is understood to involve the exertion of energy or force to move an object a certain distance. For example, digging a ditch is hard work and involves moving dirt (exerting a force) from the trench to the bankside (over a certain distance). In an office, moving a filing cabinet likewise involves work. If the filing cabinet is heavier, or the distance it needs to be moved is greater, more work is required to move it (Figures 8.77 and 8.78).

Figure 8.77

Figure 8.78

To determine how much work was done by each person, we need to quantify the concept. Consider a constant force **F,** applied to move an object a distance D *in the same direction as the force*. In this case, work is defined as the product of the force applied and the distance the object is moved: Work = (Force)(Distance) or $W = |\mathbf{F}|D$. If the force is given in pounds and the distance in feet, the amount of work is measured in a unit called **foot-pounds** (ft-lb). If the force is in Newtons and the distance in meters, the amount of work is measured in **Newton-meters** (N-m).

EXAMPLE 4 ▶ **Solving Applications of Vectors—Work and Force Parallel to the Direction of Movement**

While rearranging the office, Carrie must apply a force of 55.8 N to relocate a filing cabinet 4.5 m, while Bernard applies a 77.5 N force to move a second cabinet 3.2 m. Who did the most work?

Solution ▶

For Carrie: $W = |\mathbf{F}|D$
$= (55.8)(4.5)$
$= 251.1$ N-m

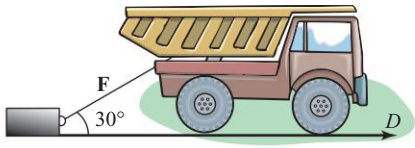
For Bernard: $W = |\mathbf{F}|D$
$= (77.5)(3.2)$
$= 248$ N-m

Carrie did $251.1 - 248 = 3.1$ N-m more work than Bernard.

Now try Exercises 31 and 32 ▶

In many applications of work, the force **F** is not applied parallel to the direction of movement, as illustrated in Figures 8.79 and 8.80.

Figure 8.79



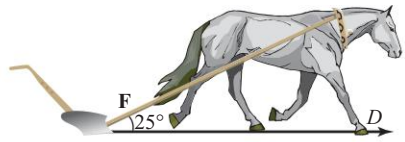


Figure 8.80

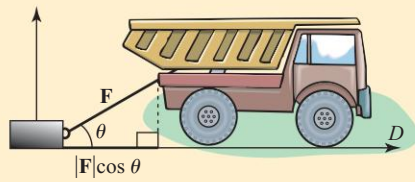
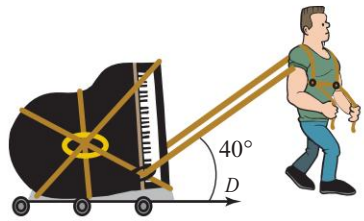
In calculating the amount of work done, the general concept of (force)(distance) is preserved, *but only the component of force in the direction of movement is used.* In terms of the component forces discussed earlier, if **F** is a constant force applied at angle θ to the direction of movement, the amount of work done is *the component of force along D times the distance the object is moved.*



WORTHY OF NOTE

In the formula $W = (|\mathbf{F}|\cos\theta)(D)$, observe that if $\theta = 0°$, we have the old formula for work when the force is applied in the direction of movement $W = \mathbf{F}D$. If $\theta \neq 0°$, $\cos\theta \neq 1$ and the "effective force" on the object becomes $|\mathbf{F}|\cos\theta$.

Force Vectors and Work *W*

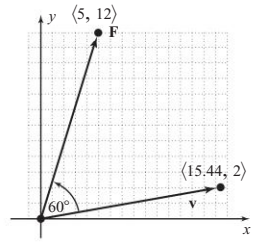


Given a force **F** applied in the direction of movement at the acute angle θ to an object, and D the distance it is moved,

$$W = (|\mathbf{F}|\cos\theta)(D)$$

EXAMPLE 5 ▶ Solving an Application of Vectors—Work and Force Applied at Angle θ to the Direction of Movement

To help move heavy pieces of furniture across the floor, movers sometime employ a body harness similar to that used for a plow horse. A mover applies a constant 200-lb force to drag a piano 100 ft down a long hallway and into another room. If the straps make a 40° angle with the direction of movement, find the amount of work performed.



Solution ▶ The component of force in the direction of movement is 200 cos 40° or about 153 lb. The amount of work done is $W \approx 153(100) = 15{,}300$ ft-lb.

Now try Exercises 35 through 40 ▶

These ideas can be generalized to include work problems where the component of force in the direction of motion is along a *nonhorizontal* vector **v.** Consider Example 6.

EXAMPLE 6 ▶ Solving an Application of Vectors—Forces Along a Nonhorizontal Vector

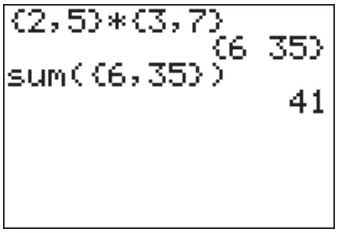
The force vector $\mathbf{F} = \langle 5, 12\rangle$ moves an object along the vector $\mathbf{v} = \langle 15.44, 2\rangle$ as shown. Find the amount of work required to move the object along the entire length of **v.** Assume force is in pounds and distance in feet.

Solution ▶ To begin, we first determine the angle between the vectors. In this case we have $\theta = \tan^{-1}\left|\frac{12}{5}\right| - \tan^{-1}\left|\frac{2}{15.44}\right| \approx 60°$.

For $|\mathbf{F}| = 13$ (5-12-13 triangle), the component of force in the direction of motion is $\text{comp}_{\mathbf{v}}\mathbf{F} = 13\cos 60° = 6.5$. With $|\mathbf{v}| = \sqrt{(15.44)^2 + (2)^2} \approx 15.57$, the work required is $W = (\text{comp}_{\mathbf{v}}\mathbf{F})(|\mathbf{v}|)$ or $(6.5)(15.57) \approx 101.2$ ft-lb.

C. You've just seen how we can solve applications involving work

Now try Exercises 41 through 44 ▶



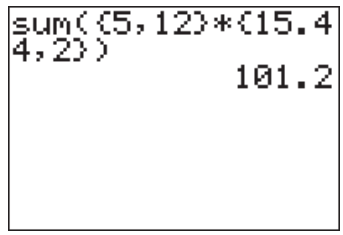
D. Dot Products and the Angle Between Two Vectors

When the component of force in the direction of motion lies along a *nonhorizontal* vector (as in Example 6), the work performed can actually be computed more efficiently using an operation called the **dot product.** For any two vectors **u** and **v,** the dot product $\mathbf{u} \cdot \mathbf{v}$ is equivalent to $(\text{comp}_{\mathbf{v}}\mathbf{u})(|\mathbf{v}|)$, yet is much easier to compute (for the proof of $\mathbf{u} \cdot \mathbf{v} = (\text{comp}_{\mathbf{v}}\mathbf{u})(|\mathbf{v}|)$, see Appendix B). The operation is defined as follows:

The Dot Product u · v

Given vectors $\mathbf{u} = \langle a, b \rangle$ and $\mathbf{v} = \langle c, d \rangle$, $\mathbf{u} \cdot \mathbf{v} = \langle a, b \rangle \cdot \langle c, d \rangle = ac + bd$. In words, it is the *real number* found by taking the sum of corresponding component products.

Figure 8.81



Earlier, we used the braces "{" and "}" to perform addition, subtraction, and scalar multiplication of vectors on a calculator. This technique can be extended to compute the dot product of two vectors, as it is simply defined as "the sum of the component products." For $\mathbf{u} = \langle 2, 5 \rangle$ and $\mathbf{v} = \langle 3, 7 \rangle$, the operation {2, 5} * {3, 7} is used for the component products, returning {6, 35} as shown in Figure 8.81. For the sum (although very simple in this case), we use the keystrokes 2nd STAT **(LIST)** ▸ ▸ **(MATH)** to access the **5:sum(** option, then **{6,35})** ENTER. The result shows $\langle 2, 5 \rangle \cdot \langle 3, 7 \rangle = 41$. To be more efficient, the calculator can combine these two operations as seen in Example 7.

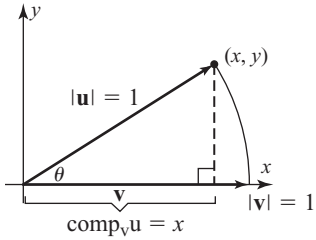
EXAMPLE 7 ▸ Using the Dot Product to Determine Force Along a Nonhorizontal Vector

Verify the answer to Example 6 using the dot product $\mathbf{u} \cdot \mathbf{v}$.

Solution ▸ For $\mathbf{u} = \langle 5, 12 \rangle$ and $\mathbf{v} = \langle 15.44, 2 \rangle$, we have $\mathbf{u} \cdot \mathbf{v} = \langle 5, 12 \rangle \cdot \langle 15.44, 2 \rangle$ giving $5(15.44) + 12(2) = 101.2$. The result is 101.2, as in Example 6. A calculator check is shown in the figure.

Now try Exercises 45 through 48 ▸

Note that dot products can also be used in the simpler case where the direction of motion is along a horizontal distance (Examples 4 and 5). While the dot product offers a powerful and efficient way to compute the work performed, it has many other applications; for example, to find the angle between two vectors. Consider that for any two vectors **u** and **v,** $\mathbf{u} \cdot \mathbf{v} = (|\mathbf{u}|\cos\theta)(|\mathbf{v}|)$, leading directly to $\cos\theta = \frac{\mathbf{u}}{|\mathbf{u}|} \cdot \frac{\mathbf{v}}{|\mathbf{v}|}$ (solve for $\cos\theta$).



In summary,

The Angle θ Between Two Vectors

Given the nonzero vectors **u** and **v:**

$$\cos\theta = \frac{\mathbf{u}}{|\mathbf{u}|} \cdot \frac{\mathbf{v}}{|\mathbf{v}|} \quad \text{and} \quad \theta = \cos^{-1}\left(\frac{\mathbf{u}}{|\mathbf{u}|} \cdot \frac{\mathbf{v}}{|\mathbf{v}|}\right)$$

Figure 8.82

In the special case where **u** *and* **v** *are unit vectors,* this simplifies to $\cos\theta = \mathbf{u} \cdot \mathbf{v}$ since $|\mathbf{u}| = |\mathbf{v}| = 1$. This relationship is shown in Figure 8.82. The dot product $\mathbf{u} \cdot \mathbf{v}$ gives $(\text{comp}_{\mathbf{v}}\mathbf{u})(|\mathbf{v}|)$, but $|\mathbf{v}| = 1$ and the component of **u** along **v** is simply the adjacent side of a right triangle whose hypotenuse is 1. Hence, $\mathbf{u} \cdot \mathbf{v} = \cos\theta$.

EXAMPLE 8 ▶ **Determining the Angle Between Two Vectors**

Find the angle between the vectors given.

a. $\mathbf{u} = \langle -3, 4\rangle$; $\mathbf{v} = \langle 5, 12\rangle$ **b.** $\mathbf{v}_1 = 2\mathbf{i} - 3\mathbf{j}$; $\mathbf{v}_2 = 6\mathbf{i} + 4\mathbf{j}$

Solution ▶

a.
$$\cos\theta = \frac{\mathbf{u}}{|\mathbf{u}|} \cdot \frac{\mathbf{v}}{|\mathbf{v}|}$$
$$= \left\langle \frac{-3}{5}, \frac{4}{5} \right\rangle \cdot \left\langle \frac{5}{13}, \frac{12}{13} \right\rangle$$
$$= \frac{-15}{65} + \frac{48}{65}$$
$$= \frac{33}{65}$$
$$\theta = \cos^{-1}\left(\frac{33}{65}\right)$$
$$\approx 59.5°$$

b.
$$\cos\theta = \frac{\mathbf{v}_1}{|\mathbf{v}_1|} \cdot \frac{\mathbf{v}_2}{|\mathbf{v}_2|}$$
$$= \left\langle \frac{2}{\sqrt{13}}, \frac{-3}{\sqrt{13}} \right\rangle \cdot \left\langle \frac{6}{\sqrt{52}}, \frac{4}{\sqrt{52}} \right\rangle$$
$$= \frac{12}{\sqrt{676}} + \frac{-12}{\sqrt{676}}$$
$$= \frac{0}{26} = 0$$
$$\theta = \cos^{-1} 0$$
$$= 90°$$

Now try Exercises 49 through 54 ▶

Note we have implicitly shown that if $\mathbf{u} \cdot \mathbf{v} = 0$, then $\mathbf{u}$ is orthogonal to $\mathbf{v}$ **(see Exercises 55 through 60).** As with other vector operations, recognizing certain properties of the dot product will enable us to work with them more efficiently.

Properties of the Dot Product

Given vectors $\mathbf{u}$, $\mathbf{v}$, and $\mathbf{w}$ and a constant k,

1. $\mathbf{u} \cdot \mathbf{v} = \mathbf{v} \cdot \mathbf{u}$
2. $\mathbf{u} \cdot \mathbf{u} = |\mathbf{u}|^2$
3. $\mathbf{w} \cdot (\mathbf{u} + \mathbf{v}) = \mathbf{w} \cdot \mathbf{u} + \mathbf{w} \cdot \mathbf{v}$
4. $k(\mathbf{u} \cdot \mathbf{v}) = k\mathbf{u} \cdot \mathbf{v} = \mathbf{u} \cdot k\mathbf{v}$
5. $\mathbf{0} \cdot \mathbf{u} = \mathbf{u} \cdot \mathbf{0} = 0$
6. $\dfrac{\mathbf{u}}{|\mathbf{u}|} \cdot \dfrac{\mathbf{v}}{|\mathbf{v}|} = \dfrac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{u}||\mathbf{v}|}$

Property 6 offers an alternative to unit vectors when finding $\cos\theta$—the dot product of the vectors can be computed first, and the result divided by the product of their magnitudes: $\cos\theta = \dfrac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{u}||\mathbf{v}|}$. Proofs of the first two properties are given here. Proofs of the others have a similar development **(see Exercises 79 through 82).** For any two nonzero vectors $\mathbf{u} = \langle a, b\rangle$ and $\mathbf{v} = \langle c, d\rangle$:

Property 1:
$$\mathbf{u} \cdot \mathbf{v} = \langle a, b\rangle \cdot \langle c, d\rangle$$
$$= ac + bd$$
$$= ca + db$$
$$= \langle c, d\rangle \cdot \langle a, b\rangle$$
$$= \mathbf{v} \cdot \mathbf{u}$$

Property 2:
$$\mathbf{u} \cdot \mathbf{u} = \langle a, b\rangle \cdot \langle a, b\rangle$$
$$= a^2 + b^2$$
$$= |\mathbf{u}|^2$$
(since $|\mathbf{u}| = \sqrt{a^2 + b^2}$)

Using $\text{comp}_{\mathbf{v}}\mathbf{u} = |\mathbf{u}|\cos\theta$ and $\mathbf{u} \cdot \mathbf{v} = (\text{comp}_{\mathbf{v}}\mathbf{u})|\mathbf{v}|$, we can also state the following relationships, which give us some flexibility on how we approach applications of the dot product.

For any two vectors $\mathbf{u} = \langle a, b \rangle$ and $\mathbf{v} = \langle c, d \rangle$:

(1)	$\mathbf{u} \cdot \mathbf{v} = ac + bd$	standard computation of the dot product
(2)	$\mathbf{u} \cdot \mathbf{v} = (\lvert\mathbf{u}\rvert \cos\theta)(\lvert\mathbf{v}\rvert)$	alternative computation of the dot product
(3)	$\mathbf{u} \cdot \mathbf{v} = (\text{comp}_\mathbf{v}\mathbf{u})(\lvert\mathbf{v}\rvert)$	replace $\lvert\mathbf{u}\rvert\cos\theta$ in (2) with $\text{comp}_\mathbf{v}\mathbf{u}$
(4)	$\dfrac{\mathbf{u} \cdot \mathbf{v}}{\lvert\mathbf{u}\rvert\lvert\mathbf{v}\rvert} = \cos\theta$	divide (2) by scalars $\lvert\mathbf{u}\rvert$ and $\lvert\mathbf{v}\rvert$
(5)	$\dfrac{\mathbf{u} \cdot \mathbf{v}}{\lvert\mathbf{v}\rvert} = \text{comp}_\mathbf{v}\mathbf{u}$	divide (3) by $\lvert\mathbf{v}\rvert$

D. You've just seen how we can compute dot products and the angle between two vectors

See Exercises 61 through 66 for practice with relationship (5).

E. Vector Projections and Orthogonal Components

In work problems and other simple applications, it is enough to find and apply $\text{comp}_\mathbf{v}\mathbf{u}$ (Figure 8.83). However, applications involving thrust and drag forces, tension and stress limits in a cable, electronic circuits, and cartoon animations often require that we also find the *vector form of* $\text{comp}_\mathbf{v}\mathbf{u}$. This is called the **projection** of **u** along **v** or $\mathbf{proj}_\mathbf{v}\mathbf{u}$, and is a vector in the same direction of **v** with magnitude $\text{comp}_\mathbf{v}\mathbf{u}$ (Figures 8.84 and 8.85).

Figure 8.83

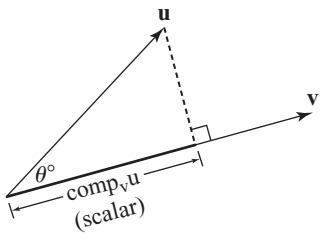


Figure 8.84

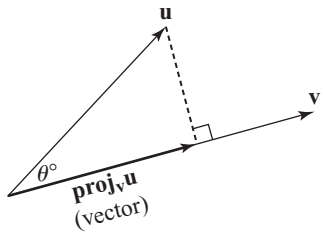

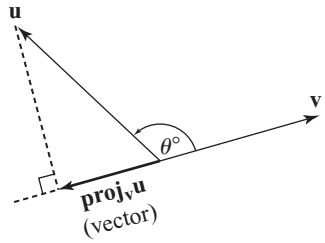

Figure 8.85

By its design, the unit vector $\dfrac{\mathbf{v}}{\lvert\mathbf{v}\rvert}$ has a length of one and points in the same direction as **v**, so $\mathbf{proj}_\mathbf{v}\mathbf{u}$ can be computed as $(\text{comp}_\mathbf{v}\mathbf{u})\left(\dfrac{\mathbf{v}}{\lvert\mathbf{v}\rvert}\right)$ (see Example 7, Section 8.3). Using equation (5) from this page and the properties shown earlier, an alternative formula for $\mathbf{proj}_\mathbf{v}\mathbf{u}$ can be found that is usually easier to simplify:

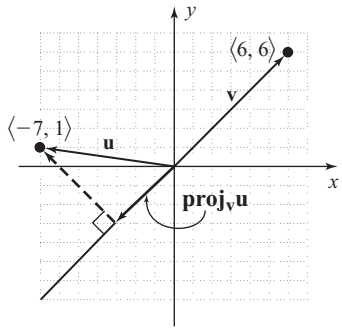
$$\begin{aligned}
\mathbf{proj}_\mathbf{v}\mathbf{u} &= (\text{comp}_\mathbf{v}\mathbf{u})\left(\frac{\mathbf{v}}{\lvert\mathbf{v}\rvert}\right) && \text{definition of a projection}\\
&= \left(\frac{\mathbf{u} \cdot \mathbf{v}}{\lvert\mathbf{v}\rvert}\right)\left(\frac{\mathbf{v}}{\lvert\mathbf{v}\rvert}\right) && \text{substitute } \frac{\mathbf{u} \cdot \mathbf{v}}{\lvert\mathbf{v}\rvert} \text{ for } \text{comp}_\mathbf{v}\mathbf{u}\\
&= \left(\frac{\mathbf{u} \cdot \mathbf{v}}{\lvert\mathbf{v}\rvert^2}\right)\mathbf{v} && \text{rewrite factors}
\end{aligned}$$

Vector Projections

Given vectors **u** and **v**, the projection of **u** along **v** is the *vector*

$$\mathbf{proj}_\mathbf{v}\mathbf{u} = \left(\frac{\mathbf{u} \cdot \mathbf{v}}{\lvert\mathbf{v}\rvert^2}\right)\mathbf{v}$$

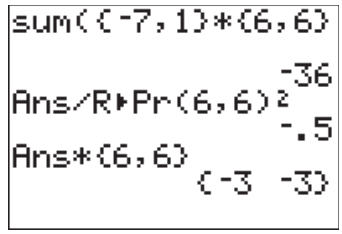
EXAMPLE 9A ▶ **Finding the Projection of One Vector Along Another**



Given $\mathbf{u} = \langle -7, 1\rangle$ and $\mathbf{v} = \langle 6, 6\rangle$, find $\mathbf{proj}_{\mathbf{v}}\mathbf{u}$.

Solution ▶ To begin, find $\mathbf{u} \cdot \mathbf{v}$ and $|\mathbf{v}|$.

$$\begin{aligned} \mathbf{u} \cdot \mathbf{v} &= \langle -7, 1\rangle \cdot \langle 6, 6\rangle \\ &= -42 + 6 \\ &= -36 \end{aligned} \qquad \begin{aligned} |\mathbf{v}| &= \sqrt{6^2 + 6^2} \\ &= \sqrt{72} \\ &= 6\sqrt{2} \end{aligned}$$



$$\begin{aligned} \mathbf{proj}_{\mathbf{v}}\mathbf{u} &= \left(\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|^2}\right)\mathbf{v} && \text{projection of } \mathbf{u} \text{ along } \mathbf{v} \\ &= \left(\frac{-36}{72}\right)\langle 6, 6\rangle && \text{substitute } -36 \text{ for } \mathbf{u} \cdot \mathbf{v},\ \sqrt{72} \text{ for } |\mathbf{v}|, \text{ and } \langle 6, 6\rangle \text{ for } \mathbf{v} \\ &= \langle -3, -3\rangle && \text{result, see Figure 8.86} \end{aligned}$$

Figure 8.86

For the calculator check shown in Figure 8.87, $\mathbf{u} \cdot \mathbf{v}$ is shown in the first entry. The second entry calculates the scalar multiplier $\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|^2}$, and the final entry confirms $\mathbf{proj}_{\mathbf{v}}\mathbf{u} = \langle -3, -3\rangle$.

Figure 8.87

WORTHY OF NOTE

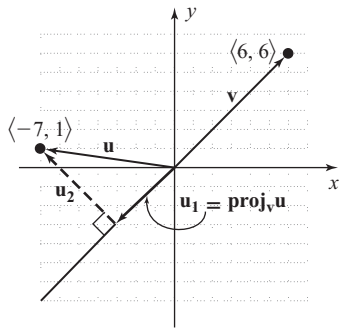
Note that $\mathbf{u}_2 = \mathbf{u} - \mathbf{u}_1$ is the shorter diagonal of the parallelogram formed by the vectors $\mathbf{u}$ and $\mathbf{u}_1 = \mathbf{proj}_{\mathbf{v}}\mathbf{u}$. This can also be seen in the graph supplied for Example 9B.

A useful consequence of computing $\mathbf{proj}_{\mathbf{v}}\mathbf{u}$ is we can then **resolve** the vector $\mathbf{u}$ into **orthogonal components** *that need not be quadrantal.* One component will be parallel to $\mathbf{v}$ and the other perpendicular to $\mathbf{v}$ (the dashed line in Figure 8.86). In general terms, this means we can write $\mathbf{u}$ as the vector sum $\mathbf{u}_1 + \mathbf{u}_2$, where $\mathbf{u}_1 = \mathbf{proj}_{\mathbf{v}}\mathbf{u}$ and $\mathbf{u}_2 = \mathbf{u} - \mathbf{u}_1$ (note $\mathbf{u}_1 \| \mathbf{v}$).

Resolving a Vector into Orthogonal Components

Given vectors $\mathbf{u}$, $\mathbf{v}$, and $\mathbf{proj}_{\mathbf{v}}\mathbf{u}$, $\mathbf{u}$ can be resolved into the orthogonal components $\mathbf{u}_1$ and $\mathbf{u}_2$, where $\mathbf{u} = \mathbf{u}_1 + \mathbf{u}_2$, $\mathbf{u}_1 = \mathbf{proj}_{\mathbf{v}}\mathbf{u}$, and $\mathbf{u}_2 = \mathbf{u} - \mathbf{u}_1$.

EXAMPLE 9B ▶ **Resolving a Vector into Orthogonal Components**



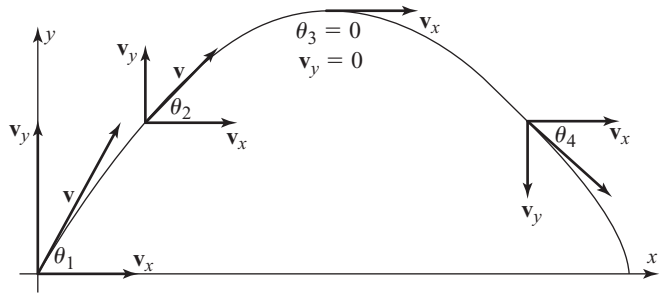
Given $\mathbf{u} = \langle -7, 1\rangle$ and $\mathbf{v} = \langle 6, 6\rangle$ from Example 9A, resolve $\mathbf{u}$ into orthogonal components $\mathbf{u}_1$ and $\mathbf{u}_2$, where $\mathbf{u}_1 \| \mathbf{v}$ and $\mathbf{u}_2 \perp \mathbf{v}$. Also verify $\mathbf{u}_1 \perp \mathbf{u}_2$.

Solution ▶ In Example 9A, we found $\mathbf{proj}_{\mathbf{v}}\mathbf{u} = \mathbf{u}_1 = \langle -3, -3\rangle$. Because $\mathbf{u} = \mathbf{u}_1 + \mathbf{u}_2$ we have

$$\begin{aligned} \mathbf{u}_2 &= \mathbf{u} - \mathbf{u}_1 && \text{subtract } \mathbf{u}_1 \text{ from both sides} \\ &= \langle -7, 1\rangle - \langle -3, -3\rangle && \text{substitute } \langle -7, 1\rangle \text{ for } \mathbf{u} \text{ and } \langle -3, -3\rangle \text{ for } \mathbf{u}_1 \\ &= \langle -4, 4\rangle && \text{result} \end{aligned}$$

To verify $\mathbf{u}_1 \perp \mathbf{u}_2$, we need only show $\mathbf{u}_1 \cdot \mathbf{u}_2 = 0$:

$$\begin{aligned} \mathbf{u}_1 \cdot \mathbf{u}_2 &= \langle -3, -3\rangle \cdot \langle -4, 4\rangle \\ &= (-3)(-4) + (-3)(4) \\ &= 0 \checkmark \end{aligned}$$



E. You've just seen how we can find the projection of one vector along another and resolve a vector into orthogonal components

Now try Exercises 67 through 72 ▶

F. Vectors and the Height of a Projectile

Our final application of vectors involves **projectile motion.** A projectile is any object that is thrown or projected upward, with no source of propulsion to sustain its motion. In this case, the only force acting on the projectile is gravity (air resistance is neglected), so the maximum height and the range of the projectile depend solely on its initial velocity and the angle θ at which it is projected. In a college algebra course, the equation $y = v_0t - 16t^2$ is developed to model the height in feet (at time t) of a projectile thrown vertically upward with initial velocity of v_0 feet per second. Here, we'll modify the equation slightly to take into account that the object is now moving horizontally as well as vertically. As you can see in Figure 8.88, the vector $\mathbf{v}$ representing the initial velocity, as well as the velocity vector at other times, can easily be decomposed into horizontal and vertical components. This will enable us to find a more general relationship for the position of the projectile. For now, we'll let $\mathbf{v}_y$ represent the component of velocity in the vertical (y) direction, and $\mathbf{v}_x$ represent the component of velocity in the horizontal (x) direction. Since gravity acts only in the vertical (and negative) direction, the horizontal component of the velocity remains constant at $|\mathbf{v}_x| = |\mathbf{v}|\cos\theta$. Using $D = RT$, the x-coordinate of the projectile at time t is $x = (|\mathbf{v}|\cos\theta)t$. For the vertical component $\mathbf{v}_y$ we use the projectile equation developed earlier, *substituting* $|\mathbf{v}|\sin\theta$ *for* v_0, since the angle of projection is no longer 90°. This gives the y-coordinate at time t as $y = v_0t - 16t^2 = (|\mathbf{v}|\sin\theta)t - 16t^2$.

Figure 8.88

Projectile Motion

Given an object is projected upward from the origin with initial velocity $|\mathbf{v}|$ at angle θ.
The x-coordinate of its position at time t is $x = (|\mathbf{v}|\cos\theta)t$.
The y-coordinate of its position at time t is $y = (|\mathbf{v}|\sin\theta)t - 16t^2$.

EXAMPLE 10 ▶ **Solving an Application of Vectors—Projectile Motion**

An arrow is shot upward with an initial velocity of 150 ft/sec at an angle of 50°.

a. Find the position of the arrow after 3 sec.

b. How many seconds does it take to reach a height of 190 ft?

Solution ▶

a. ▼ **Algebraic Solution**

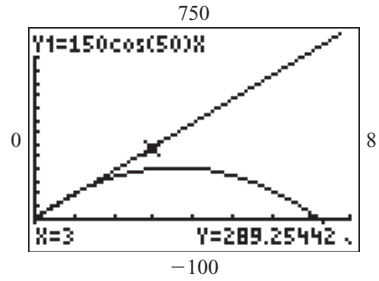
Using the preceding equations yields these coordinates for its position at $t = 3$:

$$x = (|\mathbf{v}|\cos\theta)t \qquad y = (|\mathbf{v}|\sin\theta)t - 16t^2$$
$$= (150\cos 50°)(3) \qquad = (150\sin 50°)(3) - 16(3)^2$$
$$\approx 289 \qquad \approx 201$$

▼ Graphical Solution

After entering $(150 \cos 50°)X$ as Y_1 and $(150 \sin 50°)X - 16X^2$ as Y_2 on the Y= screen, we can graph the functions and use the TRACE feature to find the arrow's position at $t = 3$ (see Figures 8.89 and 8.90).

Figure 8.89



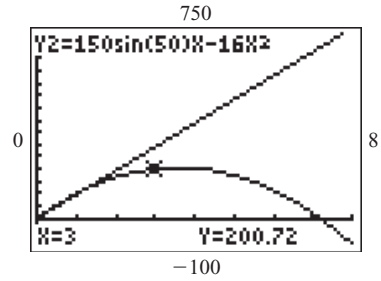


Figure 8.90

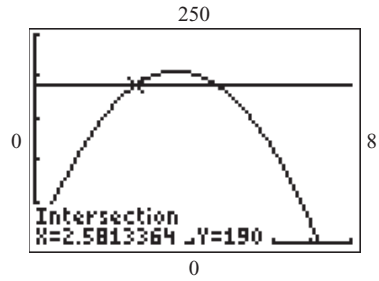
The arrow has traveled a horizontal distance of about 289 ft and is about 201 ft high.

b. ### ▼ Algebraic Solution

To find the time required to reach 190 ft in height, set the equation for the y coordinate equal to 190, which yields a quadratic equation in t:



$$y = (|\mathbf{v}|\sin\theta)t - 16t^2 \quad \text{equation for } y$$
$$190 = (150 \sin 50°)t - 16t^2 \quad \text{substitute 150 for } |\mathbf{v}| \text{ and } 50° \text{ for } \theta$$
$$0 \approx -16t^2 + 115t - 190 \quad 150 \sin 50 \approx 115$$

Using the quadratic formula we find that $t \approx 2.6$ sec and $t \approx 4.6$ sec are solutions.

▼ Graphical Solution

Begin by deactivating Y_1, entering $Y_3 = 190$, and changing the WINDOW to the dimensions shown for Figure 8.91. The intersection-of-graphs method confirms our algebraic solution. The result for the first intersection point is shown. The two solutions make sense, since the arrow reaches a given height once on the way up and again on the way down (as long as it hasn't reached its maximum height).

Figure 8.91

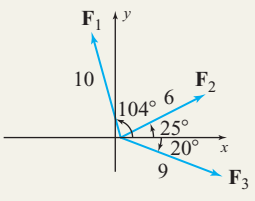
Now try Exercises 73 through 78 ▶

☑ **F.** You've just seen how we can use vectors to develop an equation for nonvertical projectile motion and solve related applications

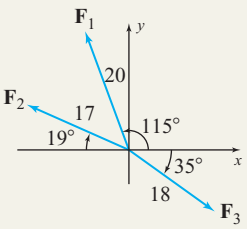
Note the GRAPH of Y_2 in Figure 8.91 does not represent the *path* of the arrow. For this important difference and more on projectile motion, see the *Calculator Exploration and Discovery* feature at the end of this chapter.

8.4 EXERCISES

▶ CONCEPTS AND VOCABULARY

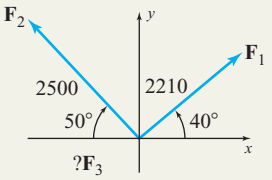


Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.



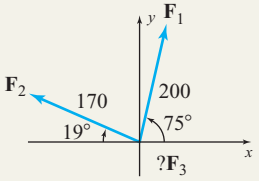
1. Vector forces are in _____ when they counterbalance each other. Such vectors have a sum of _____.
2. The component of a vector **u** along another vector **v** is written notationally as _____, and is computed as _____.
3. Two vectors that meet at a right angle are said to be _____.
4. The component of **u** along **v** is a _____ quantity. The projection of **u** along **v** is a _____.
5. Explain/Discuss exactly what information the dot product of two vectors gives us. Illustrate with a few examples.
6. Compare and contrast the projectile equations $y = v_0 t - 16t^2$ and $y = (v_0 \sin\theta)t - 16t^2$. Discuss similarities/differences using illustrative examples.

▶ DEVELOPING YOUR SKILLS



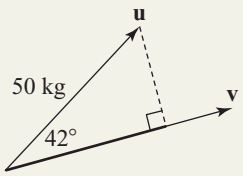
The force vectors given are acting on a common point *P*. Find an additional force vector so that equilibrium takes place.

7. $\mathbf{F}_1 = \langle -8, -3\rangle$; $\mathbf{F}_2 = \langle 2, -5\rangle$
8. $\mathbf{F}_1 = \langle -2, 7\rangle$; $\mathbf{F}_2 = \langle 5, 3\rangle$
9. $\mathbf{F}_1 = \langle -2, -7\rangle$; $\mathbf{F}_2 = \langle 2, -7\rangle$; $\mathbf{F}_3 = \langle 5, 4\rangle$
10. $\mathbf{F}_1 = \langle -3, 10\rangle$; $\mathbf{F}_2 = \langle -10, 3\rangle$; $\mathbf{F}_3 = \langle -9, -2\rangle$
11. $\mathbf{F}_1 = 5\mathbf{i} - 2\mathbf{j}$; $\mathbf{F}_2 = \mathbf{i} + 10\mathbf{j}$
12. $\mathbf{F}_1 = -7\mathbf{i} + 6\mathbf{j}$; $\mathbf{F}_2 = -8\mathbf{i} - 3\mathbf{j}$
13. $\mathbf{F}_1 = 2.5\mathbf{i} + 4.7\mathbf{j}$; $\mathbf{F}_2 = -0.3\mathbf{i} + 6.9\mathbf{j}$; $\mathbf{F}_3 = -12\mathbf{j}$
14. $\mathbf{F}_1 = 3\sqrt{2}\mathbf{i} - 2\sqrt{3}\mathbf{j}$; $\mathbf{F}_2 = -2\mathbf{i} + 7\mathbf{j}$; $\mathbf{F}_3 = 5\mathbf{i} + 2\sqrt{3}\mathbf{j}$

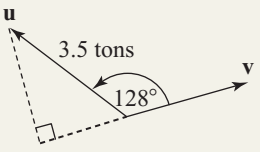


15. 

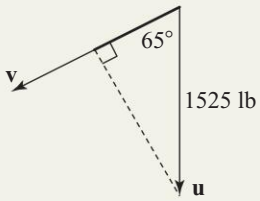
16. 



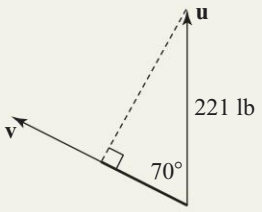
17. The force vectors $\mathbf{F}_1$ and $\mathbf{F}_2$ are simultaneously acting on a point *P*. Find a third vector $\mathbf{F}_3$ so that equilibrium takes place if $\mathbf{F}_1 = \langle 19, 10\rangle$ and $\mathbf{F}_2 = \langle 5, 17\rangle$.
18. The force vectors $\mathbf{F}_1$, $\mathbf{F}_2$, and $\mathbf{F}_3$ are simultaneously acting on a point *P*. Find a fourth vector $\mathbf{F}_4$ so that equilibrium takes place if $\mathbf{F}_1 = \langle -12, 2\rangle$, $\mathbf{F}_2 = \langle -6, 17\rangle$, and $\mathbf{F}_3 = \langle 3, 15\rangle$.
19. A new "Survivor" game involves a three-team tug-of-war. Teams 1 and 2 are pulling with the magnitudes and at the angles indicated in the diagram. If the teams are currently in a stalemate, find the magnitude and angle of the rope held by team 3.



20. Three cowhands have roped a wild stallion and are attempting to hold him steady. The first and second cowhands are pulling with the magnitude and at the angles indicated in the diagram. If the stallion is held fast by the three cowhands, find the magnitude and angle of the rope from the third cowhand.

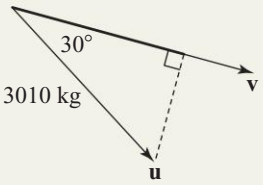


Find the component of u along v (compute $\text{comp}_{\mathbf{v}}\mathbf{u}$) for the vectors u and v given.

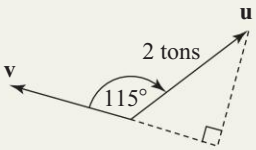


21. 

22. 

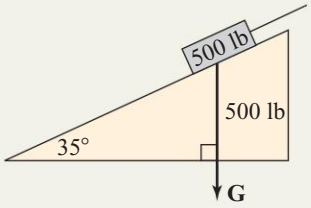


23.

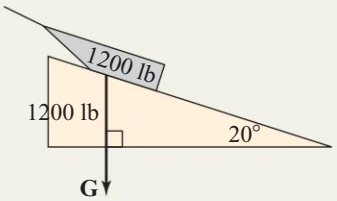


24.

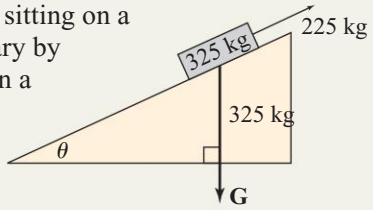
25.



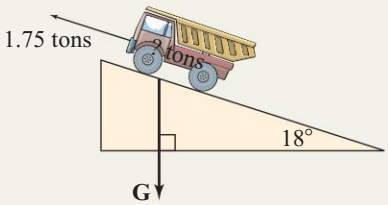
26.



Determine the requested missing component.



27. A 500-lb crate is sitting on a ramp that is inclined at 35°. Find the force needed to hold the object stationary.



28. A 1200-lb skiff is being pulled from a lake, using a boat ramp inclined at 20°. Find the minimum force needed to dock the skiff.

29. A 325-kg carton is sitting on a ramp, held stationary by 225 kg of tension in a restraining rope. Find the ramp's angle of incline.

30. A heavy dump truck is being winched up a ramp with an 18° incline. Approximate the weight of the truck if the winch is working at its maximum capacity of 1.75 tons and the truck is barely moving.

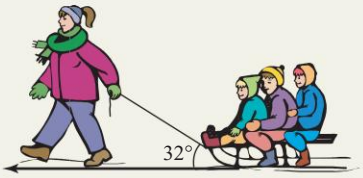
Determine the amount of work done.

31. While rearranging the patio furniture, Rick has to push the weighted base of the umbrella stand 15 m. If he uses a constant force of 75 N, how much work did he do?

32. Vinny's car just broke down in the middle of the road. Luckily, a buddy is with him and offers to steer if Vinny will get out and push. If he pushes with a constant force of 185 N to move the car 30 m, how much work did he do?

▶ WORKING WITH FORMULAS

The range of a projectile: $R = \dfrac{v^2 \sin\theta \cos\theta}{16}$



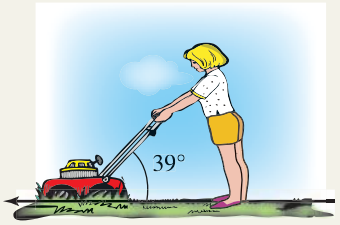
33. The range of a projected object (total horizontal distance traveled) is given by the formula shown, where v is the initial velocity and θ is the angle at which it is projected. If an arrow leaves the bow traveling 175 ft/sec at an angle of 45°, what horizontal distance will it travel?

34. A collegiate javelin thrower releases the javelin at a 40° angle, with an initial velocity of about 95 ft/sec. If the NCAA record is 280 ft, will this throw break the record? What is the smallest angle of release that will break this record? If the javelin were released at the optimum 45°, by how many feet would the record be broken?

▶ APPLICATIONS

35. Plowing a field: An old-time farmer is plowing his field with a mule. How much work does the mule do in plowing one length of a field 300 ft long, if it pulls the plow with a constant force of 250 lb and the straps make a 30° angle with the horizontal?

36. Pulling a sled: To enjoy a beautiful snowy day, a mother is pulling her three children on a sled along a level street. How much work (play) is done if the street is 100 ft long and she pulls with a constant force of 55 lb with the tow-rope making an angle of 32° with the street?



37. **Tough-man contest:** As part of a "tough-man" contest, participants are required to pull a bus along a level street for 100 ft. If one contestant did 45,000 ft-lb of work to accomplish the task and the straps used made an angle of 5° with the street, find the tension in the strap during the pull.

38. **Moving supplies:** An arctic explorer is hauling supplies from the supply hut to her tent, a distance of 150 ft, in a sled she is dragging behind her. If 9000 ft-lb of work was done and the straps used made an angle of 25° with the snow-covered ground, find the tension in the strap during the task.

39. **Wheelbarrow rides:** To break up the monotony of a long, hot, boring Saturday, a father decides to (carefully) give his kids a ride in a wheelbarrow. He applies a force of 30 N to move the "load" 100 m, then stops to rest. Find the amount of work done if the wheelbarrow makes an angle of 20° with level ground while in motion.

40. **Mowing the lawn:** A homeowner applies a force of 40 N to push her lawnmower back and forth across the back yard. Find the amount of work done if the yard is 50 m long, requires 24 passes to get the lawn mowed, and the mower arm makes an angle of 39° with the level ground.

Force vectors: For the force vector **F** and vector **v** given, find the amount of work required to move an object along the entire length of **v.** Assume force is in pounds and distance in feet.

41. $\mathbf{F} = \langle 15, 10\rangle$; $\mathbf{v} = \langle 50, 5\rangle$

42. $\mathbf{F} = \langle -5, 12\rangle$; $\mathbf{v} = \langle -25, 10\rangle$

43. $\mathbf{F} = \langle 8, 2\rangle$; $\mathbf{v} = \langle 15, -1\rangle$

44. $\mathbf{F} = \langle 15, -3\rangle$; $\mathbf{v} = \langle 24, -20\rangle$

45. Use the dot product to verify the solution to Exercise 41.

46. Use the dot product to verify the solution to Exercise 42.

47. Use the dot product to verify the solution to Exercise 43.

48. Use the dot product to verify the solution to Exercise 44.

For each pair of vectors given, (a) use a calculator to compute the dot product $\mathbf{p} \cdot \mathbf{q}$ and (b) find the angle between the vectors to the nearest tenth of a degree.

49. $\mathbf{p} = \langle 5, 2\rangle$; $\mathbf{q} = \langle 3, 7\rangle$

50. $\mathbf{p} = \langle -3, 6\rangle$; $\mathbf{q} = \langle 2, -5\rangle$

51. $\mathbf{p} = -2\mathbf{i} + 3\mathbf{j}$; $\mathbf{q} = -6\mathbf{i} - 4\mathbf{j}$

52. $\mathbf{p} = -4\mathbf{i} + 3\mathbf{j}$; $\mathbf{q} = -6\mathbf{i} - 8\mathbf{j}$

53. $\mathbf{p} = 7\sqrt{2}\mathbf{i} - 3\mathbf{j}$; $\mathbf{q} = 2\sqrt{2}\mathbf{i} + 9\mathbf{j}$

54. $\mathbf{p} = \sqrt{2}\mathbf{i} - 3\mathbf{j}$; $\mathbf{q} = 3\sqrt{2}\mathbf{i} + 5\mathbf{j}$

Determine if the pair of vectors given are orthogonal.

55. $\mathbf{u} = \langle 7, -2\rangle$; $\mathbf{v} = \langle 4, 14\rangle$

56. $\mathbf{u} = \langle -3.5, 2.1\rangle$; $\mathbf{v} = \langle -6, -10\rangle$

57. $\mathbf{u} = \langle -6, -3\rangle$; $\mathbf{v} = \langle -8, 15\rangle$

58. $\mathbf{u} = \langle -5, 4\rangle$; $\mathbf{v} = \langle -9, -11\rangle$

59. $\mathbf{u} = -2\mathbf{i} - 6\mathbf{j}$; $\mathbf{v} = 9\mathbf{i} - 3\mathbf{j}$

60. $\mathbf{u} = 3\sqrt{2}\mathbf{i} - 2\mathbf{j}$; $\mathbf{v} = 2\sqrt{2}\mathbf{i} + 6\mathbf{j}$

Find $\text{comp}_{\mathbf{v}}\mathbf{u}$ for the vectors u and v given.

61. $\mathbf{u} = \langle 3, 5\rangle$; $\mathbf{v} = \langle 7, 1\rangle$

62. $\mathbf{u} = \langle 3, 5\rangle$; $\mathbf{v} = \langle -7, 1\rangle$

63. $\mathbf{u} = -7\mathbf{i} + 4\mathbf{j}$; $\mathbf{v} = -10\mathbf{j}$

64. $\mathbf{u} = 8\mathbf{i}$; $\mathbf{v} = 10\mathbf{i} + 3\mathbf{j}$

65. $\mathbf{u} = 7\sqrt{2}\mathbf{i} - 3\mathbf{j}$; $\mathbf{v} = 6\mathbf{i} + 5\sqrt{3}\mathbf{j}$

66. $\mathbf{u} = -3\sqrt{2}\mathbf{i} + 6\mathbf{j}$; $\mathbf{v} = 2\mathbf{i} + 5\sqrt{5}\mathbf{j}$

For each pair of vectors given, (a) find the projection of u along v (compute $\text{proj}_{\mathbf{v}}\mathbf{u}$) and (b) resolve u into vectors $\mathbf{u}_1$ and $\mathbf{u}_2$, where $\mathbf{u}_1 \| \mathbf{v}$ and $\mathbf{u}_2 \perp \mathbf{v}$.

67. $\mathbf{u} = \langle 2, 6\rangle$; $\mathbf{v} = \langle 8, 3\rangle$

68. $\mathbf{u} = \langle -3, 8\rangle$; $\mathbf{v} = \langle -12, 3\rangle$

69. $\mathbf{u} = \langle -2, -8\rangle$; $\mathbf{v} = \langle -6, 1\rangle$

70. $\mathbf{u} = \langle -4.2, 3\rangle$; $\mathbf{v} = \langle -5, -8.3\rangle$

71. $\mathbf{u} = 10\mathbf{i} + 5\mathbf{j}$; $\mathbf{v} = 12\mathbf{i} + 2\mathbf{j}$

72. $\mathbf{u} = -3\mathbf{i} - 9\mathbf{j}$; $\mathbf{v} = 5\mathbf{i} - 3\mathbf{j}$

Projectile motion: A projectile is launched from a catapult with the initial velocity v_0 and angle θ indicated. Find (a) the position of the object after 3 sec and (b) the time(s) at which the object is at a height of 250 ft. Use a calculator to verify your results.

73. $v_0 = 250$ ft/sec; $\theta = 60°$

74. $v_0 = 300$ ft/sec; $\theta = 55°$

75. $v_0 = 200$ ft/sec; $\theta = 45°$

76. $v_0 = 500$ ft/sec; $\theta = 70°$

77. At the circus, a "human cannon ball" is shot from a large cannon with an initial velocity of 90 ft/sec at an angle of 65° from the horizontal. How high is the acrobat after 1.2 sec? How long until the acrobat is again at this same height?

78. A center fielder runs down a long hit by an opposing batter and whirls to throw the ball to the infield to keep the hitter to a double. If the initial velocity of the throw is 130 ft/sec and the ball is released at an angle of 30° with level ground, how high is the ball after 1.5 sec? How long until the ball again reaches this same height?

▶ EXTENDING THE CONCEPT

For the arbitrary vectors $\mathbf{u} = \langle a, b\rangle$, $\mathbf{v} = \langle c, d\rangle$, and $\mathbf{w} = \langle e, f\rangle$ and the scalar k, prove the following vector properties using the properties of real numbers.

79. $\mathbf{w} \cdot (\mathbf{u} + \mathbf{v}) = \mathbf{w} \cdot \mathbf{u} + \mathbf{w} \cdot \mathbf{v}$

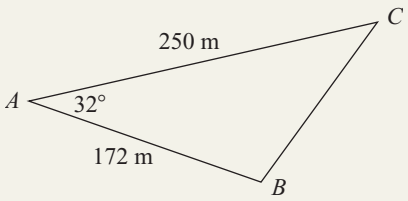
80. $k(\mathbf{u} \cdot \mathbf{v}) = k\mathbf{u} \cdot \mathbf{v} = \mathbf{u} \cdot k\mathbf{v}$

81. $\mathbf{0} \cdot \mathbf{u} = \mathbf{u} \cdot \mathbf{0} = 0$

82. $\dfrac{\mathbf{u}}{|\mathbf{u}|} \cdot \dfrac{\mathbf{v}}{|\mathbf{v}|} = \dfrac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{u}||\mathbf{v}|}$

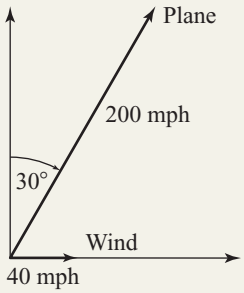
83. As alternative to $\cos\theta = \dfrac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{u}||\mathbf{v}|}$ for finding the angle between two vectors, the equation $\tan\theta = \dfrac{m_2 - m_1}{1 + m_2 m_1}$ can be used, where m_1 and m_2 represent the slopes of the vectors. Find the angle between the vectors $1\mathbf{i} + 5\mathbf{j}$ and $5\mathbf{i} + 2\mathbf{j}$ using each equation and comment on which you found more efficient. Then see if you can find a geometric connection between the two equations.

84. Use the equations for the horizontal and vertical components of the projected object's position to obtain the equation of trajectory $y = (\tan\theta)x - \dfrac{16}{v^2\cos^2\theta}x^2$. This is a quadratic equation in x. What can you say about its graph? Include comments about the concavity, x-intercepts, maximum height, and so on.



▶ MAINTAINING YOUR SKILLS

85. (5.5) Solve for t: $2.9e^{-0.25t} + 7.6 = 438$



86. (6.5) Graph the function using a reference rectangle and the *rule of fourths*:

$$y = 3\cos\left(2\theta - \frac{\pi}{4}\right)$$

87. (8.2) Solve the triangle shown, then compute its perimeter and area.

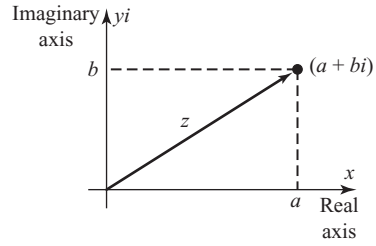
88. (8.3) A plane is flying 200 mph at heading 30°, with a 40 mph wind blowing from due west. Find the true course and speed of the plane.

8.5 Complex Numbers in Trigonometric Form

LEARNING OBJECTIVES

In Section 8.5 you will see how we can:

- ❑ **A.** Graph a complex number
- ❑ **B.** Write a complex number in trigonometric form
- ❑ **C.** Convert from trigonometric form to rectangular form
- ❑ **D.** Interpret products and quotients geometrically
- ❑ **E.** Compute products and quotients in trigonometric form
- ❑ **F.** Solve applications involving complex numbers (optional)



Once the set of complex numbers became recognized and defined, the related basic operations matured very quickly. With little modification—sums, differences, products, quotients, and powers all lent themselves fairly well to the algebraic techniques used for real numbers. But roots of complex numbers did not yield so easily and additional tools and techniques were needed. Writing complex numbers in trigonometric form enables us to find complex roots (Section 8.6) and in some cases, makes computing products, quotients, and powers more efficient.

A. Graphing Complex Numbers

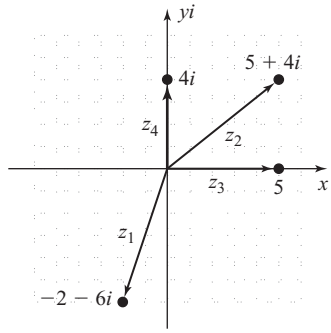
In previous sections, we defined a vector quantity as one that required more than a single component to describe its attributes. The complex number $z = a + bi$ certainly fits this description, since both a real number "component" and an imaginary "component" are needed to define it. In many respects, we can treat complex numbers in the same way we treated vectors and in fact, there is much we can learn from this connection.

Since both axes in the xy-plane have real number values, it's not possible to graph a complex number in $\mathbb{R}$ (the real plane). However, in the same way we used the x-axis for the horizontal component of a vector and the y-axis for the vertical, we can let the x-axis represent the real valued part of a complex number and the y-axis the imaginary part. The result is called the **complex plane** $\mathbb{C}$. Every point (a, b) in $\mathbb{C}$ can be associated with a complex number $a + bi$, and any complex number $a + bi$ can be associated with a point (a, b) in $\mathbb{C}$ (Figure 8.92). The point (a, b) can also be regarded as the terminal point of a position vector representing the complex number, generally named using the letter z.

Figure 8.92

WORTHY OF NOTE

Surprisingly, the study of complex numbers matured much earlier than the study of vectors, and using directed line segments to represent complex numbers actually preceded their application to vector quantities.

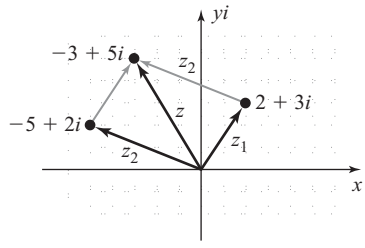


EXAMPLE 1 ▶ **Graphing Complex Numbers**

Graph the complex numbers below on the same complex plane.

a. $z_1 = -2 - 6i$ **b.** $z_2 = 5 + 4i$

c. $z_3 = 5$ **d.** $z_4 = 4i$

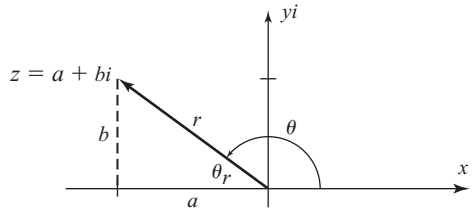


Solution ▶ The graph of each complex number is shown in the figure.

Now try Exercises 7 through 10 ▶

In Example 1, you likely noticed that from a vector perspective, z_2 is the "resultant vector" for the sum $z_3 + z_4$. To investigate further, consider $z_1 = 2 + 3i$, $z_2 = -5 + 2i$, and the sum $z_1 + z_2 = z$ shown in Figure 8.93. The figure helps to confirm that the sum of complex numbers can be illustrated geometrically using the parallelogram (tail-to-tip) method employed for vectors in Section 8.3.

Figure 8.93



☑ **A.** You've just seen how we can graph a complex number

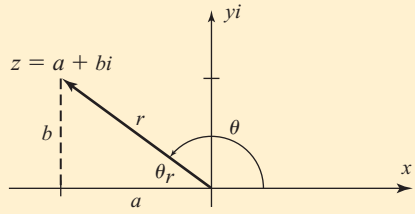
B. Complex Numbers in Trigonometric Form

The complex number $z = a + bi$ is said to be in **rectangular form** since it can be graphed using the rectangular coordinates of the complex plane. Complex numbers can also be written in **trigonometric form.** Similar to how $|x|$ represents the distance between the real number x and zero, $|z|$ represents the distance between $a + bi$ and the origin in the complex plane. It is computed as $|z| = \sqrt{a^2 + b^2}$. With any nonzero z, we can also associate an angle θ, which is the angle in standard position whose terminal side coincides with the graph of z. If we let r represent $|z|$, Figure 8.94 shows $\cos\theta = \dfrac{a}{r}$ and $\sin\theta = \dfrac{b}{r}$, yielding $r\cos\theta = a$ and $r\sin\theta = b$. The appropriate substitutions into $a + bi$ give the trigonometric form:

Figure 8.94

$$\begin{aligned} z &= a + bi \\ &= r\cos\theta + r\sin\theta \cdot i \end{aligned}$$

Factoring out r and writing the imaginary unit as the lead factor of $\sin\theta$ gives the relationship in its more common form, $z = r(\cos\theta + i\sin\theta)$, where $\tan\theta = \dfrac{b}{a}$.



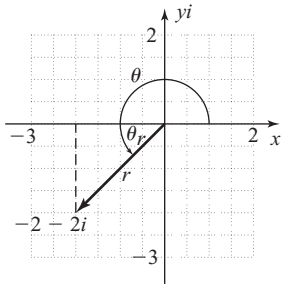
WORTHY OF NOTE

While it is true the trigonometric form can more generally be written as $z = r[\cos(\theta + 2\pi k) + i\sin(\theta + 2\pi k)]$ for $k \in \mathbb{Z}$, the result is identical for any integer k and we will select θ so that $0 \le \theta < 2\pi$ or $0° \le \theta < 360°$, depending on whether we are working in radians or degrees.

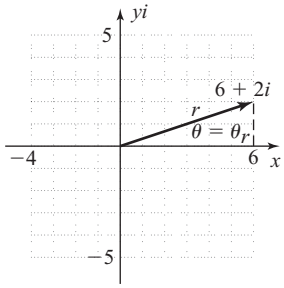
The Trigonometric Form of a Complex Number

For the complex number $z = a + bi$ and angle θ shown, $z = r(\cos\theta + i\sin\theta)$ is the trigonometric form of z, where $r = \sqrt{a^2 + b^2}$, and $\tan\theta = \dfrac{b}{a}$; $a \ne 0$.

- $r = |z|$ represents the magnitude of z (also called the **modulus**).
- θ is often referred to as the **argument** of z.



Be sure to note that for $\tan\theta = \dfrac{b}{a}$, $\tan^{-1}\left|\dfrac{b}{a}\right|$ is equal to θ_r (the reference angle for θ) and the value of θ will ultimately *depend on the quadrant of z.*



EXAMPLE 2 ▶ **Converting a Complex Number from Rectangular to Trigonometric Form**

State the quadrant of the complex number, then write each in trigonometric form.

a. $z_1 = -2 - 2i$ **b.** $z_2 = 6 + 2i$

Solution ▶ Knowing that modulus r and angle θ are needed for the trigonometric form, we first determine these values. Once again, to find the correct value of θ, *it's important to note the quadrant of the complex number.* When θ is not a standard angle, we will often answer in exact form as seen in Example 2(b).

a. $z_1 = -2 - 2i$; QIII

$$r = \sqrt{(-2)^2 + (-2)^2} = \sqrt{8} = 2\sqrt{2}$$

$$\theta_r = \tan^{-1}\left|\frac{-2}{-2}\right| = \tan^{-1}(1) = 45°$$

With z_1 in QIII, $\theta = 225°$, and we have

$$z_1 = 2\sqrt{2}(\cos 225° + i \sin 225°).$$

b. $z_2 = 6 + 2i$; QI

$$r = \sqrt{(6)^2 + (2)^2} = \sqrt{40} = 2\sqrt{10}$$

$$\theta_r = \tan^{-1}\left|\frac{2}{6}\right| = \tan^{-1}\left(\frac{1}{3}\right)$$

z_2 is in QI, so $\theta = \tan^{-1}\left(\frac{1}{3}\right)$ and

$$z_2 = 2\sqrt{10}\left(\cos\left[\tan^{-1}\left(\frac{1}{3}\right)\right] + i \sin\left[\tan^{-1}\left(\frac{1}{3}\right)\right]\right).$$

See the figures.

Now try Exercises 11 through 26 ▶

With a graphing calculator in "$a + bi$" (MODE), we can confirm the intermediate steps of Example 2(a). To confirm that the modulus of $-2 - 2i$ is $2\sqrt{2}$, and to find the modulus of other complex numbers, we press (MATH) then (›) (›) and select option **5:abs(** from the **CPX** (complex) submenu. We then enter $-2 - 2i$ with a right parenthesis and press (ENTER). The result is shown in Figure 8.95 and confirms the modulus of z_1 is $2\sqrt{2}$. Similarly, option **4:angle(** of the (MATH)**:CPX** submenu finds and displays the angle (argument) of a complex number. In the third entry of Figure 8.95, we find the argument of z_1 is $-135°$, coterminal with the $\theta = 225°$ which we computed earlier (see *Worthy of Note* on page 803).

Figure 8.95

```
abs(-2-2i)
        2.828427125
2√(2)
        2.828427125
angle(-2-2i)
             -135
```

Since the angle θ is repeated for both cosine and sine, we often use an abbreviated notation for the trigonometric form, called "cis" (sis) notation: $z = r(\cos\theta + i \sin\theta) = r \operatorname{cis}\theta$. The results of Example 2(a) and 2(b) would then be written $z = 2\sqrt{2} \operatorname{cis} 225°$ and $z = 2\sqrt{10} \operatorname{cis}\left[\tan^{-1}\left(\frac{1}{3}\right)\right]$, respectively.

☑ **B.** You've just seen how we can write a complex number in trigonometric form

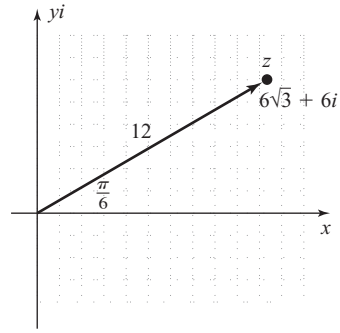
As in Example 2(b), when $\theta_r = \tan^{-1}\left|\frac{b}{a}\right|$ is not a standard angle we can either answer in exact form as shown, or use a four-decimal-place approximation: $2\sqrt{10} \operatorname{cis}(0.3218)$.

C. Converting from Trigonometric Form to Rectangular Form

Converting from trigonometric form back to rectangular form is simply a matter of evaluating $r \operatorname{cis}\theta$. This can be done regardless of whether θ is a standard angle or in the form $\tan^{-1}\left(\frac{b}{a}\right)$, since in the latter case we can construct a right triangle with side b opposite θ and side a adjacent to θ, and find the needed values as in Section 7.5.

EXAMPLE 3 ▶ **Converting a Complex Number from Trigonometric to Rectangular Form**

Graph the following complex numbers, then write them in rectangular form.



a. $z = 12\,\text{cis}\left(\frac{\pi}{6}\right)$ **b.** $z = 13\,\text{cis}\left[\tan^{-1}\left(\frac{5}{12}\right)\right]$

Solution ▶

a. We have $r = 12$ and $\theta = \frac{\pi}{6}$, which yields the graph in Figure 8.96. In the nonabbreviated form we have $z = 12\left[\cos\left(\frac{\pi}{6}\right) + i\sin\left(\frac{\pi}{6}\right)\right]$. Evaluating within the brackets gives

$$z = 12\left[\frac{\sqrt{3}}{2} + \frac{1}{2}i\right] = 6\sqrt{3} + 6i.$$

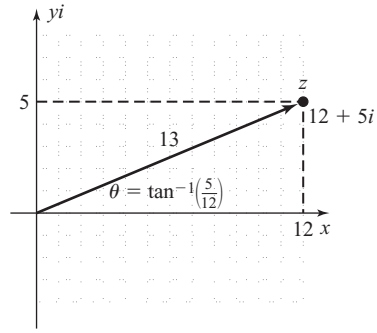


Figure 8.96

b. For $r = 13$ and $\theta = \tan^{-1}\left(\frac{5}{12}\right)$, we construct the graph shown in Figure 8.97 with 5 opposite θ, 12 adjacent to θ, and a vector magnitude of 13. From the diagram we note that $\cos\theta = \frac{12}{13}$ and $\sin\theta = \frac{5}{13}$, meaning

$$z = 13(\cos\theta + i\sin\theta)$$
$$= 13\left[\frac{12}{13} + \frac{5}{13}i\right]$$
$$= 12 + 5i.$$

Figure 8.97

☑ **C.** You've just seen how we can convert from trigonometric form to rectangular form

Now try Exercises 27 through 34 ▶

D. Interpreting Products and Quotients Geometrically

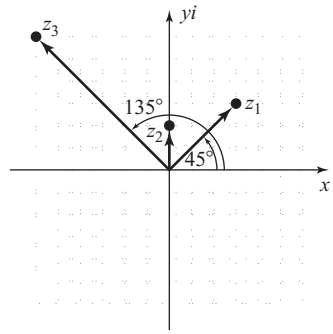
The multiplication and division of complex numbers has some geometric connections that can help us understand their computation in trigonometric form. Note the relationship between the modulus and argument of the following product, with the moduli (plural of modulus) and arguments from each factor.

EXAMPLE 4 ▶ **Noting Graphical Connections for the Product of Two Complex Numbers**

For $z_1 = 3 + 3i$ and $z_2 = 0 + 2i$,

a. Graph the complex numbers and compute their moduli and arguments.

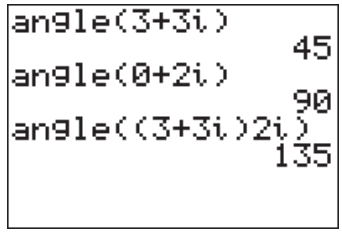
b. Compute and graph the product z_1z_2 and find its modulus and argument. Discuss any connections you see between the factors and the resulting product.



Solution ▶

a. The graphs of z_1 and z_2 are shown in Figure 8.98. For the modulus and argument we have:

$z_1 = 3 + 3i$; QI
$r = \sqrt{(3)^2 + (3)^2}$
$= \sqrt{18} = 3\sqrt{2}$
$\theta = \tan^{-1}1$
$\Rightarrow \theta = 45°$



$z_2 = 0 + 2i$; (quadrantal)
$r = 2$ directly
$\theta = 90°$ directly

Figure 8.98

b. The product z_1z_2 is $(3 + 3i)(2i) = -6 + 6i$, which is in QII. The modulus is $\sqrt{(-6)^2 + (6)^2} = \sqrt{72} = 6\sqrt{2}$, with $\theta_r = \tan^{-1}|-1| = 45°$ and an argument $\theta = 135°$ (QII). Note the product of the two moduli *is equal to the modulus of the final product:* $2 \cdot 3\sqrt{2} = 6\sqrt{2}$. Also note that the sum of the arguments for z_1 and z_2 *is equal to the argument of the product:* $45° + 90° = 135°$! See Figure 8.99.

Figure 8.99

Now try Exercises 35 and 36 ▶

D. You've just seen how we can interpret products and quotients geometrically

A similar geometric connection exists for the division of complex numbers. This connection is explored in **Exercises 37 and 38** of the Exercise Set.

E. Products and Quotients in Trigonometric Form

The connections in Example 4 are not a coincidence, and can be proven to hold for all complex numbers. Consider any two nonzero complex numbers $z_1 = r_1(\cos\alpha + i\sin\alpha)$ and $z_2 = r_2(\cos\beta + i\sin\beta)$. For the product z_1z_2 we have

$$\begin{aligned}
z_1z_2 &= r_1(\cos\alpha + i\sin\alpha)\, r_2(\cos\beta + i\sin\beta) && \text{product in trig form}\\
&= r_1r_2[(\cos\alpha + i\sin\alpha)(\cos\beta + i\sin\beta)] && \text{rearrange factors}\\
&= r_1r_2[\cos\alpha\cos\beta + i\sin\beta\cos\alpha + i\sin\alpha\cos\beta + i^2\sin\alpha\sin\beta] && \text{F - O - I - L}\\
&= r_1r_2[(\cos\alpha\cos\beta - \sin\alpha\sin\beta) + i(\sin\beta\cos\alpha + \sin\alpha\cos\beta)] && \text{commute terms; } i^2 = -1\\
&= r_1r_2[\cos(\alpha + \beta) + i\sin(\alpha + \beta)] && \text{use sum/difference identities for sine/cosine}
\end{aligned}$$

In words, the proof says that to *multiply* complex numbers in trigonometric form, we *multiply* the moduli and *add* the arguments. For *division*, we *divide* the moduli and *subtract* the arguments. The proof for division resembles that for multiplication and is asked for in **Exercise 71.**

Products and Quotients of Complex Numbers in Trigonometric Form

For the complex numbers $z_1 = r_1(\cos\alpha + i\sin\alpha)$ and $z_2 = r_2(\cos\beta + i\sin\beta)$,

- $z_1z_2 = r_1r_2[\cos(\alpha + \beta) + i\sin(\alpha + \beta)]$

and

- $\dfrac{z_1}{z_2} = \dfrac{r_1}{r_2}[\cos(\alpha - \beta) + i\sin(\alpha - \beta)],\ z_2 \neq 0.$

EXAMPLE 5 ▶ Multiplying Complex Numbers in Trigonometric Form

For $z_1 = -3 + i\sqrt{3}$ and $z_2 = \sqrt{3} + 1i$,

a. Write z_1 and z_2 in trigonometric form and compute z_1z_2.

b. Compute the quotient $\dfrac{z_1}{z_2}$ in trigonometric form.

c. Verify the product using the rectangular form.

Solution ▶

a. For z_1 in QII we find $r = 2\sqrt{3}$ and $\theta = 150°$, for z_2 in QI, $r = 2$ and $\theta = 30°$. In trigonometric form,

$$z_1 = 2\sqrt{3}(\cos 150° + i \sin 150°) \text{ and}$$
$$z_2 = 2(\cos 30° + i \sin 30°):$$
$$\begin{aligned} z_1z_2 &= 2\sqrt{3}(\cos 150° + i \sin 150°) \cdot 2(\cos 30° + i \sin 30°) \\ &= 2\sqrt{3} \cdot 2[\cos(150° + 30°) + i \sin(150° + 30°)] \quad \text{multiply moduli, add arguments} \\ &= 4\sqrt{3}(\cos 180° + i \sin 180°) \\ &= 4\sqrt{3}\,(-1 + 0i) \\ &= -4\sqrt{3} \end{aligned}$$

b.
$$\begin{aligned} \frac{z_1}{z_2} &= \frac{2\sqrt{3}(\cos 150° + i \sin 150°)}{2(\cos 30° + i \sin 30°)} \\ &= \sqrt{3}[\cos(150° - 30°) + i \sin(150° - 30°)] \quad \text{divide moduli, subtract arguments} \\ &= \sqrt{3}(\cos 120° + i \sin 120°) \\ &= \sqrt{3}\left(-\frac{1}{2} + \frac{\sqrt{3}}{2}i\right) \\ &= -\frac{\sqrt{3}}{2} + \frac{3}{2}i \end{aligned}$$

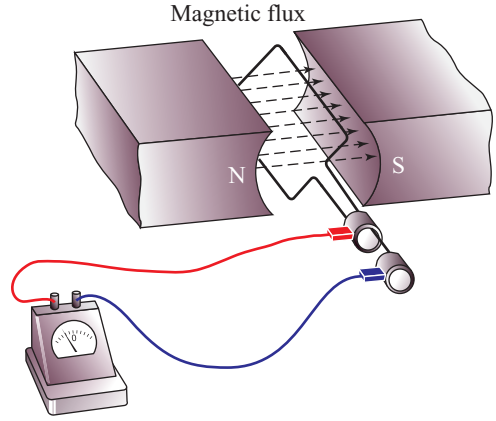
c.
$$\begin{aligned} z_1z_2 &= (-3 + i\sqrt{3})(\sqrt{3} + 1i) \\ &= -3\sqrt{3} - 3i + 3i + i^2\sqrt{3} \\ &= -4\sqrt{3} \quad \text{verified [matches part (a)]} \end{aligned}$$

Now try Exercises 39 through 42 ▶

Converting to trigonometric form for multiplication and division seems too clumsy for practical use, as we can often compute these results more efficiently in rectangular form. However, this approach leads to powers and roots of complex numbers, *an indispensable part of advanced equation solving,* and these are not easily found in rectangular form. In any case, note that the power and simplicity of computing products/quotients in trigonometric form is highly magnified when the complex numbers are *given in trig form:*

$$(12 \text{ cis } 50°)(3 \text{ cis } 20°) = 36 \text{ cis } 70° \qquad \frac{12 \text{ cis } 50°}{3 \text{ cis } 20°} = 4 \text{ cis } 30°$$

☑ **E.** You've just seen how we can compute products and quotients in trigonometric form



See Exercises 43 through 50.

F. (Optional) Applications of Complex Numbers

Somewhat surprisingly, complex numbers have several applications in the real world. Many of these involve a study of electricity, and in particular **AC (alternating current) circuits.**

In simplistic terms, when an armature (molded wire) is rotated in a uniform magnetic field, a voltage V is generated that depends on the strength of the field. As the armature is rotated, the voltage varies between a maximum and a minimum value, with the amount of voltage modeled by $V(\theta) = V_{\max}\sin(B\theta)$, with θ in degrees. Here, $V_{\max}$ represents the maximum voltage attained, and the input variable θ represents the angle the armature makes with the **magnetic flux,** indicated in Figure 8.100 by the dashed arrows between the magnets.

Figure 8.100

WORTHY OF NOTE

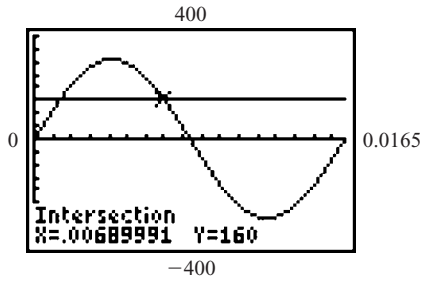
You may have wondered why we're using an amplitude of 311 for a 220-V appliance. Due to the nature of the sine wave, the average value of an alternating current is always zero and gives no useful information about the voltage generated. Instead, the root-mean-square (rms) of the voltage is given on most appliances. While the maximum voltage is 311 V, the rms voltage is $\frac{311}{\sqrt{2}} \approx 220$ V. **See Exercise 72.**

When the armature is perpendicular to the flux, we say $\theta = 0°$. At $\theta = 0°$ and $\theta = 180°$, no voltage is produced, while at $\theta = 90°$ and $\theta = 270°$, the voltage reaches its maximum and minimum values, respectively (hence the name *alternating current*). Many electric dryers and other large appliances are labeled as 220 volt (V) appliances, but use an alternating current that varies from 311 V to −311 V (see *Worthy of Note*). This means when $\theta = 52°$, $V(52°) = 311 \sin(52°) = 245$ V is being generated. In practical applications, we use time t as the independent variable, rather than the angle of the armature. These large appliances usually operate with a frequency of 60 cycles per second, or 1 cycle every $\frac{1}{60}$ of a second $\left(P = \frac{1}{60}\right)$. Using $B = \frac{2\pi}{P}$, we obtain $B = 120\pi$ and our equation model becomes $V(t) = 311 \sin(120\pi t)$ with t in radians. This variation in voltage is an excellent example of a simple harmonic model.

EXAMPLE 6 ▶ Analyzing Alternating Current Using Trigonometry

Use the equation $V(t) = 311 \sin(120\pi t)$ to:

a. Create a table of values illustrating the voltage produced every thousandth of a second for the first half-cycle $\left(t = \frac{1}{120} \approx 0.008\right)$.



b. Use a graphing calculator to find the times t in this half-cycle when 160 V is being produced.

Solution ▶

a. Starting at $t = 0$ and using increments of 0.001 s produces the table shown.

Time t	Voltage
0	0
0.001	114.5
0.002	212.9
0.003	281.4
0.004	310.4
0.005	295.8
0.006	239.6
0.007	149.8
0.008	39.0

b. From the table we note $V(t) = 160$ when $t \in (0.001, 0.002)$ and $t \in (0.006, 0.007)$. Using the intersection-of-graphs method places these values at $t \approx 0.0014$ and $t \approx 0.0069$ (see graph).

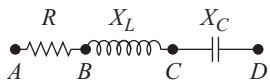
Figure 8.101



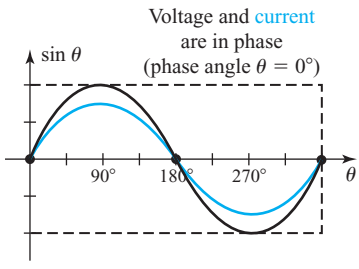


Figure 8.102

The chief components of AC circuits are **voltage** (V) and **current** (I). Due to the nature of how the current is generated, V and I can be modeled by sine functions. Other characteristics of electricity include pure **resistance** (R), **inductive reactance** (X_L), and **capacitive reactance** (X_C) (see Figure 8.101). Each of these is measured in a unit called ohms (Ω), while current I is measured in amperes (A), and voltages are measured in volts (V). These components of electricity *are related by fixed and inherent traits,* which include the following: (1) voltage across a resistor is always *in phase* with the current, meaning the phase shift or **phase angle** between them is 0° (Figure 8.102); (2) voltage across an inductor *leads the current* by 90° (Figure 8.103); (3) voltage across a capacitor *lags the current* by 90° (Figure 8.104); and (4) voltage is equal to the product of the current times the resistance or reactance: $V = IR$, $V = IX_L$, and $V = IX_C$.

Figure 8.103

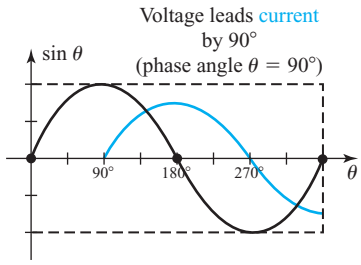

Figure 8.104

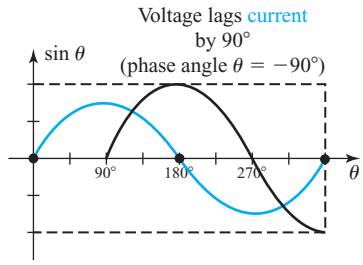

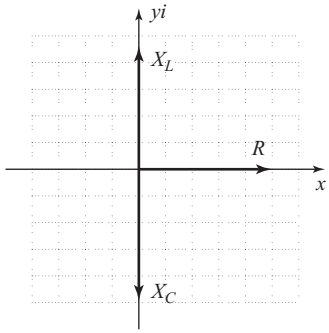

Figure 8.105

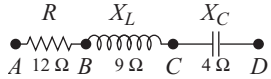
Different combinations of R, X_L, and X_C in a combined (series) circuit alter the phase angle and the resulting voltage. Since voltage across a resistance is always in phase with the current (trait 1), we can model the resistance as a vector along the positive real axis (since the phase angle is 0°). For traits (2) and (3), X_L is modeled on the positive imaginary axis since voltage leads current by 90°, and X_C on the negative imaginary axis since voltage lags current by 90° (see Figure 8.105). These natural characteristics make the complex plane *a perfect fit for describing the characteristics of the circuit.*

Consider a series circuit (Figure 8.101), where $R = 12\ \Omega$, $X_L = 9\ \Omega$, and $X_C = 4\ \Omega$. For a current of $I = 2$ amps through this circuit, the voltage across each individual element would be $V_R = (2)(12) = 24$ V (A to B), $V_L = (2)(9) = 18$ V (B to C), and $V_C = (2)(4) = 8$ V (C to D). However, the resulting voltage across this circuit *cannot be an arithmetic sum,* since R is real, while X_L and X_C are represented by imaginary numbers. The joint effect of resistance (R) and reactance (X_L, X_C) in a circuit is called the **impedance,** denoted by the letter Z, and is a measure of the total resistance to the flow of electrons. It is computed $Z = R + X_L j - X_C j$ (see *Worthy of Note*), due to the phase angle relationship of the voltage in each element (X_L and X_C point in opposite directions, hence the subtraction). The expression for Z is more commonly written $R + (X_L - X_C)j$, where we more clearly note *Z is a complex number* whose magnitude and angle with the x-axis can be found as before: $|Z| = \sqrt{R^2 + (X_L - X_C)^2}$ and $\theta_r = \tan^{-1}\left(\dfrac{X_L - X_C}{R}\right)$. The angle θ represents the phase angle between the voltage and current brought about by this combination of elements. The resulting voltage of the circuit is then calculated as the product of the current with the magnitude of the impedance, or $V_{RLC} = I|Z|$ (Z is also measured in ohms, Ω).



WORTHY OF NOTE

While mathematicians generally use the symbol i to represent $\sqrt{-1}$, the "i" is used in other fields to represent an electric current so the symbol $j = \sqrt{-1}$ is used instead. In conformance with this convention, we will temporarily use j for $\sqrt{-1}$ as well.

EXAMPLE 7 ▶ **Finding the Impedence and Phase Angle of the Current in a Circuit**

For the circuit diagrammed in the figure, (a) find the magnitude of Z, the phase angle between current and voltage, and write the result in trigonometric form; and (b) find the total voltage for a current of $I = 2$ amps across this circuit.

Solution ▶

a. Using the values given, we find

$$\begin{aligned} Z &= R + (X_L - X_C)j \\ &= 12 + (9 - 4)j \\ &= 12 + 5j \text{ (QI):} \end{aligned}$$

This gives a magnitude of

$|Z| = \sqrt{(12)^2 + (5)^2} = \sqrt{169} = 13\ \Omega$, with a phase angle of

$\theta = \tan^{-1}\left(\dfrac{5}{12}\right) \approx 22.6°$ (voltage leads the current by about 22.6°).

In trigonometric form $Z \approx 13 \text{ cis } 22.6°$.

b. With $I = 2$ amps, the total voltage across this circuit is $V_{RLC} = I|Z| = 2(13) = 26$ V.

☑ **F.** You have just seen how we can solve applications involving complex numbers

8.5 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. For a complex number written in the form $z = r(\cos\theta + i\sin\theta)$, r is called the _____ and θ is called the _____.

2. The complex number $z = 2\left[\cos\left(\frac{\pi}{4}\right) + i\sin\left(\frac{\pi}{4}\right)\right]$ can be written as the abbreviated "cis" notation as _____.

3. To multiply complex numbers in trigonometric form, we _____ the moduli and _____ the arguments.

4. To divide complex numbers in trigonometric form, we _____ the moduli and _____ the arguments.

5. Write $z = -1 - i\sqrt{3}$ in trigonometric form and explain why the argument is $\theta = 240°$ instead of $60°$ as indicated by your calculator's evaluation of $\tan^{-1}\sqrt{3}$.

6. Discuss the similarities between finding the components of a vector and writing a complex number in trigonometric form.

▶ DEVELOPING YOUR SKILLS

Graph the complex numbers z_1, z_2, and z_3 given, then express one as the sum of the other two.

7. $z_1 = 7 + 2i$, $z_2 = 8 + 6i$, $z_3 = 1 + 4i$

8. $z_1 = 2 + 7i$, $z_2 = 3 + 4i$, $z_3 = -1 + 3i$

9. $z_1 = -2 - 5i$, $z_2 = 1 - 7i$, $z_3 = 3 - 2i$

10. $z_1 = -2 + 6i$, $z_2 = 7 - 2i$, $z_3 = 5 + 4i$

State the quadrant of each complex number, then write it in trigonometric form. For Exercises 11 through 14, answer in degrees. For 15 through 18, answer in radians. Use the abs(and angle(features of a calculator to verify your results.

11. $-2 - 2i$

12. $7 - 7i$

13. $-5\sqrt{3} - 5i$

14. $2 - 2i\sqrt{3}$

15. $-3\sqrt{2} + 3i\sqrt{2}$

16. $5\sqrt{7} - 5i\sqrt{7}$

17. $4\sqrt{3} - 4i$

18. $-6 + 6i\sqrt{3}$

Write each complex number in trigonometric form. For Exercises 19 through 22, answer in degrees using both an exact form and an approximate form, rounding to tenths. For 23 through 26, answer in radians using both an exact form and an approximate form, rounding to four decimal places.

19. $8 + 6i$

20. $-9 + 12i$

21. $-5 - 12i$

22. $-8 + 15i$

23. $6 + 17.5i$

24. $30 - 5.5i$

25. $-6 + 10i$

26. $12 - 4i$

Graph each complex number using its trigonometric form, then convert each to rectangular form.

27. $2\operatorname{cis}\left(\frac{\pi}{4}\right)$

28. $12\operatorname{cis}\left(\frac{\pi}{6}\right)$

29. $4\sqrt{3}\operatorname{cis}\left(\frac{\pi}{3}\right)$

30. $5\sqrt{3}\operatorname{cis}\left(\frac{7\pi}{6}\right)$

31. $17\operatorname{cis}\left[\tan^{-1}\left(\frac{15}{8}\right)\right]$

32. $10\operatorname{cis}\left[\tan^{-1}\left(\frac{3}{4}\right)\right]$

33. $6\operatorname{cis}\left[\pi - \tan^{-1}\left(\frac{5}{\sqrt{11}}\right)\right]$

34. $4\operatorname{cis}\left[\pi + \tan^{-1}\left(\frac{\sqrt{7}}{3}\right)\right]$

For the complex numbers z_1 and z_2 given, find their moduli r_1 and r_2 and arguments θ_1 and θ_2. Then compute their *product* in rectangular form. For modulus r and argument θ of the product, verify that $r_1r_2 = r$ and $\theta_1 + \theta_2 = \theta$.

35. $z_1 = -2 + 2i$; $z_2 = 3 + 3i$

36. $z_1 = 1 + i\sqrt{3}$; $z_2 = 3 + i\sqrt{3}$

For the complex numbers z_1 and z_2 given, find their moduli r_1 and r_2 and arguments θ_1 and θ_2. Then compute their *quotient* in rectangular form. For modulus r and argument θ of the quotient, verify that $\frac{r_1}{r_2} = r$ and $\theta_1 - \theta_2 = \theta$.

37. $z_1 = \sqrt{3} + i; \quad z_2 = 1 + i\sqrt{3}$

38. $z_1 = -\sqrt{3} + i; \quad z_2 = 3 + 0i$

Compute the product z_1z_2 and quotient $\frac{z_1}{z_2}$ using the trigonometric form. Answer in exact rectangular form where possible, otherwise round all values to two decimal places.

39. $z_1 = -4\sqrt{3} + 4i$
$z_2 = \frac{3\sqrt{3}}{2} + \frac{3}{2}i$

40. $z_1 = \frac{5\sqrt{3}}{2} + \frac{5}{2}i$
$z_2 = 0 + 6i$

41. $z_1 = -2\sqrt{3} + 0i$
$z_2 = -\frac{21}{2} + \frac{7\sqrt{3}}{2}i$

42. $z_1 = 0 - 6i\sqrt{2}$
$z_2 = \frac{3\sqrt{2}}{2} + \frac{3\sqrt{6}}{2}i$

43. $z_1 = 9\left[\cos\left(\frac{\pi}{15}\right) + i\sin\left(\frac{\pi}{15}\right)\right]$
$z_2 = 1.8\left[\cos\left(\frac{2\pi}{3}\right) + i\sin\left(\frac{2\pi}{3}\right)\right]$

44. $z_1 = 2\left[\cos\left(\frac{3\pi}{5}\right) + i\sin\left(\frac{3\pi}{5}\right)\right]$
$z_2 = 8.4\left[\cos\left(\frac{\pi}{5}\right) + i\sin\left(\frac{\pi}{5}\right)\right]$

45. $z_1 = 10(\cos 60° + i\sin 60°)$
$z_2 = 4(\cos 30° + i\sin 30°)$

46. $z_1 = 7(\cos 120° + i\sin 120°)$
$z_2 = 2(\cos 300° + i\sin 300°)$

47. $z_1 = 5\sqrt{2}\ \text{cis}\ 210°$
$z_2 = 2\sqrt{2}\ \text{cis}\ 30°$

48. $z_1 = 5\sqrt{3}\ \text{cis}\ 240°$
$z_2 = \sqrt{3}\ \text{cis}\ 90°$

49. $z_1 = 6\ \text{cis}\ 82°$
$z_2 = 1.5\ \text{cis}\ 27°$

50. $z_1 = 1.6\ \text{cis}\ 59°$
$z_2 = 8\ \text{cis}\ 275°$

▶ WORKING WITH FORMULAS

51. Equilateral triangles in the complex plane: $u^2 + v^2 + w^2 = uv + uw + vw$

If the line segments connecting the complex numbers u, v, and w form the vertices of an equilateral triangle, the formula shown above holds true. Verify that $u = 2 + i\sqrt{3}$, $v = 10 + i\sqrt{3}$, and $w = 6 + 5i\sqrt{3}$ form the vertices of an equilateral triangle using the distance formula, then verify the formula given.

52. The cube of a complex number: $(A + B)^3 = A^3 + 3A^2B + 3AB^2 + B^3$

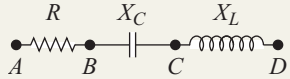
The cube of any binomial can be found using the formula here, where A and B are the terms of the binomial. Use the formula to compute the cube of $1 - 2i$ (note $A = 1$ and $B = -2i$).

▶ APPLICATIONS

53. Electric current: In the United States, electric power is supplied to homes and offices via a "120 V circuit," using an alternating current that varies from 170 V to −170 V, at a frequency of 60 cycles/sec. (a) Write the voltage equation for U.S. households, (b) create a table of values illustrating the voltage produced every thousandth of a second for the first half-cycle, and (c) find the first time t in this half-cycle when exactly 140 V is being produced.

54. Electric current: While the electricity supplied in Europe is still not quite uniform, most countries employ 230-V circuits, using an alternating current that varies from 325 V to −325 V. However, the frequency is only *50 cycles per second.* (a) Write the voltage equation for these European countries, (b) create a table of values illustrating the voltage produced every thousandth of a second for the first half-cycle, and (c) find the first time t in this half-cycle when exactly 215 V is being produced.

AC circuits: For the circuits indicated in Exercises 55 through 60, (a) find the magnitude of Z, the phase angle between current and voltage, and write the result in trigonometric form; and (b) find the total voltage across this circuit. Recall $Z = R + (X_L - X_C)j$ and $|Z| = \sqrt{R^2 + (X_L - X_C)^2}$.

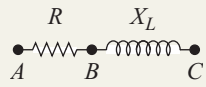


55. $R = 15\ \Omega$, $X_L = 12\ \Omega$, and $X_C = 4\ \Omega$, with $I = 3$ A

56. $R = 24\ \Omega$, $X_L = 12\ \Omega$, and $X_C = 5\ \Omega$, with $I = 2.5$ A

57. $R = 7\ \Omega$, $X_L = 6\ \Omega$, and $X_C = 11\ \Omega$, with $I = 1.8$ A

58. $R = 9.2\ \Omega$, $X_L = 5.6\ \Omega$, and $X_C = 8.3\ \Omega$, with $I = 2.0$ A



Exercises 55 through 58

59. $R = 12\ \Omega$ and $X_L = 5\ \Omega$, with $I = 1.7$ A

60. $R = 35\ \Omega$ and $X_L = 12\ \Omega$, with $I = 4$ A

Exercises 59 and 60

AC circuits—voltage: The current I and the impedance Z for certain AC circuits are given. Write I and Z in trigonometric form and find the voltage in each circuit. Recall $V = IZ$.

61. $I = \sqrt{3} + 1j$ A and $Z = 5 + 5j\ \Omega$

62. $I = \sqrt{3} - 1j$ A and $Z = 2 + 2j\ \Omega$

63. $I = 3 - 2j$ A and $Z = 2 + 3.75j\ \Omega$

64. $I = 4 + 3j$ A and $Z = 2 - 4j\ \Omega$

AC circuits—current: If the voltage and impedance are known, the current I in the circuit is calculated as the quotient $I = \dfrac{V}{Z}$. Write V and Z in trigonometric form to find the current in each circuit.

65. $V = 2 + 2\sqrt{3}j$ and $Z = 4 - 4j\ \Omega$

66. $V = 4\sqrt{3} - 4j$ and $Z = 1 - 1j\ \Omega$

67. $V = 3 - 4j$ and $Z = 4 + 7.5j\ \Omega$

68. $V = 2.8 + 9.6j$ and $Z = 1.4 - 4.8j\ \Omega$

Parallel circuits: For AC circuits *wired in parallel*, the total impedance is given by $Z = \dfrac{Z_1 Z_2}{Z_1 + Z_2}$, where Z_1 and Z_2 represent the impedance in each branch. Find the total impedance for the values given. Compute the product in the numerator using trigonometric form, and the sum in the denominator in rectangular form.

69. $Z_1 = 1 + 2j$ and $Z_2 = 3 - 2j$

70. $Z_1 = 3 - j$ and $Z_2 = 2 + j$

▶ EXTENDING THE CONCEPT

71. Verify that for the complex numbers
$z_1 = r_1(\cos\alpha + i\sin\alpha)$ and
$z_2 = r_2(\cos\beta + i\sin\beta)$,
$\dfrac{z_1}{z_2} = \dfrac{r_1}{r_2}[\cos(\alpha - \beta) + i\sin(\alpha - \beta)]$.

72. Using the Internet, a trade manual, or some other resource, find the voltage and frequency at which electricity is supplied to most of Japan (oddly enough—two different frequencies are in common use). As in Example 6, the voltage given will likely be the root-mean-square (rms) voltage. Use the information to find the true voltage and the equation model for voltage in most of Japan.

73. Recall that two lines are perpendicular if their slopes have a product of -1. For the directed line segment representing the complex number $z_1 = 7 + 24i$, find complex numbers z_2 and z_3 whose directed line segments are perpendicular to z_1 and have a magnitude one-fifth as large.

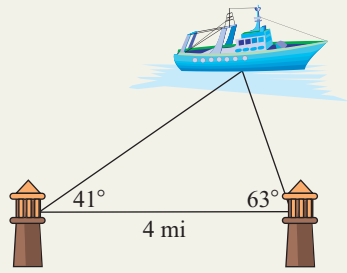
74. The magnitude of the impedance is $|Z| = \sqrt{R^2 + (X_L - X_C)^2}$. If R, X_L, and X_C are all nonzero, what conditions would make the magnitude of Z as small as possible?

▶ MAINTAINING YOUR SKILLS

75. (7.7) Solve for $x \in [0, 2\pi)$:

$$350 = 750\sin\left(2x - \frac{\pi}{4}\right) - 25$$

76. (4.5) Name all asymptotes of the function



$$h(x) = \frac{1 + x^3}{x^2}$$

77. (2.5) Graph the piecewise-defined function given:

$$f(x) = \begin{cases} 2 & x < -2 \\ x^2 & -2 \le x < 1 \\ x & x \ge 1 \end{cases}$$

78. (8.1) A ship is spotted by two observation posts that are 4 mi apart. Using the line between them for reference, the first post reports the ship is at an angle of 41°, while the second reports an angle of 63°, as shown. How far is the ship from the closest post?

Exercise 78

8.6 De Moivre's Theorem and the Theorem on *n*th Roots

LEARNING OBJECTIVES

In Section 8.6 you will see how we can:

- ❑ **A.** Use De Moivre's theorem to raise complex numbers to any power
- ❑ **B.** Use De Moivre's theorem to check solutions to polynomial equations
- ❑ **C.** Use the *n*th roots theorem to find the *n*th roots of a complex number

The material in this section represents some of the most significant developments in the history of mathematics. After hundreds of years of struggle, mathematical scientists had not only come to recognize the existence of complex numbers, but were able to make operations on them commonplace and routine. This allowed for the unification of many ideas related to the study of polynomial equations, and answered questions that had puzzled scientists from many different fields for centuries. In this section, we will look at two fairly simple theorems that actually represent over 1000 years in the evolution of mathematical thought.

A. De Moivre's Theorem

Having found acceptable means for applying the four basic operations to complex numbers, our attention naturally shifts to the computation of powers and roots. Without them, we'd remain wholly unable to offer complete solutions to polynomial equations and find solutions for many applications. The computation of powers, squares, and cubes offer little challenge, as they can be computed easily using the formula for binomial squares $[(A + B)^2 = A^2 + 2AB + B^2]$ or by applying the **binomial theorem.** For larger powers, the binomial theorem becomes too time-consuming and a more efficient method is desired. The key here is to use the trigonometric form of the complex number. In Section 8.5, we noted the product of two complex numbers involved multiplying their moduli and adding their arguments:

For $z_1 = r_1(\cos\theta_1 + i\sin\theta_1)$ and $z_2 = r_2(\cos\theta_2 + i\sin\theta_2)$ we have

$$z_1z_2 = r_1r_2[\cos(\theta_1 + \theta_2) + i\sin(\theta_1 + \theta_2)]$$

For the square of a complex number, $r_1 = r_2$ and $\theta_1 = \theta_2$. Using θ itself yields

$$\begin{aligned} z^2 &= r^2[\cos(\theta + \theta) + i\sin(\theta + \theta)] \\ &= r^2[\cos(2\theta) + i\sin(2\theta)] \end{aligned}$$

Multiplying this result by $z = r(\cos\theta + i\sin\theta)$ to compute z^3 gives

$$\begin{aligned} r^2[\cos(2\theta) + i\sin(2\theta)]\, r(\cos\theta + i\sin\theta) &= r^3[\cos(2\theta + \theta) + i\sin(2\theta + \theta)] \\ &= r^3[\cos(3\theta) + i\sin(3\theta)]. \end{aligned}$$

The result can be extended further and generalized into **De Moivre's theorem.**

WORTHY OF NOTE

Sometimes the argument of cosine and sine becomes very large after applying De Moivre's theorem. In these cases, we use the fact that $\theta = \theta \pm 360°k$ and $\theta = \theta \pm 2\pi k$ represent coterminal angles for integers k, and use the coterminal angle θ where $0° \le \theta < 360°$ or $0 \le \theta < 2\pi$.

De Moivre's Theorem

For any positive integer n, and $z = r(\cos\theta + i\sin\theta)$,

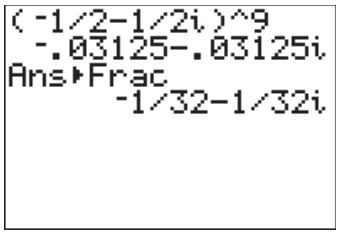
$$z^n = r^n[\cos(n\theta) + i\sin(n\theta)]$$

For a proof of the theorem where n is an integer and $n \ge 1$, see Appendix B.

EXAMPLE 1 ▶ **Using De Moivre's Theorem to Compute the Power of a Complex Number**

Use De Moivre's theorem to compute z^9, given $z = -\frac{1}{2} - \frac{1}{2}i$.

Solution ▶ Here we have $r = \sqrt{\left(-\frac{1}{2}\right)^2 + \left(-\frac{1}{2}\right)^2} = \frac{\sqrt{2}}{2}$. With z in QIII, $\tan\theta = 1$ yields $\theta = \frac{5\pi}{4}$. The trigonometric form is $z = \frac{\sqrt{2}}{2}\left[\cos\left(\frac{5\pi}{4}\right) + i\sin\left(\frac{5\pi}{4}\right)\right]$ and applying the theorem with $n = 9$ gives



$$z^9 = \left(\frac{\sqrt{2}}{2}\right)^9\left[\cos\left(9\cdot\frac{5\pi}{4}\right) + i\sin\left(9\cdot\frac{5\pi}{4}\right)\right] \quad \text{De Moivre's theorem}$$

$$= \frac{\sqrt{2}}{32}\left[\cos\left(\frac{45\pi}{4}\right) + i\sin\left(\frac{45\pi}{4}\right)\right] \quad \text{simplify}$$

$$= \frac{\sqrt{2}}{32}\left[\cos\left(\frac{5\pi}{4}\right) + i\sin\left(\frac{5\pi}{4}\right)\right] \quad \text{coterminal angles}$$

$$= \frac{\sqrt{2}}{32}\left(-\frac{\sqrt{2}}{2} - \frac{\sqrt{2}}{2}i\right) \quad \text{evaluate functions}$$

$$= -\frac{1}{32} - \frac{1}{32}i \quad \text{result}$$

A calculator in $a + bi$ MODE can be used to check our work (see figure).

Now try Exercises 7 through 14 ▶

As with products and quotients, if the complex number is *given* in trigonometric form, computing any power of the number is both elegant and efficient. For instance, if $z = 2\text{ cis }40°$, then $z^4 = 16\text{ cis }160°$. **See Exercises 15 through 18.**

For cases where θ is not a standard angle, De Moivre's theorem requires an intriguing application of the skills developed in Chapter 7, including the use of multiple angle identities and working from a right triangle drawn relative to $\theta_r = \tan^{-1}\left|\frac{b}{a}\right|$. **See Exercises 57 and 58.**

☑ **A.** You've just seen how we can use De Moivre's theorem to raise complex numbers to any power

B. Checking Solutions to Polynomial Equations

One application of De Moivre's theorem is checking the complex roots of a polynomial, as in Example 2.

EXAMPLE 2 ▶ Using De Moivre's Theorem to Check Solutions to a Polynomial Equation

Use De Moivre's theorem to show that $z = -2 - 2i$ is a solution to $z^4 - 3z^3 - 38z^2 - 128z - 144 = 0$.

Solution ▶ We will apply the theorem to the third and fourth degree terms, and compute the square directly. Since z is in QIII, the trigonometric form is $z = 2\sqrt{2}\text{ cis }225°$. In the following illustration, note that 900° and 180° are coterminal, as are 675° and 315°.

$(-2-2i)^4$	$(-2-2i)^3$	$(-2-2i)^2$
$= (2\sqrt{2})^4\text{cis}(4\cdot 225°)$	$= (2\sqrt{2})^3\text{cis}(3\cdot 225°)$	$= 4 + 8i + (2i)^2$
$= (2\sqrt{2})^4\text{cis }900°$	$= (2\sqrt{2})^3\text{cis }675°$	$= 4 + 8i + 4i^2$
$= 64\text{ cis }180°$	$= (2\sqrt{2})^3\text{cis }315°$	$= 4 + 8i - 4$
$= 64(-1 + 0i)$	$= 16\sqrt{2}\left(\frac{\sqrt{2}}{2} - \frac{\sqrt{2}}{2}i\right)$	$= 0 + 8i$
$= -64$	$= 16 - 16i$	$= 8i$

Substituting back into the original equation gives

$$\begin{aligned} z^4 - 3z^3 - 38z^2 - 128z - 144 &= 0 \\ (-64) - 3(16 - 16i) - 38(8i) - 128(-2 - 2i) - 144 &= 0 \\ -64 - 48 + 48i - 304i + 256 + 256i - 144 &= 0 \\ (-64 - 48 + 256 - 144) + (48 - 304 + 256)i &= 0 \\ 0 &= 0\ \checkmark \end{aligned}$$

Now try Exercises 19 through 26 ▶

☑ **B.** You've just seen how we can use De Moivre's theorem to check solutions to polynomial equations

Regarding Example 2, we know from a study of algebra that complex roots must occur in conjugate pairs, meaning $-2 + 2i$ is also a root. This equation actually has two real and two complex roots, with $z = 9$ and $z = -2$ being the two real roots.

C. The *n*th Roots Theorem

Having looked at De Moivre's theorem, which raises a complex number to any power, we now consider the ***n*th roots theorem,** which will compute the nth roots of a complex number. If we allow that De Moivre's theorem also holds for rational values $\frac{1}{n}$, instead of only the integers n illustrated previously, the formula for computing an nth root would be a direct result:

$$z^{\frac{1}{n}} = r^{\frac{1}{n}}\left[\cos\left(\frac{1}{n}\theta\right) + i\sin\left(\frac{1}{n}\theta\right)\right] \quad \text{replace } n \text{ with } \frac{1}{n} \text{ in De Moivre's theorem}$$

$$= \sqrt[n]{r}\left[\cos\left(\frac{\theta}{n}\right) + i\sin\left(\frac{\theta}{n}\right)\right] \quad \text{simplify}$$

However, this formula would *find only the principal nth root*! In other words, periodic solutions would be ignored. As in Section 8.5, it's worth noting the most general form of a complex number is $z = r[\cos(\theta + 360°k) + i\sin(\theta + 360°k)]$, for $k \in \mathbb{Z}$. When De Moivre's theorem is applied to this form for *integers* n, we obtain $z^n = r^n[\cos(n\theta + 360°kn) + i\sin(n\theta + 360°kn)]$, which returns a result identical to $r^n[\cos(n\theta) + i\sin(n\theta)]$. However, for the rational exponent $\frac{1}{n}$, the general form takes additional solutions into account and will return all n, nth roots.

$$z^{\frac{1}{n}} = r^{\frac{1}{n}}\left\{\cos\left[\frac{1}{n}(\theta + 360°k)\right] + i\sin\left[\frac{1}{n}(\theta + 360°k)\right]\right\} \quad \text{De Moivre's theorem for rational exponents}$$

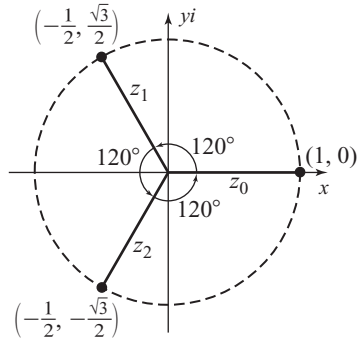
$$= \sqrt[n]{r}\left[\cos\left(\frac{\theta}{n} + \frac{360°k}{n}\right) + i\sin\left(\frac{\theta}{n} + \frac{360°k}{n}\right)\right] \quad \text{simplify}$$

The *n*th Roots Theorem

For $z = r(\cos\theta + i\sin\theta)$, a positive integer n, and $r \in \mathbb{R}$, z has exactly n distinct nth roots determined by

$$\sqrt[n]{z} = \sqrt[n]{r}\left[\cos\left(\frac{\theta}{n} + \frac{360°k}{n}\right) + i\sin\left(\frac{\theta}{n} + \frac{360°k}{n}\right)\right]$$

where $k = 0, 1, 2, \ldots, n - 1$.



For ease of computation, it helps to note that once the argument for the principal root is found using $k = 0$, $\frac{\theta}{n} + \frac{360°k}{n}$ simply adds $\frac{360°}{n}\left(\text{or } \frac{2\pi}{n}\right)$ to the previous argument for $k = 1, 2, 3, \ldots, n - 1$.

In Example 3 you're asked to find the three cube roots of 1, also called the **cube roots of unity,** and graph the results. The nth roots of unity play a significant role in the solution of many polynomial equations. For an in-depth study of this connection, visit www.mhhe.com/coburn and go to **Section 8.8: Trigonometry, Complex Numbers, and Cubic Equations.**

EXAMPLE 3 ▶ **Finding *n*th Roots**

Use the *n*th roots theorem to solve the equation $x^3 - 1 = 0$. Write the results in rectangular form and graph.

Solution ▶ From $x^3 - 1 = 0$, we have $x^3 = 1$ and must find the three cube roots of unity. As before, we begin in trigonometric form: $1 + 0i = 1(\cos 0° + i \sin 0°)$ since $\theta = \tan^{-1}(0) = 0°$ (or by observation). With $n = 3$, $r = 1$, and $\theta = 0°$, we have $\sqrt[3]{r} = \sqrt[3]{1} = 1$, and $\frac{0°}{3} + \frac{360°k}{3} = 0° + 120°k$.

The principal root ($k = 0$) is $z_0 = 1(\cos 0° + i \sin 0°) = 1$. Adding 120° to each previous argument, we find the other roots are

$$z_1 = 1(\cos 120° + i \sin 120°)$$
$$z_2 = 1(\cos 240° + i \sin 240°).$$

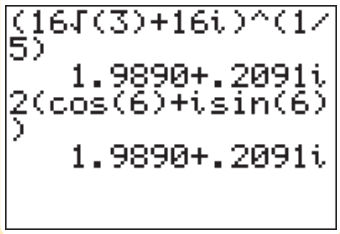
In rectangular form these are $-\frac{1}{2} + \frac{\sqrt{3}}{2}i$, and $-\frac{1}{2} - \frac{\sqrt{3}}{2}i$, as shown in the figure.

Now try Exercises 27 through 40 ▶

EXAMPLE 4 ▶ **Finding *n*th Roots**

Use the *n*th roots theorem to find the five fifth roots of $z = 16\sqrt{3} + 16i$.

Solution ▶ In trigonometric form, $16\sqrt{3} + 16i = 32(\cos 30° + i \sin 30°)$ since $\theta = \tan^{-1}\left(\frac{16}{16\sqrt{3}}\right) = 30°$. With $n = 5$, $r = 32$, and $\theta = 30°$, we have $\sqrt[5]{r} = \sqrt[5]{32} = 2$, and $\frac{30°}{5} + \frac{360°k}{5} = 6° + 72°k$. The principal root is $z_0 = 2(\cos 6° + i \sin 6°)$.

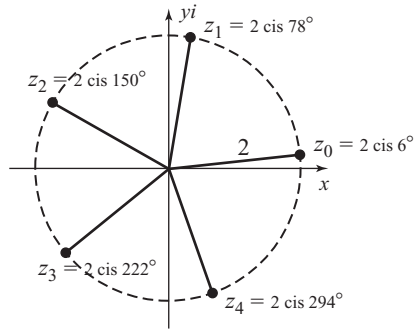


Adding 72° to each previous argument, we find the other four roots are

$$z_1 = 2(\cos 78° + i \sin 78°) \qquad z_2 = 2(\cos 150° + i \sin 150°)$$
$$z_3 = 2(\cos 222° + i \sin 222°) \qquad z_4 = 2(\cos 294° + i \sin 294°)$$

Now try Exercises 41 through 44 ▶

WORTHY OF NOTE



Using a calculator in degree MODE to find the fifth root of $z = 16\sqrt{3} + 16i$ in Example 4 will only result in the principal root, as shown here (note the MODE was set to round to four decimal places). The *n*th roots theorem is necessary to find the other four roots!

Of the five roots in Example 4, only $z_2 = 2(\cos 150° + i \sin 150°)$ uses a standard angle. Applying De Moivre's theorem with $n = 5$ gives $(2 \text{ cis } 150°)^5 = 32 \text{ cis } 750° = 32 \text{ cis } 30°$ or $16\sqrt{3} + 16i$. ✓ **See Exercise 52.**

As a consequence of the arguments in a solution being uniformly separated by $\frac{360°}{n}$, the graphs of complex roots are equally spaced about a circle of radius $\sqrt[n]{r}$. The five fifth roots from Example 4 are shown in Figure 8.106 (note each argument differs by 72°). This

Figure 8.106

characteristic of *n*th roots also simplifies a search for all *n*th roots when some form of technology is used. For instance, once a template has been set, a graphing calculator can easily cycle through the values of *k* and display the results in a table.

EXAMPLE 5 ▶ **Using a Calculator to Find *n*th Roots**

Use the *n*th roots theorem and the **TABLE** feature of a graphing calculator to find all six sixth roots of $z = -4 - 4i\sqrt{3}$.

Solution ▶ For $z = -4 - 4i\sqrt{3}$, we have $r = \sqrt{(-4)^2 + (-4\sqrt{3})^2} = \sqrt{16 + 48} = 8$. With z in QIII, $\theta_r = 60°$ yields $\theta = 240°$. Using the *n*th roots theorem with $n = 6$ gives

$$\sqrt[n]{z} = \sqrt[n]{r}\left[\cos\left(\frac{\theta}{n} + \frac{360°k}{n}\right) + i\sin\left(\frac{\theta}{n} + \frac{360°k}{n}\right)\right] \quad \text{nth roots theorem}$$

$$\sqrt[6]{z} = \sqrt[6]{8}\left[\cos\left(\frac{240°}{6} + \frac{360°k}{6}\right) + i\sin\left(\frac{240°}{6} + \frac{360°k}{6}\right)\right] \quad \text{substitute 6 for } n, 8 \text{ for } r, 240° \text{ for } \theta$$

$$= \sqrt[6]{8}[\cos(40° + 60°k) + i\sin(40° + 60°k)] \quad \text{simplify}$$

While the **TABLE** feature cannot display complex numbers (even in $a + bi$ MODE), we can separate these roots into their real and imaginary parts. Consider the following.

$$\sqrt[6]{z} = \sqrt[6]{8}[\cos(40° + 60°k) + i\sin(40° + 60°k)] \quad \text{sixth roots of } z$$

$$= \sqrt[6]{8}\cos(40° + 60°k) + \sqrt[6]{8}\sin(40° + 60°k)i \quad \text{distribute } \sqrt[6]{8}$$

On the Y= screen, simply enter the real part as $Y_1 = \sqrt[6]{8}\cos(40 + 60X)$ and the coefficient of the imaginary part as $Y_2 = \sqrt[6]{8}\sin(40 + 60X)$ as shown in Figure 8.107. After setting **TblStart = 0** and **ΔTbl = 1**, we can quickly produce *all* sixth roots of $z = -4 - 4i\sqrt{3}$. Reading from the table shown in Figure 8.108, we find the six sixth roots of z (rounded to 3 decimal places) are

$$z_0 = 1.083 + 0.909i \qquad z_1 = -0.246 + 1.393i \qquad z_2 = -1.329 + 0.484i$$
$$z_3 = -1.083 - 0.909i \qquad z_4 = 0.246 - 1.393i \qquad z_5 = 1.329 - 0.484i$$

As a check, each root z_k from $k = 0$ to $k = 5$ can be raised to the sixth power on the home screen, using the expression $Y_1(k) + iY_2(k)$. The check for $k = 0$ is shown in Figure 8.109 (note that $4\sqrt{3} \approx 6.92820323$).

WORTHY OF NOTE

In Example 5, when $k = 6$, the argument of the root is 400°. This is coterminal with 40°, the argument when $k = 0$. As seen in Figure 8.108, these coterminal angles produce the same complex root.

Figure 8.107

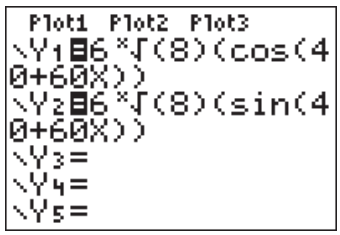


Figure 8.108

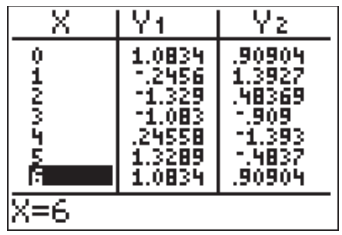

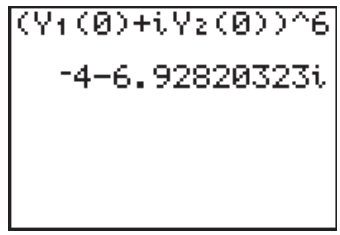

Figure 8.109

Now try Exercises 45 through 48 ▶

For additional insight into roots of complex numbers, we reason that the *n*th roots of a complex number must also be complex. To find the four fourth roots of $z = 8 + 8i\sqrt{3} = 16(\cos 60° + i\sin 60°)$, we seek a number of the form $r(\cos\alpha + i\sin\alpha)$ such that $[r(\cos\alpha + i\sin\alpha)]^4 = 16(\cos 60° + i\sin 60°)$. Applying De Moivre's theorem to the left-hand side and equating equivalent parts we obtain

$$r^4[\cos(4\alpha) + i\sin(4\alpha)] = 16(\cos 60° + i\sin 60°), \text{ which leads to}$$
$$r^4 = 16 \text{ and}$$
$$4\alpha = 60°$$

From this it is obvious that $r = 2$, but as with similar equations solved in Chapter 7, the equation $4\alpha = 60°$ has multiple solutions. To find them, we first add $360°k$ to $60°$, *then* solve for α.

$$\begin{aligned} 4\alpha &= 60° + 360°k && \text{add } 360°k \\ \alpha &= \frac{60° + 360°k}{4} && \text{divide by 4} \\ &= 15° + 90°k && \text{result} \end{aligned}$$

For convenience, we start with $k = 0, 1, 2$, and so on, which leads to

$$\begin{aligned} \text{For } k = 0\text{:}\quad \alpha &= 15° + 90°(0) & \text{For } k = 1\text{:}\quad \alpha &= 15° + 90°(1) \\ &= 15° & &= 105° \\ \text{For } k = 2\text{:}\quad \alpha &= 15° + 90°(2) & \text{For } k = 3\text{:}\quad \alpha &= 15° + 90°(3) \\ &= 195° & &= 285° \end{aligned}$$

At this point it should strike us that we have four roots—exactly the number required. Indeed, using $k = 4$ gives $\alpha = 15° + 90°(4) = 375°$, which is coterminal with the $15°$ obtained when $k = 0$. Hence, the four fourth roots are

$$\begin{aligned} z_0 &= 2(\cos 15° + i \sin 15°) & z_1 &= 2(\cos 105° + i \sin 105°) \\ z_2 &= 2(\cos 195° + i \sin 195°) & z_3 &= 2(\cos 285° + i \sin 285°). \end{aligned}$$

The check for these solutions is asked for in **Exercise 51.**

As a final note, it must have struck the mathematicians who pioneered these discoveries with some amazement that complex numbers and the trigonometric functions should be so closely related. The amazement must have been all the more profound upon discovering an additional connection between complex numbers and *exponential functions*. For more on these connections, visit www.mhhe.com/coburn and review **Section 8.7: Complex Numbers in Exponential Form.**

C. You've just seen how we can use the *n*th roots theorem to find the *n*th roots of a complex number

8.6 EXERCISES

CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. For $z = r(\cos\theta + i\sin\theta)$, z^5 is computed as _____ according to _____ theorem.

2. If $z = 6i$, then z raised to an _____ power will be real and z raised to an _____ power will be _____ since $\theta =$ _____.

3. One application of De Moivre's theorem is to check _____ solutions to a polynomial equation.

4. The nth roots of a complex number are equally spaced on a circle of radius $\sqrt[n]{r}$, since their arguments all differ by _____ degrees or _____ radians.

5. From Example 4, go ahead and compute the value of z_5, z_6, and z_7. What do you notice? Discuss how this reaffirms that there are exactly n, nth roots.

6. Use a calculator to find $(1 - 3i)^4$. Then use it again to find the fourth root of the result. What do you notice? Explain the discrepancy and then resolve it using the nth roots theorem to find all four roots.

▶ DEVELOPING YOUR SKILLS

Use De Moivre's theorem to compute the following. Clearly state the values of *r*, *n*, and *θ* before you begin. Use a calculator to check your results.

7. $(3 + 3i)^4$

8. $(-2 + 2i)^6$

9. $(-1 + i\sqrt{3})^3$

10. $(\sqrt{3} - i)^3$

11. $\left(\frac{1}{2} - \frac{\sqrt{3}}{2}i\right)^5$

12. $\left(-\frac{\sqrt{3}}{2} + \frac{1}{2}i\right)^6$

13. $\left(\frac{\sqrt{2}}{2} - \frac{\sqrt{2}}{2}i\right)^6$

14. $\left(-\frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2}i\right)^5$

15. $(4 \text{ cis } 330°)^3$

16. $(4 \text{ cis } 300°)^3$

17. $\left(\frac{\sqrt{2}}{2} \text{ cis } 135°\right)^5$

18. $\left(\frac{\sqrt{2}}{2} \text{ cis } 135°\right)^8$

Use De Moivre's theorem to verify the solution given for each polynomial equation.

19. $z^4 + 3z^3 - 6z^2 + 12z - 40 = 0; z = 2i$

20. $z^4 - z^3 + 7z^2 - 9z - 18 = 0; z = -3i$

21. $z^4 + 6z^3 + 19z^2 + 6z + 18 = 0; z = -3 - 3i$

22. $2z^4 + 3z^3 - 4z^2 + 2z + 12 = 0; z = 1 - i$

23. $z^5 + z^4 - 4z^3 - 4z^2 + 16z + 16 = 0; z = \sqrt{3} - i$

24. $z^5 + z^4 - 16z^3 - 16z^2 + 256z + 256 = 0;$ $z = 2\sqrt{3} + 2i$

25. $z^4 - 4z^3 + 7z^2 - 6z - 10 = 0; z = 1 + 2i$

26. $z^4 - 2z^3 - 7z^2 + 28z + 52 = 0; z = 3 - 2i$

Find the *n*th roots indicated by writing and solving the related equation.

27. five fifth roots of unity

28. six sixth roots of unity

29. five fifth roots of 243

30. three cube roots of 8

31. three cube roots of $-27i$

32. five fifth roots of $32i$

Find all solutions of each equation using the *n*th roots theorem.

33. $x^5 - 32 = 0$

34. $x^5 - 243 = 0$

35. $x^3 - 27i = 0$

36. $x^3 + 64i = 0$

37. $x^5 - \sqrt{2} - i\sqrt{2} = 0$

38. $x^5 - 1 + i\sqrt{3} = 0$

39. Solve the equation $x^3 - 1 = 0$ by factoring it as the difference of cubes and applying the quadratic formula. Compare results to those obtained in Example 3.

40. Use the *n*th roots theorem to find the four fourth roots of unity, then find all solutions to $x^4 - 1 = 0$ by factoring it as a difference of squares. What do you notice?

Use the *n*th roots theorem to find the *n*th roots. Clearly state *r*, *n*, and *θ* (from the trigonometric form of *z*) as you begin. Answer in exact form when possible, otherwise use a four decimal place approximation.

41. four fourth roots of $-8 + 8i\sqrt{3}$

42. five fifth roots of $16 - 16i\sqrt{3}$

43. four fourth roots of $-7 - 7i$

44. three cube roots of $9 + 9i$

Use the *n*th roots theorem and the TABLE feature of a graphing calculator to find *all* roots indicated. Clearly state *r*, *θ*, *n*, and *k* for each root. Round to three decimal places when necessary.

45. three third roots of $-4\sqrt{3} - 4i$

46. four fourth roots of $-8 + 8i\sqrt{3}$

47. four fourth roots of -81

48. three third roots of $27i$

▶ WORKING WITH FORMULAS

The discriminant of a cubic equation: $D = \frac{4p^3 + 27q^2}{108}$

For cubic equations of the form $z^3 + pz + q = 0$, where *p* and *q* are real numbers, one solution has the form $z = \sqrt[3]{-\frac{q}{2} + \sqrt{D}} + \sqrt[3]{-\frac{q}{2} - \sqrt{D}}$, where *D* is called the discriminant. Compute the value of *D* for the cubic equations given, then use the *n*th roots theorem to find the three cube roots of $-\frac{q}{2} + \sqrt{D}$ and $-\frac{q}{2} - \sqrt{D}$ in trigonometric form (also see Exercises 59 and 60).

49. $z^3 - 6z + 4 = 0$

50. $z^3 - 12z - 8 = 0$

▶ APPLICATIONS

51. Powers and roots: Just after Example 5, the four fourth roots of $z = 8 + 8i\sqrt{3}$ were given as

$z_0 = 2(\cos 15° + i \sin 15°)$
$z_1 = 2(\cos 105° + i \sin 105°)$
$z_2 = 2(\cos 195° + i \sin 195°)$
$z_3 = 2(\cos 285° + i \sin 285°)$.

Verify these are the four fourth roots of $z = 8 + 8i\sqrt{3}$ using a calculator and De Moivre's theorem.

52. Powers and roots: In Example 4 we found the five fifth roots of $z = 16\sqrt{3} + 16i$ were

$z_0 = 2(\cos 6° + i \sin 6°)$
$z_1 = 2(\cos 78° + i \sin 78°)$
$z_2 = 2(\cos 150° + i \sin 150°)$
$z_3 = 2(\cos 222° + i \sin 222°)$
$z_4 = 2(\cos 294° + i \sin 294°)$

Verify these are the five fifth roots of $16\sqrt{3} + 16i$ using a calculator and De Moivre's theorem.

Electrical circuits: For an AC circuit with three branches wired in parallel, the total impedance is given by $Z_T = \dfrac{Z_1Z_2Z_3}{Z_1Z_2 + Z_1Z_3 + Z_2Z_3}$, where Z_1, Z_2, and Z_3 represent the impedance in each branch of the circuit. If the impedance in each branch is identical, $Z_1 = Z_2 = Z_3 = Z$, and the numerator becomes Z^3 and the denominator becomes $3Z^2$, (a) use De Moivre's theorem to calculate the numerator and denominator for each value of Z given, (b) find the total impedance by computing the quotient $\dfrac{Z^3}{3Z^2}$, and (c) verify your result is identical to $\dfrac{Z}{3}$.

53. $Z = 3 + 4j$ in all three branches

54. $Z = 5\sqrt{3} + 5j$ in all three branches

▶ EXTENDING THE CONCEPT

In Chapter 7, you were asked to verify that $\sin(3\theta) = 3\sin\theta - 4\sin^3\theta$ and $\cos(4\theta) = 8\cos^4\theta - 8\cos^2\theta + 1$ were identities (Section 7.4, Exercises 21 and 22). For $z = 3 + i\sqrt{7}$, verify $|z| = 4$ and $\theta = \tan^{-1}\left(\dfrac{\sqrt{7}}{3}\right)$, then draw a right triangle with $\sqrt{7}$ opposite θ and 3 adjacent to θ. Discuss how this right triangle and the identities given can be used in conjunction with De Moivre's theorem to find the exact value of the powers given (also see Exercises 57 and 58).

55. $(3 + i\sqrt{7})^3$

56. $(3 + i\sqrt{7})^4$

For cases where θ is not a standard angle, working toward an exact answer using De Moivre's theorem requires the use of multiple angle identities and drawing the right triangle related to $\theta_r = \tan^{-1}\left|\dfrac{b}{a}\right|$. For Exercises 57 and 58, use De Moivre's theorem to compute the complex powers by (a) constructing the related right triangle for θ_r, (b) evaluating $\sin(4\theta)$ using two applications of double-angle identities, and (c) evaluating $\cos(4\theta)$ using a Pythagorean identity and the computed value of $\sin(4\theta)$.

57. $z = (1 + 2i)^4$

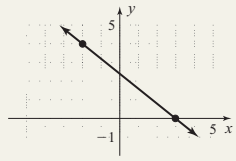
58. $(2 + i\sqrt{5})^4$

The solutions to the cubic equations in Exercises 49 and 50 (repeated in Exercises 59 and 60) can be found by adding the cube roots of $-\dfrac{q}{2} + \sqrt{D}$ and $-\dfrac{q}{2} - \sqrt{D}$ that have arguments summing to 360°.

59. Find the roots of $z^3 - 6z + 4 = 0$

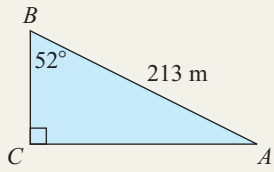
60. Find the roots of $z^3 - 12z - 8 = 0$

▶ MAINTAINING YOUR SKILLS



61. **(7.2)** Prove the following is a identity:

$$\frac{\tan^2 x}{\sec x + 1} = \frac{1 - \cos x}{\cos x}$$

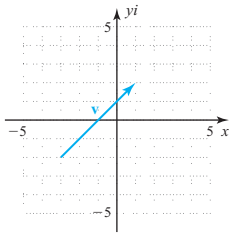


62. **(1.3)** Given $f(x) = 2x^2 - 3x$, determine:

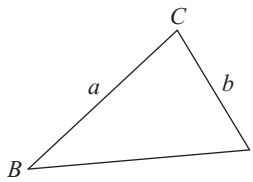
$f(-1), f\left(\frac{1}{3}\right), f(a)$, and $f(a + h)$.

63. **(1.4)** Find an equation of the line whose graph is given.

64. **(6.6)** Solve the triangle given. Round lengths to hundredths of a meter.



MAKING CONNECTIONS



Making Connections: Graphically, Symbolically, Numerically, and Verbally

Eight graphs (a) through (h) are given. Match the characteristics shown in 1 through 16 to one of the eight graphs.

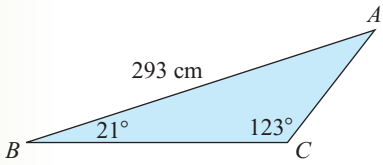
16. ____ $\dfrac{\sin B}{b} = \dfrac{\sin C}{c}$

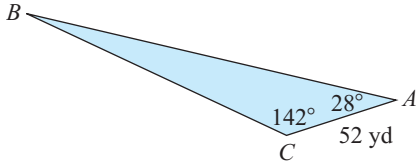
SUMMARY AND CONCEPT REVIEW

SECTION 8.1 Oblique Triangles and the Law of Sines



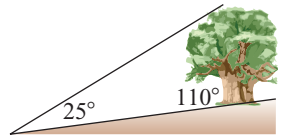
KEY CONCEPTS

- In any triangle, the ratio of the sine of an angle to its opposite side is constant: $\frac{\sin A}{a} = \frac{\sin B}{b} = \frac{\sin C}{c}$.
- The law of sines requires a known angle, a side opposite this angle and an additional side or angle, hence cannot be applied for SSS or SAS triangles.
- For AAS and ASA triangles, the law of sines yields a unique solution.
- When given two sides of a triangle and an angle opposite one of these sides (SSA), the number of solutions is *in doubt,* giving rise to the designation, "the ambiguous case."
- SSA triangles may have no solution, one solution, or two solutions, depending on the length of the side opposite the given angle.
- When solving triangles, always remember:
  - The sum of all angles must be 180°: $\angle A + \angle B + \angle C = 180°$.
  - The sum of any two sides must exceed the length of the remaining side.
  - Longer sides are opposite larger angles.
  - $k = \sin^{-1}\theta$ has no solution for $|k| > 1$.
  - $k = \sin^{-1}\theta$ has two solutions in $[0°, 360°)$ for $0 < |k| < 1$.



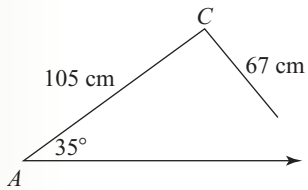
EXERCISES

Solve the following triangles.

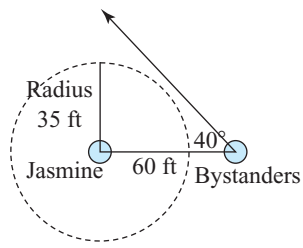


1.

2.



3. A tree is growing vertically on a hillside. Find the height of the tree if it makes an angle of 110° with the hillside and the angle of elevation from the base of the hill to the top of the tree is 25° at a distance of 70 ft.



4. Find two values of θ that will make the equation true: $\frac{\sin\theta}{14} = \frac{\sin 50°}{31}$.

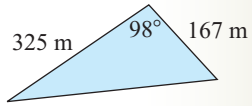
5. Solve using the law of sines. If two solutions exist, find both (figure not drawn to scale).

6. Jasmine is flying her tethered, gas-powered airplane at a local park, where a group of bystanders is watching from a distance of 60 ft, as shown. If the tether has a radius of 35 ft and one of the bystanders walks away at an angle of 40°, will he get hit by the plane? What is the smallest angle of exit he could take (to the nearest whole) without being struck by Jasmine's plane?

SECTION 8.2 The Law of Cosines; the Area of a Triangle

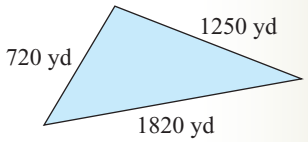
KEY CONCEPTS

- The law of cosines is used to solve SSS and SAS triangles.
- The law of cosines states that in any triangle, the square of any side is equal to the sums of the squares of the other two sides, minus twice their product times the cosine of the included angle:



$$a^2 = b^2 + c^2 - 2bc \cos A$$

- When using the law of cosines to solve a SSS triangle, always begin with the largest angle or the angle opposite the largest side.
- The area of a nonright triangle can be found using the following formulas. The choice of formula depends on the information given.
  - two sides a and b with included angle C: $\mathcal{A} = \frac{1}{2}ab \sin C$
  - two angles A and B with included side c: $\mathcal{A} = \frac{c^2 \sin A \sin B}{2 \sin C}$
  - three sides a, b, and c with $s = \frac{a + b + c}{2}$: $\mathcal{A} = \sqrt{s(s-a)(s-b)(s-c)}$



EXERCISES

7. Solve for B: $9^2 = 12^2 + 15^2 - 2(12)(15) \cos B$

8. Use the law of cosines to find the missing side of the triangle shown.

9. While preparing for the day's orienteering meet, Rick finds that the distances between the first three markers he wants to pick up are 1250 yd, 1820 yd, and 720 yd. Find the measure of each angle in the triangle formed so that Rick is sure to find all three markers.

10. The Great Pyramid of Giza, also known as Khufu's pyramid, is the sole remaining member of the Seven Wonders of the Ancient World. It was built as a tomb for the Egyptian pharaoh Khufu from the fourth dynasty. This square pyramid is made up of four isosceles triangles, each with a base of 230.0 m and a slant height along the edges of about 218.7 m. Approximate the total surface area of Khufu's pyramid (excluding the base).

SECTION 8.3 Vectors and Vector Diagrams

KEY CONCEPTS

- Quantities/concepts that can be described using a single number are called scalar quantities. Examples are time, perimeter, area, volume, energy, temperature, weight, and so on.
- Quantities/concepts that require more than a single number to describe their attributes are called vector quantities. Examples are force, velocity, displacement, pressure, and so on.
- Vectors can be represented using directed line segments to indicate magnitude and direction. The origin of the segment is called the initial point, with the arrowhead pointing to the terminal point. When used solely for comparative analysis, they are called geometric vectors.
- Two vectors are equal if they have the same magnitude and direction.
- Vectors can be represented graphically in the xy-plane by naming the initial and terminal points of the vector or by giving the magnitude and angle of the related position vector [initial point at (0, 0)].
- For a vector with initial point (x_1, y_1) and terminal point (x_2, y_2), the related position vector can be written in the component form $\langle a, b \rangle$, where $a = x_2 - x_1$ and $b = y_2 - y_1$.
- For a vector written in the component form $\langle a, b \rangle$, a is called the horizontal component and b is called the vertical component of the vector.
- For vector $\mathbf{v} = \langle a, b \rangle$, the magnitude of $\mathbf{v}$ is $|\mathbf{v}| = \sqrt{a^2 + b^2}$.
- Vector components can also be written in trigonometric form. See page 774.
- For $\mathbf{u} = \langle a, b \rangle$, $\mathbf{v} = \langle c, d \rangle$, and any scalar k, we have the following operations defined:

$$\mathbf{u} + \mathbf{v} = \langle a + c, b + d \rangle \qquad \mathbf{u} - \mathbf{v} = \langle a - c, b - d \rangle \qquad k\mathbf{u} = \langle ka, kb \rangle \text{ for } k \in \mathbb{R}$$

If $k > 0$, the new vector has the same direction as $\mathbf{u}$; $k < 0$, it has the opposite direction.

- Vectors can be written in algebraic form using **i**, **j** notation, where **i** is an x-axis unit vector and **j** is a y-axis unit vector. The vector $\langle a, b\rangle$ is written as a linear combination of **i** and **j:** $\langle a, b\rangle = a\mathbf{i} + b\mathbf{j}$.
- For any nonzero vector **v**, vector $\mathbf{u} = \dfrac{\mathbf{v}}{|\mathbf{v}|}$ is a unit vector in the same direction as **v**.
- In aviation and shipping, the heading of a ship or plane is understood to be the amount of rotation in the clockwise direction from due north.

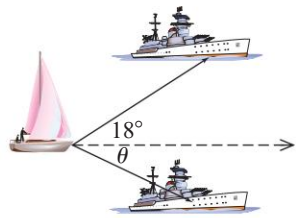
EXERCISES

11. Graph the vector $\mathbf{v} = \langle 9, 5\rangle$, then compute its magnitude and direction angle.

12. Write the vector $\mathbf{u} = \langle -8, 3\rangle$ in **i**, **j** form and compute its magnitude and direction angle.

13. Approximate the horizontal and vertical components of the vector **u**, where $|\mathbf{u}| = 18$ and $\theta = 52°$.

14. Compute $2\mathbf{u} + \mathbf{v}$, then find the magnitude and direction of the resultant: $\mathbf{u} = \langle -3, -5\rangle$ and $\mathbf{v} = \langle 2, 8\rangle$.



15. Find a unit vector that points in the same direction as $\mathbf{u} = 7\mathbf{i} + 12\mathbf{j}$.

16. Without computing, if $\mathbf{u} = \langle -9, 2\rangle$ and $\mathbf{v} = \langle 2, 8\rangle$, will the resultant sum lie in Quadrant I or II? Why?

17. It's once again time for the Great River Race, a $\frac{1}{2}$-mi swim across the Panache River. If Karl fails to take the river's 1-mph current into account and he swims the race at 3 mph, how far from the finish marker does he end up when he makes it to the other side?

18. Two Coast Guard vessels are towing a large yacht into port. The first is pulling with a force of 928 N and the second with a force of 850 N. Determine the angle θ for the second Coast Guard vessel that will keep the ship moving safely in a straight line.

Exercise 18

SECTION 8.4 Vector Applications and the Dot Product

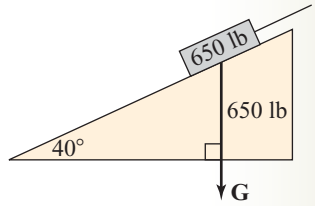
KEY CONCEPTS

- Vector forces are in equilibrium when the sum of their components is the zero vector.
- When the components of vector **u** are nonquadrantal, with one of its components lying along vector **v**, we call this component the "component of **u** along **v**" or $\text{comp}_\mathbf{v}\mathbf{u}$.
- For vectors **u** and **v**, $\text{comp}_\mathbf{v}\mathbf{u} = |\mathbf{u}|\cos\theta$, where θ is the angle between **u** and **v**.
- Work done is computed as the product of the constant force **F** applied, times the distance D the force is applied: $W = |\mathbf{F}| \cdot D$.
- If force is not applied parallel to the direction of movement, only the component of the force in the direction of movement is used in the computation of work. If **u** is a force vector not parallel to the direction of vector **v**, the equation becomes $W = \text{comp}_\mathbf{v}\mathbf{u} \cdot |\mathbf{v}|$.
- For vectors $\mathbf{u} = \langle a, b\rangle$ and $\mathbf{v} = \langle c, d\rangle$, the dot product $\mathbf{u} \cdot \mathbf{v}$ is defined as the scalar $ac + bd$.
- The dot product $\mathbf{u} \cdot \mathbf{v}$ is equivalent to $\text{comp}_\mathbf{u}\mathbf{v} \cdot |\mathbf{v}|$ and to $|\mathbf{u}||\mathbf{v}|\cos\theta$.
- The angle between two vectors can be computed using $\cos\theta = \dfrac{\mathbf{u}}{|\mathbf{u}|} \cdot \dfrac{\mathbf{v}}{|\mathbf{v}|} = \dfrac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{u}||\mathbf{v}|}$.
- Given vectors **u** and **v**, the projection of **u** along **v** is the *vector* $\textbf{proj}_\mathbf{v}\mathbf{u}$ defined by $\textbf{proj}_\mathbf{v}\mathbf{u} = \left(\dfrac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|^2}\right)\mathbf{v}$.
- Given vectors **u** and **v**, $\textbf{proj}_\mathbf{v}\mathbf{u}$, **u** can be resolved into the orthogonal components $\mathbf{u}_1$ and $\mathbf{u}_2$ where $\mathbf{u} = \mathbf{u}_1 + \mathbf{u}_2$, $\mathbf{u}_1 = \textbf{proj}_\mathbf{v}\mathbf{u}$, and $\mathbf{u}_2 = \mathbf{u} - \mathbf{u}_1$.
- The horizontal distance x a projectile travels in t seconds is $x = (|\mathbf{v}|\cos\theta)t$, where $|\mathbf{v}|$ is the magnitude of the initial velocity, and θ is the angle of projection.
- The vertical height y of a projectile after t seconds is $y = (|\mathbf{v}|\sin\theta)t - 16t^2$.

EXERCISES

19. For the force vectors $\mathbf{F}_1$ and $\mathbf{F}_2$ given, find the resultant and an additional force vector so that equilibrium takes place: $\mathbf{F}_1 = \langle -20, 70 \rangle$; $\mathbf{F}_2 = \langle 45, 53 \rangle$.

20. Find $\text{comp}_{\mathbf{v}}\mathbf{u}$ for $\mathbf{u} = -12\mathbf{i} - 16\mathbf{j}$ and $\mathbf{v} = 19\mathbf{i} - 13\mathbf{j}$.



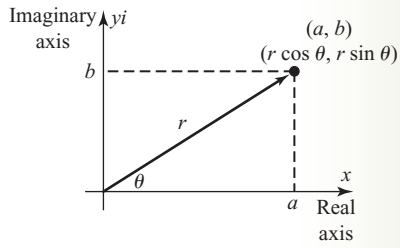
21. Find the component d that ensures vectors $\mathbf{u}$ and $\mathbf{v}$ are orthogonal: $\mathbf{u} = \langle 2, 9 \rangle$ and $\mathbf{v} = \langle -18, d \rangle$.

22. Compute $\mathbf{p} \cdot \mathbf{q}$ and find the angle between them: $\mathbf{p} = \langle -5, -2 \rangle$; $\mathbf{q} = \langle 4, -7 \rangle$.

23. Given force vector $\mathbf{F} = \langle 50, 15 \rangle$ and $\mathbf{v} = \langle 85, 6 \rangle$, find the work required to move an object along the entire length of $\mathbf{v}$. Assume force is in pounds and distance in feet.

24. A 650-lb crate is sitting on a ramp that is inclined at 40°. Find the force needed to hold the crate stationary.

Exercise 24



25. An arctic explorer is hauling supplies from the supply hut to her tent, a distance of 120 ft, in a sled she is dragging behind her. If the straps used make an angle of 25° with the snow-covered ground and she pulls with a constant force of 75 lb, find the amount of work done.

26. A projectile is launched from a slingshot with an initial velocity of $v_0 = 280$ ft/sec at an angle of $\theta = 50°$. Find (a) the position of the object after 1.5 sec and (b) the time required to reach a height of 150 ft.

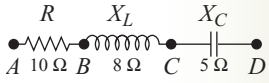
SECTION 8.5 Complex Numbers in Trigonometric Form

KEY CONCEPTS

- A complex number $a + bi = (a, b)$ can be written in trigonometric form by noting (from its graph) that $a = r\cos\theta$ and $b = r\sin\theta$: $a + bi = r(\cos\theta + i\sin\theta)$.
- The angle θ is called the argument of z and r is called the modulus of z.
- The argument of a complex number z is not unique, since any rotation of $\theta + 2\pi k$ (k an integer) will yield a coterminal angle.
- To convert from trigonometric to rectangular form, evaluate $\cos\theta$ and $\sin\theta$ and multiply by the modulus.
- To multiply complex numbers in trig form, multiply the moduli and add the arguments. To divide complex numbers in trig form, divide the moduli and subtract the arguments.
- Complex numbers have numerous real-world applications, particularly in a study of AC electrical circuits.
- The impedance of an AC circuit is given as $Z = R + j(X_L - X_C)$, where R is a pure resistance, X_C is the capacitive reactance, X_L is the inductive reactance, and $j = \sqrt{-1}$.
- Z is a complex number with magnitude $|Z| = \sqrt{R^2 + (X_L - X_C)^2}$ and phase angle $\theta = \tan^{-1}\left(\dfrac{X_L - X_C}{R}\right)$ (θ represents the angle between the voltage and current).
- In an AC circuit, voltage $V = IZ$; current $I = \dfrac{V}{Z}$.

EXERCISES

27. Write in trigonometric form: $z = -1 - \sqrt{3}i$



28. Write in rectangular form: $z = 3\sqrt{2}\left[\text{cis}\left(\dfrac{\pi}{4}\right)\right]$

29. Graph in the complex plane: $z = 5(\cos 30° + i\sin 30°)$

30. For $z_1 = 8\,\text{cis}\left(\dfrac{\pi}{4}\right)$ and $z_2 = 2\,\text{cis}\left(\dfrac{\pi}{6}\right)$, compute $z_1 z_2$ and $\dfrac{z_1}{z_2}$.

31. Find the current I in a circuit where $V = 4\sqrt{3} - 4j$ and $Z = 1 - \sqrt{3}j\ \Omega$.

32. In the V_{RLC} series circuit shown, $R = 10\ \Omega$, $X_L = 8\ \Omega$, and $X_C = 5\ \Omega$. Find the magnitude of Z and the phase angle between current and voltage. Express the result in trigonometric form.

SECTION 8.6 De Moivre's Theorem and the Theorem on *n*th Roots

KEY CONCEPTS

- For complex number $z = r(\cos\theta + i\sin\theta)$, $z^n = r^n[\cos(n\theta) + i\sin(n\theta)]$ (De Moivre's theorem).
- De Moivre's theorem can be used to check complex solutions of polynomial equations.
- For complex number $z = r(\cos\theta + i\sin\theta)$, $\sqrt[n]{z} = \sqrt[n]{r}\left[\cos\left(\frac{\theta}{n} + \frac{2\pi k}{n}\right) + i\sin\left(\frac{\theta}{n} + \frac{2\pi k}{n}\right)\right]$, for $k = 1, 2, 3, \ldots, n-1$ (nth roots theorem).
- The nth roots of a complex number are equally spaced around a circle of radius $\sqrt[n]{r}$ in the complex plane.

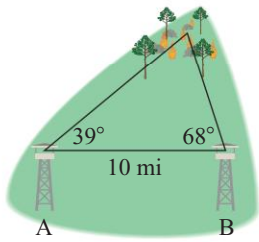
EXERCISES

33. Use De Moivre's theorem to compute the value of $(-1 + i\sqrt{3})^5$.

34. Use De Moivre's theorem to verify that $z = 1 - i$ is a solution of $z^4 + z^3 - 2z^2 + 2z + 4 = 0$.

35. Use the nth roots theorem to find the three cube roots of $125i$.

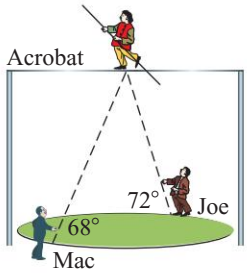
36. Solve the equation using the nth roots theorem: $x^3 - 216 = 0$.



37. Given that $z = 2 + 2i$ is a fourth root of -64, state the other three roots.

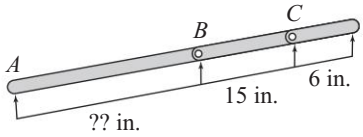
38. Solve using the quadratic formula and the nth roots theorem: $z^4 + 6z^2 + 25 = 0$.

39. Use De Moivre's theorem to verify the three roots of $125i$ found in Exercise 35.

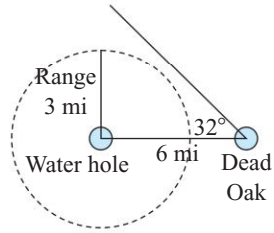


PRACTICE TEST

1. Within the Kilimanjaro Game Reserve, a fire is spotted by park rangers stationed in two towers known to be 10 mi apart. Using the line between them as a baseline, tower A reports the fire is at an angle of 39°, while tower B reports an angle of 68°. How far is the fire from the closer tower?

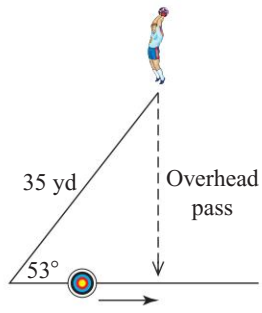


2. At the circus, Mac and Joe are watching a high-wire act from first-row seats on opposite sides of the center ring. Find the height of the performing acrobat at the instant Mac measures an angle of elevation of 68° while Joe measures an angle of 72°. Assume Mac and Joe are 100 ft apart.

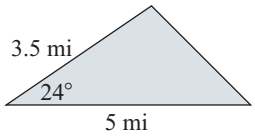


Exercise 2

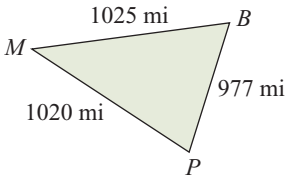
3. Three rods are attached via two joints and shaped into a triangle. How many triangles can be formed if the angle at the joint B must measure 20°? If two triangles can be formed, solve both.



4. Jackie and Sam are rounding up cattle in the brush country, and are communicating via walkie-talkie. Jackie is at the water hole and Sam is at Dead Oak, which are 6 mi apart. Sam finds some strays and heads them home at the 32° indicated. (a) If the maximum range of Jackie's unit is 3 mi, will she be able to communicate with Sam as he heads home? (b) If the maximum range were 4 mi, how far from Dead Oak is Sam when he is first contacted by Jackie?

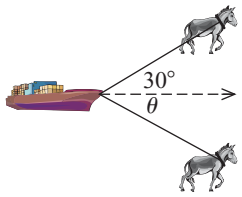


5. As part of an All-Star competition, a group of soccer players (forwards) stand where shown in the diagram and attempt to hit a moving target with a two-handed overhead pass. If a player has a maximum effective range of approximately (a) 25 yd, can the target be hit? (b) about 28 yd, how many "effective" throws can be made? (c) 35 yd and the target is moving at 5 yd/sec, how many seconds is the target within range?

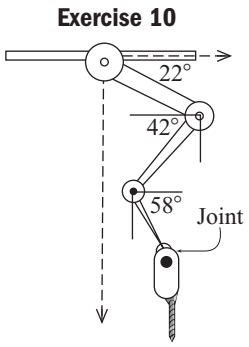


Exercise 5

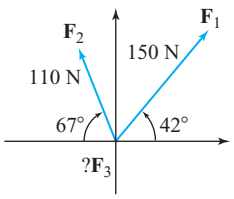
6. The summit of Triangle Peak can only be reached from one side, using a trail straight up the side that is approximately 3.5 mi long. If the mountain is 5 mi wide at its base and the trail makes a 24° angle with the horizontal, (a) what is the approximate length of the opposing side? (b) How tall is the peak (in feet)?



7. The Bermuda Triangle is generally thought to be the triangle formed by Miami, Florida, San Juan, Puerto Rico, and Bermuda itself. If the distances between these locations are the 1025 mi, 1020 mi, and 977 mi indicated, find the measure of each angle and the area of the Bermuda Triangle.



8. A helicopter is flying at 90 mph on a heading of 40°. A 20-mph wind is blowing from the NE on a heading of 190°. What is the true course and speed of the helicopter relative to the ground? Draw a diagram as part of your solution.



9. Two mules walking along a river bank are pulling a heavy barge up river. The first is pulling with a force of 250 N and the second with a force of 210 N. Determine the angle θ for the second mule that will ensure the barge stays midriver and does not collide with the shore.

10. Along a production line, various tools are attached to the ceiling with a multijointed arm so that workers can draw one down, position it for use, then move it up out of the way for the next tool (see the diagram). If the first segment is 100 cm, the second is 75 cm, and the third is 50 cm, determine the approximate coordinates of the last joint.

11. Three ranch hands have roped a runaway steer and are attempting to hold him steady. The first and second ranch hands are pulling with the magnitude and at the angles indicated in the diagram. If the steer is held fast by the efforts of all three, find the magnitude of the tension and angle of the rope from the third cowhand.

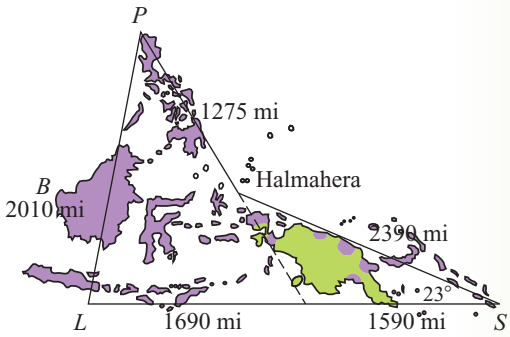
12. For $\mathbf{u} = \langle -9, 5\rangle$ and $\mathbf{v} = \langle -2, 6\rangle$, (a) compute the angle between $\mathbf{u}$ and $\mathbf{v}$; (b) find the projection of $\mathbf{u}$ along $\mathbf{v}$ (find $\mathbf{proj}_{\mathbf{v}}\mathbf{u}$); and (c) resolve $\mathbf{u}$ into vectors $\mathbf{u}_1$ and $\mathbf{u}_2$, where $\mathbf{u}_1 \| \mathbf{v}$ and $\mathbf{u}_2 \perp \mathbf{v}$.

13. A lacrosse player flips a long pass to a teammate way downfield who is near the opponent's goal. If the initial velocity of the pass is 110 ft/sec and the ball is released at an angle of 50° with level ground, how high is the ball after 2 sec? How long after launch until the ball reaches this height again?

14. Compute the quotient $\dfrac{z_1}{z_2}$, given

$$z_1 = 6\sqrt{5}\,\text{cis}\left(\frac{\pi}{8}\right) \text{and } z_2 = 3\sqrt{5}\,\text{cis}\left(\frac{\pi}{12}\right).$$

15. Compute the product $z = z_1 z_2$ in trigonometric form, then verify $|z_1||z_2| = |z|$ and $\theta_1 + \theta_2 = \theta$: $z_1 = -6 + 6i$; $z_2 = 4 - 4i\sqrt{3}$



16. Use De Moivre's theorem to compute the value of $(\sqrt{3} - i)^4$.

17. Use De Moivre's theorem to verify $2 + 2i\sqrt{3}$ is a solution to $z^5 + 3z^3 + 64z^2 + 192 = 0$.

18. Use the nth roots theorem to solve $x^3 - 125i = 0$.

19. Solve using u-substitution, the quadratic formula, and the nth roots theorem: $z^4 - 6z^2 + 58 = 0$.

20. Due to its huge biodiversity, preserving Southeast Asia's Coral Triangle has become a top priority for conservationists. Stretching from the northern Philippines (P), south along the coast of Borneo (B) to the Lesser Sunda Islands (L), then eastward to the Solomon Islands (S), this area is home to over 75% of all coral species known. Use Heron's formula to help find the total area of this natural wonderland, given the dimensions shown.

CALCULATOR EXPLORATION AND DISCOVERY

Investigating Projectile Motion

There are two important aspects of projectile motion that were not discussed earlier, the **range** of the projectile and the **optimum angle** θ that will maximize this range. Both can be explored using the equations for the horizontal and vertical components of the projectile's position: horizontal $\rightarrow (|\mathbf{v}|\cos\theta)t$ and vertical $\rightarrow (|\mathbf{v}|\sin\theta) - 16t^2$. In Example 10 of Section 8.4, an arrow was shot from a bow with initial velocity $|\mathbf{v}| = 150$ ft/sec at an angle of $\theta = 50°$. Enter the equations above on the Y= screen as Y_1 and Y_2, using these values (Figure 8.110). To find the *range* of the arrow, we must find where the height (Y_2) is zero (the arrow has hit the ground). From the GRAPH of Y_1 and Y_2, the zero in question can be found by applying the **CALC:zero** feature to Y_2 with a left bound of 7 and right bound of 8. As Figure 8.111 shows, the arrow hits the ground after approximately 7.2 seconds. Pressing the up arrow key jumps the cursor to Y_1 *at this same X value,* and we see in Figure 8.112 that the horizontal range of the arrow is approximately 692.4 feet. The question now is how to *compute these values exactly.* We begin with the equation for the arrow's vertical position $y = (|\mathbf{v}|\sin\theta)t - 16t^2$. Since the object returns to Earth when $y = 0$, we substitute 0 for y and factor out t: $0 = t(|\mathbf{v}|\sin\theta - 16t)$. Solving for t gives $t = 0$ or $t = \dfrac{|\mathbf{v}|\sin\theta}{16}$. Since the component of velocity in the horizontal direction is $|\mathbf{v}|\cos\theta$, the basic distance relationship $D = r \cdot t$ gives the horizontal range of $R = |\mathbf{v}|\cos\theta \cdot \dfrac{|\mathbf{v}|\sin\theta}{16}$ or $\dfrac{|\mathbf{v}|^2\sin\theta\cos\theta}{16}$. Checking the values given for the arrow ($|\mathbf{v}| = 150$ ft/sec and $\theta = 50°$) verifies the range is $R \approx 692.4$. But what about the *maximum possible range* for the arrow? Using $|\mathbf{v}| = 150$ for R results in an equation in theta only: $R(\theta) = \dfrac{150^2\sin\theta\cos\theta}{16}$, which we can enter as Y_3 and investigate for various θ. After carefully entering $R(\theta)$ as Y_3 and resetting TBLSET to TblStart = 30 and ΔTbl = 5, the TABLE in Figure 8.113 shows a maximum range of about 703 ft at 45°. Resetting TBLSET to TblStart = 40 and ΔTbl = 1 verifies this fact.

Figure 8.110

50	692.44
55	660.72
60	608.92

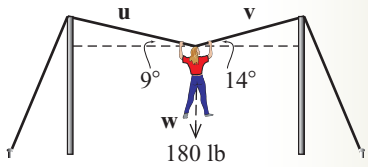
X=30

For each of the following exercises, find (a) the height of the projectile after 1.75 sec, (b) the maximum height of the projectile, (c) the range of the projectile, and (d) the number of seconds the projectile is airborne.

Exercise 1: A javelin is thrown with an initial velocity of 85 ft/sec at an angle of 42°.

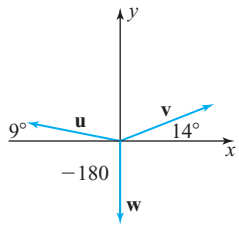
Exercise 2: A cannonball is shot with an initial velocity of 1120 ft/sec at an angle of 30°.

Exercise 3: A baseball is hit with an initial velocity of 120 ft/sec at an angle of 50°. Will it clear thecenter field fence, 10 ft high and 375 ft away?



Exercise 4: A field goal (American football) is kicked with an initial velocity of 65 ft/sec at an angle of 35°. Will it clear the crossbar, 10 ft high and 40 yd away?

STRENGTHENING CORE SKILLS



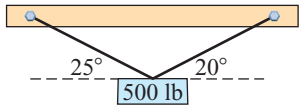
Vectors and Static Equilibrium

In Sections 8.3 and 8.4, the concepts of vector forces, resultant forces, and equilibrium were studied extensively. A nice extension of these concepts involves what is called **static equilibrium.** Assuming that only coplanar forces are acting on an object, the object is said to be in static equilibrium if *the sum of all vector forces acting on it is* $\mathbf{0}$. This implies that the object is stationary, since the forces all counterbalance each other. The methods involved are simple and direct, with a wonderful connection to the systems of equations you've likely seen previously. Consider the following example.

Illustration 1 ▶ As part of their training, prospective FBI agents must move hand-over-hand across a rope strung between two towers. An agent-in-training weighing 180 lb is two-thirds of the way across, causing the rope to deflect from the horizontal at the angles shown. What is the tension in each part of the rope at this point?

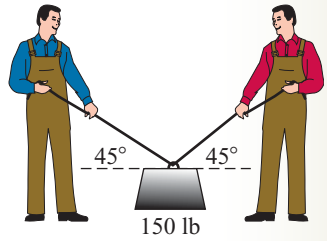
Solution ▶ We have three concurrent forces acting on the point where the agent grasps the rope. Begin by drawing a vector diagram and computing the components of each force, using the **i**, **j** notation. Note that $\mathbf{w} = -180\mathbf{j}$.

$$\begin{aligned}\mathbf{u} &= -|\mathbf{u}|\cos(9°)\mathbf{i} + |\mathbf{u}|\sin(9°)\mathbf{j}\\ &\approx -0.9877|\mathbf{u}|\mathbf{i} + 0.1564|\mathbf{u}|\mathbf{j}\\ \mathbf{v} &= |\mathbf{v}|\cos(14°)\mathbf{i} + |\mathbf{v}|\sin(14°)\mathbf{j}\\ &\approx 0.9703|\mathbf{v}|\mathbf{i} + 0.2419|\mathbf{v}|\mathbf{j}\end{aligned}$$



For equilibrium, all vector forces must sum to the zero vector: $\mathbf{u} + \mathbf{v} + \mathbf{w} = \mathbf{0}$, which results in the following equation: $-0.9877|\mathbf{u}|\mathbf{i} + 0.1564|\mathbf{u}|\mathbf{j} + 0.9703|\mathbf{v}|\mathbf{i} + 0.2419|\mathbf{v}|\mathbf{j} - 180\mathbf{j} = 0\mathbf{i} + 0\mathbf{j}$. Factoring out **i** and **j** from the left-hand side yields $(-0.9877|\mathbf{u}| + 0.9703|\mathbf{v}|)\mathbf{i} + (0.1564|\mathbf{u}| + 0.2419|\mathbf{v}| - 180)\mathbf{j} = 0\mathbf{i} + 0\mathbf{j}$. Since any two vectors are equal only when corresponding components are equal, we obtain a system in the two variables $|\mathbf{u}|$ and $|\mathbf{v}|$:

$$\begin{cases} -0.9877|\mathbf{u}| + 0.9703|\mathbf{v}|) = 0 \\ 0.1564|\mathbf{u}| + 0.2419|\mathbf{v}| - 180 = 0 \end{cases}.$$

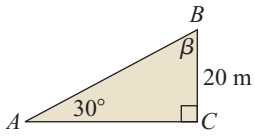


Solving the system using matrix equations and a calculator (or any desired method), gives $|\mathbf{u}| \approx 447$ lb and $|\mathbf{v}| \approx 455$ lb.

At first it may seem surprising that the vector forces (tension) in each part of the rope are so much greater than the 180-lb the agent weighs. But with a 180-lb object hanging from the middle of the rope, the tension required to keep the rope taut (with small angles of deflection) must be very great. This should become more obvious to you after you work Exercise 2.

Exercise 1: A 500-lb crate is suspended by two ropes attached to the ceiling rafters. Find the tension in each rope.

Exercise 2: Two people team up to carry a 150-lb weight by passing a rope through an eyelet in the object. Find the tension in each rope.

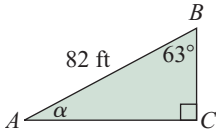


Exercise 3: Referring to Illustration 1, if the rope has a tension limit of 600-lb (before it snaps), can it suspend a 200-lb agent at the same location shown?

CUMULATIVE REVIEW CHAPTERS 1–8

1. Solve using a standard triangle.

$a = 20$, $b =$ ____, $c =$ ____



$\alpha = 30°$, $\beta =$ ____, $\gamma =$ ____

2. Solve using trigonometric ratios.

$a \approx$ ____, $b \approx$ ____, $c = 82$

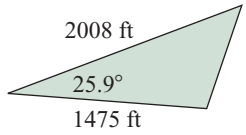
$\alpha =$ ____, $\beta = 63°$, $\gamma =$ ____

3. A torus is a donut-shaped solid figure. Its surface area is given by the formula $A = \pi^2(R^2 - r^2)$, where R is the outer radius of the donut, and r is the inner radius. Solve the formula for R in terms of r and A.

4. For a complex number $a + bi$, (a) verify the sum of a complex number and its conjugate is a real number, and (b) verify the product of a complex number and its conjugate is a real number.

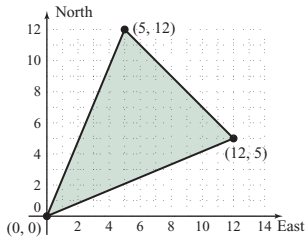
5. State the values of all six trig functions given $\tan\alpha = -\frac{3}{4}$ with $\cos\alpha > 0$.

6. Sketch the graph of $y = 4\cos\left(\frac{\pi}{6}x - \frac{\pi}{3}\right)$ using transformations of $y = \cos x$.



7. Solve using the quadratic formula: $5x^2 + 8x + 2 = 0$.

8. Solve by completing the square: $3x^2 - 72x + 427 = 0$.



9. Given $\cos 53° \approx 0.6$ and $\cos 72° \approx 0.3$, approximate the value of $\cos 19°$ and $\cos 125°$ without using a calculator.

10. Find all real values of x that satisfy the equation $\sqrt{3} + 2\sin(2x) = 2\sqrt{3}$. State the answer in degrees.

11. **a.** Given that 1 acre $= 43{,}560$ ft^2, find the cost of a lot with the dimensions shown (to the nearest dollar) if land in this area is going for \$4500 per acre.

b. After an accident at sea, a search-and-rescue team decides to focus their efforts on the area shown due to prevailing winds and currents. Find the distances between each vertex (use Pythagorean triples and a special triangle) and the number of square miles in the search area.

12. State the domain of each function:

a. $f(x) = \sqrt{2x - 3}$

b. $g(x) = \log_b(x + 3)$

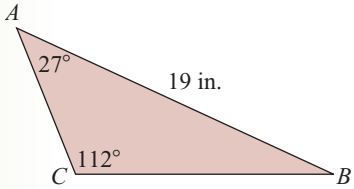
c. $h(x) = \dfrac{x + 3}{x^2 - 5}$

d. $v(x) = \sqrt{x^2 - x - 6}$

13. Write the following formulas from memory:

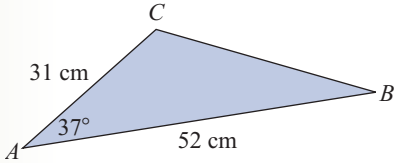
a. slope formula

b. midpoint formula



c. quadratic formula

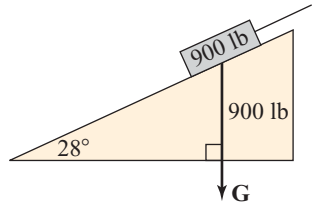
d. distance formula



e. interest formula (compounded continuously)

Solve each triangle using the law of sines or the law of cosines, whichever is appropriate.

14.



15.

16. A commercial fishery stocks a lake with 250 fish. Based on previous experience, the population of fish is expected to grow according to the model $P(t) = \dfrac{12{,}000}{1 + 25e^{-0.2t}}$, where t is the time in months. From on this model, (a) how many months are required for the population to grow to 7500 fish? (b) If the fishery expects to harvest three-fourths of the fish population in 2 yr, approximately how many fish will be taken?

17. A 900-lb crate is sitting on a ramp which is inclined at 28°. Find the force needed to hold the object stationary.

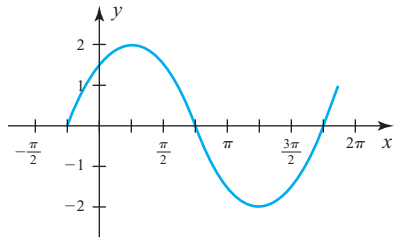
18. A jet plane is flying at 750 mph on a heading of 30°. There is a strong 50-mph wind blowing from due south (heading 0°). What is the true course and speed of the plane (relative to the ground)?

19. Use the *Guidelines for Graphing* to sketch the graph of function f given, then use it to solve $f(x) < 0$.

$$f(x) = x^3 - 4x^2 + x + 6$$

20. Use the *Guidelines for Graphing* to sketch the graph of function g given, then use it to name the intervals where $g(x)\downarrow$ and $g(x)\uparrow$.

$$g(x) = \frac{x^2 - 4}{x^2 - 1}$$



21. Find $(1 - i\sqrt{3})^8$ using De Moivre's theorem.

22. Solve $\ln(x + 2) + \ln(x - 3) = \ln(4x)$.

23. If I saved \$200 each month in an annuity program that paid 8% annual interest compounded monthly, how long would it take to save \$10,000?

24. Mount Tortolas lies on the Argentine-Chilean border. When viewed from a distance of 5 mi, the angle of elevation to the top of the peak is 38°. How tall is Mount Tortolas? State the answer in feet.

25. The graph given is of the form $y = A\sin(Bx + C)$. Find the values of A, B, and C.

Exercises 26 through 30 require the use of a graphing calculator.

26. For $\mathbf{v} = \langle -2.0807, 4.5465 \rangle$, use the **R▶Pr** and **R▶Pθ** features of a calculator to find the magnitude and angle θ (in radians) for $\mathbf{v}$. Round your answer to four decimal places.

27. Solve the inequality on the interval $[0, 2\pi)$. Round your values to two decimal places when necessary.
$\cos^{-1}(\sin x) \geq \tan x$

28. Determine where the graphs of $f(x) = x^{1.234}$ and $g(x) = x^{0.234}$ intersect.

29. Given $\mathbf{u} = \langle \pi + 1, 1 - \pi \rangle$ and $\mathbf{v} = \langle \pi - 1, \pi + 1 \rangle$, use a calculator to determine $\mathbf{u} \cdot \mathbf{v}$ (recall that the braces "{" and "}" must be used). What does your result say about these two vectors?

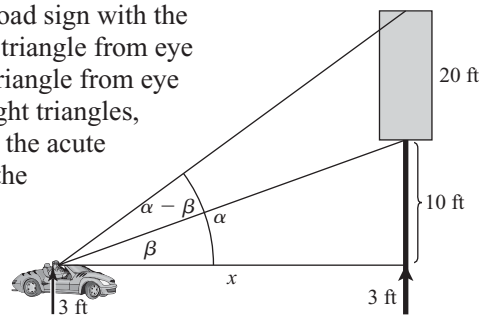
30. The average fuel consumption of passenger cars produced by Alpha Motors can be modeled by the function $A(t) = 5\sqrt[3]{10t} + 15$, where A is in miles per gallon (mpg) and $t = 0$ corresponds to the year 2005. In 2010, Beta Motors began producing passenger cars and the function $B(t) = 5\sqrt{10t} - 10$ models their average fuel consumption, with B in mpg and $t = 0$ once again corresponding to the year 2005. When will the two companies' passenger cars have the same average fuel consumption? What is that average gas mileage? Round your answers to two decimal places.

Chapter 8 unites our study of trigonometry with many of the skills you likely developed in previous coursework. Certainly *algebraic skills* continue to play a significant role, but here we've chosen to review and highlight certain *problem-solving skills* as well. From the vector diagrams seen in Chapter 8 to the triangle diagrams used in numerous applications, a careful sketch can highlight relationships and suggest a solution process, and this will certainly serve us well throughout the calculus sequence.

Trigonometry and Problem Solving

Perhaps to a higher degree in a calculus course, the quality of the diagrams we draw have a greater impact on our ability to understand and solve applications. Draw the diagrams very carefully and to scale, if possible. Label the various parts of the diagram, make a list of all given information, assign variable names to unknown quantities, and build any needed relationships—in short, use the total accumulation of your problem-solving skills.

EXAMPLE 1 ▶ **Determining Sight Angles**



A 20-ft-tall road sign is to be placed along a busy highway by attaching it to a support pole, with the bottom edge of the sign 13 ft above the ground.

a. Find a simplified expression for the "sight angle" (the angle at a person's eyes subtended by the sign) in terms of x, when the driver is x ft away from the base of the pole (assume that eye level for an average driver is 3 ft above the ground).

b. Find the sight angle at the moment a driver is 50 ft away.

Solution ▶

a. Draw a car that is x ft away from a road sign with the dimensions described. Note that the triangle from eye level to the top of the sign, and the triangle from eye level to the bottom of the sign are right triangles, *while the sight angle is not*. Naming the acute angle of the larger right triangle (at the eyes of the driver) α, and the acute angle of the smaller right triangle β (see the figure), we see that the sight angle is then $\alpha - \beta$. Since we need to involve the distance x in our equation model, it appears the tangent function should be used, giving $\tan\alpha = \frac{30}{x}$ and $\tan\beta = \frac{10}{x}$. Knowing the identity for $\tan(\alpha - \beta)$ expressed *in terms of tan α and tan β individually,* we have $\tan(\alpha - \beta) = \frac{\tan\alpha - \tan\beta}{1 + \tan\alpha\tan\beta}$.

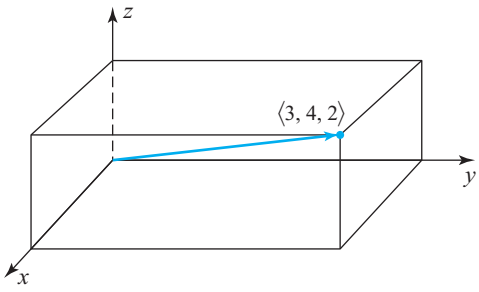
Our algebraic expression is then

$$\tan(\alpha - \beta) = \frac{\frac{30}{x} - \frac{10}{x}}{1 + \left(\frac{30}{x}\right)\left(\frac{10}{x}\right)} \quad \text{make substitutions}$$

$$= \frac{\frac{20}{x}}{1 + \frac{300}{x^2}} \quad \text{simplify}$$

$$= \frac{\frac{20}{x}}{\frac{x^2 + 300}{x^2}} \qquad \text{combine terms}$$

$$= \frac{20x}{x^2 + 300} \qquad \text{result}$$



The expression for the sight angle is $\alpha - \beta = \tan^{-1}\left(\frac{20x}{x^2 + 300}\right)$

b. When $x = 50$ ft, $\alpha - \beta = \tan^{-1}\left(\frac{1000}{2800}\right)$, or about 19.65°. For comparison, the sight angle at 25 ft is about 28.39°, and at 100 ft the angle is about 10.99°.

Now try Exercises 1 through 4 ▶

Vectors in Three Dimensions

Many elements of a study of vectors in two dimensions transfer directly to the study of vectors in three dimensions. To help visualize a three-dimensional vector, consider a large 3 ft × 4 ft × 2 ft cardboard box placed snugly in the corner of a room. The floor of the room forms the positive xy-plane (the axes are where the walls meet the floor, the x-axis to the left), with the third dimension (the z-axis) formed where the two walls meet (see the figure). The origin is then (0, 0, 0), where the three axes meet, and the position vector $\langle 3, 4, 2\rangle$ forms an interior diagonal of the box. For three-dimensional vectors $\mathbf{u} = \langle a, b, c\rangle$ and $\mathbf{v} = \langle d, e, f\rangle$, the formulas for the magnitude of $\mathbf{v}$ and the dot product $\mathbf{u} \cdot \mathbf{v}$ are an extension of the two-dimensional cases, and are offered here without proof:

$$|\mathbf{u}| = \sqrt{a^2 + b^2 + c^2}, \text{ and } \mathbf{u} \cdot \mathbf{v} = ad + be + cf.$$

EXAMPLE 2 ▶ **Finding the Angle between Two Vectors**

For vector $\mathbf{u} = \langle 3, 4, 2\rangle$ forming the interior diagonal of the box and $\mathbf{v} = \langle 3, 4, 0\rangle$ forming the diagonal of the base,

a. Find $|\mathbf{u}|$, then verify the result using the Pythagorean theorem and $|\mathbf{v}|$.

b. Use the formula $\cos\theta = \frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{u}||\mathbf{v}|}$ to find the angle θ between $\mathbf{u}$ and $\mathbf{v}$, then verify the result using right-triangle trig.

Solution ▶

a. First find $|\mathbf{u}| = \sqrt{3^2 + 4^2 + 2^2} = \sqrt{29}$. To verify, we use $|\mathbf{v}| = \sqrt{3^2 + 4^2 + 0^2} = 5$ and the height of the box in the Pythagorean theorem (since the triangle formed by (0, 0, 0), (3, 4, 0), and (3, 4, 2) is a right triangle): $|\mathbf{v}|^2 + 2^2 = 25 + 4 = 29 = |\mathbf{u}|^2$ ✓.

b. For $\cos\theta = \frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{u}||\mathbf{v}|}$, $\cos\theta = \frac{9 + 16 + 0}{5\sqrt{29}} = \frac{5}{\sqrt{29}}$, so $\theta = \cos^{-1}\left(\frac{5}{\sqrt{29}}\right) \approx 21.8°$.

To verify, we use $|\mathbf{v}| = 5$ and the height of the box, giving $\theta = \tan^{-1}\left(\frac{2}{5}\right) \approx 21.8°$ ✓.

Now try Exercises 5 through 10 ▶

Occasionally we need to determine the angle a three-dimensional vector forms with the x-, y-, or z-axis. To do so, we apply the method and formulas shown in Example 2, by utilizing a secondary vector lying along the axis in question. For example, the angle that $\mathbf{u} = \langle 3, 4, 2 \rangle$ forms with the z-axis is *exactly* the angle θ between the vector $\mathbf{u}$ itself and $\mathbf{k} = \langle 0, 0, 1 \rangle$. Verify that in this case, $\theta = \cos^{-1}\left(\frac{2}{\sqrt{29}}\right) \approx 68.2°$.

Connections to Calculus Exercises

For the following applications, draw a diagram and develop an appropriate equation model. Note that the emphasis on these exercises is shared equally between the *quality of diagram* and *developing the correct equation model*.

1. A jet plane is flying at a constant altitude of 9000 ft, straight toward a searchlight on the ground that is tracking it. (a) Find an expression for the angle the searchlight makes with the ground in terms of the horizontal distance d from the light to a point on the ground directly below the plane. (b) Find the angle θ at the moment $d = 12{,}850$ ft.

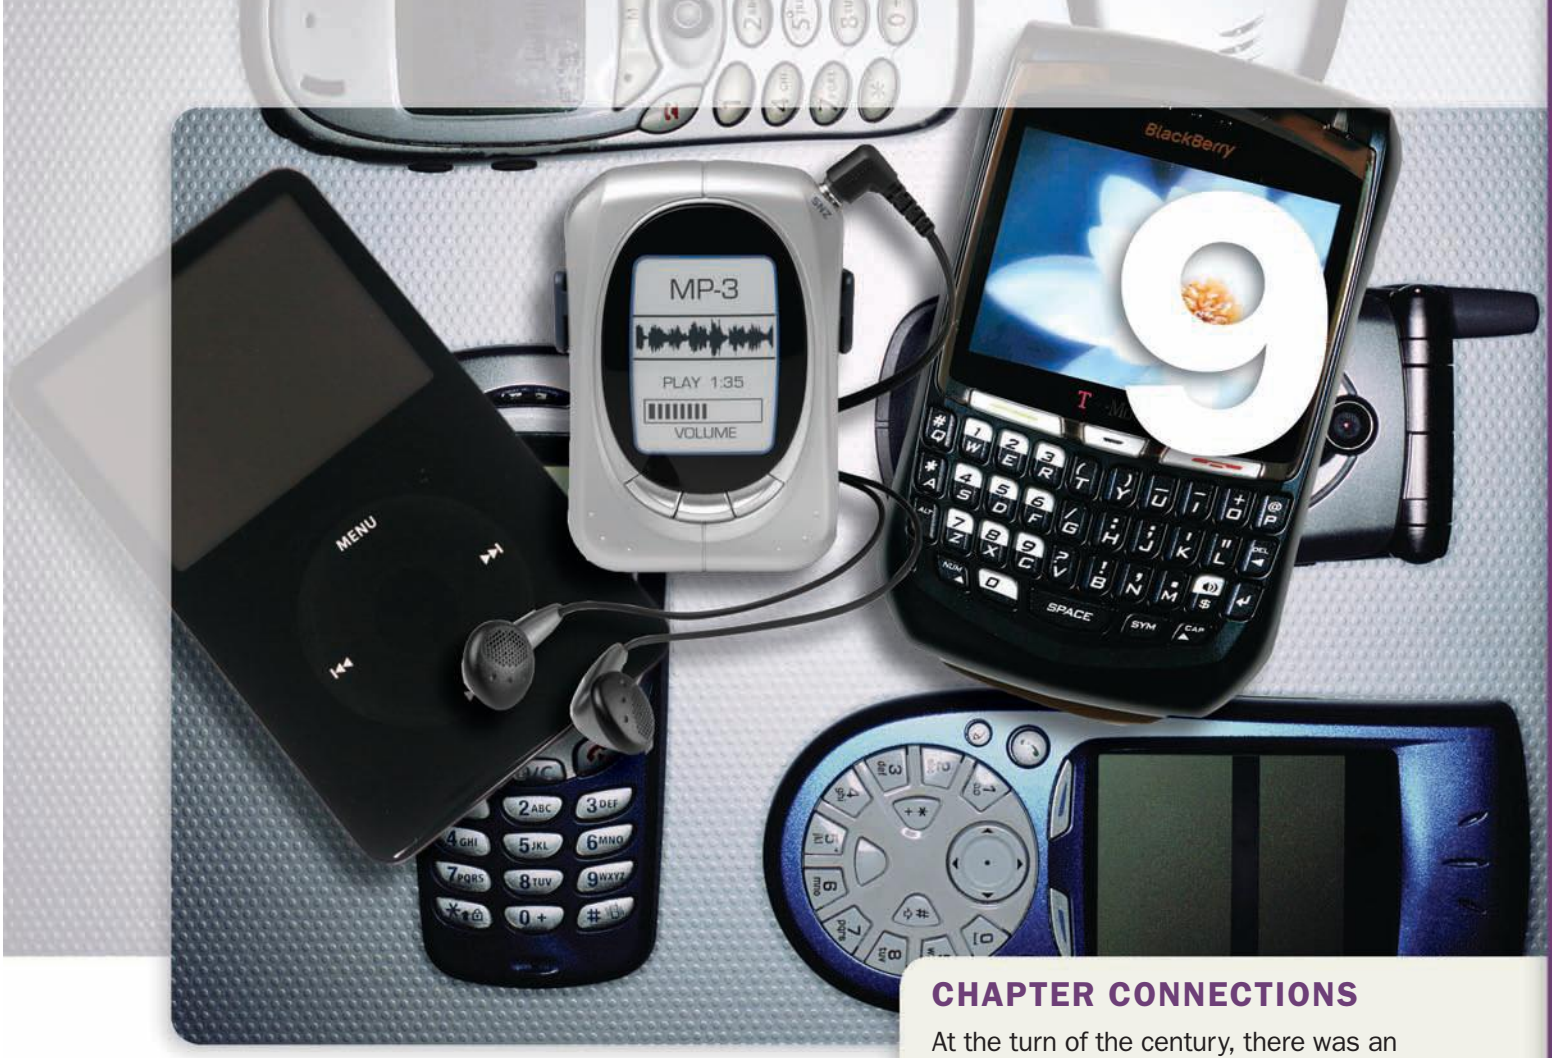
2. A light is hung from the rafters at a height h m above the floor, providing a circle of illumination. The illuminance E (in lumens/square meter or lm/m^2) at any point P on the floor varies directly as the cosine of the angle θ at which the rays leave the light source toward P, and inversely as the square of the height h of the light source. Using k as the constant of variation, (a) write an expression for the illuminance in terms of k, h, and θ. (b) If the distance from the light source to point P is 13 m, write an expression for the illuminance in terms of k and h alone. (c) For $k = 15{,}600$, what is the height of the light source if $E = 100$ lm/m^2? (d) For k and h as in part (c), at what angle θ is the illuminance 83 lm/m^2?

3. In a large factory, two automated carts run on concentric circular tracks. The inner track has a radius of 24 m, while the outer track has a radius of 32 m. (a) Write an expression for the straight-line distance x between the two carts in terms of the angle θ formed by the line segments from the center to each cart. (b) Determine the straight-line distance between the carts at the moment $\theta = 150°$. (c) At what angle θ are the carts 45 m apart?

4. A rectangle is inscribed in a semicircle of radius r. A straight line from the center of the circle to the point where a vertex of the rectangle meets the circle, forms an angle θ. (a) Find an expression for the area of the rectangle in terms of r and a sine function. (*Hint:* Write the length and width of the rectangle in terms of sine and cosine.) (b) Find the area of the circle if $r = 5$ cm and $\theta = 26°$. (c) At what angle θ does the rectangle have an area of 22 cm^2?

Solve each application of three-dimensional vectors using a careful sketch drawn from the information given. The emphasis on these exercises continues to be shared equally between the *quality of diagram* and *developing the correct equation model*.

5. A rectangular playground is 64 ft long and 48 ft wide. There is a light pole for evening play in one corner of the playground, with the light placed 18 ft high. (a) Find $|\mathbf{v}|$, the length of the vector formed from the top of the light pole to the opposite corner of the playground. (b) If $\mathbf{u}$ is the vector formed by the opposite end of the playground and the base of the pole, find the angle between these two vectors using $\cos\theta = \frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{u}||\mathbf{v}|}$ and verify the result using right triangle trig.



6. A gallery is about to open an exhibit in a room that is 22 ft long, 24 ft wide, and 16 ft high. The edge of the door to the exhibit is on the 22-ft side, 4 ft from one wall. For special effects lighting as guests enter the door, let $\mathbf{u}$ be the vector representing the distance from the edge of the door (at the floor) to the farthest bottom corner of the room, and let $\mathbf{v}$ be the vector from the same point to the farthest upper corner. (a) Find $|\mathbf{v}|$, then (b) find the angle between $\mathbf{u}$ and $\mathbf{v}$ using $\cos\theta = \frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{u}||\mathbf{v}|}$ and verify the result using right triangle trig.

7. At a small jungle airport, bush pilots are practicing their approaches to drop zones for food aid. There is an observation post 525 ft from the middle of one end of an 1800-ft straight dirt runway. At the moment the pilot of the first drop plane is over the opposite end of the runway, her altitude is 1000 ft. Let **d** be the vector representing the distance from the observation post to the opposite end of the runway, and let **D** represent the vector for the straight-line distance from the post to the plane at this moment. (a) Find $|\mathbf{D}|$, then (b) find the angle between **d** and **D** using $\cos\theta = \dfrac{\mathbf{d}\cdot\mathbf{D}}{|\mathbf{d}||\mathbf{D}|}$ and verify the result using right triangle trig.

8. An ornithologist is in the field studying what ornithologists study (in this case, a formation of geese), and is 180 m south and 385 m west of where she parked her car. Let **u** be the vector representing the distance between the ornithologist and her car, and let **v** be the vector representing the straight-line distance from the ornithologist to the formation. If the lead goose flies directly over her car at an altitude of 319 m, (a) find $|\mathbf{v}|$ then, (b) find the angle between **u** and **v** using $\cos\theta = \dfrac{\mathbf{u}\cdot\mathbf{v}}{|\mathbf{u}||\mathbf{v}|}$ and verify the result using right triangle trig.

9. A person is sitting in the center seat, in the center row, on the inclined seating of a new movie theater. The movie screen is 25 ft tall with the bottom of the screen 8 ft above a level floor. The person's eye level is 15 ft above the floor and the person's seat is a horizontal distance of x ft from the movie screen. (a) Write an expression for the person's sight angle to the screen in terms of x. (b) Find the sight angle if the person is 46 ft from the screen.

10. The main road in front of a school runs north/south along the east side. A sidewalk runs east/west along the south side of the school, leading to a crosswalk. A secondary road intersects the west side of the main road near the crosswalk, forming a 30° angle with the sidewalk. For the safety of the school children using the sidewalk, engineers are interested in the sight angle that drivers have as they drive on the secondary road approaching this intersection. (a) Find an expression for the sight angle of a driver in terms of x, the distance between their car and a point on the sidewalk 100 ft from the intersection. (b) Find the sight angle at the moment $x = 125$ ft.

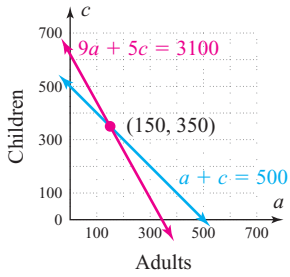
CHAPTER CONNECTIONS

At the turn of the century, there was an explosion in the number of handheld electronic devices available to consumers. One device in particular, the popular MP3 player, experienced a phenomenal growth in demand. With high demand and a large market, competition between manufacturers and suppliers is often fierce, with each fighting to earn and hold a share of the market. One significant factor in who gains the largest share is the price charged for the player, with suppliers willing to supply more at a greater price, and consumers willing to buy more at a lesser price. Determining where the price will stabilize is an important component in the economics of *"supply and demand."*

▶ This application occurs as Exercise 78 in Section 9.1.

Connections to Calculus

Recall that for exponential functions, the rate of growth is proportional to the current population as shown in (1) below. For logistic functions, the rate of growth is proportional to the current population times the *difference* between the carrying capacity c and the current population (2). For further analysis, this relationship can be rewritten as in (3), with a technique known as *partial fraction decomposition* then applied. This technique is presented in Section 9.4, and further explored in the *Connections to Calculus* feature for Chapter 9.



$$(1)\ \frac{\Delta P}{\Delta t} = kP \qquad (2)\ \frac{\Delta P}{\Delta t} = kP(c - P) \qquad (3)\ \frac{\Delta P}{P(c - P)} = k\Delta t$$

9.1 Linear Systems in Two Variables with Applications

LEARNING OBJECTIVES

In Section 9.1 you will see how we can:

- ❑ **A.** Verify ordered pair solutions
- ❑ **B.** Solve linear systems by graphing
- ❑ **C.** Solve linear systems by substitution
- ❑ **D.** Solve linear systems by elimination
- ❑ **E.** Recognize inconsistent systems and dependent systems
- ❑ **F.** Use a system of equations to model and solve applications

In earlier chapters, we used linear equations in two variables to model a number of real-world situations. Graphing these equations gave us a visual image of how the variables were related, and helped us better understand this relationship. In many applications, two different measures of the independent variable must be considered simultaneously, leading to a **system of two linear equations in two unknowns.** Here, a graphical presentation once again supports a better understanding, as we explore systems and their many applications.

A. Solutions to a System of Equations

A **system of equations** is a set of two or more equations for which a common solution is sought. Systems are widely used to model and solve applications when the information given enables the relationship between variables to be stated in different ways. For example, consider an amusement park that brought in $3100 in revenue by charging $9.00 for adults and $5.00 for children, while selling 500 tickets. Using a for adult and c for children, we could write one equation modeling the number of tickets sold: $a + c = 500$, and a second modeling the amount of revenue brought in: $9a + 5c = 3100$. To show that we're considering both equations simultaneously, a large "left brace" is used and the result is called a **system of two equations in two variables:**

$$\begin{cases} a + c = 500 & \text{number of tickets} \\ 9a + 5c = 3100 & \text{amount of revenue} \end{cases}$$

We note that both equations are linear and will have different slope values, so their graphs must intersect at some point. Since every point on a line satisfies the equation of that line, this point of intersection must satisfy *both* equations simultaneously and is the solution to the system. The figure that accompanies Example 1 shows the point of intersecion for this system is (150, 350).

EXAMPLE 1 ▶ **Verifying Solutions to a System**

Verify that (150, 350) is a solution to $\begin{cases} a + c = 500 \\ 9a + 5c = 3100 \end{cases}$.

Solution ▶ Substitute the 150 for a and 350 for c in each equation.

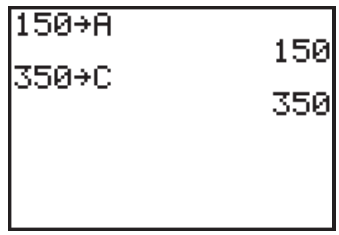
$a + c = 500$	first equation	$9a + 5c = 3100$	second equation
$(150) + (350) = 500$		$9(150) + 5(350) = 3100$	
$500 = 500$ ✓		$3100 = 3100$ ✓	

Since (150, 350) satisfies both equations, it is the solution to the system and we find the park sold 150 adult tickets and 350 tickets for children.

Now try Exercises 7 through 18 ▶

To check the solution to Example 1 on a graphing calculator, recall that we can store values in any of the ALPHA characters using the STO▸ key. The home screen shown in Figure 9.1 shows that we've stored a value of 150 in alpha location **A**, and 350 in location **C**. The solution to a system can then be checked using these alpha keys and the operations indicated, as shown in Figure 9. 2.

Figure 9.1



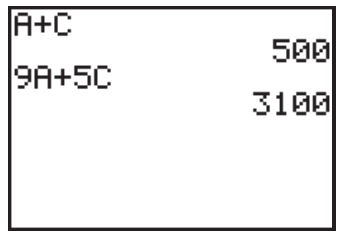


Figure 9.2

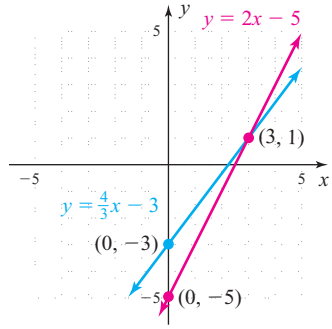
A. You've just seen how we can verify ordered pair solutions

B. Solving Systems Graphically



To **solve a system of equations** means we apply various methods in an attempt to find ordered pair solutions. As Example 1 suggests, one method for finding solutions is to graph the system. Any method for graphing the lines can be employed, but to keep important concepts fresh, the slope-intercept method is used here.

EXAMPLE 2 ▶ **Solving a System Graphically**

Solve the system by graphing: $\begin{cases} 4x - 3y = 9 \\ -2x + y = -5 \end{cases}$.

Solution ▶ First write each equation in slope-intercept form (solve for y):

$$\begin{cases} 4x - 3y = 9 \\ -2x + y = -5 \end{cases} \rightarrow \begin{cases} y = \frac{4}{3}x - 3 \\ y = 2x - 5 \end{cases}$$

For the first line, $\frac{\Delta y}{\Delta x} = \frac{4}{3}$ with y-intercept $(0, -3)$. The second equation yields $\frac{\Delta y}{\Delta x} = \frac{2}{1}$ with $(0, -5)$ as the y-intercept. Both are then graphed on the grid as shown. The point of intersection appears to be $(3, 1)$, and checking this point in both equations gives

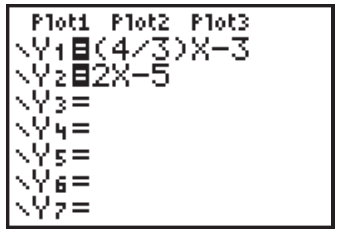
$$\begin{aligned} 4x - 3y &= 9 \\ 4(3) - 3(1) &= 9 \\ 9 &= 9 \checkmark \end{aligned} \qquad \begin{aligned} &\text{substitute 3} \\ &\text{for } x \text{ and 1 for } y \end{aligned} \qquad \begin{aligned} -2x + y &= -5 \\ -2(3) + (1) &= -5 \\ -5 &= -5 \checkmark \end{aligned}$$

This verifies that $(3, 1)$ is the solution to the system.

Now try Exercises 19 through 22 ▶

Graphical solutions to a system of equations can be found using a graphing calculator and the intersection-of-graphs method seen earlier. After solving for y and entering the equations on the Y= screen (Figure 9.3), use the keystrokes 2nd TRACE **(CALC) 5:Intersect** to determine the point of intersection, if it exists (Figure 9.4).

Figure 9.3



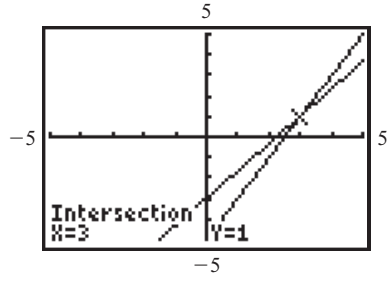


Figure 9.4

B. You've just seen how we can solve linear systems by graphing

C. Solving Systems by Substitution

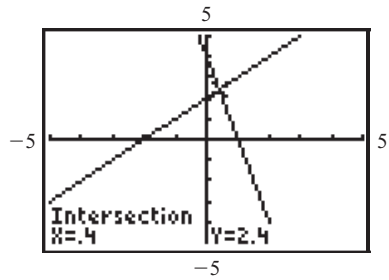
While a graphical approach best illustrates *why* the solution must be an ordered pair, it does have one obvious drawback—noninteger solutions are difficult to spot. The ordered pair $(\frac{2}{5}, \frac{12}{5})$ is the solution to $\begin{cases} 4x + y = 4 \\ y = x + 2 \end{cases}$, but this would be difficult to "pinpoint" as a precise location on a hand-drawn graph. To overcome this limitation, we next consider a method known as **substitution.** The method involves converting a system of two equations in two variables into a single equation in one variable by using an appropriate substitution. For $\begin{cases} 4x + y = 4 \\ y = x + 2 \end{cases}$, the second equation says "y is two more than x." We reason that *all* points on this line are related this way, *including the point where this line intersects the other.* For this reason, we can substitute $x + 2$ for y *in the first equation,* obtaining a single equation in x.

EXAMPLE 3 ▶ **Solving a System Using Substitution**

Solve using substitution: $\begin{cases} 4x + y = 4 \\ y = x + 2 \end{cases}$.

Solution ▶ Since $y = x + 2$, we can replace y with $x + 2$ in the first equation.

$$\begin{aligned} 4x + y &= 4 && \text{first equation} \\ 4x + (x + 2) &= 4 && \text{substitute } x + 2 \text{ for } y \\ 5x + 2 &= 4 && \text{simplify} \\ x &= \frac{2}{5} && \text{result} \end{aligned}$$



The x-coordinate is $\frac{2}{5}$. To find the y-coordinate, we substitute $\frac{2}{5}$ for x into either of the original equations, a process known as **back-substitution.** Substituting in the second equation gives

$$\begin{aligned} y &= x + 2 && \text{second equation} \\ &= \frac{2}{5} + 2 && \text{substitute } \frac{2}{5} \text{ for } x \\ &= \frac{12}{5} && \frac{2}{1} = \frac{10}{5}, \frac{2}{5} + \frac{10}{5} = \frac{12}{5} \end{aligned}$$

The solution to the system is $(\frac{2}{5}, \frac{12}{5})$, which can be verified using the intersection-of-graphs method, and noting $\frac{2}{5} = 0.4$ and $\frac{12}{5} = 2.4$. See Figure 9.5. Recall that the keystrokes MATH 1:▶FRAC ENTER can be used to convert decimal numbers to fractions.

Figure 9.5

$Y_1 = -4X + 4, Y_2 = X + 2$

Now try Exercises 23 through 32 ▶

If neither equation allows an immediate substitution, we first solve for one of the variables, either x or y, and *then* substitute. The method is summarized here, and can actually be used with either like variables or like variable *expressions*. **See Exercises 33 to 36.**

☑ **C.** You've just seen how we can solve linear systems by substitution

Solving Systems Using Substitution

1. Solve one of the equations for x in terms of y or y in terms of x.
2. Substitute for the appropriate variable in the *other* equation and solve for the variable that remains.
3. Substitute the value from step 2 into either of the original equations and solve for the other unknown.
4. Write the answer as an ordered pair and check the solution in both original equations.

D. Solving Systems Using Elimination

Now consider the system $\begin{cases} -2x + 5y = 13 \\ 2x - 3y = -7 \end{cases}$, where solving for any one of the variables will result in fractional values. The substitution method can still be used, but often the **elimination method** is more efficient. The method takes its name from what happens when you add certain equations in a system (by adding the like terms from each). If the coefficients of either x or y are additive inverses—they sum to zero and are *eliminated*. For the system shown, "adding the equations" produces $2y = 6$, giving $y = 3$, then $x = 1$ using back-substitution (verify).

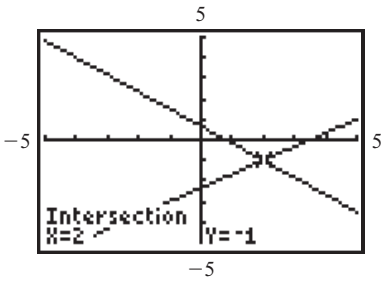
If neither of the like-variable terms sum to zero, we can multiply one or both equations by a nonzero constant to "match up" the coefficients, so an elimination will take place. In doing so, we create an **equivalent system of equations,** meaning one that has the same solution as the original system. For $\begin{cases} 7x - 4y = 16 \\ -3x + 2y = -6 \end{cases}$, multiplying the second equation by 2 produces $\begin{cases} 7x - 4y = 16 \\ -6x + 4y = -12 \end{cases}$, and after adding the equations, we see that $x = 4$. Note the three systems produced are equivalent, and all have (4, 3) as a solution ($y = 3$ was found using back-substitution).

1. $\begin{cases} 7x - 4y = 16 \\ -3x + 2y = -6 \end{cases}$ **2.** $\begin{cases} 7x - 4y = 16 \\ -6x + 4y = -12 \end{cases}$ **3.** $\begin{cases} 7x - 4y = 16 \\ x = 4 \end{cases}$

In summary,

Operations that Produce an Equivalent System

1. Changing the order of the equations.
2. Replacing an equation by a nonzero constant multiple of that equation.
3. Replacing an equation with the sum of two equations from the system.



Before beginning a solution using elimination, check to make sure the equations are written in the **standard form** $Ax + By = C$, so that like terms will appear above/below each other. Throughout this chapter, we will use R1 to represent the equation in *row 1* of the system, R2 to represent the equation in *row 2*, and so on. These designations are used to help describe and document the steps being used to solve a system, as in Example 4 where 2R1 + R2 indicates the first equation has been multiplied by two, with the result added to the second equation.

EXAMPLE 4 ▶ Solving a System by Elimination

Solve using elimination: $\begin{cases} 2x - 3y = 7 \\ 6y + 5x = 4 \end{cases}$

Solution ▶ The second equation is not in standard form, so we rewrite the system as $\begin{cases} 2x - 3y = 7 \\ 5x + 6y = 4 \end{cases}$. If we "added the equations" now, we would get $7x + 3y = 11$, with neither variable eliminated. However, if we multiply *both sides* of the first equation by 2, the y-coefficients will become additive inverses. The sum then results in an equation with x as the only unknown.

$Y_1 = \frac{7 - 2X}{-3}$, $Y_2 = \frac{4 - 5X}{6}$

$$\begin{array}{rl} 2\text{R1} & 4x - 6y = 14 \\ + & \\ \text{R2} & 5x + 6y = 4 \\ \hline \text{sum} & 9x + 0y = 18 \end{array} \quad \text{add}$$

$$9x = 18$$

$$x = 2 \quad \text{solve for } x$$

Substituting 2 for x back into either of the original equations yields $y = -1$. The ordered pair solution is $(2, -1)$. A graphical check is shown in the figure.

Now try Exercises 37 through 42 ▶

The elimination method is summarized here. If either equation has fraction or decimal coefficients, we can "clear" them using an appropriate constant multiplier.

WORTHY OF NOTE

As the elimination method involves adding two equations, it is sometimes referred to as the *addition method* for solving systems.

Solving Systems Using Elimination

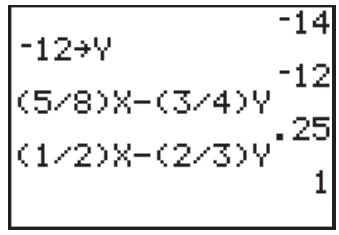
1. Write each equation in standard form: $Ax + By = C$.
2. Multiply one or both equations by a constant that will create coefficients of x (or y) that are additive inverses.
3. Combine the two equations using vertical addition and solve for the variable that remains.
4. Substitute the value from step 3 into either of the original equations and solve for the other unknown.
5. Write the answer as an ordered pair and check the solution in both original equations.

EXAMPLE 5 ▶ **Solving a System Using Elimination**

Solve using elimination: $\begin{cases} \frac{5}{8}x - \frac{3}{4}y = \frac{1}{4} \\ \frac{1}{2}x - \frac{2}{3}y = 1 \end{cases}$.

Solution ▶ Multiplying the first equation by 8 (8R1) and the second equation by 6 (6R2) will clear the fractions from each.

$$\begin{array}{ll} 8\text{R1} & \frac{8}{1}\left(\frac{5}{8}\right)x - \frac{8}{1}\left(\frac{3}{4}\right)y = \frac{8}{1}\left(\frac{1}{4}\right) \\ 6\text{R2} & \frac{6}{1}\left(\frac{1}{2}\right)x - \frac{6}{1}\left(\frac{2}{3}\right)y = 6(1) \end{array} \rightarrow \begin{cases} 5x - 6y = 2 \\ 3x - 4y = 6 \end{cases}$$



The x-terms can now be eliminated if we use $3\text{R1} + (-5\text{R2})$.

$$\begin{array}{rl} 3\text{R1} & 15x - 18y = 6 \\ + & \\ -5\text{R2} & -15x + 20y = -30 \\ \hline \text{sum} & 0x + 2y = -24 \end{array} \quad \text{add}$$

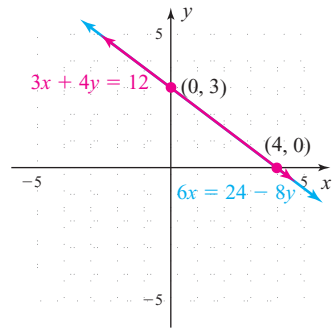
$$y = -12 \quad \text{solve for } y$$

D. You've just seen how we can solve linear systems by elimination

Substituting $y = -12$ in either of the original equations yields $x = -14$, and the solution is $(-14, -12)$. We can check this solution by graphing, as we did for the solution to Example 4, or by substituting the x- and y-values into the original equations, as we did for Example 1. The check using substitution is shown in the figure. Note that -14 STO▸ X has scrolled out of view.

Now try Exercises 43 through 48 ▶

CAUTION ▶ Be sure to multiply *all* terms (on both sides) of the equation when using a constant multiplier. Also, note that for Example 5, we could have eliminated the y-terms using 2R1 with −3R2.



E. Inconsistent and Dependent Systems

A system having *at least one* solution is called a **consistent system.** As seen in Example 2, if the lines have different slopes, they intersect at a single point and the system has exactly one solution. Here, the lines are *independent* of each other and the system is called an **independent system.** If the lines have equal slopes *and* the same y-intercept, they are identical or **coincident lines.** Since one is right atop the other, they *intersect at all points,* and the system has an infinite number of solutions. Here, one line *depends* on the other and the system is called a **dependent system.** Using substitution or elimination on a dependent system results in the elimination of all variable terms and leaves a statement that is *always true,* such as $0 = 0$ or some other simple identity.

EXAMPLE 6 ▶ **Solving a Dependent System**

Solve using elimination: $\begin{cases} 3x + 4y = 12 \\ 6x = 24 - 8y \end{cases}$.

Solution ▶ Writing the system in standard form gives $\begin{cases} 3x + 4y = 12 \\ 6x + 8y = 24 \end{cases}$. By applying −2R1, we can eliminate the variable x:

$$\begin{array}{rl} -2\text{R1} & \left\{\begin{array}{rcl} -6x - 8y & = & -24 \\ 6x + 8y & = & 24 \end{array}\right. \\ + & \\ \text{R2} & \\ \hline \text{sum} & \begin{array}{rcl} 0x + 0y & = & 0 \\ 0 & = & 0 \end{array} \end{array} \quad \begin{array}{l} \text{add} \\ \text{variables are eliminated} \\ \text{true statement} \end{array}$$

Although we didn't expect it, both variables were eliminated and the final statement is true $(0 = 0)$. This indicates the system is dependent, which the graph verifies (the lines are coincident). Writing both equations in slope-intercept form shows they represent the same line.

$$\begin{cases} 3x + 4y = 12 \\ 6x + 8y = 24 \end{cases} \longrightarrow \begin{cases} 4y = -3x + 12 \\ 8y = -6x + 24 \end{cases} \longrightarrow \begin{cases} y = -\frac{3}{4}x + 3 \\ y = -\frac{3}{4}x + 3 \end{cases}$$

WORTHY OF NOTE

When writing the solution to a dependent system using a parameter, the solution can be written in many different ways. For instance, if we let $p = 4b$ for the first coordinate of the solution to Example 6, we have $\frac{-3(4b)}{4} + 3 = -3b + 3$ as the second coordinate, and the solution becomes $(4b, -3b + 3)$ for any constant b.

The solutions of a dependent system are often written in set notation as the set of ordered pairs (x, y), where y is a specified function of x. Here the solution would be $\{(x, y) | y = -\frac{3}{4}x + 3\}$. Using an ordered pair with an arbitrary variable, called a **parameter,** is also common: $\left(p, \frac{-3p}{4} + 3\right)$.

Now try Exercises 49 through 60 ▶

If we had attempted to solve the system in Example 6 by graphing (Figure 9.6), we could be mislead into thinking something is wrong—because only one line is visible (Figure 9.7). In this case, using the **TABLE** feature of the calculator would help verify that the system is dependent. Since the ordered pair solutions are identical (try scrolling through positive and negative values), the equations must be dependent (Figure 9.8).

Figure 9.6

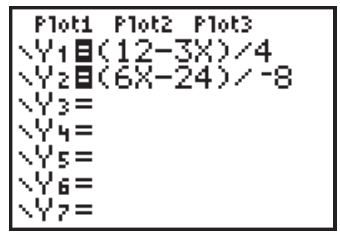


Figure 9.7

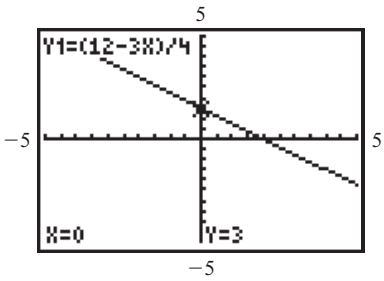

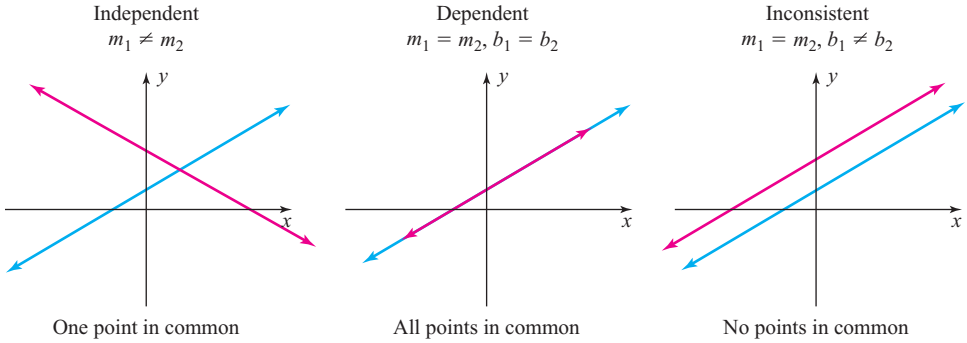

Figure 9.8

X	Y1	Y2
-3	5.25	5.25
-2	4.5	4.5
-1	3.75	3.75
0	3	3
1	2.25	2.25
2	1.5	1.5
3	.75	.75

X=3

Finally, if the lines have equal slopes and *different y-intercepts,* they are parallel and the system will have no solution. A system without a solution is called an **inconsistent system.** An "inconsistent system" produces an "inconsistent answer," such as $12 = 0$ or some other false statement when substitution or elimination is applied. In other words, all variable terms are once again eliminated, but the remaining statement is *false.* A summary of the three possibilities is shown in Figure 9.9 for arbitrary slope m and y-intercept $(0, b)$.

Figure 9.9

☑ **E.** You've just seen how we can recognize inconsistent systems and dependent systems

F. Systems and Modeling

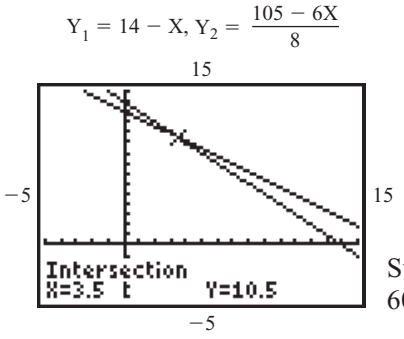
In previous chapters, we solved numerous real-world applications by writing all given relationships in terms of a single variable. Many situations are easier to model using a system of equations with each relationship modeled independently using *two* variables. We begin here with a **mixture** application. Although they appear in many different forms (coin problems, metal alloys, investments, merchandising, and so on), mixture problems all have a similar theme. Generally one equation is related to *quantity* (how much of each item is being combined) and one equation is related to *value* (what is the value of each item being combined).

EXAMPLE 7 ▶ Solving a Mixture Application

A jeweler is commissioned to create a piece of artwork that will weigh 14 oz and consist of 75% gold. She has on hand two alloys that are 60% and 80% gold, respectively. How much of each should she use?

Solution ▶

WORTHY OF NOTE



As an estimation tool, note that if equal amounts of the 60% and 80% alloys were used (7 oz each), the result would be a 70% alloy (halfway in between). Since a 75% alloy is needed, more of the 80% gold will be used.

Let x represent ounces of the 60% alloy and y represent ounces of the 80% alloy. The first equation must be $x + y = 14$, since the piece of art must weigh exactly 14 oz (this is the *quantity* equation). The x ounces are 60% gold, the y ounces are 80% gold, and the 14 oz will be 75% gold. This gives the *value* equation: $0.6x + 0.8y = 0.75(14)$. The system is $\begin{cases} x + y = 14 \\ 6x + 8y = 105 \end{cases}$ (after clearing decimals).

Solving for y in the first equation gives $y = 14 - x$. Substituting $14 - x$ for y in the second equation gives

$$\begin{aligned} 6x + 8y &= 105 && \text{second equation} \\ 6x + 8(14 - x) &= 105 && \text{substitute } 14 - x \text{ for } y \\ 6x + 112 - 8x &= 105 && \text{distribute} \\ -2x + 112 &= 105 && \text{simplify} \\ x &= \frac{7}{2} && \text{solve for } x \end{aligned}$$

Substituting $\frac{7}{2}$ for x in the first equation gives $y = \frac{21}{2}$. She should use 3.5 oz of the 60% alloy and 10.5 oz of the 80% alloy. A graphical check is shown in the figure.

Now try Exercises 63 through 70 ▶

A second example involves an application of uniform motion (distance = rate · time), and explores concepts of great importance to the navigation of ships and airplanes. As a simple illustration, if you've ever walked at your normal rate r on the "moving walkways" at an airport, you likely noticed an increase in your total speed. This is because the resulting speed combines your walking rate r with the speed w of the walkway: *total speed* $= r + w$. If you walk in the opposite direction of the walkway, your total speed is much slower, as now *total speed* $= r - w$.

This same phenomenon is observed when an airplane is flying with or against the wind, or a ship is sailing with or against the current.

EXAMPLE 8 ▶ **Solving an Application of Systems—Uniform Motion**

An airplane flying due south from St. Louis, Missouri, to Baton Rouge, Louisiana, uses a strong, steady tailwind to complete the trip in only 2.5 hr. On the return trip, the same wind slows the flight and it takes 3 hr to get back. If the flight distance between these cities is 912 km, what is the cruising speed of the airplane (speed with no wind)? How fast is the wind blowing?

Solution ▶

Let r represent the rate of the plane and w the rate of the wind. Since $D = RT$, the flight to Baton Rouge can be modeled by $912 = (r + w)(2.5)$, and the return flight by $912 = (r - w)(3)$. This produces the system $\begin{cases} 912 = 2.5r + 2.5w \\ 912 = 3r - 3w \end{cases}$.

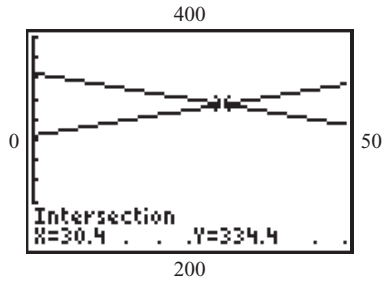
▼ Algebraic Solution

Dividing R1 by 2.5 and R2 by 3 produces the following sequence:

$$\begin{matrix} \frac{R1}{2.5} \\ \frac{R2}{3} \end{matrix} \begin{cases} 912 = 2.5r + 2.5w \\ 912 = 3r - 3w \end{cases} \rightarrow \begin{cases} 364.8 = r + w \\ 304.0 = r - w \end{cases}$$

▼ Graphical Solution

Using x for w and y for r, we solve each equation for y and obtain:



$$Y_1 = \frac{912 - 2.5X}{2.5} \qquad Y_2 = \frac{912 + 3X}{3}$$

Using R1 + R2 gives $668.8 = 2r$, showing $334.4 = r$. The speed of the plane is 334.4 kph. Substituting 334.4 for r in the second equation, we have:

$$\begin{aligned} 912 &= 3r - 3w && \text{equation} \\ 912 &= 3(334.4) - 3w && \text{substitute} \\ 912 &= 1003.2 - 3w && \text{multiply} \\ -91.2 &= -3w && \text{subtract 1003.2} \\ 30.4 &= w && \text{divide by } -3 \end{aligned}$$

The speed of the wind is 30.4 kph.

We then set an appropriate window and graph these equations to find the point of intersection.

The speed of the wind (x) is 30.4 kph, and the speed of the plane (y) is 334.4 kph.

Now try Exercises 71 through 74 ▶

Systems of equations also play a significant role in *cost-based pricing* in the business world. The costs involved in running a business can broadly be understood as either a **fixed cost** ***k*** or a **variable cost** ***v.*** Fixed costs might include the monthly rent paid for facilities, which remains the same regardless of how many items are produced and sold. Variable costs would include the cost of materials needed to produce the item, which depends on the number of items made. The total cost can then be modeled by $C(x) = vx + k$ for x number of items. Once a **selling price** ***p*** has been determined, the revenue equation is simply $R(x) = px$ (price times number of items sold). We can now set up and solve a system of equations that will determine how many items must be sold to break even, performing what is called a **break-even analysis** where $C(x) = R(x)$.

EXAMPLE 9 ▶ Solving an Application of Systems: Break-Even Analysis

In home businesses that produce items to sell on Ebay®, fixed costs are easily determined by rent and utilities, and variable costs by the price of materials needed to produce the item. Karen's home business makes large decorative candles for all occasions. The cost of materials is $3.50 per candle, and her rent and utilities average $900 per month. If her candles sell for $9.50, how many candles must be sold each month to break even?

Solution ▶ Let x represent the number of candles sold. Her total cost is $C(x) = 3.5x + 900$ (variable cost plus fixed cost), and projected revenue is $R(x) = 9.5x$. This gives the system $\begin{cases} C(x) = 3.5x + 900 \\ R(x) = 9.5x \end{cases}$. To break even, *Cost* = *Revenue* which gives

$$\begin{aligned} 9.5x &= 3.5x + 900 \\ 6x &= 900 \\ x &= 150 \end{aligned}$$

The analysis shows that Karen must sell 150 candles each month to break even.

Now try Exercises 75 through 78 ▶

WORTHY OF NOTE

There are limitations to this model, and this interplay can be affected by the number of available consumers, production limits, "shelf-life" issues, and so on, but at any given moment in the life cycle of a product, consumer demand responds to price in this way. Producers also respond to price in a very predictable way.

In a "free-market" economy, also referred to as a "supply-and-demand" economy, there are naturally occurring forces that invariably come into play if no outside forces act on the producers (suppliers) and consumers (demanders). Generally speaking, the higher the price of an item, the lower the demand. A good advertising campaign can increase the demand, but the increasing demand brings an increase in price, which moderates the demand—and so it goes until a balance is reached. These free-market forces ebb and flow until **market equilibrium** occurs, at the specific price where the supply and demand are equal.

In **Exercises 75 to 78,** the equation models were artificially constructed to yield a "nice" solution. In actual practice, the equations and coefficients are not so "well behaved" and are based on the collection and interpretation of real data. While market analysts have sophisticated programs and numerous models to help develop these equations, here we'll use our experience with regression to develop the supply and demand curves.

EXAMPLE 10 ▶ Using Technology to Find Market Equilibrium

A manufacturer of MP3 players has hired a consulting firm to do market research on their "next-generation" player. Over a 10-week period, the firm collected the data shown for the MP3 player market (data includes MP3 players sold and expected to sell).

Price (dollars)	Demand	Supply (Inventory)
107.10	6900	12,200
85.50	7900	9900
64.80	13,200	8000
52.20	13,500	7900
108.00	6700	14,000
91.80	7600	12,000
77.40	9200	9400
46.80	13,800	6100
74.70	10,600	8800
68.40	12,800	8600

a. Use a graphing calculator to simultaneously display the demand and supply scatterplots.

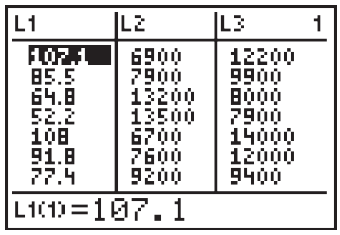
b. Calculate a line of best fit for each and graph them with the scatterplots (identify each curve).

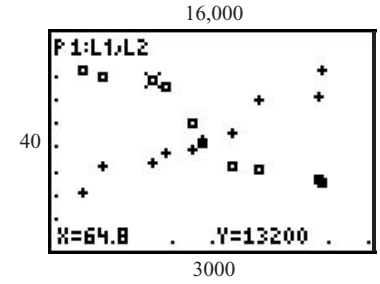
c. Find the equilibrium point.

Solution ▶

a. Begin by clearing all lists. This can be done manually, or by pressing 2nd + **(MEM)** and selecting option **4:ClrAllLists** (the command appears on the home screen). Pressing ENTER will execute the command, and the word DONE will appear. Carefully input price in L1, demand in L2, and supply in L3 (see Figure 9.10). With the window settings given in Figure 9.11, pressing GRAPH will display the price/demand and price/supply scatterplots shown. If this is not the case, use 2nd Y= **(STAT PLOT)** to be sure that "On" is highlighted in Plot1 and Plot2, and that Plot1 uses L1 and L2, while Plot2 uses L1 and L3 (Figure 9.12). Note we've chosen a different mark to indicate the data points in Plot2.

Figure 9.10





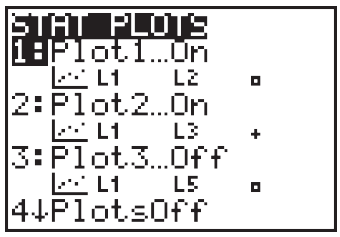


Figure 9.11

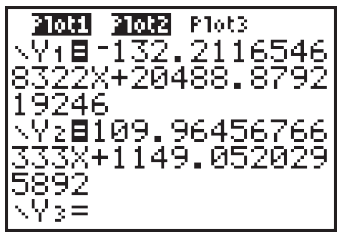
b. Calculate the linear regression equation for L1 and L2 (demand), and paste it in Y_1: **LinReg (ax + b) L1, L2, Y_1** ENTER. Next, calculate the linear regression for L1 and L3 (supply) and paste it in Y_2: **LinReg (ax + b) L1, L3, Y_2** ENTER (recall that Y_1 and Y_2 are accessed using the VARS key). The resulting equations and graphs are shown in Figures 9.13 and 9.14.

Figure 9.12

c. Once again we use 2nd TRACE **(CALC) 5:intersect** to find the equilibrium point, which is approximately (80, 9931). Supply and demand for this MP3 player model are approximately equal at a price of about $80, with 9931 MP3 players bought and sold.

Figure 9.13



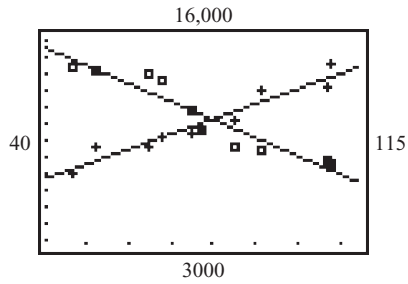


Figure 9.14

Now try Exercises 79 through 82 ▶

☑ **F.** You've just seen how we can use a system of equations to model and solve applications

Other interesting applications can be found in the Exercise Set. **See Exercises 83 through 88.**

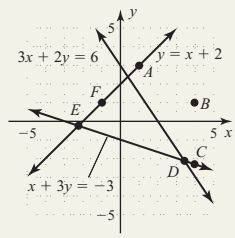
9.1 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. Systems that have no solution are called _____ systems.
2. Systems having at least one solution are called _____ systems.
3. If the lines in a system intersect at a single point, the system is said to be _____ and _____.
4. If the lines in a system are coincident, the system is referred to as _____ and _____.
5. The given systems are equivalent. How do we obtain the second system from the first?

$$\begin{cases} \frac{2}{3}x + \frac{1}{2}y = \frac{5}{3} \\ 0.2x + 0.4y = 1 \end{cases} \qquad \begin{cases} 4x + 3y = 10 \\ 2x + 4y = 10 \end{cases}$$



6. For $\begin{cases} 2x + 5y = 8 \\ 3x + 4y = 5 \end{cases}$, which solution method would be more efficient, substitution or elimination? Discuss/Explain why.

▶ DEVELOPING YOUR SKILLS

Show the lines in each system would intersect in a single point by writing the equations in slope-intercept form.

7. $\begin{cases} 7x - 4y = 24 \\ 4x + 3y = 15 \end{cases}$
8. $\begin{cases} 0.3x - 0.4y = 2 \\ 0.5x + 0.2y = -4 \end{cases}$

An ordered pair is a solution to an equation if it makes the equation true. Given the graph shown here, determine which equation(s) have the indicated point as a solution. If the point satisfies more than one equation, write the system for which it is a solution.

9. *A*
10. *B*
11. *C*
12. *D*
13. *E*
14. *F*

Substitute the *x*- and *y*-values indicated by the ordered pair to determine if it is a solution to the system. Also check using the ALPHA keys on the home screen of a graphing calculator.

15. $\begin{cases} 3x + y = 11 \\ -5x + y = -13; \end{cases} (3, 2)$
16. $\begin{cases} 3x + 7y = -4 \\ 7x + 8y = -21; \end{cases} (-6, 2)$
17. $\begin{cases} 8x - 24y = -17 \\ 12x + 30y = 2; \end{cases} \left(-\frac{7}{8}, \frac{5}{12}\right)$

18. $\begin{cases} 4x + 15y = 7 \\ 8x + 21y = 11; \end{cases} \left(\frac{1}{2}, \frac{1}{3}\right)$

Solve each system by *graphing* manually. Check results by graphing the system on a graphing calculator, and locating any points of intersection.

19. $\begin{cases} 3x + 2y = 12 \\ x - y = 9 \end{cases}$

20. $\begin{cases} 5x + 2y = -2 \\ -3x + y = 10 \end{cases}$

21. $\begin{cases} 5x - 2y = 5 \\ x + 3y = -16 \end{cases}$

22. $\begin{cases} 3x + y = -2 \\ 5x + 3y = 2 \end{cases}$

Solve each system using *substitution.* Write solutions as an ordered pair, and verify solutions using a graphing calculator.

23. $\begin{cases} x = 5y - 9 \\ x - 2y = -6 \end{cases}$

24. $\begin{cases} 4x - 5y = 7 \\ 2x - 5 = y \end{cases}$

25. $\begin{cases} y = \frac{2}{3}x - 7 \\ 3x - 2y = 19 \end{cases}$

26. $\begin{cases} 2x - y = 6 \\ y = \frac{3}{4}x - 1 \end{cases}$

Identify the equation and variable that makes the substitution method easiest to use, then solve the system. Verify solutions using a graphing calculator.

27. $\begin{cases} 3x - 4y = 24 \\ 5x + y = 17 \end{cases}$

28. $\begin{cases} 3x + 2y = 19 \\ x - 4y = -3 \end{cases}$

29. $\begin{cases} 0.7x + 2y = 5 \\ x - 1.4y = 11.4 \end{cases}$

30. $\begin{cases} 0.8x + y = 7.4 \\ 0.6x + 1.5y = 9.3 \end{cases}$

31. $\begin{cases} 5x - 6y = 2 \\ x + 2y = 6 \end{cases}$

32. $\begin{cases} 2x + 5y = 5 \\ 8x - y = 6 \end{cases}$

The substitution method can be used for like variables *or for like expressions.* Solve the following systems, *using the expression* common to both equations (do not solve for *x* or *y* alone).

33. $\begin{cases} 2x + 4y = 6 \\ x + 12 = 4y \end{cases}$

34. $\begin{cases} 8x = 3y + 24 \\ 8x - 5y = 36 \end{cases}$

35. $\begin{cases} 5x - 11y = 21 \\ 11y = 5 - 8x \end{cases}$

36. $\begin{cases} -6x = 5y - 16 \\ 5y - 6x = 4 \end{cases}$

Solve using *elimination.* In some cases, the system must first be written in standard form. Verify solutions using a graphing calculator.

37. $\begin{cases} 2x - 4y = 10 \\ 3x + 4y = 5 \end{cases}$

38. $\begin{cases} -x + 5y = 8 \\ x + 2y = 6 \end{cases}$

39. $\begin{cases} 4x - 3y = 1 \\ 3y = -5x - 19 \end{cases}$

40. $\begin{cases} 5y - 3x = -5 \\ 3x + 2y = 19 \end{cases}$

41. $\begin{cases} 2x = -3y + 17 \\ 4x - 5y = 12 \end{cases}$

42. $\begin{cases} 2y = 5x + 2 \\ -4x = 17 - 6y \end{cases}$

43. $\begin{cases} 0.5x + 0.4y = 0.2 \\ 0.3y = 1.3 + 0.2x \end{cases}$

44. $\begin{cases} 0.2x + 0.3y = 0.8 \\ 0.3x + 0.4y = 1.3 \end{cases}$

45. $\begin{cases} 0.32m - 0.12n = -1.44 \\ -0.24m + 0.08n = 1.04 \end{cases}$

46. $\begin{cases} 0.06g - 0.35h = -0.67 \\ -0.12g + 0.25h = 0.44 \end{cases}$

47. $\begin{cases} -\frac{1}{6}u + \frac{1}{4}v = 4 \\ \frac{1}{2}u - \frac{2}{3}v = -11 \end{cases}$

48. $\begin{cases} \frac{3}{4}x + \frac{1}{3}y = -2 \\ \frac{3}{2}x + \frac{1}{5}y = 3 \end{cases}$

Solve using any method and identify the system as consistent, inconsistent, or dependent. Verify solutions using a graphing calculator.

49. $\begin{cases} 4x + \frac{3}{4}y = 14 \\ -9x + \frac{5}{8}y = -13 \end{cases}$

50. $\begin{cases} \frac{2}{3}x + y = 2 \\ 2y = \frac{5}{6}x - 9 \end{cases}$

51. $\begin{cases} 0.2y = 0.3x + 4 \\ 0.6x - 0.4y = -1 \end{cases}$

52. $\begin{cases} 1.2x + 0.4y = 5 \\ 0.5y = -1.5x + 2 \end{cases}$

53. $\begin{cases} 6x - 22 = -y \\ 3x + \frac{1}{2}y = 11 \end{cases}$

54. $\begin{cases} 15 - 5y = -9x \\ -3x + \frac{5}{3}y = 5 \end{cases}$

55. $\begin{cases} -10x + 35y = -5 \\ y = 0.25x \end{cases}$

56. $\begin{cases} 2x + 3y = 4 \\ x = -2.5y \end{cases}$

57. $\begin{cases} 7a + b = -25 \\ 2a - 5b = 14 \end{cases}$

58. $\begin{cases} -2m + 3n = -1 \\ 5m - 6n = 4 \end{cases}$

59. $\begin{cases} 4a = 2 - 3b \\ 6b + 2a = 7 \end{cases}$

60. $\begin{cases} 3p - 2q = 4 \\ 9p + 4q = -3 \end{cases}$

▶ WORKING WITH FORMULAS

61. Uniform motion with current: $\begin{cases} (R + C)T_1 = D_1 \\ (R - C)T_2 = D_2 \end{cases}$

The formula shown can be used to solve uniform motion problems involving a *current,* where D represents distance traveled, R is the rate of the object with no current, C is the speed of the current, and T is the time. Chan-Li rows 9 mi up river (against the current) in 3 hr. It only took him 1 hr to row 5 mi downstream (with the current). How fast was the current? How fast can he row in still water?

62. Fahrenheit and Celsius temperatures: $\begin{cases} y = \frac{9}{5}x + 32 & °\text{F} \\ y = \frac{5}{9}(x - 32) & °\text{C} \end{cases}$

Many people are familiar with temperature measurement in degrees Celsius and degrees Fahrenheit, but few realize that the equations are linear and there is one temperature at which the two scales agree. Solve the system using the method of your choice and find this temperature.

▶ APPLICATIONS

Solve each application by modeling the situation with a linear system. Be sure to clearly indicate what each variable represents. Check answers using a graphing calculator and the method of your choice.

Mixture

63. Theater productions: At a recent production of *A Comedy of Errors,* the Community Theater brought in a total of $30,495 in revenue. If adult tickets were $9 and children's tickets were $6.50, how many tickets of each type were sold if 3800 tickets in all were sold?

64. Milkfat requirements: A dietician needs to mix 10 gal of milk that is $2\frac{1}{2}$% milkfat for the day's rounds. He has some milk that is 4% milkfat and some that is $1\frac{1}{2}$% milkfat. How much of each should be used?

65. Filling the family cars: Cherokee just filled both of the family vehicles at a service station. The total cost for 20 gal of regular unleaded and 17 gal of premium unleaded was $144.89. The premium gas was $0.10 more per gallon than the regular gas. Find the price per gallon for each type of gasoline.

66. Household cleaners: As a cleaning agent, a solution that is 24% vinegar is often used. How much pure (100%) vinegar and 5% vinegar must be mixed to obtain 50 oz of a 24% solution?

67. Alumni contributions: A wealthy alumnus donated $10,000 to his alma mater. The college used the funds to make a loan to a science major at 7% interest and a loan to a nursing student at 6% interest. That year the college earned $635 in interest. How much was loaned to each student?

68. Investing in bonds: A total of $12,000 is invested in two municipal bonds, one paying 10.5% and the other 12% simple interest. Last year the annual interest earned on the two investments was $1335. How much was invested at each rate?

69. Saving money: Bryan has been doing odd jobs around the house, trying to earn enough money to buy a new Dirt-Surfer©. He saves all quarters and dimes in his piggy bank, while he places all nickels and pennies in a drawer to spend. So far, he has 225 coins in the piggy bank, worth a total of $45.00. How many of the coins are quarters? How many are dimes?

70. Coin investments: In 1990, Molly attended a coin auction and purchased some rare "Flowing Hair" fifty-cent pieces, and a number of very rare two-cent pieces from the Civil War Era. If she bought 47 coins with a face value of $10.06, how many of each denomination did she buy?

Uniform Motion

71. Canoeing on a stream: On a recent camping trip, it took Molly and Sharon 2 hr to row 4 mi upstream from the drop in point to the campsite. After a leisurely weekend of camping, fishing, and relaxation, they rowed back downstream to the drop in point in just 30 min. Use this information to find (a) the speed of the current and (b) the speed Sharon and Molly would be rowing in still water.

72. Taking a luxury cruise: A luxury ship is taking a Caribbean cruise from Caracas, Venezuela, to just off the coast of Belize City on the Yucatan Peninsula, a distance of 1435 mi. En route they encounter the Caribbean Current, which flows to the northwest, parallel to the coastline. From Caracas to the Belize coast, the trip took 70 hr. After a few days of fun in the sun, the ship leaves for Caracas, with the return trip taking 82 hr. Use this information to find (a) the speed of the Caribbean Current and (b) the cruising speed of the ship.

73. Airport walkways: As part of an algebra field trip, Jason takes his class to the airport to use their moving walkways for a demonstration. The class measures the longest walkway, which turns out to be 256 ft long. Using a stop watch, Jason shows it takes him just 32 sec to complete the walk going in the same direction as the walkway. Walking in a direction opposite the walkway, it takes him 320 sec—10 times as long! The next day in class, Jason hands out a two-question quiz: (1) What was the speed of the walkway in feet per second? (2) What is my (Jason's) normal walking speed? Create the answer key for this quiz.

74. Racing pigeons: The American Racing Pigeon Union often sponsors opportunities for owners to fly their birds in friendly competitions. During a recent competition, Steve's birds were liberated in Topeka, Kansas, and headed almost due north to their loft in Sioux Falls, South Dakota, a distance of 308 mi. During the flight, they encountered a steady wind from the north and the trip took 4.4 hr. The next month, Steve took his birds to a competition in Grand Forks, North Dakota, with the birds heading almost due south to home, also a distance of 308 mi. This time the birds were aided by the same wind from the north, and the trip took only 3.5 hr. Use this information to (a) find the racing speed of Steve's birds and (b) find the speed of the wind.

75. Lawn service: Dave and his sons run a lawn service, which includes mowing, edging, trimming, and aerating lawns. His fixed cost includes insurance, his salary, and monthly payments on equipment, and amounts to $4000/mo. The variable costs include gas, oil, hourly wages for his employees, and miscellaneous expenses, which run about $75 per lawn. The average charge for full-service lawn care is $115 per visit. Do a break-even analysis to (a) determine how many lawns Dave must service each month to break even and (b) the revenue required to break even.

76. Production of mini-microwave ovens: Due to high market demand, a manufacturer decides to introduce a new line of mini-microwave ovens for personal and office use. By using existing factory space and retraining some employees, fixed costs are estimated at $8400/mo. The components to assemble and test each microwave are expected to run $45 per unit. If market research shows consumers are willing to pay at least $69 for this product, find (a) how many units must be made and sold each month to break even and (b) the revenue required to break even.

77. Farm commodities: One area where the law of supply and demand is clearly at work is farm commodities. Both growers and consumers watch this relationship closely, and use data collected by government agencies to track the relationship and make adjustments, as when a farmer decides to convert a large portion of her farmland from corn to soybeans to improve profits. Suppose that for x billion bushels of soybeans, supply is modeled by $y = 1.5x + 3$, where y is the current market price (in dollars per bushel). The related demand equation might be $y = -2.20x + 12$. (a) How many billion bushels will be supplied at a market price of $5.40? What will the demand be at this price? Is supply less than demand? (b) How many billion bushels will be supplied at a market price of $7.05? What will the demand be at this price? Is demand less than supply? (c) To the nearest cent, at what price does the market reach equilibrium? How many bushels are being supplied/demanded?

78. Digital media: Market research has indicated that by 2015, sales of MP3 players and similar products will mushroom into a $70 billion dollar market. With a market this large, competition is often fierce—with suppliers fighting to earn and hold market shares. For x million MP3 players sold, supply is modeled by $y = 10.5x + 25$, where y is the current market price (in dollars). The related demand equation might be $y = -5.20x + 140$. (a) How many million MP3 players will be supplied at a market price of $88? What will the demand be at this price? Is supply less than demand? (b) How many million MP3 players will be supplied at a market price of $114? What will the demand be at this price? Is demand less than supply? (c) To the nearest cent, at what price does the market reach equilibrium? How many units are being supplied/demanded?

79. Pricing wakeboards: A water sports company that manufactures high-end wakeboards has hired an outside consulting firm to do some market research on their best wakeboard. This consulting firm collected the following supply and demand data for this and comparable wakeboards over a 10-week period. Find the equilibrium point. Round your answer to the nearest integer and dollar.

Average Price (in U.S. dollars)	Quantity Demanded	Available Inventory
424.85	175	232
445.25	166	247
389.55	291	215
349.98	391	201
402.22	218	226
413.87	200	222
481.73	139	251
419.45	177	235
397.05	220	219
361.90	317	212

80. Pricing pet care products: A metal shop that manufactures pens for pet rabbits has collected some data on sales and production over the past 8 weeks. The following table shows the supply and demand data for these pens. Find the equilibrium point (round to the nearest cent and whole cage).

Average Price (in U.S. dollars)	Quantity Sold (Demand)	Production (Supply)
22.99	12	7
21.49	14	6
23.99	11	7
26.99	9	11
25.99	8	10
27.99	8	13
24.49	10	9
26.49	9	11

81. Tracking supply and demand—oil products: The U.S. Bureau of Labor and Statistics tracks important data from many different markets. In May 2008, it collected the following supply-and-demand data for refined gasoline. Data were collected every Tuesday and Friday. Find the equilibrium point, rounding your answer to the nearest hundred thousand gallons and whole cent.

Average Price (in U.S. dollars)	Quantity Demanded (1×10^7 gal)	Available Inventory (1×10^7 gal)
3.17	8.82	9.10
3.12	8.87	9.05
3.04	9.08	8.97
2.84	9.22	8.91
3.11	8.92	9.02
3.15	8.76	9.08
3.10	9.01	8.99
3.11	8.94	9.01
2.93	9.13	8.93

82. Tracking supply and demand—energy efficient lightbulbs: The U.S. Bureau of Labor and Statistics has collected the following supply and demand data for the energy-efficient fluorescent lightbulbs sold each month for the past year. Find the equilibrium point, rounding your answer to the nearest ten thousand lightbulbs and whole cent. What is the yearly demand at the equilibrium point?

Average Price (in U.S. dollars)	Quantity Demanded (in millions)	Available Inventory (in millions)
9.40	0.84	1.23
8.51	1.17	0.95
8.78	1.05	1.11
10.82	0.68	1.29
6.77	1.47	0.77
9.33	0.91	1.21
8.34	1.25	0.88
10.37	0.76	1.27
8.62	1.09	1.02
8.44	1.21	0.92
8.58	1.18	0.97
8.96	1.01	1.17

Descriptive Translation

83. Important dates in U.S. history: If you sum the year that the Declaration of Independence was signed and the year that the Civil War ended, you get 3641. There are 89 yr that separate the two events. What year was the Declaration signed? What year did the Civil War end?

84. Architectural wonders: When it was first constructed in 1889, the Eiffel Tower in Paris, France, was the tallest structure in the world. In 1975, the CN Tower in Toronto, Canada, became the world's tallest structure. The CN Tower is 153 ft less than twice the height of the Eiffel Tower, and the sum of their heights is 2799 ft. How tall is each tower?

85. Pacific islands land area: In the South Pacific, the island nations of Tahiti and Tonga have a combined land area of 692 mi^2. Tahiti's land area is 112 mi^2 more than Tonga's. What is the land area of each island group?

86. Card games: On a cold winter night, in the lobby of a beautiful hotel in Sante Fe, New Mexico, Marc and Klay just barely beat John and Steve in a close game of Trumps. If the sum of the team scores was 990 points, and there was a 12-point margin of victory, what was the final score?

Given any two points, the equation of a line through these points can be found using a system of equations. While there are certainly more efficient methods, using a system here will lead to finding equations for polynomials of higher degree. The key is to note that each point will yield an equation of the form $y = mx + b$. For instance, the points (3, 6) and $(-2, -4)$ yield the system $\begin{cases} 6 = 3m + b \\ -4 = -2m + b \end{cases}$.

87. Use a system of equations to find the equation of the line containing the points (2, 7) and $(-4, -5)$.

88. Use a system of equations to find the equation of the line containing the points $(9, -1)$ and $(-3, 7)$.

▶ EXTENDING THE CONCEPT

89. Federal income tax reform has been a hot political topic for many years. Suppose tax plan A calls for a flat tax of 20% tax on all income (no deductions or loopholes). Tax plan B requires taxpayers to pay $5000 plus 10% of all income. For what income level do both plans require the same tax?

90. Suppose a certain amount of money was invested at 6% per year, and another amount at 8.5% per year, with a total return of $1250. If the amounts invested at each rate were switched, the yearly income would have been $1375. To the nearest whole dollar, how much was invested at each rate?

▶ MAINTAINING YOUR SKILLS

91. (2.2) Given the toolbox function $f(x) = |x|$, sketch the graph of $F(x) = -|x + 3| - 2$.

92. (6.1) Find two positive and two negative angles that are coterminal with $\theta = 112°$.

93. (5.5) Solve for x (rounded to the nearest thousandth): $33 = 77.5e^{-0.0052x} - 8.37$

94. (7.2) Verify that $\dfrac{\sin x - \csc x}{\csc x} = -\cos^2 x$ is an identity.

9.2 Linear Systems in Three Variables with Applications

LEARNING OBJECTIVES

In Section 9.2 you will see how we can:

- ❑ **A.** Visualize a solution in three dimensions
- ❑ **B.** Check ordered triple solutions
- ❑ **C.** Solve linear systems in three variables
- ❑ **D.** Recognize inconsistent and dependent systems
- ❑ **E.** Use a system of three equations in three variables to solve applications

The transition to systems of three equations in three variables requires a fair amount of "visual gymnastics" along with good organizational skills. Although the techniques used are identical and similar results are obtained, the third equation and variable give us more to track, and we must work more carefully toward the solution.

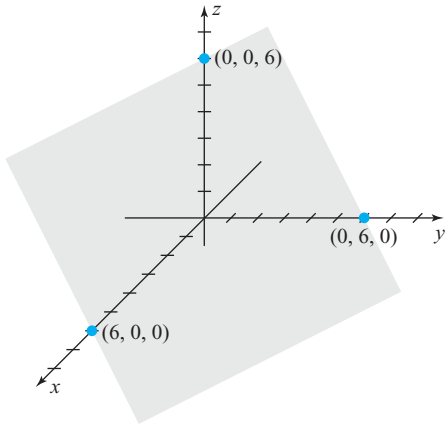
A. Visualizing Solutions in Three Dimensions

The solution to an equation in one variable is the single number that satisfies the equation. For $x + 1 = 3$, the solution is $x = 2$ and its graph is a single *point* on the number line, a **one-dimensional graph.** The solution to an equation in two variables, such as $x + y = 3$, is an ordered pair (x, y) that satisfies the equation. When we graph this solution set, the result is a *line* on the xy-coordinate grid, a **two-dimensional graph.** The solutions to an equation in three variables, such as $x + y + z = 6$, are the **ordered triples** (x, y, z) that satisfy the equation. When we graph this solution set, the result is a **plane** in **space,** a *graph in three dimensions.* Recall a plane is a flat surface having infinite length and width, but no depth. We can graph this plane using the intercept method and the result is shown in Figure 9.15. For graphs in three dimensions, the xy-plane is parallel to the ground (the y-axis points to the right) and z is the **vertical axis.** To find an additional point on this plane, we use any three numbers whose sum is 6, such as (2, 3, 1). Move 2 units along the x-axis, 3 units parallel to the y-axis, and 1 unit parallel to the z-axis, as shown in Figure 9.16.

WORTHY OF NOTE

We can visualize the location of a point in space by considering a large rectangular box 2 ft long × 3 ft wide × 1 ft tall, placed snugly in the corner of a room. The floor is the *xy*-plane, one wall is the *xz*-plane, and the other wall is the *yz*-plane. The *z*-axis is formed where the two walls meet and the corner of the room is the origin (0, 0, 0). To find the corner of the box located at (2, 3, 1), first locate the point (2, 3) in the *xy*-plane (the floor), then move up 1 ft.

Figure 9.15



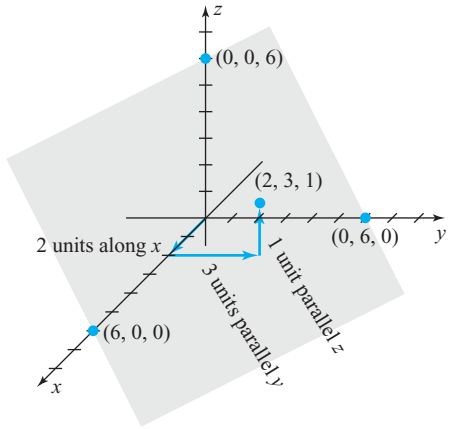


Figure 9.16

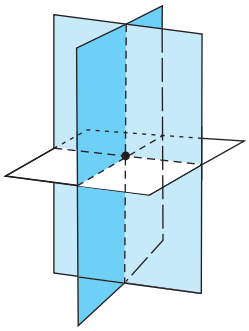
EXAMPLE 1 ▶ **Finding Solutions to an Equation in Three Variables**

Use a guess-and-check method to find four additional points on the plane determined by $x + y + z = 6$.

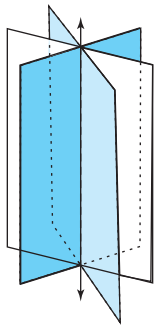
Solution ▶ We can begin by letting $x = 0$, then use any combination of y and z that sum to 6. Two examples are (0, 2, 4) and (0, 5, 1). We could also select any two values for x and y, then determine a value for z that results in a sum of 6. Two examples are $(-2, 9, -1)$ and $(8, -3, 1)$.



A. You've just seen how we can visualize a solution in three dimensions

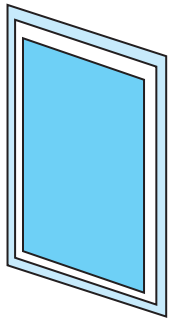
Now try Exercises 7 through 10 ▶

B. Solutions to a System of Three Equations in Three Variables



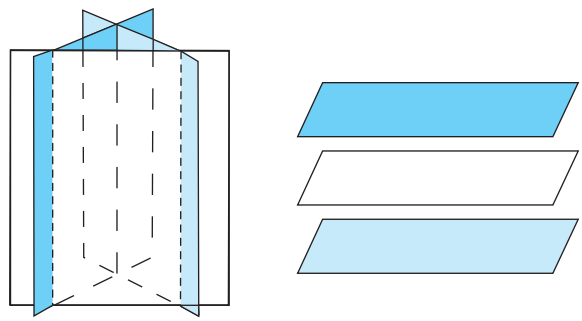
When solving a system of three equations in three variables, remember each equation represents a plane in space. These planes can intersect in various ways, creating different possibilities for a solution set (see Figures 9.17 to 9.20). The system could have a **unique solution** (a, b, c), if the planes intersect at a single point (Figure 9.17) (the point satisfies all three equations simultaneously). If the planes intersect in a line (Figure 9.18), the system is **linearly dependent** and there is an infinite number of solutions. Unlike the two-dimensional case, the equation of a line in three dimensions is somewhat complex, and the coordinates of all points on this line are usually *represented* by a specialized ordered triple, which we use to state the solution set. If the planes intersect at all points, the system has **coincident dependence** (see Figure 9.19). This indicates the equations of the system differ by only a constant multiple—they are all "disguised forms" of the *same equation*. The solution set is any ordered triple (a, b, c) satisfying this equation. Finally, the system may have no solutions. This can happen a number of different ways, most notably if the planes either intersect or are parallel, as shown in Figure 9.20 (other possibilities are discussed in the exercises). In the case of "no solutions," an ordered triple may satisfy none of the equations, only one of the equations, only two of the equations, but not all three equations.

Figure 9.17



Unique solution

Figure 9.18



Linear dependence

Figure 9.19

Coincident dependence

Figure 9.20

No solutions

EXAMPLE 2 ▶ **Determining If an Ordered Triple Is a Solution**

Determine if the ordered triple $(1, -2, 3)$ is a solution to the systems shown.

a. $\begin{cases} x + 4y - z = -10 \\ 2x + 5y + 8z = 4 \\ x - 2y - 3z = -4 \end{cases}$ **b.** $\begin{cases} 3x + 2y - z = -4 \\ 2x - 3y - 2z = 2 \\ x - y + 2z = 9 \end{cases}$

Solution ▶ Substitute 1 for x, -2 for y, and 3 for z in the first system.

a. $\begin{cases} x + 4y - z = -10 \\ 2x + 5y + 8z = 4 \\ x - 2y - 3z = -4 \end{cases} \rightarrow \begin{cases} (1) + 4(-2) - (3) = -10 \\ 2(1) + 5(-2) + 8(3) = 4 \\ (1) - 2(-2) - 3(3) = -4 \end{cases} \rightarrow \begin{cases} -10 = -10 \text{ true} \\ 16 = 4 \text{ false} \\ -4 = -4 \text{ true} \end{cases}$

No, the ordered triple $(1, -2, 3)$ is not a solution to the first system. Now use the same substitutions in the second system.

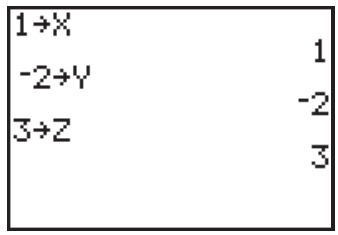
b. $\begin{cases} 3x + 2y - z = -4 \\ 2x - 3y - 2z = 2 \\ x - y + 2z = 9 \end{cases} \rightarrow \begin{cases} 3(1) + 2(-2) - (3) = -4 \\ 2(1) - 3(-2) - 2(3) = 2 \\ (1) - (-2) + 2(3) = 9 \end{cases} \rightarrow \begin{cases} -4 = -4 \text{ true} \\ 2 = 2 \text{ true} \\ 9 = 9 \text{ true} \end{cases}$

The ordered triple $(1, -2, 3)$ is a solution to the second system only.

Now try Exercises 11 and 12 ▶

As with systems of two equations in two variables, solutions to larger systems can also be checked by storing values using the ALPHA keys, and entering each equation on the home screen of a graphing calculator. The screens shown in Figures 9.21 and 9.22 illustrate this process for Example 2(b).

Figure 9.21



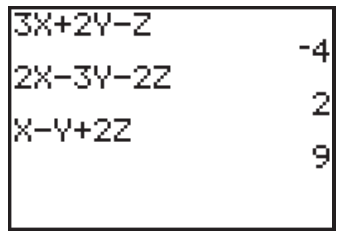


Figure 9.22

☑ **B.** You've just seen how we can check ordered triple solutions

C. Solving Systems of Three Equations in Three Variables Using Elimination

From Section 9.1, we know that two systems of equations are **equivalent** if they have the same solution set. The systems

$$\begin{cases} 2x + y - 2z = -7 \\ x + y + z = -1 \\ -2y - z = -3 \end{cases} \quad \text{and} \quad \begin{cases} 2x + y - 2z = -7 \\ y + 4z = 5 \\ z = 1 \end{cases}$$

are equivalent, as both have the unique solution $(-3, 1, 1)$. In addition, it is evident that the second system can be solved more easily, since R2 and R3 have fewer variables than the first system. In the simpler system, mentally substituting 1 for z into R2 immediately gives $y = 1$, and these values can be back-substituted into the first equation to find that $x = -3$. This observation guides us to a general approach for solving larger systems—we would like to *eliminate variables in the second and third equations, until we obtain an equivalent system that can easily be solved by back-substitution.* To begin, let's review the three operations that "transform" a given system, and produce an equivalent system.

Operations That Produce an Equivalent System

1. Changing the order of the equations.
2. Replacing an equation by a nonzero constant multiple of that equation.
3. Replacing an equation with the sum of two equations from the system.

Building on the ideas from Section 9.1, we develop the following approach for solving a system of three equations in three variables.

Solving a System of Three Equations in Three Variables

1. Write each equation in standard form: $Ax + By + Cz = D$.
2. If the "x" term in any equation has a coefficient of 1, interchange equations (if necessary) so this equation becomes R1.
3. Use the x-term in R1 to eliminate the x-terms from R2 and R3. The original R1, with the new R2 and R3, form an equivalent system that contains a smaller "subsystem" of two equations in two variables.
4. Solve the subsystem for either x or y and keep the result as the new R3. The result is an equivalent system that can be solved using back-substitution.

We'll begin by solving the system $\begin{cases} 2x + y - 2z = -7 \\ x + y + z = -1 \\ -2y - z = -3 \end{cases}$ using the elimination method and the procedure outlined. In Example 3, the notation $-2\text{R1} + \text{R2} \rightarrow \text{R2}$ indicates the equation in row 1 has been multiplied by -2 and added to the equation in row 2, with the result placed in the system as the new row 2.

EXAMPLE 3 ▶ **Solving a System of Three Equations in Three Variables**

Solve using elimination: $\begin{cases} 2x + y - 2z = -7 \\ x + y + z = -1 \\ -2y - z = -3 \end{cases}$.

Solution ▶

1. The system is in standard form.
2. If the x-term in any equation has a coefficient of 1, interchange equations so this equation becomes R1.

$$\begin{cases} 2x + y - 2z = -7 \\ x + y + z = -1 \\ -2y - z = -3 \end{cases} \xrightarrow{\text{R2} \leftrightarrow \text{R1}} \begin{cases} x + y + z = -1 \\ 2x + y - 2z = -7 \\ -2y - z = -3 \end{cases}$$

3. Use R1 to eliminate the x-term in R2 and R3. Since R3 has no x-term, the only elimination needed is the x-term from R2. Using $-2\text{R1} + \text{R2}$ will eliminate this term:

$$\begin{array}{rrcl} -2\text{R1} & -2x - 2y - 2z = & 2 & \\ + & & & \\ \underline{\text{R2}} & \underline{2x + y - 2z = } & \underline{-7} & \\ & 0x - 1y - 4z = & -5 & \text{sum} \\ & y + 4z = & 5 & \text{simplify} \end{array}$$

The new R2 is $y + 4z = 5$. The original R1 and R3, along with the new R2 form an equivalent system that contains a smaller **subsystem**

$$\begin{cases} x + y + z = -1 \\ 2x + y - 2z = -7 \\ -2y - z = -3 \end{cases} \xrightarrow[\text{R3} \rightarrow \text{R3}]{-2\text{R1} + \text{R2} \rightarrow \text{R2}} \begin{cases} x + y + z = -1 \\ y + 4z = 5 \\ -2y - z = -3 \end{cases}$$

new equivalent system

4. Solve the subsystem for either y or z, and keep the result as a *new* R3. We choose to eliminate y using 2R2 + R3:

$$\begin{array}{rrl} 2\text{R2} & 2y + 8z = 10 & \\ + & & \\ \underline{\text{R3}} & \underline{-2y - z = -3} & \\ & 0y + 7z = 7 & \text{sum} \\ & z = 1 & \text{simplify} \end{array}$$

The new R3 is $z = 1$.

$$\begin{cases} x + y + z = -1 \\ y + 4z = 5 \\ -2y - z = -3 \end{cases} \xrightarrow{2\text{R2} + \text{R3} \to \text{R3}} \begin{cases} x + y + z = -1 \\ y + 4z = 5 \\ z = 1 \end{cases}$$ new equivalent system

The new R3, along with the original R1 and R2 from step 3, form an equivalent system that can be solved using back-substitution. Substituting 1 for z in R2 yields $y = 1$. Substituting 1 for z and 1 for y in R1 yields $x = -3$. The solution is $(-3, 1, 1)$. Check this result using the ALPHA keys, as illustrated following Example 2.

Now try Exercises 13 through 16 ▶

While not absolutely needed for the elimination process, there are two reasons for wanting the coefficient of x to be "1" in R1. First, it makes the elimination method more efficient since we can more easily see what to use as a multiplier. Second, it lays the foundation for developing other methods of solving larger systems. If no equation has an x-coefficient of 1, we simply use the y- or z-variable instead (see Example 7). Since solutions to larger systems generally are worked out in stages, we will sometimes track the transformations used by writing them *between* the original system and the equivalent system, rather than to the left as we did in Section 9.1.

Here is an additional example illustrating the elimination process, but in *abbreviated form*. Verify the calculations indicated using a separate sheet.

EXAMPLE 4 ▶ Solving a System of Three Equations in Three Variables

Solve using elimination: $\begin{cases} -5y + 2x - z = -8 \\ -x + 3z + 2y = 13 \\ -z + 3y + x = 5 \end{cases}$.

Solution ▶

1. Write the equations in standard form: $\begin{cases} 2x - 5y - z = -8 \\ -x + 2y + 3z = 13 \\ x + 3y - z = 5 \end{cases}$

2. $\begin{cases} 2x - 5y - z = -8 \\ -x + 2y + 3z = 13 \\ x + 3y - z = 5 \end{cases} \xrightarrow{\text{R3} \leftrightarrow \text{R1}} \begin{cases} x + 3y - z = 5 \\ -x + 2y + 3z = 13 \\ 2x - 5y - z = -8 \end{cases}$ equivalent system

3. Using R1 + R2 will eliminate the x-term from R2, yielding $5y + 2z = 18$. Using -2R1 + R3 eliminates the x-term from R3, yielding $-11y + z = -18$.

$$\begin{cases} x + 3y - z = 5 \\ -x + 2y + 3z = 13 \\ 2x - 5y - z = -8 \end{cases} \xrightarrow[-2\text{R1} + \text{R3} \to \text{R3}]{\text{R1} + \text{R2} \to \text{R2}} \begin{cases} x + 3y - z = 5 \\ 5y + 2z = 18 \\ -11y + z = -18 \end{cases}$$ equivalent system

4. Using -2R3 + R2 will eliminate z from the subsystem, leaving $27y = 54$.

$$\begin{cases} x + 3y - z = 5 \\ 5y + 2z = 18 \\ -11y + z = -18 \end{cases} \xrightarrow{-2\text{R3} + \text{R2} \to \text{R3}} \begin{cases} x + 3y - z = 5 \\ 5y + 2z = 18 \\ 27y = 54 \end{cases}$$ equivalent system

Solving for y in R3 yields: $\frac{27y}{27} = \frac{54}{27}$, showing $y = 2$. Substituting 2 for y in R2 gives,

$$\begin{aligned} 5(2) + 2z &= 18 && \text{substitute 2 for } y \\ 10 + 2z &= 18 && \text{simplify} \\ 2z &= 8 && \text{subtract 10} \\ z &= 4 && \text{divide by 2} \end{aligned}$$

Substituting 2 for y and 4 for z in R1 gives,

$$\begin{aligned} x + 3(2) - 4 &= 5 && \text{substitute 2 for } y, \text{ 4 for } z \\ x + 2 &= 5 && \text{simplify} \\ x &= 3 && \text{subtract 2} \end{aligned}$$

C. You've just seen how we can solve linear systems in three variables

The solution is (3, 2, 4).

Now try Exercises 17 through 20 ▶

D. Inconsistent and Dependent Systems

As mentioned, it is possible for larger systems to have no solutions or an infinite number of solutions. As with our work in Section 9.1, an inconsistent system (no solutions) will produce inconsistent results, ending with a statement such as $0 = -3$ or some other contradiction.

EXAMPLE 5 ▶ **Attempting to Solve an Inconsistent System**

Solve using elimination: $\begin{cases} 2x + y - 3z = -3 \\ 3x - 2y + 4z = 2 \\ 4x + 2y - 6z = -7 \end{cases}$.

Solution ▶

1. This system has no equation where the coefficient of x is 1.
2. We can still use R1 to begin the solution process, but this time we'll use the variable y since it *does* have coefficient 1.

   Using 2R1 + R2 eliminates the y-term from R2, leaving $7x - 2z = -4$. But using -2R1 + R3 to eliminate the y-term from R3 results in a contradiction:

$$\begin{array}{lll} 2\text{R1} & 4x + 2y - 6z = -6 & \\ + & & \\ \underline{\text{R2}} & \underline{3x - 2y + 4z = \ \ 2} & \\ & 7x \quad\ - 2z = -4 & \end{array} \qquad \begin{array}{lll} -2\text{R1} & -4x - 2y + 6z = \ \ 6 & \\ + & & \\ \underline{\text{R3}} & \underline{4x + 2y - 6z = -7} & \\ & 0x + 0y + 0z = -1 & \\ & 0 = -1 & \text{contradiction} \end{array}$$

   We conclude the system is inconsistent. The answer is the empty set $\varnothing$, and we need work no further.

Now try Exercises 21 and 22 ▶

Unlike our work with systems having only two variables, systems in three variables can have two forms of dependence—*linear dependence* (Figure 9.18) or *coincident dependence* (Figure 9.19). To help understand linear dependence, consider a system of two equations in three variables: $\begin{cases} -2x + 3y - z = 5 \\ x - 3y + 2z = -1 \end{cases}$. Each of these equations represents a plane, and unless the planes are parallel, their intersection will be a line. As in Section 9.1, we can state solutions to a dependent system using set notation with two of the variables written in terms of the third, or as an ordered triple using a parameter. The relationships named can then be used to generate specific solutions to the system.

Systems with two equations and two variables or three equations and three variables are called **square systems,** meaning there are exactly as many equations as there are variables. A system of linear equations cannot have a unique solution unless there are at least as many equations as there are variables in the system.

EXAMPLE 6 ▶ Solving a Dependent System

Solve using elimination: $\begin{cases} 2x + 5y - 3z = -5 \\ -x - 5y + 2z = 1 \end{cases}$.

Solution ▶ We immediately note that R1 + R2 eliminates the y-term from R2, yielding $x - z = -4$ and the new system $\begin{cases} 2x + 5y - 3z = -5 \\ x \quad - \quad z = -4 \end{cases}$. This means (x, y, z) will satisfy both equations only when $x = z - 4$ (the x-coordinate must be 4 less than the z-coordinate). Since x is written in terms of z, we substitute $z - 4$ for x *in either equation* to find how y is related to z. Using R2 in the original system we have: $-(z - 4) - 5y + 2z = 1$, which yields $y = \frac{1}{5}z + \frac{3}{5}$ (verify). This means the y-coordinate of the solution must be $\frac{3}{5}$ more than $\frac{1}{5}z$. In set notation, the solution is $\{(x, y, z,) \mid x = z - 4, y = \frac{1}{5}z + \frac{3}{5}, z \in \mathbb{R}\}$. Randomly choosing $z = -3$, 2, and 7, the solutions would be $(-7, 0, -3)$, $(-2, 1, 2)$, and $(3, 2, 7)$, respectively. Verify that these satisfy both equations. Using p as a parameter, the solution could be written $(p - 4, \frac{1}{5}p + \frac{3}{5}, p)$ in parameterized form.

Now try Exercises 23 through 26 ▶

The system in Example 6 was nonsquare, and we knew ahead of time the system would be dependent. The system in Example 7 *is* square, but only by applying the elimination process can we determine the nature of its solution(s).

EXAMPLE 7 ▶ Solving a Dependent System

Solve using elimination: $\begin{cases} 3x - 2y + z = -1 \\ 2x + \quad y - z = 5 \\ 10x - 2y \quad = 8 \end{cases}$.

Solution ▶ This system has no equation where the coefficient of x is 1. We will still use R1, but eliminate z in R2 (there is no z-term in R3).

Using R1 + R2 eliminates the z-term from R2, yielding $5x - y = 4$.

$$\begin{cases} 3x - 2y + z = -1 \\ 2x + \quad y - z = 5 \\ 10x - 2y \quad = 8 \end{cases} \xrightarrow[\text{R3} \to \text{R3}]{\text{R1} + \text{R2} \to \text{R2}} \begin{cases} 3x - 2y + z = -1 \\ 5x - \quad y \quad = 4 \\ 10x - 2y \quad = 8 \end{cases}$$

We next solve the subsystem. Using -2R2 + R3 eliminates the y-term in R3, but also all other terms:

$$\begin{array}{rrl} -2\text{R2} & -10x + 2y = -8 & \\ + & & \\ \underline{\text{R3}} & \underline{10x - 2y = \ 8} & \\ & 0x + 0y = \ 0 & \text{sum} \\ & 0 = \ 0 & \text{result} \end{array}$$

Since R3 is the same as 2R2, the system is linearly dependent and equivalent to $\begin{cases} 3x - 2y + z = -1 \\ 5x - \quad y \quad = 4 \end{cases}$. We can solve for y in R2 to write y in terms of x: $y = 5x - 4$. Substituting $5x - 4$ for y in R1 enables us to also write z in terms of x:

$$\begin{aligned}
3x - 2y \quad\quad + z &= -1 && \text{R1}\\
3x - 2(5x - 4) + z &= -1 && \text{substitute } 5x - 4 \text{ for } y\\
3x - 10x + 8 + z &= -1 && \text{distribute}\\
-7x + z &= -9 && \text{simplify}\\
z &= 7x - 9 && \text{solve for } z
\end{aligned}$$

The solution set is $\{(x, y, z) | x \in \mathbb{R}, y = 5x - 4, z = 7x - 9\}$. Three of the infinite number of solutions are $(0, -4, -9)$ for $x = 0$, $(2, 6, 5)$ for $x = 2$, and $(-1, -9, -16)$ for $x = -1$. Verify these triples satisfy all three equations. Again using the parameter p, the solution could be written as $(p, 5p - 4, 7p - 9)$.

Now try Exercises 27 through 30 ▶

D. You've just seen how we can recognize inconsistent and dependent systems

For **coincident dependence** the equations in a system differ by only a constant multiple. After applying the elimination process—all variables are eliminated from the other equations, leaving statements that are always true (such as $2 = 2$ or some other). For additional practice solving various kinds of systems, **see Exercises 31 through 44.**

E. Applications

Applications of larger systems are simply an extension of our work with systems of two equations in two variables. Once again, the applications come in a variety of forms and from many fields. In the world of business and finance, systems can be used to diversify investments or spread out liabilities, a financial strategy hinted at in Example 8.

EXAMPLE 8 ▶ Modeling the Finances of a Business

A small business borrowed $225,000 from three different lenders to expand their product line. The interest rates were 5%, 6%, and 7%. Find how much was borrowed at each rate if the annual interest came to $13,000 and twice as much was borrowed at the 5% rate than was borrowed at the 7% rate.

Solution ▶ Let x, y, and z represent the amounts borrowed at 5%, 6%, and 7%, respectively. This means our first equation is $x + y + z = 225$ (in thousands). The second equation is determined by the total interest paid, which was $13,000: $0.05x + 0.06y + 0.07z = 13$. The third is found by carefully reading the problem.

"*twice as much was borrowed at the 5% rate than was borrowed at the 7% rate,*" *or* $x = 2z$.

These equations form the system: $\begin{cases} x + y + z = 225 \\ 0.05x + 0.06y + 0.07z = 13 \\ x = 2z \end{cases}$. The x-term of the first equation has a coefficient of 1. Written in standard form we have:

$$\begin{cases} x + y + z = 225 & \text{R1} \\ 5x + 6y + 7z = 1300 & \text{R2} \quad \text{multiply R2 by 100} \\ x - 2z = 0 & \text{R3} \end{cases}$$

Using $-5\text{R1} + \text{R2}$ will eliminate the x term in R2, while $-\text{R1} + \text{R3}$ will eliminate the x-term in R3.

$$\begin{array}{rl} -5\text{R1} & -5x - 5y - 5z = -1125 \\ + & \\ \text{R2} & 5x + 6y + 7z = 1300 \\ \hline & y + 2z = 175 \end{array} \qquad \begin{array}{rl} -\text{R1} & -x - y - z = -225 \\ + & \\ \text{R3} & x \quad - 2z = 0 \\ \hline & -y - 3z = -225 \end{array}$$

The new R2 is $y + 2z = 175$, and the new R3 (after multiplying by -1) is $y + 3z = 225$, yielding the equivalent system $\begin{cases} x + y + z = 225 \\ y + 2z = 175. \\ y + 3z = 225 \end{cases}$

Solving the 2×2 subsystem using $-$R2 + R3 yields $z = 50$. Back-substitution shows $y = 75$ and $x = 100$, yielding the solution (100, 75, 50). This means \$50,000 was borrowed at the 7% rate, \$75,000 was borrowed at 6%, and \$100,000 at 5%.

A "substitution check" on a graphing calculator verifies this solution is correct (see Figures 9.23 and 9.24).

Now try Exercises 47 through 56 ▶

9.2 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. The solution to an equation in three variables is an ordered _____.
2. The graph of the solutions to an equation in three variables is a(n) _____.
3. Systems that have the same solution set are called _____ _____.
4. If a 3×3 system is linearly dependent, the ordered triple solutions can be written in terms of a single variable called a(n) _____.
5. Find a value of z that makes the ordered triple $(2, -5, z)$ a solution to $2x + y + z = 4$. Discuss/Explain how this is accomplished.
6. Explain the difference between linear dependence and coincident dependence, and describe how the equations are related.

▶ DEVELOPING YOUR SKILLS

Find any four ordered triples that satisfy the equation given.

7. $x + 2y + z = 9$
8. $3x + y - z = 8$
9. $-x + y + 2z = -6$
10. $2x - y + 3z = -12$

Use the ALPHA keys on a graphing calculator to determine if the given ordered triples are solutions to the system. If not a solution, identify which equation(s) are not satisfied.

11. $\begin{cases} x + y - 2z = -1 \\ 4x - y + 3z = 3 \\ 3x + 2y - z = 4 \end{cases}$; $(0, 3, 2)$ $(-3, 4, 1)$

12. $\begin{cases} 2x + 3y + z = 9 \\ 5x - 2y - z = -32 \\ x - y - 2z = -13 \end{cases}$; $(-4, 5, 2)$ $(5, -4, 11)$

Solve each system using elimination and back-substitution.

13. $\begin{cases} x - y - 2z = -10 \\ x \quad\quad - z = 1 \\ \quad\quad\quad z = 4 \end{cases}$ **14.** $\begin{cases} x + y + 2z = -1 \\ 4x - y \quad\quad = 3 \\ 3x \quad\quad\quad = 6 \end{cases}$

15. $\begin{cases} x + 3y + 2z = 16 \\ -2y + 3z = 1 \\ 8y - 13z = -7 \end{cases}$ **16.** $\begin{cases} -x + y + 5z = 1 \\ 4x + y \quad\quad = 1 \\ -3x - 2y \quad\quad = 8 \end{cases}$

17. $\begin{cases} -x + y + 2z = -10 \\ x + y - z = 7 \\ 2x + y + z = 5 \end{cases}$ **18.** $\begin{cases} x + y - 2z = -1 \\ 4x - y + 3z = 3 \\ 3x + 2y - z = 4 \end{cases}$

19. $\begin{cases} 2x - 3y + 2z = 0 \\ 3x - 4y + z = -20 \\ x + 2y - z = 16 \end{cases}$ **20.** $\begin{cases} 3x - y + z = 6 \\ 2x + 2y - z = 5 \\ 2x - y + z = 5 \end{cases}$

Solve using the elimination method. If a system is inconsistent or dependent, so state. For systems with linear dependence, write solutions in set notation and as an ordered triple in terms of a parameter.

21. $\begin{cases} 3x + y + 2z = 3 \\ x - 2y + 3z = 1 \\ 4x - 8y + 12z = 7 \end{cases}$ **22.** $\begin{cases} 2x - y + 3z = 8 \\ 3x - 4y + z = 4 \\ -4x + 2y - 6z = 5 \end{cases}$

23. $\begin{cases} 4x + y + 3z = 8 \\ x - 2y + 3z = 2 \end{cases}$ **24.** $\begin{cases} 4x - y + 2z = 9 \\ 3x + y + 5z = 5 \end{cases}$

25. $\begin{cases} 6x - 3y + 7z = 2 \\ 3x - 4y + z = 6 \end{cases}$ **26.** $\begin{cases} 2x - 4y + 5z = -2 \\ 3x - 2y + 3z = 7 \end{cases}$

Solve using elimination. If the system is linearly dependent, state the general solution in terms of a parameter (different forms of the solution are possible). Then find four specific ordered triples that satisfy the system (answers will vary).

27. $\begin{cases} 3x - 4y + 5z = 5 \\ -x + 2y - 3z = -3 \\ 3x - 2y + z = 1 \end{cases}$

28. $\begin{cases} 5x - 3y + 2z = 4 \\ -9x + 5y - 4z = -12 \\ -3x + y - 2z = -12 \end{cases}$

29. $\begin{cases} x + 2y - 3z = 1 \\ 3x + 5y - 8z = 7 \\ x + y - 2z = 5 \end{cases}$

30. $\begin{cases} -2x + 3y - 5z = 3 \\ 5x - 7y + 12z = -8 \\ x - y + 2z = -2 \end{cases}$

Solve using the elimination method. If a system is inconsistent or dependent, so state. For systems with linear dependence, write the answer in terms of a parameter. For coincident dependence, state the solution in set notation.

31. $\begin{cases} 4x + 2y - 8z = 24 \\ -x - 0.5y + 2z = -6 \\ 2x + y - 4z = 12 \end{cases}$

32. $\begin{cases} 2x - 5y - 4z = 6 \\ x - 2.5y - 2z = 3 \\ -3x + 7.5y + 6z = -9 \end{cases}$

33. $\begin{cases} x - 2y + 2z = 6 \\ 2x - 6y + 3z = 13 \\ 3x + 4y - z = -11 \end{cases}$ **34.** $\begin{cases} 4x - 5y - 6z = 5 \\ 2x - 3y + 3z = 0 \\ x + 2y - 3z = 5 \end{cases}$

35. $\begin{cases} x - 5y - 4z = 3 \\ 2x - 9y - 7z = 2 \\ 3x - 14y - 11z = 5 \end{cases}$ **36.** $\begin{cases} 2x + 3y - 5z = 4 \\ x + y - 2z = 3 \\ x + 3y - 4z = -1 \end{cases}$

37. $\begin{cases} \frac{1}{6}x + \frac{1}{3}y - \frac{1}{2}z = 2 \\ \frac{3}{4}x - \frac{1}{3}y + \frac{1}{2}z = 9 \\ \frac{1}{2}x - y + \frac{1}{2}z = 2 \end{cases}$ **38.** $\begin{cases} \frac{x}{2} + \frac{y}{3} - \frac{z}{2} = 2 \\ \frac{2x}{3} - y - z = 8 \\ \frac{x}{6} + 2y + \frac{3z}{2} = 6 \end{cases}$

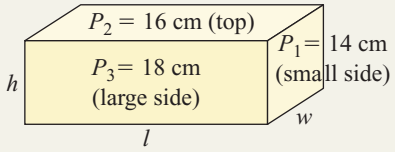
Some applications of systems lead to systems similar to those that follow. Solve using elimination.

39. $\begin{cases} -2A - B - 3C = 21 \\ B - C = 1 \\ A + B \quad\quad = -4 \end{cases}$

40. $\begin{cases} -A + 3B + 2C = 11 \\ 2B + C = 9 \\ B + 2C = 8 \end{cases}$

41. $\begin{cases} A + \quad 2C = 7 \\ 2A - 3B \quad = 8 \\ 3A + 6B - 8C = -33 \end{cases}$

42. $\begin{cases} A - 2B \quad = 5 \\ B + 3C = 7 \\ 2A - B - C = 1 \end{cases}$



43. $\begin{cases} C = -2 \\ 5A \quad - 2C = 5 \\ -4B - 9C = 16 \end{cases}$

44. $\begin{cases} C = 3 \\ 2A + \quad 3C = 10 \\ 3B - 4C = -11 \end{cases}$

▶ WORKING WITH FORMULAS

45. Dimensions of a rectangular solid:

$$\begin{cases} 2w + 2h = P_1 \\ 2l + 2w = P_2 \\ 2l + 2h = P_3 \end{cases}$$

Using the formula shown, the dimensions of a rectangular solid can be found if the perimeters of the three distinct faces are known. Find the dimensions of the solid shown.

46. Distance from a point (x, y, z) to the plane $Ax + By + Cz = D$:

$$\left| \frac{Ax + By + Cz - D}{\sqrt{A^2 + B^2 + C^2}} \right|$$

The perpendicular distance from a given point (x, y, z) to the plane defined by $Ax + By + Cz = D$ is given by the formula shown. Consider the plane given in Figure 9.15 $(x + y + z = 6)$. What is the distance from this plane to the point (3, 4, 5)?

▶ APPLICATIONS

Solve the following applications by setting up and solving a system of three equations in three variables. Note that some equations may have only two of the three variables used to create the system. Check answers using back-substitution or the ALPHA keys on the home screen of a graphing calculator.

Investment/Finance and Simple Interest Problems

47. Investing the winnings: After winning $280,000 in the lottery, Maurika decided to place the money in three different investments: a certificate of deposit paying 4%, a money market certificate paying 5%, and some Aa bonds paying 7%. After 1 yr she earned $15,400 in interest. Find how much was invested at each rate if $20,000 more was invested at 7% than at 5%.

48. Purchase at auction: At an auction, a wealthy collector paid $7,000,000 for three paintings: a Monet, a Picasso, and a van Gogh. The Monet cost $800,000 more than the Picasso. The price of the van Gogh was $200,000 more than twice the price of the Monet. What was the price of each painting?

Descriptive Translation

49. Major wars: The United States has fought three major wars in modern times: World War II, the Korean War, and the Vietnam War. If you sum the years that each conflict ended, the result is 5871. The Vietnam War ended 20 years after the Korean War and 28 years after World War II. In what year did each end?

50. Animal gestation periods: The average gestation period (in days) of an elephant, rhinoceros, and camel sum to 1520 days. The gestation period of a rhino is 58 days longer than that of a camel. Twice the camel's gestation period decreased by 162 gives the gestation period of an elephant. What is the gestation period of each?

51. Moments in U.S. history: If you sum the year the Declaration of Independence was signed, the year the 13th Amendment to the Constitution abolished slavery, and the year the Civil Rights Act was signed, the total would be 5605. Ninety-nine years separate the 13th Amendment and the Civil Rights Act. The Civil Rights Act was signed 188 years after the Declaration of Independence. What year was each signed?

52. Aviary wingspan: If you combine the wingspan of the California Condor, the Wandering Albatross (see photo), and the prehistoric Quetzalcoatlus, you get an astonishing 18.6 m (over 60 ft). If the wingspan of the Quetzalcoatlus is equal to five times that of the Wandering Albatross minus twice that of the California Condor, and six times the wingspan of the Condor is equal to five times the wingspan of the Albatross, what is the wingspan of each?

Mixtures

53. Chemical mixtures: A chemist mixes three different solutions with concentrations of 20%, 30%, and 45% glucose to obtain 10 L of a 38% glucose solution. If the amount of 30% solution used is 1 L more than twice the amount of 20% solution used, find the amount of each solution used.

54. Value of gold coins: As part of a promotion, a local bank invites its customers to view a large sack full of $5, $10, and $20 gold pieces, promising to give the sack to the first person able to state the number of coins for each

denomination. Customers are told there are exactly 250 coins, with a total face value of $1875. If there are also seven times as many $5 gold pieces as $20 gold pieces, how many of each denomination are there?

Nutrition

55. Industrial food production: Acampana Soups is creating a new sausage and shrimp gumbo that contains three different types of fat: saturated, monounsaturated, and polyunsaturated. As a new member of the "Heart Healthy" menu, this soup must contain only 2.8 g of total fat per serving. The head chef Yev Kasem demands that the recipe provides exactly twice as much saturated fat as polyunsaturated fat. At the same time, the lead nutrition expert Florencia requires the amount of saturated fat in a serving to be 0.4 g less than the *combined* amount of unsaturated fats. How many grams of each type of fat will a serving of this soup contain?

56. Geriatric nutrition: The dietician at McKnight Place must create a balanced diet for Fred, consisting of a daily total of 1600 calories. For his successful rehabilitation, exact quantities of complex carbohydrates, fat, and protein must provide these calories. In this diet, carbohydrates provide 160 more calories than fat and protein together, while fat provides 1.25 times more calories than protein alone. How many calories should each nutrient provide on a daily basis?

In Exercises 87 and 88 from Section 9.1, we found the equation of a line through two points by creating a system of two equations of the form $y = mx + b$. Just as any two points determine a unique line, three noncollinear points determine a unique parabola (as long as no two have the same first coordinate). Similar to the method used there, each point gives an equation of the form $y = ax^2 + bx + c$, and we create a 3×3 system that can be solved using elimination. For instance, the point (2, 41) gives the equation $41 = a(2)^2 + 2b + c$.

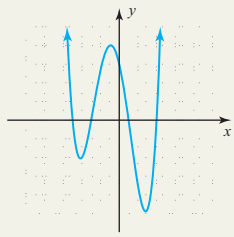
57. Height of a soccer ball: One second after being kicked ($t = 1$), a soccer ball is 26 ft high. After 2 sec ($t = 2$), the ball is 41 ft high, and after 6 sec the ball is 1 ft above the ground. Use the ordered pairs (time, height) to find a function $h(t)$ modeling the height of the ball after t sec, then use the equation to find (a) the maximum height of the kick, and (b) the height of the ball after 5.4 sec.

58. Height of an arrow: An archer is out in a large field testing a new bow. Pulling back the bow to near its breaking point, the archer lets the arrow fly. Suppose that 1 sec after release ($t = 1$) the arrow was 184 ft high, four sec later ($t = 5$) it was 600 ft high, and after 12 sec, the arrow was 96 ft high. Use the ordered pairs (time, height) to find a function $h(t)$ modeling the height of the arrow after t sec, then use the equation to (a) find the maximum height of the shot and (b) determine how long the arrow was airborne.

▶ EXTENDING THE CONCEPT

59. The system $\begin{cases} x - 2y - z = 2 \\ x - 2y + kz = 5 \\ 2x - 4y + 4z = 10 \end{cases}$ is dependent if $k =$ ____, and inconsistent otherwise.

60. One form of the equation of a circle is $x^2 + y^2 + Dx + Ey + F = 0$. Use a system to find the equation of the circle through the points $(2, -1)$, $(4, -3)$, and $(2, -5)$.



▶ MAINTAINING YOUR SKILLS

61. (8.3) Given $\mathbf{u} = \langle 1, -7 \rangle$ and $\mathbf{v} = \langle -3, \frac{1}{2} \rangle$, compute $\mathbf{u} + 4\mathbf{v}$ and $3\mathbf{u} - \mathbf{v}$.

62. (6.2) Given $\cot A = 1.6831$, use a calculator to find the acute angle A to the nearest tenth of a degree.

63. (5.5) Solve the logarithmic equation: $\log(x + 2) + \log x = \log 3$

64. (2.1) Analyze the graph of g shown. Clearly state the domain and range, the zeroes of g, intervals where $g(x) > 0$, intervals where $g(x) < 0$, local maximums or minimums, and intervals where the function is increasing or decreasing. Assume each tick mark is one unit and estimate endpoints to the nearest tenths.

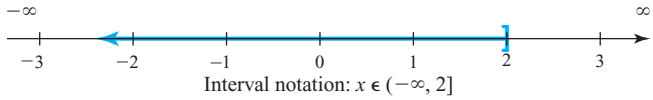
9.3 Systems of Inequalities and Linear Programming

LEARNING OBJECTIVES

In Section 9.3 you will see how we can:

- ❑ **A.** Solve a linear inequality in two variables
- ❑ **B.** Solve a system of linear inequalities
- ❑ **C.** Solve applications using a system of linear inequalities
- ❑ **D.** Solve applications using linear programming

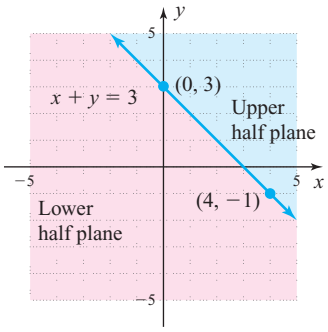
In this section, we'll build on many of the ideas from Section 9.1, with a focus on systems of linear inequalities. While systems of linear equations have an unlimited number of applications, there are many situations that can only be modeled using linear inequalities. For example, decisions in business and industry are often based on a large number of limitations or constraints, with many different ways these constraints can be satisfied.



A. Linear Inequalities in Two Variables

A linear equation in two variables is any equation that can be written in the form $Ax + By = C$, where A and B are real numbers, not simultaneously equal to zero. A **linear inequality** in two variables is similarly defined, with the " $=$ " sign replaced by the " $<$," " $>$," " $\leq$," or " $\geq$ " symbol:

$$Ax + By < C \qquad Ax + By > C$$
$$Ax + By \leq C \qquad Ax + By \geq C$$



Solving a linear inequality in two variables has many similarities with the one variable case. For one variable, we graph a *boundary point* on a number line, decide whether the endpoint is *included* or *excluded,* and *shade the appropriate half line.* For $x + 1 \leq 3$, we have the solution $x \leq 2$ with the endpoint (boundary point) included and the line shaded to the left (Figure 9.25):

Figure 9.25

Interval notation: $x \in (-\infty, 2]$

Figure 9.26

For linear inequalities in two variables, we graph a *boundary line,* decide whether the boundary line is *included* or *excluded,* and *shade the appropriate half plane.* For $x + y \leq 3$, the boundary line $x + y = 3$ is graphed in Figure 9.26. Note it divides the coordinate plane into two regions called **half planes,** and it forms the **boundary** between the two regions. If the boundary is **included** in the solution set, we graph it using a *solid line.* If the boundary is **excluded,** a *dashed line* is used. Recall that solutions to a linear equation are ordered pairs that make the equation true. We use a similar idea to find or verify solutions to linear inequalities. If any one point in a half plane makes the inequality true, all points in that half plane will satisfy the inequality.

EXAMPLE 1 ▶ **Checking Solutions to an Inequality in Two Variables**

Determine whether the given ordered pairs are solutions to $-x + 2y \leq 2$:

a. $(4, -3)$ **b.** $(-2, 1)$ **c.** $(-4, -1)$

Solution ▶

a. Substitute 4 for x and -3 for y: $-(4) + 2(-3) \leq 2$ substitute 4 for x, -3 for y

$-10 \leq 2$ true

$(4, -3)$ is a solution.

b. Substitute -2 for x and 1 for y: $-(-2) + 2(1) \leq 2$ substitute -2 for x, 1 for y

$4 \leq 2$ false

$(-2, 1)$ is not a solution.

c. Substitute -4 for x and -1 for y: $-(-4) + 2(-1) \leq 2$ substitute -4 for x, -1 for y

$2 \leq 2$ true

$(-4, -1)$ is a solution.

Now try Exercises 7 through 10 ▶

WORTHY OF NOTE

This relationship is often called the **trichotomy axiom** or the "*three-part truth.*" Given any two quantities, they are either equal to each other, or the first is less than the second, or the first is greater than the second.

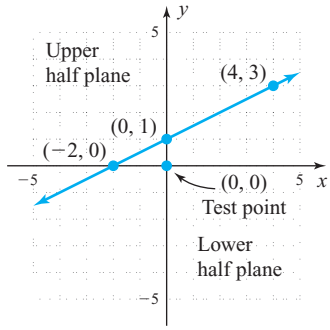
Earlier we graphed linear equations by plotting a small number of ordered pairs or by solving for y and using the slope-intercept method. The line represented all ordered pairs that made the equation true, meaning *the left-hand expression was equal to the right-hand expression.* To graph linear inequalities, we reason that if the line represents all ordered pairs that make the expressions *equal,* then any point *not on that line* must make the expressions *unequal*—either greater than or less than. These ordered pair solutions must lie in one of the half planes formed by the line, which we shade to indicate the **solution region.** Note this implies the boundary line for any inequality *is determined by the related equation,* created by temporarily replacing the inequality symbol with an "=" sign.

EXAMPLE 2 ▶ **Solving an Inequality in Two Variables**

Solve the inequality $-x + 2y \le 2$.

Solution ▶ The related equation and boundary line is $-x + 2y = 2$. Since the inequality is inclusive (less than *or equal to*), we graph a solid line. Using the intercepts, we graph the line through (0, 1) and (−2, 0) shown in Figure 9.27. To determine the solution region and which side to shade, we select (0, 0) as a test point, which results in a true statement: $-(0) + 2(0) \le 2$✓. Since (0, 0) is in the "lower" half plane, we shade this side of the boundary (see Figure 9.28).

Figure 9.27



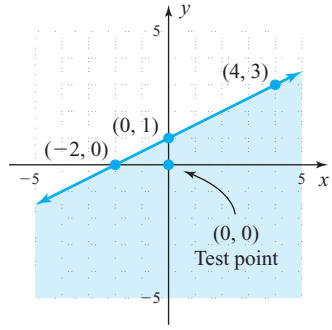


Figure 9.28

Now try Exercises 11 through 14 ▶

The same solution would be obtained if we first solved for y and graphed the boundary line using the slope-intercept method. However, using the slope-intercept method offers a distinct advantage—test points are no longer necessary since solutions to "less than" inequalities will always appear *below* the boundary line and solutions to "greater than" inequalities appear *above* the line. Written in slope-intercept form, the inequality from Example 2 is $y \le \frac{1}{2}x + 1$. Note that (0, 0) still results in a true statement, but the "less than or equal to" symbol now indicates directly that solutions will be found in the lower half plane. These observations lead to our general approach for solving linear inequalities:

Solving a Linear Inequality

1. Graph the boundary line by solving for y and using the slope-intercept form.
   - Use a solid line if the boundary is included in the solution set.
   - Use a dashed line if the boundary is excluded from the solution set.
2. For "greater than" inequalities shade the upper half plane. For "less than" inequalities shade the lower half plane.

EXAMPLE 3 ▶ **Solving linear Inequalities in Two Variables Using Technology**

Solve the inequality $3x + 5y \le 10$ using a graphing calculator.

Solution ▶ We begin by solving the inequality for y, so we can enter the equation on the Y= screen.

$$\begin{aligned} 3x + 5y &\le 10 && \text{given inequality} \\ 5y &\le -3x + 10 && \text{subtract } 3x \text{ (isolate } y\text{-term)} \\ y &\le \frac{-3}{5}x + 2 && \text{divide by 5} \end{aligned}$$

Entering $Y_1 = \frac{-3}{5}X + 2$ on the Y= screen, and graphing the boundary line using ZOOM **6:ZStandard** produces the graph shown in Figure 9.29. The "less than" inequality indicates the region below the line should be shaded, so we return to the Y= screen and move the cursor to the far left. From the default "connected line" setting, pressing ENTER three times brings the "shade below the graph" marker "◣" into view (Figure 9.30), and pressing GRAPH gives the solution shown in Figure 9.31. As a check, note that (0, 0) is in the solution region, and is a solution to $3x + 5y \le 10$.

Figure 9.29

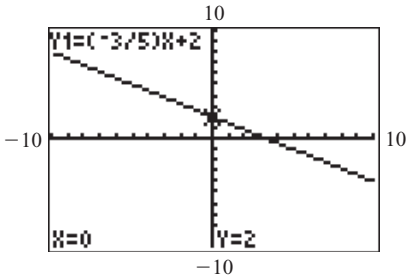

Figure 9.30

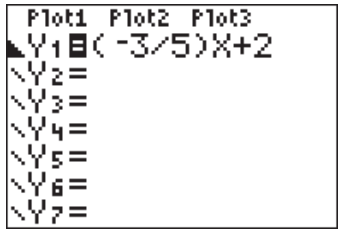

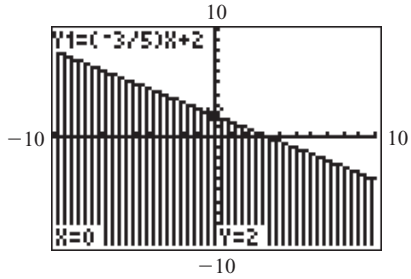

Figure 9.31

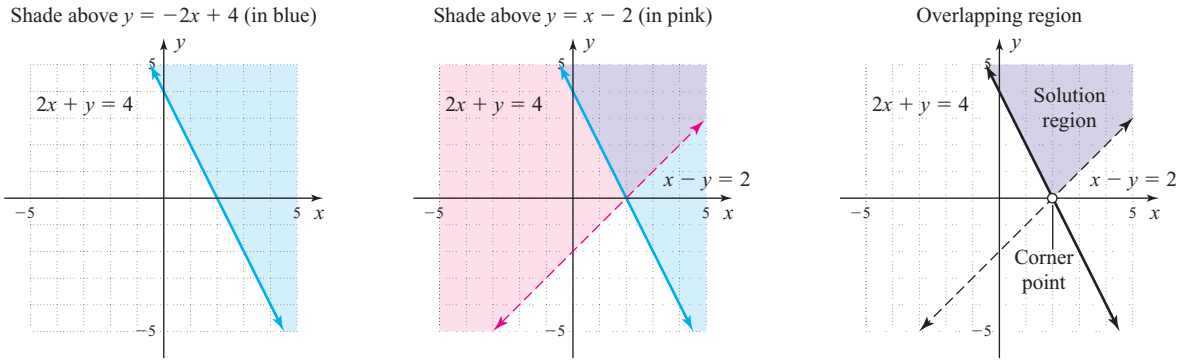
Now try Exercises 15 through 18 ▶

☑ **A.** You've just seen how we can solve a linear inequality in two variables



B. Solving Systems of Linear Inequalities

To solve a **system of inequalities,** we apply the procedure outlined above to all inequalities in the system, and note the ordered pairs that satisfy *all inequalities simultaneously.* In other words, we find *the intersection of all solution regions* (where they overlap), which then represents the solution for the system. In the case of vertical boundary lines, the designations *"above"* or *"below" the line* cannot be applied, and instead we simply note that for any vertical line $x = k$, points with x-coordinates larger than k will occur to the right.

EXAMPLE 4 ▶ **Solving a System of Linear Inequalities**

Solve the system of inequalities: $\begin{cases} 2x + y \ge 4 \\ x - y < 2 \end{cases}$.

Solution ▶ Solving for y, we obtain $y \ge -2x + 4$ and $y > x - 2$. The line $y = -2x + 4$ will be a solid boundary line (included), while $y = x - 2$ will be dashed (not included). Both inequalities are "greater than" and so we shade the upper half plane for each. The regions overlap and form the solution region (the lavender region shown). This sequence of events is illustrated here:

The solutions are all ordered pairs found in this region and its included boundaries. To verify the result, test the point (2, 3) from inside the region, and (5, −2) from outside the region [the point (2, 0) is not a solution since it does not satisfy $x - y < 2$].

Now try Exercises 19 through 36 ▶

For future reference, the point of intersection (2, 0) is called a **corner point** or **vertex** of the solution region. If the point of intersection is not easily found from the graph, we can find it by solving a linear system using the two lines. For Example 4, the system is

$$\begin{cases} 2x + y = 4 \\ x - y = 2 \end{cases}$$

and solving by elimination gives $3x = 6$, $x = 2$, and (2, 0) as the point of intersection.

A graphing calculator can also be used to solve a system of linear inequalities. One method (there are several) involves these three steps, which are performed on each equation:

1. Solve for y and enter the results on the Y= screen to create the boundary lines.
2. Graph each line and test the related half plane.
3. Shade the appropriate half plane.

This process is illustrated in Example 5. Since many real-world applications of linear inequalities do not use negative numbers, we often include $x \geq 0$ and $y \geq 0$ as part of the system, and set **Xmin = 0** and **Ymin = 0** as part of the WINDOW size. The value of Xmax and Ymax will depend on equations or context given.

EXAMPLE 5 ▶ **Solving a System of Inequalities Using Technology**

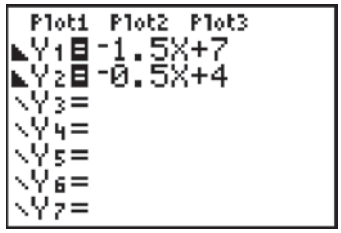
Use a graphing calculator to solve the system: $\begin{cases} 3x + 2y < 14 \\ x + 2y < 8 \\ x \geq 0 \\ y \geq 0 \end{cases}$

Solution ▶ Following the steps outlined above, we have

1. *Enter the related equations*. For $3x + 2y = 14$, we have $y = -1.5x + 7$. For $x + 2y = 8$, we have $y = -0.5x + 4$. Enter these as Y_1 and Y_2 on the Y= screen.
2. *Graph the boundary lines*. Note the x- and y-intercepts of both lines are less than 10, so we can graph them using a "friendly window" where $x \in [0, 9.4]$ and $y \in [0, 6.2]$. After setting the window, press GRAPH to graph the lines.

3. *Shade the appropriate half plane*. Since both equations are in slope-intercept form and solving for y resulted in two "less than" inequalities, we shade *below* both lines, using the "◣" feature located to the far left of Y_1 and Y_2. Simply overlay the diagonal line and press ENTER repeatedly until the symbol appears (Figure 9.32). After pressing the GRAPH key, the calculator draws both lines and shades the appropriate regions (Figure 9.33). Note the calculator uses two different kinds of shading. This makes it easy to identify the solution region—it will be the "checker-board area" where the horizontal and vertical lines cross.

Figure 9.32



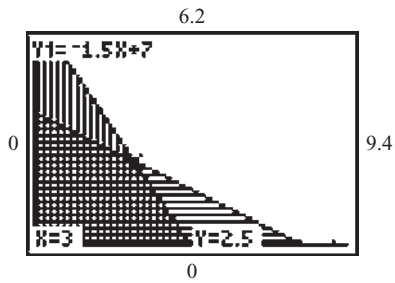


Figure 9.33

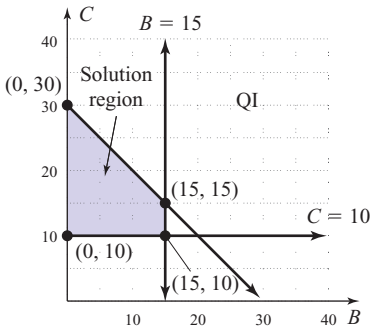
As a final check, we can navigate the position marker into the solution region and test a few points in both inequalities. Using the test point (2, 2) from within the region yields

$3x + 2y < 14$	first inequality	$x + 2y < 8$	second inequality
$3(2) + 2(2) \le 14$	substitute 2 for x, 2 for y	$(2) + 2(2) \le 8$	substitute 2 for x, 2 for y
$10 \le 14$	true	$6 \le 8$	true

B. You've just seen how we can solve a system of linear inequalities

Now try Exercises 37 through 50 ▶



C. Applications of Systems of Linear Inequalities

Systems of inequalities give us a way to model the decision-making process when certain ***constraints*** must be satisfied. A constraint is a fact or consideration that somehow limits or governs possible solutions, like the number of acres a farmer plants—which may be limited by time, size of land, government regulations, and so on.

EXAMPLE 6 ▶ **Solving Applications of Linear Inequalities**

As part of their retirement planning, James and Lily decide to invest up to $30,000 in two separate investment vehicles. The first is a bond issue paying 9% and the second is a money market certificate paying 5%. A financial adviser suggests they invest at least $10,000 in the certificate and not more than $15,000 in bonds. What various amounts can be invested in each?

Solution ▶

Consider the ordered pairs (B, C) where B represents the money invested in bonds and C the money invested in the certificate. Since they plan to invest no more than $30,000, the investment constraint would be $B + C \le 30$ (in thousands). Following the adviser's recommendations, the constraints on each investment would be $B \le 15$ and $C \ge 10$. Since they cannot invest less than zero dollars, the last two constraints are $B \ge 0$ and $C \ge 0$.

$$\begin{cases} B + C \le 30 \\ B \le 15 \\ C \ge 10 \\ B \ge 0 \\ C \ge 0 \end{cases}$$

The resulting system is shown in the figure, and indicates solutions will be in the first quadrant.

There is a vertical boundary line at $B = 15$ with shading to the left (less than) and a horizontal boundary line at $C = 10$ with shading above (greater than). After graphing $C = 30 - B$, we see the solution region is a quadrilateral with vertices at (0, 10), (0, 30), (15, 10), and (15, 15), as shown.

Now try Exercises 61 and 62 ▶

☑ **C.** You've just seen how we can solve applications using a system of linear inequalities

From Example 6, any ordered pair in this region or on its boundaries would represent an investment of the form (money in bonds, money in CDs) → (B, C), and would satisfy all constraints in the system. A natural follow-up question would be—What combination of (money in bonds, money in CDs) would offer the greatest return? This would depend on the interest being paid on each investment, and introduces us to a study of **linear programming,** which follows soon.

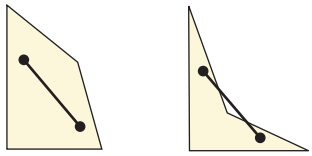
D. Linear Programming

To become as profitable as possible, corporations look for ways to maximize their revenue and minimize their costs, while keeping up with delivery schedules and product demand. To operate at peak efficiency, plant managers must find ways to maximize productivity, while minimizing related costs and considering employee welfare, union agreements, and other factors. Problems where the goal is to **maximize** or **minimize** the value of a given quantity under certain **constraints** or restrictions are called programming problems. The quantity we seek to maximize or minimize is called the **objective function.** For situations where *linear* programming is used, the objective function is given as a linear function in two variables and is denoted $f(x, y)$. A function in two variables is evaluated in much the same way as a single variable function. To evaluate $f(x, y) = 2x + 3y$ at the point (4, 5), we substitute 4 for x and 5 for y: $f(4, 5) = 2(4) + 3(5) = 23$.

EXAMPLE 7 ▶ Determining Maximum Values

Determine which of the following ordered pairs maximizes the value of $f(x, y) = 5x + 4y$: (0, 6), (5, 0), (0, 0), or (4, 2).

Solution ▶ Organizing our work in table form gives



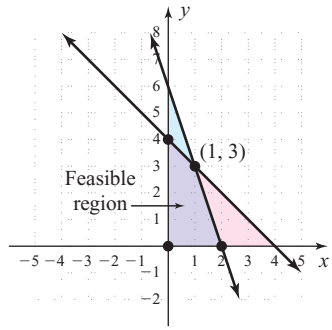
Given Point	Evaluate $f(x, y) = 5x + 4y$
(0, 6)	$f(0, 6) = 5(0) + 4(6) = 24$
(5, 0)	$f(5, 0) = 5(5) + 4(0) = 25$
(0, 0)	$f(0, 0) = 5(0) + 4(0) = 0$
(4, 2)	$f(4, 2) = 5(4) + 4(2) = 28$

The function $f(x, y) = 5x + 4y$ is maximized at (4, 2).

Now try Exercises 51 through 54 ▶

When the objective is stated as a linear function in two variables and the constraints are expressed as a system of linear inequalities, we have what is called a **linear programming** problem. The systems of inequalities solved earlier produced solution regions that were either **bounded** (as in Example 6) or **unbounded** (as in Example 4).

Figure 9.34

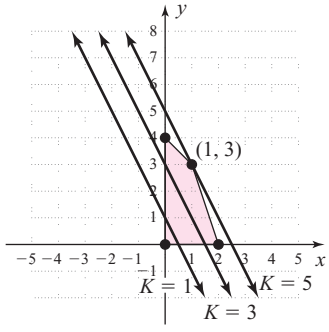


We interpret the word *bounded* to mean we can enclose the solution region within a circle of appropriate size. If we cannot draw a circle around the region because it extends indefinitely in some direction, the region is said to be *unbounded.* In this study, we will consider only situations that produce bounded solution regions, meaning the regions will have three or more vertices. The regions we study will also be **convex,** meaning that for any two points in the enclosed region, the line segment between them is also in the region (Figure 9.34). Under these conditions, it can be shown that the maximum or minimum values *must occur at one of the corner points of the solution region,* also called the **feasible region.**

EXAMPLE 8 ▶ Finding the Maximum of an Objective Function

Find the maximum value of the objective function $f(x, y) = 2x + y$ given the constraints shown: $\begin{cases} x + y \le 4 \\ 3x + y \le 6 \\ x \ge 0 \\ y \ge 0 \end{cases}$.

Solution ▶ Begin by noting that the solutions must be in QI, since $x \ge 0$ and $y \ge 0$. Graph the boundary lines $y = -x + 4$ and $y = -3x + 6$, shading the lower half plane in each case since they are "less than" inequalities. This produces the feasible region shown in lavender. There are four corner points to this region: (0, 0), (0, 4), (2, 0), and (1, 3). Three of these points are intercepts and can be found quickly. The point (1, 3) was found by solving the system $\begin{cases} x + y = 4 \\ 3x + y = 6 \end{cases}$. Knowing that the objective function will be maximized at one of the corner points, we test them in the objective function, using a table to organize our work.



Corner Point	Objective Function $f(x, y) = 2x + y$
(0, 0)	$f(0, 0) = 2(0) + (0) = 0$
(0, 4)	$f(0, 4) = 2(0) + (4) = 4$
(2, 0)	$f(2, 0) = 2(2) + (0) = 4$
(1, 3)	$f(1, 3) = 2(1) + (3) = 5$

The objective function $f(x, y) = 2x + y$ is maximized at (1, 3).

Now try Exercises 55 through 58 ▶

Figure 9.35

To help understand why solutions must occur at a vertex, note the objective function $f(x, y)$ is maximized using only (x, y) ordered pairs from the feasible region. If we let K represent this maximum value, the function from Example 8 becomes $K = 2x + y$ or $y = -2x + K$, which is a line with slope -2 and y-intercept K. The table in Example 8 suggests that K should range from 0 to 5 and graphing $y = -2x + K$ for $K = 1$, $K = 3$, and $K = 5$ produces the family of parallel lines shown in Figure 9.35. Note that values of K larger than 5 will cause the line to miss the solution region, and the maximum value of 5 occurs where the line intersects the feasible region at the vertex (1, 3). These observations lead to the following principles, which we offer without a formal proof.

Linear Programming Solutions

1. If the feasible region is convex and bounded, a maximum and a minimum value exist.
2. If a unique solution exists, it will occur at a vertex of the feasible region.
3. If more than one solution exists, at least one of them occurs at a vertex of the feasible region with others on a boundary line.
4. If the feasible region is unbounded, a linear programming problem may have no solutions.

Solving linear programming problems depends in large part on two things: (1) identifying the **objective** and the **decision variables** (what each variable represents in context), and (2) using the decision variables to write the *objective function* and **constraint inequalities.** This brings us to our five-step approach for solving linear programming applications.

Solving Linear Programming Applications

1. Identify the main objective and the decision variables (descriptive variables may help) and write the objective function in terms of these variables.
2. Organize all information in a table, with the *decision variables* and *constraints* heading up the columns, and their *components* leading each row.
3. Complete the table using the information given, and write the constraint inequalities using the decision variables, constraints, and the domain.
4. Graph the constraint inequalities, determine the feasible region, and identify all corner points.
5. Test these points in the objective function to determine the optimal solution(s).

EXAMPLE 9 ▶ Solving an Application of Linear Programming

The owner of a snack food business wants to create two nut mixes for the holiday season. The regular mix will have 14 oz of peanuts and 4 oz of cashews, while the deluxe mix will have 12 oz of peanuts and 6 oz of cashews. The owner estimates he will make a profit of $3 on the regular mixes and $4 on the deluxe mixes. How many of each should be made in order to maximize profit, if only 840 oz of peanuts and 348 oz of cashews are available?

Solution ▶ Our *objective* is to maximize profit, and the *decision variables* could be r to represent the regular mixes sold, and d for the number of deluxe mixes. This gives $P(r, d) = \$3r + \$4d$ as our *objective function.* The information is organized in Table 9.1, using the variables r, d, and the constraints to head each column. Since the mixes are composed of peanuts and cashews, these lead the rows in the table.

Table 9.1

$P(r, d) = \$3r + \$4d$

	Regular r	Deluxe d	Constraints: Total Ounces Available
Peanuts	14	12	840
Cashews	4	6	348

After filling in the appropriate values, reading the table from left to right along the "peanut" row and the "cashew" row, gives the constraint inequalities $14r + 12d \le 840$

and $4r + 6d \le 348$. Realizing we won't be making negative numbers of mixes, the remaining constraints are $r \ge 0$ and $d \ge 0$. The complete system is

$$\begin{cases} 14r + 12d \le 840 \\ 4r + 6d \le 348 \\ r \ge 0 \\ d \ge 0 \end{cases}$$

Note once again that the solutions must be in QI, since $r \ge 0$ and $d \ge 0$. Graphing the first two inequalities using slope-intercept form gives $d \le -\frac{7}{6}r + 70$ and $d \le -\frac{2}{3}r + 58$ producing the feasible region shown in lavender. The four corner points are (0, 0), (60, 0), (0, 58), and (24, 42). Three of these points are intercepts and can be read from a table of values or the graph itself. The point (24, 42) was found by solving the system $\begin{cases} 14r + 12d = 840 \\ 4r + 6d = 348 \end{cases}$. Knowing the solution must occur at one of these points, we test them in the objective function (Table 9.2).

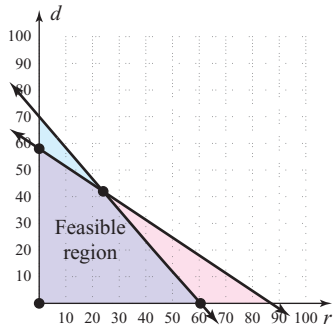


Table 9.2

Corner Point	Objective Function $P(r, d) = \$3r + \$4d$
(0, 0)	$P(0, 0) = \$3(0) + \$4(0) = \$0$
(60, 0)	$P(60, 0) = \$3(60) + \$4(0) = \$180$
(0, 58)	$P(0, 58) = \$3(0) + \$4(58) = \$232$
(24, 42)	$P(24, 42) = \$3(24) + \$4(42) = \$240$

Profit will be maximized if 24 boxes of the regular mix and 42 boxes of the deluxe mix are made and sold.

Now try Exercises 63 through 68 ▶

Linear programming can also be used to minimize an objective function, as in Example 10.

EXAMPLE 10 ▶ Minimizing Costs Using Linear Programming

A beverage producer needs to minimize shipping costs from its two primary plants in Kansas City (KC) and St. Louis (STL). All wholesale orders within the state are shipped from one of these plants. An outlet in Macon orders 200 cases of soft drinks on the same day an order for 240 cases comes from Springfield. The plant in KC has 300 cases ready to ship and the plant in STL has 200 cases. The cost of shipping each case to Macon is \$0.50 from KC, and \$0.70 from STL. The cost of shipping each case to Springfield is \$0.60 from KC, and \$0.65 from STL. How many cases should be shipped from each warehouse to minimize costs?

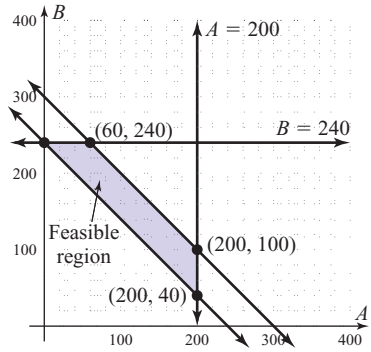
Solution ▶ Our *objective* is to minimize costs, which depends on the number of cases shipped from each plant. To begin we use the following assignments:

$A \rightarrow$ cases shipped from KC to Macon
$B \rightarrow$ cases shipped from KC to Springfield
$C \rightarrow$ cases shipped from STL to Macon
$D \rightarrow$ cases shipped from STL to Springfield

From this information, the equation for total cost T is

$$T = 0.5A + 0.6B + 0.7C + 0.65D,$$

an equation in *four* variables. To make the cost equation more manageable, note since Macon ordered 200 cases, $A + C = 200$. Similarly, Springfield ordered 240 cases, so $B + D = 240$. After solving for C and D, respectively, these equations enable us to substitute for C and D, resulting in an equation with just two variables. For $C = 200 - A$ and $D = 240 - B$ we have



$$\begin{aligned} T(A, B) &= 0.5A + 0.6B + 0.7(200 - A) + 0.65(240 - B) \\ &= 0.5A + 0.6B + 140 - 0.7A + 156 - 0.65B \\ &= 296 - 0.2A - 0.05B \end{aligned}$$

The constraints involving the KC plant are $A + B \le 300$ with $A \ge 0$, $B \ge 0$. The constraints for the STL plant are $C + D \le 200$ with $C \ge 0$, $D \ge 0$. Since we want a system in terms of A and B only, we again substitute $C = 200 - A$ and $D = 240 - B$ in all the STL inequalities:

$C + D \le 200$	STL inequalities	$C \ge 0$	$D \ge 0$
$(200 - A) + (240 - B) \le 200$	substitute $200 - A$ for C, $240 - B$ for D	$200 - A \ge 0$	$240 - B \ge 0$
$440 - A - B \le 200$	simplify	$200 \ge A$	$240 \ge B$
$240 \le A + B$	result		

Combining the new STL constraints with those from KC produces the following system and solution. All points of intersection were read from the graph or located using the related system of equations.

$$\begin{cases} A + B \le 300 \\ A + B \ge 240 \\ A \le 200 \\ B \le 240 \\ A \ge 0 \\ B \ge 0 \end{cases}$$

To find the minimum cost, we check each vertex in the objective function.

Vertices	Objective Function $T(A, B) = 296 - 0.2A - 0.05B$
(0, 240)	$P(0, 240) = 296 - 0.2(0) - 0.05(240) = \$284$
(60, 240)	$P(60, 240) = 296 - 0.2(60) - 0.05(240) = \$272$
(200, 100)	$P(200, 100) = 296 - 0.2(200) - 0.05(100) = \$251$
(200, 40)	$P(200, 40) = 296 - 0.2(200) - 0.05(40) = \$254$

The minimum cost occurs when $A = 200$ and $B = 100$, meaning the producer should ship the following quantities:

$A \rightarrow$ cases shipped from KC to Macon $= 200$
$B \rightarrow$ cases shipped from KC to Springfield $= 100$
$C \rightarrow$ cases shipped from STL to Macon $= 0$
$D \rightarrow$ cases shipped from STL to Springfield $= 140$

D. You've just seen how we can solve applications using linear programming

Now try Exercises 69 and 70 ▶

9.3 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. Any line $y = mx + b$ drawn in the coordinate plane divides the plane into two regions called _____ _____.
2. For the line $y = mx + b$ drawn in the coordinate plane, solutions to $y > mx + b$ are found in the region _____ the line.
3. The overlapping region of two or more linear inequalities in a system is called the _____ region.
4. If a linear programming problem has a unique solution (x, y), it must be a _____ of the feasible region.
5. Suppose two boundary lines in a system of linear inequalities intersect, but the point of intersection is not a vertex of the feasible region. Describe how this is possible.
6. Describe the conditions necessary for a linear programming problem to have multiple solutions. (*Hint:* Consider the diagram in Figure 9.35, and the slope of the line from the objective function.)

▶ DEVELOPING YOUR SKILLS

Determine whether the ordered pairs given are solutions.

7. $2x + y > 3$; $(0, 0), (3, -5), (-3, -4), (-3, 9)$
8. $3x - y > 5$; $(0, 0), (4, -1), (-1, -5), (1, -2)$
9. $4x - 2y \le -8$; $(0, 0), (-3, 5), (-3, -2), (-1, 1)$
10. $3x + 5y \ge 15$; $(0, 0), (3, 5), (-1, 6), (7, -3)$

Solve the linear inequalities by shading the appropriate half plane. Verify your answer using a graphing calculator.

11. $x + 2y < 8$
12. $x - 3y > 6$
13. $2x - 3y \ge 9$
14. $4x + 5y \ge 15$

Solve the following inequalities using a graphing calculator. Your answer should include a screen shot or facsimile, and comments regarding a test point.

15. $3x + 2y \le 8$
16. $2x + 5y \ge 10$
17. $4x - 5y > -20$
18. $6x - 3y < 18$

Determine whether the ordered pairs given are solutions to the accompanying system.

19. $\begin{cases} 5y - x \ge 10 \\ 5y + 2x \le -5 \end{cases}$; $(-2, 1), (-5, -4), (-6, 2), (-8, 2.2)$
20. $\begin{cases} 8y + 7x \ge 56 \\ 3y - 4x \ge -12 \\ y \ge 4 \end{cases}$; $(1, 5), (4, 6), (8, 5), (5, 3)$

Solve each system of inequalities by graphing the solution region. Verify the solution using a test point.

21. $\begin{cases} x + 2y \ge 1 \\ 2x - y \le -2 \end{cases}$
22. $\begin{cases} -x + 5y < 5 \\ x + 2y \ge 1 \end{cases}$
23. $\begin{cases} 3x + y > 4 \\ x > 2y \end{cases}$
24. $\begin{cases} 3x \le 2y \\ y \ge 4x + 3 \end{cases}$
25. $\begin{cases} 2x + y < 4 \\ 2y > 3x + 6 \end{cases}$
26. $\begin{cases} x - 2y < -7 \\ 2x + y > 5 \end{cases}$
27. $\begin{cases} x > -3y - 2 \\ x + 3y \le 6 \end{cases}$
28. $\begin{cases} 2x - 5y < 15 \\ 3x - 2y > 6 \end{cases}$
29. $\begin{cases} 5x + 4y \ge 20 \\ x - 1 \ge y \end{cases}$
30. $\begin{cases} 10x - 4y \le 20 \\ 5x - 2y > -1 \end{cases}$
31. $\begin{cases} 0.2x > -0.3y - 1 \\ 0.3x + 0.5y \le 0.6 \end{cases}$
32. $\begin{cases} x > -0.4y - 2.2 \\ x + 0.9y \le -1.2 \end{cases}$
33. $\begin{cases} y \le \frac{3}{2}x \\ 4y \ge 6x - 12 \end{cases}$
34. $\begin{cases} 3x + 4y > 12 \\ y < \frac{2}{3}x \end{cases}$

35. $\begin{cases} \frac{-2}{3}x + \frac{3}{4}y \le 1 \\ \frac{1}{2}x + 2y \ge 3 \end{cases}$

36. $\begin{cases} \frac{1}{2}x + \frac{2}{5}y \le 5 \\ \frac{5}{6}x - 2y \ge -5 \end{cases}$

37. $\begin{cases} x - y \ge -4 \\ 2x + y \le 4 \\ x \ge 0, y \ge 0 \end{cases}$

38. $\begin{cases} 2x - y \le 5 \\ x + 3y \le 6 \\ x \ge 0, y \ge 0 \end{cases}$

39. $\begin{cases} y \le x + 3 \\ x + 2y \le 4 \\ x \ge 0, y \ge 0 \end{cases}$

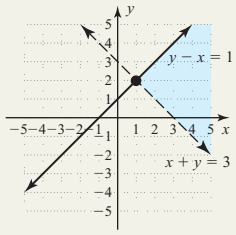
40. $\begin{cases} 4y < 3x + 12 \\ y \le x + 1 \\ x \ge 0, y \ge 0 \end{cases}$

41. $\begin{cases} 2x + 3y \le 18 \\ 2x + y \le 10 \\ x \ge 0, y \ge 0 \end{cases}$

42. $\begin{cases} 8x + 5y \le 40 \\ x + y \le 7 \\ x \ge 0, y \ge 0 \end{cases}$

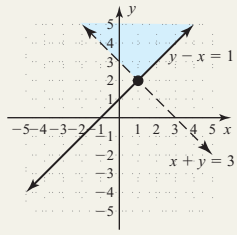
Use a graphing calculator to find the solution region for each system of linear inequalities. Your answer should include a screen shot or facsimile, and the location of any points of intersection.

43. $\begin{cases} y + 2x < 8 \\ y + x < 6 \\ x \ge 0 \\ y \ge 0 \end{cases}$



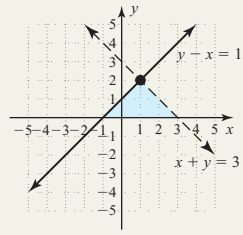
44. $\begin{cases} x + 2y < 10 \\ x + y < 7 \\ x \ge 0 \\ y \ge 0 \end{cases}$

45. $\begin{cases} -2x - y > -8 \\ -x - 2y < -7 \\ x \ge 0 \\ y \ge 0 \end{cases}$

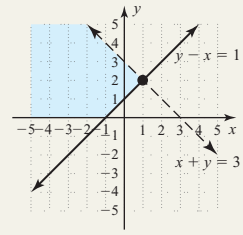


46. $\begin{cases} y + 2x \ge 10 \\ 2y + x \le 11 \\ x \ge 0 \\ y \ge 0 \end{cases}$

Use the equations given to write the system of linear inequalities represented by each graph.



47.



48.

49.

50.

Determine which of the ordered pairs given produces the maximum value of $f(x, y)$.

51. $f(x, y) = 12x + 10y$; (0, 0), (0, 8.5), (7, 0), (5, 3)

52. $f(x, y) = 50x + 45y$; (0, 0), (0, 21), (15, 0), (7.5, 12.5)

Determine which of the ordered pairs given produces the minimum value of $f(x, y)$.

53. $f(x, y) = 8x + 15y$; (0, 20), (35, 0), (5, 15), (12, 11)

54. $f(x, y) = 75x + 80y$; (0, 9), (10, 0), (4, 5), (5, 4)

For Exercises 55 and 56, find the *maximum* value of the objective function $f(x, y) = 8x + 5y$ and where this value occurs, given the constraints shown.

55. $\begin{cases} x + 2y \le 6 \\ 3x + y \le 8 \\ x \ge 0 \\ y \ge 0 \end{cases}$

56. $\begin{cases} 2x + y \le 7 \\ x + 2y \le 5 \\ x \ge 0 \\ y \ge 0 \end{cases}$

For Exercises 57 and 58, find the *minimum* value of the objective function $f(x, y) = 36x + 40y$ and where this value occurs, given the constraints shown.

57. $\begin{cases} 3x + 2y \ge 18 \\ 3x + 4y \ge 24 \\ x \ge 0 \\ y \ge 0 \end{cases}$

58. $\begin{cases} 2x + y \ge 10 \\ x + 4y \ge 3 \\ x \ge 2 \\ y \ge 0 \end{cases}$

▶ WORKING WITH FORMULAS

Area Formulas

59. The area of a triangle is usually given as $A = \frac{1}{2}BH$, where B and H represent the base and height, respectively. The area of a rectangle can be stated as $A = BH$. If the base of both a triangle and rectangle is equal to 20 in., what are the possible values for H if the triangle must have an area *greater than* 50 in^2 and the rectangle must have an area *less than* 200 in^2?

Volume Formulas

60. The volume of a cone is $V = \frac{1}{3}\pi r^2 h$, where r is the radius of the base and h is the height. The volume of a cylinder is $V = \pi r^2 h$. If the radius of both a cone and cylinder is equal to 10 cm, what are the possible values for h if the cone must have a volume *greater than* 200 cm^3 and the volume of the cylinder must be *less than* 850 cm^3?

▶ APPLICATIONS

Write a system of linear inequalities that models the information given, then solve. Verify the solution region using a graphing calculator.

61. **Gifts to grandchildren:** Grandpa Augustus is considering how to divide a $50,000 gift between his two grandchildren, Julius and Anthony. After weighing their respective positions in life and family responsibilities, he decides he must bequeath at least $20,000 to Julius, but no more than $25,000 to Anthony. Determine the possible ways that Grandpa can divide the $50,000.

62. **Guns versus butter:** Every year, governments around the world have to make the decision as to how much of their revenue must be spent on national defense and domestic improvements (guns versus butter). Suppose total revenue for these two needs was $120 billion, and a government decides they need to spend at least $42 billion on butter and no more than $80 billion on defense. Determine the possible amounts that can go toward each need.

Solve the following applications of linear programming.

63. **Land/crop allocation:** A farmer has 500 acres of land to plant corn and soybeans. During the last few years, market prices have been stable and the farmer anticipates a profit of $900 per acre on the corn harvest and $800 per acre on the soybeans. The farmer must take into account the time it takes to plant and harvest each crop, which is 3 hr/acre for corn and 2 hr/acre for soybeans. If the farmer has at most 1300 hr to plant, care for, and harvest each crop, how many acres of each crop should be planted in order to maximize profits?

64. **Coffee blends:** The owner of a coffee shop has decided to introduce two new blends of coffee in order to attract new customers—a *Deluxe Blend* and a *Savory Blend.* Each pound of the deluxe blend contains 30% Colombian and 20% Arabian coffee, while each pound of the savory blend contains 35% Colombian and 15% Arabian coffee (the remainder of each is made up of cheap and plentiful domestic varieties). The profit on the deluxe blend will be $1.25 per pound, while the profit on the savory blend will be $1.40 per pound. How many pounds of each should the owner make in order to maximize profit, if only 455 lb of Colombian coffee and 250 lb of Arabian coffee are currently available?

65. **Manufacturing screws:** A machine shop manufactures two types of screws—sheet metal screws and wood screws, using three different machines. Machine Moe can make a sheet metal screw in 20 sec and a wood screw in 5 sec. Machine Larry can make a sheet metal screw in 5 sec and a wood screw in 20 sec. Machine Curly, the newest machine (nyuk, nyuk) can make a sheet metal screw in 15 sec and a wood screw in 15 sec. (Shemp couldn't get a job because he failed the math portion of the employment exam.) Each machine can operate for only 3 hr each day before shutting down for maintenance. If sheet metal screws sell for 10 cents and wood screws sell for 12 cents, how many of each type should the machines be programmed to make in order to maximize revenue? (*Hint:* Standardize time units.)

66. **Hauling hazardous waste:** A waste disposal company is contracted to haul away some hazardous waste material. A full container of liquid waste weighs 800 lb and has a volume of 20 ft^3. A full container of solid waste weighs 600 lb and has a volume of 30 ft^3. The trucks used can carry at most 10 tons (20,000 lb) and have a carrying volume of 800 ft^3. If the trucking company makes $300 for disposing of liquid waste and $400 for disposing of solid waste, what is the maximum revenue per truck that can be generated?

67. **Maximizing profit—food service:** P. Barrett & Justin, Inc., is starting up a fast-food restaurant specializing in peanut butter and jelly sandwiches. Some of the peanut butter varieties are smooth, crunchy, reduced fat, and reduced sugar. The jellies will include those expected and common, as well as some exotic varieties such as kiwi and mango. Independent research has determined the two most popular sandwiches will be the traditional P&J (smooth peanut butter and grape jelly), and the Double-T (three slices of bread). A traditional P&J uses 2 oz of peanut butter and 3 oz of jelly. The Double-T uses 4 oz of peanut butter and 5 oz of jelly. The traditional sandwich will be priced at $2.00, and a Double-T at $3.50. If the restaurant has 250 oz of smooth peanut butter and 345 oz of grape jelly on hand for opening day, how many of each should they make and sell to maximize revenue?

68. Maximizing profit—construction materials: Mooney and Sons produces and sells two varieties of concrete mixes. The mixes are packaged in 50-lb bags. Type A is appropriate for finish work, and contains 20 lb of cement and 30 lb of sand. Type B is appropriate for foundation and footing work, and contains 10 lb of cement and 20 lb of sand. The remaining weight comes from gravel aggregate. The profit on type A is \$1.20/bag, while the profit on type B is \$0.90/bag. How many bags of each should the company make to maximize profit, if 2750 lb of cement and 4500 lb of sand are currently available?

69. Minimizing transportation costs: Robert's Las Vegas Tours needs to drive 375 people and 19,450 lb of luggage from Salt Lake City, Utah, to Las Vegas, Nevada, and can charter buses from two companies. The buses from company X carry 45 passengers and 2750 lb of luggage at a cost of \$1250 per trip. Company Y offers buses that carry 60 passengers and 2800 lb of luggage at a cost of \$1350 per trip. How many buses should be chartered from each company in order for Robert to minimize the cost?

70. Minimizing shipping costs: An oil company is trying to minimize shipping costs from its two primary refineries in Tulsa, Oklahoma, and Houston, Texas. All orders within the region are shipped from one of these two refineries. An order for 220,000 gal comes in from a location in Colorado, and another for 250,000 gal from a location in Mississippi. The Tulsa refinery has 320,000 gal ready to ship, while the Houston refinery has 240,000 gal. The cost of transporting each gallon to Colorado is \$0.05 from Tulsa and \$0.075 from Houston. The cost of transporting each gallon to Mississippi is \$0.06 from Tulsa and \$0.065 from Houston. How many gallons should be distributed from each refinery to minimize the cost of filling both orders?

▶ EXTENDING THE CONCEPT

71. Graph the feasible region formed by the system $\begin{cases} x \geq 0 \\ y \geq 0 \\ y \leq 3 \\ x \leq 3 \end{cases}$. (a) How would you describe this region? (b) Select random points within the region or on any boundary line and evaluate the objective function $f(x, y) = 4.5x + 7.2y$. At what point (x, y) will this function be maximized? (c) How does this relate to optimal solutions to a linear programing problem?

72. Find the maximum value of the objective function $f(x, y) = 22x + 15y$ given the constraints $\begin{cases} 2x + 5y \leq 24 \\ 3x + 4y \leq 29 \\ x + 6y \leq 26 \\ x \geq 0 \\ y \geq 0 \end{cases}$.

▶ MAINTAINING YOUR SKILLS

73. (6.7) Given the point $(-3, 4)$ is on the terminal side of angle θ with θ in standard position, find

a. $\cos\theta$

b. $\csc\theta$

c. $\cot\theta$

74. (4.6) Solve the rational inequality. Write your answer in interval notation. $\dfrac{x + 2}{x^2 - 9} > 0$

75. (2.6) The resistance to current flow in copper wire varies directly as its length and inversely as the square of its diameter. A wire 8 m long with a 0.004-m diameter has a resistance of 1500 Ω. Find the resistance in a wire of like material that is 2.7 m long with a 0.005-m diameter.

76. (7.4) Use a half-angle identity to find an exact value for $\cos\left(\dfrac{7\pi}{12}\right)$.

9.4 Partial Fraction Decomposition

LEARNING OBJECTIVES

In Section 9.4 you will see how we can:

- ❑ **A.** Set up a decomposition template to help rewrite a rational expression as the sum of its partial fractions
- ❑ **B.** Decompose a rational expression using convenient values
- ❑ **C.** Decompose a rational expression by equating coefficients and using a system of equations
- ❑ **D.** Apply partial fraction decomposition to a telescoping sum

One application of linear systems often seen in higher mathematics involves rewriting a rational expression as a sum of its **partial fractions.** While most often used as a prelude to the application of other mathematical techniques, practical applications of the process range from a study of chemical reactions to the analysis of thermodynamic experiments.

A. Setting Up a Decomposition Template

Recall that a rational expression is one of the form $\frac{P(x)}{Q(x)}$, where P and Q are polynomials and $Q(x) \neq 0$. The addition of rational expressions is widely taught in courses prior to college algebra, and involves combining two rational expressions into a single term using a common denominator. For the *decomposition* of rational expressions, we seek to reverse this process. To begin, we make the following observations:

1. Consider the sum $\frac{7}{x+2} + \frac{5}{x-3}$, noting both terms are proper fractions (the degree of the numerator is less than the degree of the denominator) and have distinct linear denominators.

$$\begin{aligned} \frac{7}{x+2} + \frac{5}{x-3} &= \frac{7(x-3)}{(x+2)(x-3)} + \frac{5(x+2)}{(x-3)(x+2)} && \text{common denominator} \\ &= \frac{7(x-3)+5(x+2)}{(x+2)(x-3)} && \text{combine numerators} \\ &= \frac{12x-11}{(x+2)(x-3)} && \text{result} \end{aligned}$$

Assuming we didn't have the original sum to look at, reversing the process would require us to begin with the template

$$\frac{12x-11}{(x+2)(x-3)} = \frac{A}{x+2} + \frac{B}{x-3}$$

and solve for the *constants* A and B. We know the numerators must be constant, otherwise the fraction(s) would be improper while the original expression is not.

2. Consider the sum $\frac{3}{x-1} + \frac{5}{x^2-2x+1}$, again noting both terms are proper fractions.

$$\begin{aligned} \frac{3}{x-1} + \frac{5}{x^2-2x+1} &= \frac{3}{x-1} + \frac{5}{(x-1)(x-1)} && \text{factor denominators} \\ &= \frac{3(x-1)}{(x-1)(x-1)} + \frac{5}{(x-1)(x-1)} && \text{common denominator} \\ &= \frac{(3x-3)+5}{(x-1)(x-1)} && \text{combine numerators} \\ &= \frac{3x+2}{(x-1)^2} && \text{result} \end{aligned}$$

Note that while the new denominator is the repeated factor $(x-1)^2$, *both* $(x-1)$ and $(x-1)^2$ were denominators in the original sum. Assuming we didn't know the original sum, reversing the process would require us to begin with the template

$$\frac{3x+2}{(x-1)^2} = \frac{A}{x-1} + \frac{B}{(x-1)^2}$$

and solve for the constants A and B. As before, the numerator of the first term must be constant. While the second term would still be a proper fraction if the numerator were linear (degree 1), the denominator is a *repeated* linear factor and using a single constant in the numerator of *all such fractions* will ensure we obtain unique values for A and B **(see Exercise 58).** Note that for any repeated linear factor $(x + a)^n$ in the original denominator, terms of the form $\frac{A_1}{x + a} + \frac{A_2}{(x + a)^2} + \frac{A_3}{(x + a)^3} + \cdots + \frac{A_{n-1}}{(x + a)^{n-1}} + \frac{A_n}{(x + a)^n}$ must appear in the decomposition template, although some of these numerators may turn out to be zero.

EXAMPLE 1 ▶ Setting Up the Decomposition Template for Linear Factors

Write the decomposition template for

a. $\frac{x - 8}{2x^2 + 5x + 3}$ **b.** $\frac{x + 1}{x^2 - 6x + 9}$

Solution ▶

a. Factoring the denominator gives $\frac{x - 8}{(2x + 3)(x + 1)}$. Since the denominator consists of two distinct linear factors, the decomposition template is:

$$\frac{x - 8}{(2x + 3)(x + 1)} = \frac{A}{2x + 3} + \frac{B}{x + 1}$$ decomposition template

b. After factoring the denominator we have $\frac{x + 1}{(x - 3)^2}$, where the denominator consists of a repeated linear factor. Using our previous observations, the decomposition template would be:

$$\frac{x + 1}{(x - 3)^2} = \frac{A}{x - 3} + \frac{B}{(x - 3)^2}$$ decomposition template

Now try Exercises 7 through 16 ▶

When both distinct and repeated linear factors are present in the denominator, the decomposition template maintains the elements illustrated above. Each distinct linear factor appearing in the denominator, and all powers of a repeated linear factor, will have a constant numerator.

EXAMPLE 2 ▶ Setting Up the Decomposition Template for Repeated Linear Factors

Write the decomposition template for $\frac{x^2 - 4x - 15}{x^3 - 2x^2 + x}$.

Solution ▶ Factoring the denominator gives $\frac{x^2 - 4x - 15}{x(x^2 - 2x + 1)}$ or $\frac{x^2 - 4x - 15}{x(x - 1)^2}$ after factoring completely. With a distinct linear factor of x, and the repeated linear factor $(x - 1)^2$, the decomposition template becomes:

$$\frac{x^2 - 4x - 15}{x(x - 1)^2} = \frac{A}{x} + \frac{B}{x - 1} + \frac{C}{(x - 1)^2}$$ decomposition template

Now try Exercises 17 through 20 ▶

Returning to our observations:

3. Consider the sum $\frac{4}{x} + \frac{2x+3}{x^2+1}$, noting the denominator of the first term is linear, while the denominator of the second is an irreducible quadratic.

$$\begin{aligned}\frac{4}{x} + \frac{2x+3}{x^2+1} &= \frac{4(x^2+1)}{x(x^2+1)} + \frac{(2x+3)x}{(x^2+1)x} && \text{find common denominator}\\ &= \frac{(4x^2+4)+(2x^2+3x)}{x(x^2+1)} && \text{combine numerators}\\ &= \frac{6x^2+3x+4}{x(x^2+1)} && \text{result}\end{aligned}$$

Here, reversing the process would require us to begin with the template

$$\frac{6x^2+3x+4}{x(x^2+1)} = \frac{A}{x} + \frac{Bx+C}{x^2+1}$$

allowing that the numerator of the second term might be linear since it is quadratic but *not a repeated linear factor,* and noting the fraction would still be proper in cases where $B = 0$.

4. Finally, consider the sum $\frac{1}{x^2+3} + \frac{x-2}{(x^2+3)^2}$, where we note the denominator of the first term is an irreducible quadratic, with the denominator of the second term being *the same factor* with multiplicity two.

$$\begin{aligned}\frac{1}{x^2+3} + \frac{x-2}{(x^2+3)^2} &= \frac{1(x^2+3)}{(x^2+3)(x^2+3)} + \frac{x-2}{(x^2+3)(x^2+3)} && \text{common denominator}\\ &= \frac{(x^2+3)+(x-2)}{(x^2+3)(x^2+3)} && \text{combine numerators}\\ &= \frac{x^2+x+1}{(x^2+3)^2} && \text{result after simplifying}\end{aligned}$$

WORTHY OF NOTE

Note that the second term in the decomposition template would still be a proper fraction if the numerator were quadratic or cubic, but since the denominator is a *repeated* quadratic factor, using only a linear form ensures we obtain unique values for all coefficients.

Reversing the process would require us to begin with the template

$$\frac{x^2+x+1}{(x^2+3)^2} = \frac{Ax+B}{x^2+3} + \frac{Cx+D}{(x^2+3)^2}$$

allowing that the numerator of either term might be nonconstant for the reasons in observation 3. Similar to our reasoning in observation 2, all powers of a repeated quadratic factor must be present in the decomposition template.

EXAMPLE 3 ▶ Setting Up the Decomposition Template for Quadratic Factors

Write the decomposition template for

a. $\frac{x^2+10x+1}{(x+1)(x^2+3x+4)}$ **b.** $\frac{x^2}{(x^2+2)^3}$

Solution ▶

a. With the denominator having one distinct linear factor and one irreducible quadratic factor, the decomposition template would be:

$$\frac{x^2+10x+1}{(x+1)(x^2+3x+4)} = \frac{A}{x+1} + \frac{Bx+C}{x^2+3x+4} \quad \text{decomposition template}$$

b. The denominator consists of a repeated quadratic factor. Using our previous observations, the decomposition template would be:

$$\frac{x^2}{(x^2+2)^3} = \frac{Ax+B}{x^2+2} + \frac{Cx+D}{(x^2+2)^2} + \frac{Ex+F}{(x^2+2)^3} \quad \text{decomposition template}$$

Now try Exercises 21 through 24 ▶

When both distinct and repeated factors are present in the denominator, the decomposition template maintains the essential elements determined by observations 1 through 4. Using these observations, we can formulate a general approach to the decomposition template.

The Decomposition Template

For the rational expression $\frac{P(x)}{Q(x)}$ and constants $A, B, C, D, \ldots$,

1. If the degree of P is greater than or equal to the degree of Q, find the quotient and remainder using polynomial division. Only the remainder portion need be decomposed into partial fractions.
2. Factor Q completely into linear factors and irreducible quadratic factors.
3. For the linear factors, each distinct linear factor and each power of a repeated linear factor must appear in the decomposition template and have a constant numerator.
4. For the irreducible quadratic factors, each distinct quadratic factor and each power of a repeated quadratic factor must appear in the decomposition template and have a linear numerator.

☑ **A.** You've just seen how we can set up a decomposition template

B. Decomposition Using Convenient Values

Once the decomposition template is obtained, we multiply both sides of the equation by the factored form of the original denominator and simplify. The resulting equation is an identity (a true statement for all real numbers x), and in many cases, all that's required is a choice of **convenient values** for x to identify the constants A, B, C, and so on.

EXAMPLE 4 ▶ **Decomposing a Rational Expression Using Convenient Values**

Decompose the expression $\frac{4x + 11}{x^2 + 7x + 10}$ into partial fractions. Use the **TABLE** feature of a calculator to check your answer.

Solution ▶ Factoring the denominator gives $\frac{4x + 11}{(x + 5)(x + 2)}$, and we note there are two distinct linear factors in the denominator. The decomposition template will be

$$\frac{4x + 11}{(x + 5)(x + 2)} = \frac{A}{x + 5} + \frac{B}{x + 2} \quad \text{decomposition template}$$

Multiplying both sides by $(x + 5)(x + 2)$ clears all denominators and yields

$$4x + 11 = A(x + 2) + B(x + 5) \quad \text{clear denominators}$$

Since the equation must be true for all x, using $x = -5$ will *conveniently* eliminate the term with B, and enable us to solve for A directly:

$$\begin{aligned} 4(-5) + 11 &= A(-5 + 2) + B(-5 + 5) && \text{substitute } -5 \text{ for } x \\ -20 + 11 &= -3A + B(0) && \text{simplify} \\ -9 &= -3A && \text{term with } B \text{ is eliminated} \\ 3 &= A && \text{solve for } A \end{aligned}$$

To find B, we repeat this procedure, using a value that *conveniently* eliminates the term with A, namely $x = -2$.

$$\begin{aligned} 4x + 11 &= A(x + 2) + B(x + 5) && \text{original equation} \\ 4(-2) + 11 &= A(-2 + 2) + B(-2 + 5) && \text{substitute } -2 \text{ for } x \\ -8 + 11 &= A(0) + 3B && \text{simplify} \\ 3 &= 3B && \text{term with } A \text{ is eliminated} \\ 1 &= B && \text{solve for } B \end{aligned}$$

With $A = 3$ and $B = 1$, the complete decomposition is:

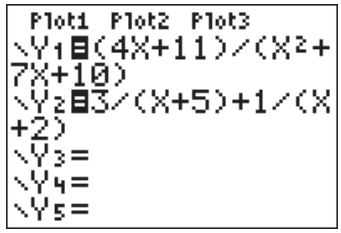
$$\frac{4x + 11}{(x + 5)(x + 2)} = \frac{3}{x + 5} + \frac{1}{x + 2}$$

Check ▶ In the Y= screen, enter the original expression as $Y_1 = \dfrac{4X + 11}{X^2 + 7X + 10}$ and the decomposition as $Y_2 = \dfrac{3}{X + 5} + \dfrac{1}{X + 2}$ (see Figure 9.36). Next, set the **TABLE** to start at –3 with a step size of 1 and press 2nd GRAPH to produce the table shown in Figure 9.37. Scrolling through the table, note the Y_1 and Y_2 outputs for any given X are the same, providing strong evidence that $Y_1 = Y_2$. For a rigorous check that $\dfrac{4x + 11}{x^2 + 7x + 10} = \dfrac{3}{x + 5} + \dfrac{1}{x + 2}$, simply add the rational expressions on the right.

WORTHY OF NOTE

Keep in mind the zeroes of any denominator in rational functions are excluded from the domain. The calculator reminds us of this in Example 4 by indicating that X = −2 and X = −5 result in an "ERROR," *for both Y_1 and Y_2.*

Figure 9.36



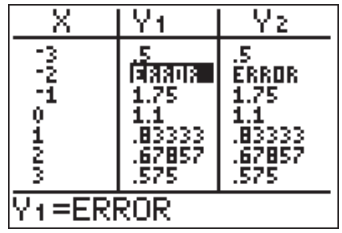


Figure 9.37

Now try Exercises 25 through 28 ▶

EXAMPLE 5 ▶ Decomposing a Rational Expression Using Convenient Values

Decompose the expression $\dfrac{9}{(x + 5)(x^2 + 7x + 10)}$ into partial fractions.

Solution ▶ Factoring the denominator gives $\dfrac{9}{(x + 5)(x + 2)(x + 5)}$ or $\dfrac{9}{(x + 2)(x + 5)^2}$ in simplified form. With one distinct linear factor and a repeated linear factor, the decomposition template will be $\dfrac{9}{(x + 2)(x + 5)^2} = \dfrac{A}{x + 2} + \dfrac{B}{x + 5} + \dfrac{C}{(x + 5)^2}$. Multiplying both sides by $(x + 2)(x + 5)^2$ clears all denominators and yields

$$9 = A(x + 5)^2 + B(x + 2)(x + 5) + C(x + 2)$$

Using $x = -5$ will conveniently eliminate the terms with A and B, enabling us to solve for C directly:

$$\begin{aligned} 9 &= A(-5 + 5)^2 + B(-5 + 2)(-5 + 5) + C(-5 + 2) && \text{substitute } -5 \text{ for } x \\ 9 &= A(0) + B(-3)(0) - 3C && \text{simplify} \\ 9 &= -3C && \text{terms with } A \text{ and } B \text{ are eliminated} \\ -3 &= C && \text{solve for } C \end{aligned}$$

Using $x = -2$ will conveniently eliminate the terms with B and C, enabling us to solve for A:

$$\begin{aligned} 9 &= A(x+5)^2 + B(x+2)(x+5) + C(x+2) && \text{original equation}\\ 9 &= A(-2+5)^2 + B(-2+2)(-2+5) + C(-2+2) && \text{substitute } -2 \text{ for } x\\ 9 &= A(3)^2 + B(0)(3) + C(0) && \text{simplify}\\ 9 &= 9A && \text{terms with } B \text{ and } C \text{ are eliminated}\\ 1 &= A && \text{solve for } A \end{aligned}$$

To find the value of B, we can substitute $A = 1$ and $C = -3$ into the previous equation, *and any value of x that does not eliminate B*. For efficiency's sake, we often elect to use $x = 0$ or $x = 1$ for this purpose (if possible).

$$\begin{aligned} 9 &= A(x+5)^2 + B(x+2)(x+5) + C(x+2) && \text{original equation}\\ 9 &= 1(0+5)^2 + B(0+2)(0+5) - 3(0+2) && \text{substitute 1 for } A, -3 \text{ for } C, 0 \text{ for } x\\ 9 &= 25 + 10B - 6 && \text{simplify}\\ -10 &= 10B\\ -1 &= B && \text{solve for } B \end{aligned}$$

Figure 9.38

X	Y1	Y2
-5	ERROR	ERROR
-4	-4.5	-4.5
-3	-2.25	-2.25
-2	ERROR	ERROR
-1	.5625	.5625
0	.18	.18
1	.08333	.08333

Y1 ■ 9/((X+5)(X²+...

With $A = 1$, $B = -1$, and $C = -3$, the complete decomposition is:

$$\frac{9}{(x+2)(x+5)^2} = \frac{1}{x+2} + \frac{-1}{x+5} + \frac{-3}{(x+5)^2},$$

which can also be written as $\frac{1}{x+2} - \frac{1}{x+5} - \frac{3}{(x+5)^2}$. Figure 9.38 shows a **TABLE** check, where the original expression and decomposition have been entered into Y_1 and Y_2, respectively.

Now try Exercises 29 and 30 ▶

EXAMPLE 6 ▶ Decomposing a Rational Expression Using Convenient Values

Decompose the expression $\frac{3x+11}{x^3 - 3x^2 + x - 3}$ into partial fractions.

Solution ▶ After inspection, we note the denominator can be factored by grouping, resulting in the expression $\frac{3x+11}{(x-3)(x^2+1)}$. With one distinct linear factor and one irreducible quadratic factor, the decomposition template will be

$$\frac{3x+11}{(x-3)(x^2+1)} = \frac{A}{x-3} + \frac{Bx+C}{x^2+1}.$$

Multiplying both sides by $(x-3)(x^2+1)$ yields

$$3x + 11 = A(x^2+1) + (Bx+C)(x-3) \quad \text{clear denominators}$$

Using $x = 3$ will conveniently eliminate the term with B and C, giving

$$\begin{aligned} 3(3) + 11 &= A(3^2+1) + (B[3]+C)(3-3) && \text{substitute 3 for } x\\ 20 &= 10A + (B[3]+C)(0) && \text{simplify}\\ 20 &= 10A && \text{term with } B \text{ and } C \text{ is eliminated}\\ 2 &= A && \text{solve for } A \end{aligned}$$

Noting $x = 0$ will conveniently eliminate the term with B, we substitute 0 for x and 2 for A in order to solve for C:

$$\begin{aligned} 3x + 11 &= A(x^2+1) + (Bx+C)(x-3) && \text{original equation}\\ 3(0) + 11 &= 2(0^2+1) + (B[0]+C)(0-3) && \text{substitute 2 for } A \text{ and 0 for } x \end{aligned}$$

$$\begin{aligned} 11 &= 2 + C(-3) && \text{simplify} \\ 9 &= -3C && \text{solve for } C \\ -3 &= C && \text{result} \end{aligned}$$

To find the value of B, we substitute 2 for A, -3 for C, and any value of x that does not eliminate B. Here we chose $x = 1$.

$$\begin{aligned} 3x + 11 &= A(x^2 + 1) + (Bx + C)(x - 3) && \text{original equation} \\ 3(1) + 11 &= 2(1^2 + 1) + (B[1] + [-3])(1 - 3) && \text{substitute 2 for } A, -3 \text{ for } C, \text{ and 1 for } x \\ 14 &= 2(2) + (B - 3)(-2) && \text{simplify} \\ 14 &= 4 - 2B + 6 && \text{distribute} \\ 4 &= -2B && \text{solve for } B \\ -2 &= B && \text{result} \end{aligned}$$

With $A = 2$, $B = -2$, and $C = -3$, the complete decomposition is:

$$\frac{3x + 11}{(x - 3)(x^2 + 1)} = \frac{2}{x - 3} + \frac{-2x - 3}{x^2 + 1}.$$

The result can actually be written with fewer negative signs, as $\dfrac{2}{x - 3} - \dfrac{2x + 3}{x^2 + 1}$. Check the result by combining these fractions.

B. You've just seen how we can decompose a rational expression using convenient values

Now try Exercises 31 through 38 ▶

C. Decomposition Using a System of Equations

As an alternative to using convenient values, a system of equations can be set up by multiplying out the right-hand side (after clearing fractions) and equating coefficients of the terms with like degrees. Here we'll re-solve Example 6 using this method.

EXAMPLE 7 ▶ Decomposing a Rational Expression Using a System of Equations

Decompose the expression $\dfrac{3x + 11}{x^3 - 3x^2 + x - 3}$ into partial fractions by equating coefficients of like degree terms and using a system.

Solution ▶ From Example 6 we obtain

$$\frac{3x + 11}{(x - 3)(x^2 + 1)} = \frac{A}{x - 3} + \frac{Bx + C}{x^2 + 1} \qquad \text{decomposition template}$$

Multiplying both sides by $(x - 3)(x^2 + 1)$ yields

$$\begin{aligned} 3x + 11 &= A(x^2 + 1) + (Bx + C)(x - 3) && \text{clear denominators} \\ &= Ax^2 + A + Bx^2 - 3Bx + Cx - 3C && \text{distribute/FOIL} \\ &= (A + B)x^2 + (-3B + C)x + (A - 3C) && \text{collect like terms} \end{aligned}$$

By comparing the like terms on the left and right, we find $A + B = 0$, $-3B + C = 3$, and $A - 3C = 11$, resulting in the system $\begin{cases} A + B = 0 \\ -3B + C = 3 \\ A - 3C = 11 \end{cases}$.

Using $A = -B$ (from R1) in R3 results in the 2×2 subsystem $\begin{cases} -3B + C = 3 \\ -B - 3C = 11 \end{cases}$, and 3R1 + R2 of this system yields $-10B = 20$, giving $B = -2$ as before. Back-substitution again verifies $C = -3$ and $A = 2$.

Now try Exercises 39 and 40 ▶

In some cases, there are no "convenient values" to use and a system of equations is our best and only approach. More often than not, this happens when one or more of the denominators are irreducible quadratic factors.

EXAMPLE 8 ▶ **Decomposing a Rational Expression Using a System of Equations**

Decompose the expression $\dfrac{5x^2 + 2x + 12}{x^4 + 6x^2 + 9}$ into partial fractions by equating coefficients of like degree terms and using a system.

Solution ▶ By inspection or using a u-substitution, we find the denominator factors into a perfect square: $x^4 + 6x^2 + 9 = (x^2 + 3)^2$. The decomposition template is then

$$\frac{5x^2 + 2x + 12}{(x^2 + 3)^2} = \frac{Ax + B}{x^2 + 3} + \frac{Cx + D}{(x^2 + 3)^2}$$

After clearing fractions we obtain $5x^2 + 2x + 12 = (Ax + B)(x^2 + 3) + Cx + D$. The only "candidate" for a convenient value is $x = 0$, but this still leaves the unknowns B *and* D. Instead, we multiply out the right-hand side and equate coefficients of like terms as before.

$$\begin{aligned} \mathbf{5}x^2 + 2x + 12 &= (Ax + B)(x^2 + 3) + Cx + D \\ &= Ax^3 + 3Ax + Bx^2 + 3B + Cx + D \\ &= Ax^3 + \boldsymbol{B}x^2 + (3A + C)x + (3B + D) \end{aligned}$$

By equating coefficients we find $A = 0$, since the left-hand side has no cubic term, and $B = 5$ by direct comparison. This yields the system

$$\begin{cases} A = 0 \\ B = 5 \\ 3A + C = 2 \\ 3B + D = 12 \end{cases}$$

With $A = 0$ the third equation shows $C = 2$, and by substituting 5 for B in the fourth equation we find that $D = -3$. The final form of the decomposition is

$$\frac{5x^2 + 2x + 12}{(x^2 + 3)^2} = \frac{5}{x^2 + 3} + \frac{2x - 3}{(x^2 + 3)^2}$$

C. You've just seen how we can decompose a rational expression by equating coefficients and using a system of equations

Now try Exercises 41 through 46 ▶

D. Partial Fractions and Telescoping Sums

From movies or the popular media (*Pirates of the Caribbean, Dances With Wolves*, etc.), you might be aware that the telescopes of old were *retractable*. Since they were constructed as a series of nested tubes, you could compress the length with the lengths of the interior tubes being "negated" (see figure). In a similar fashion, some very extensive sums, called **telescoping sums,** can be rewritten in a more "compressed" form, where the interior terms are likewise negated and the resulting sum easily computed.

EXAMPLE 9 ▶ **Using Decomposition to Evaluate a Telescoping Sum**

For $t(x) = \dfrac{3}{x^2 + x}$

a. Evaluate the function for $x = 1, 2, 3$, and 4, then find the sum of these four terms.

b. Decompose the expression into partial fractions.

c. Evaluate the decomposed form for $x = 1, 2, 3$, and 4, leaving each result in unsimplified form.

d. Rewrite the sum from part (a) using the decomposed form of each term, and see if you can detect a pattern that enables you to compute the original sum more efficiently.

e. Note $\dfrac{3}{x^2 + x} = \dfrac{3}{(x)(x + 1)}$ and use the pattern noted in part (d) to find the following sum: $\dfrac{3}{1 \cdot 2} + \dfrac{3}{2 \cdot 3} + \dfrac{3}{3 \cdot 4} + \cdots + \dfrac{3}{24 \cdot 25}$.
Use a calculator to check your result.

Solution ►

a. $$\frac{3}{1+1} + \frac{3}{4+2} + \frac{3}{9+3} + \frac{3}{16+4} = \frac{3}{2} + \frac{1}{2} + \frac{1}{4} + \frac{3}{20}$$
$$= \frac{30}{20} + \frac{10}{20} + \frac{5}{20} + \frac{3}{20}$$
$$= \frac{48}{20} = \frac{12}{5}$$

b. The denominator has two distinct linear factors and the decomposition template will be

$$\frac{3}{x(x+1)} = \frac{A}{x} + \frac{B}{x+1} \quad \text{decomposition template}$$

Multiplying both sides by $x(x + 1)$ clears all denominators and gives

$$3 = A(x + 1) + Bx \quad \text{clear denominators}$$

Since the equation must be true for all x, using $x = -1$ will eliminate the term with A, and enable us to solve for B directly:

$$\begin{aligned} 3 &= A(-1 + 1) + B(-1) && \text{substitute } -1 \text{ for } x \\ 3 &= -B && \text{simplify, term with } A \text{ is eliminated} \\ -3 &= B && \text{solve for } B \end{aligned}$$

Repeat this procedure using $x = 1$ to solve for A.

$$\begin{aligned} 3 &= A(x + 1) + Bx && \text{from template} \\ 3 &= A(1 + 1) - 3(1) && \text{substitute } -3 \text{ for } B, 1 \text{ for } x \\ 6 &= 2A && \text{add 3 to both sides} \\ 3 &= A && \text{result} \end{aligned}$$

With $A = 3$ and $B = -3$, the decomposition is

$$\frac{3}{x(x+1)} = \frac{3}{x} - \frac{3}{x+1} \quad \text{decomposed form}$$

c. For $t(x) = \dfrac{3}{x} - \dfrac{3}{x+1}$, we have

$$t(1) = \frac{3}{1} - \frac{3}{1+1} = 3 - \frac{3}{2} \qquad t(2) = \frac{3}{2} - \frac{3}{2+1} = \frac{3}{2} - \frac{3}{3}$$
$$t(3) = \frac{3}{3} - \frac{3}{3+1} = \frac{3}{3} - \frac{3}{4} \qquad t(4) = \frac{3}{4} - \frac{3}{4+1} = \frac{3}{4} - \frac{3}{5}$$

d. Replacing each term in the given sum by the equivalent term in decomposed form yields

$$\frac{3}{1+1}+\frac{3}{4+2}+\frac{3}{9+3}+\frac{3}{16+4}=\left(\frac{3}{1}-\frac{3}{2}\right)+\left(\frac{3}{2}-\frac{3}{3}\right)+\left(\frac{3}{3}-\frac{3}{4}\right)+\left(\frac{3}{4}-\frac{3}{5}\right)$$

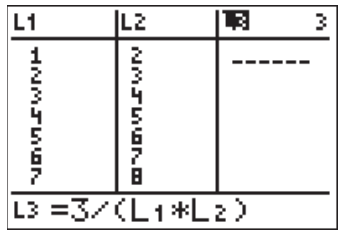
and we note that all interior terms will cancel (add to zero) leaving only the first and last terms of the sum. The result is $\frac{3}{1}-\frac{3}{5}=\frac{15}{5}-\frac{3}{5}=\frac{12}{5}$.

e. From the pattern in part (d) we note that regardless of the number of terms in the sum, all interior terms will cancel (add to zero) leaving only the first and last terms.

$$\begin{aligned}\frac{3}{1\cdot 2}+\frac{3}{2\cdot 3}+\frac{3}{3\cdot 4}+\cdots+\frac{3}{24\cdot 25}&=\left(\frac{3}{1}-\frac{3}{2}\right)+\left(\frac{3}{2}-\frac{3}{3}\right)+\left(\frac{3}{3}-\frac{3}{4}\right)+\cdots+\left(\frac{3}{24}-\frac{3}{25}\right)\\&=\frac{3}{1}-\frac{3}{25}=\frac{75}{25}-\frac{3}{25}\\&=\frac{72}{25}\end{aligned}$$

Check ▶ To check this result using a calculator, we begin by clearing out lists L1, L2, and L3 and entering the integers 1 through 24 into L1. These values will serve as the first factors of each denominator in the given sum. Next, move the cursor onto the L2 column header and use the keystrokes 2nd 1 + 1) ENTER **(L_1+1)** to fill L2 with the second factors of each denominator. Now we can use L3 to generate each individual term in the sum, as shown in Figure 9.39. At this point, pressing ENTER will cause these terms appear and we **QUIT** to the home screen. From here, use the calculator to sum the L3 terms with the keystrokes 2nd STAT **(LIST)** › › **5:sum(** 2nd 3) ENTER. As Figure 9.40 shows, this sum is equal to $\frac{72}{25}$ and the result from part (e) checks.

Figure 9.39



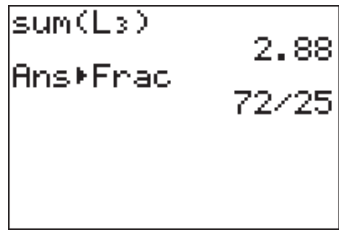


Figure 9.40

Now try Exercises 51 through 54 ▶

D. You've just seen how we can apply partial fraction decomposition to a telescoping sum

As a final note, if the degree of the numerator is *greater than* the degree of the denominator in the original expression, divide using long division and apply the methods above to the rational remainder. For instance, you can check that $\frac{3x^3+6x^2+5x-7}{x^2+2x+1}=3x+\frac{2x-7}{(x+1)^2}$, and decomposing the remainder expression gives a final result of $3x+\frac{2}{x+1}-\frac{9}{(x+1)^2}$.

9.4 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. In order to rewrite a rational expression as the sum of its partial fractions, we must set up a decomposition _____.
2. Before beginning the process of partial fraction decomposition, the rational expression must be _____. If not, use polynomial division.
3. If the denominator of a rational expression contains a _____ _____ factor, each power of the factor must appear in the decomposition template and have a constant numerator.
4. If the denominator of a rational expression contains a distinct irreducible quadratic factor, it must appear in the decomposition template with a _____ numerator.
5. Discuss/Explain the process of writing $\frac{8x-3}{x^2-x}$ as a sum of partial fractions.
6. Discuss/Explain the first steps of the process of writing $\frac{x^2}{x^2-7x+12}$ as a sum of partial fractions.

▶ DEVELOPING YOUR SKILLS

The exercises below are designed solely to reinforce the various possibilities for decomposing a rational expression. All are proper fractions whose denominators are completely factored. Write the decomposition template, but *do not solve*.

7. $\frac{3x+2}{(x+3)(x-2)}$
8. $\frac{-4x+1}{(x-2)(x-5)}$
9. $\frac{2x+5}{(x-1)^2}$
10. $\frac{x-7}{(x+3)^2}$
11. $\frac{3x^2-2x+5}{(x-1)(x+2)(x-3)}$
12. $\frac{-2x^2+3x-4}{(x+3)(x+1)(x-2)}$
13. $\frac{x^2+5}{x(x-3)(x+1)}$
14. $\frac{x^2-7}{(x+4)(x-2)x}$
15. $\frac{x^2+2x-4}{(x-5)^3}$
16. $\frac{x^2+2x+3}{(x+4)^3}$
17. $\frac{x^2+x-1}{x^2(x+2)}$
18. $\frac{x^2-3x+5}{(x-3)(x+2)^2}$
19. $\frac{x^3+2x-5}{x^2(x-5)^2}$
20. $\frac{3x^2-5}{x^2(2x+1)^2}$
21. $\frac{2x^2+3}{(x-3)(x^2+5x+7)}$
22. $\frac{7x^2+3x-1}{(x+1)(x^2+2x+5)}$
23. $\frac{x^3+3x-2}{(x+1)(x^2+2)^2}$
24. $\frac{2x^3+3x^2-4x+1}{x(x^2+3)^2}$

Decompose each rational expression into partial fractions using convenient values. Use the TABLE feature of a calculator to verify your results.

25. $\frac{2x-27}{2x^2+x-15}$
26. $\frac{-11x+6}{5x^2-4x-12}$
27. $\frac{8x^2-3x-7}{x^3-x}$
28. $\frac{x^2+24x-12}{x^3-4x}$
29. $\frac{3x^2+7x-1}{x^3+2x^2+x}$
30. $\frac{-2x^2-7x+28}{x^3-4x^2+4x}$
31. $\frac{3x^3+3x^2+3x+5}{x^4+3x^2+2}$
32. $\frac{2x^3-2x^2+6x}{x^4+4x^2+3}$
33. $\frac{6x^2+x+13}{x^3+2x^2+3x+6}$
34. $\frac{3x^2+4x-1}{x^3-1}$
35. $\frac{x^4-3x^2-2x+1}{x^5+2x^3+x}$
36. $\frac{-3x^4-11x^2+x-12}{x^5-4x^3+4x}$
37. $\frac{3x^3+2x^2+7x+3}{x^4+x^3+3x^2}$
38. $\frac{2x^3-x+6}{x^4-2x^3+3x^2}$
39. $\frac{3x^2+10x+4}{8-x^3}$
40. $\frac{2x^2-14x-7}{x^3-2x^2+5x-10}$

When the denominator of the rational expression contains repeated factors, using a system of equations sometimes offers a more efficient way to find the needed coefficients. Decompose each rational expression into partial fractions by equating coefficients and using a system of equations.

41. $\dfrac{5x + 13}{x^2 + 6x + 9}$

42. $\dfrac{14 - 3x}{x^2 - 8x + 16}$

43. $\dfrac{2x^3 + x^2 + 5x + 1}{x^4 + 2x^2 + 1}$

44. $\dfrac{x^3 + 5x^2 + 6x + 37}{x^4 + 14x^2 + 49}$

45. $\dfrac{2x^2 - 4x + 5}{x^3 - 3x^2 + 3x - 1}$

46. $\dfrac{5x^2 + 20x + 21}{x^3 + 6x^2 + 12x + 8}$

▶ WORKING WITH FORMULAS

Logistic equations and population size: Logistic equations are often used to model the growth of various populations. Initially growth is very near to exponential, but then due to certain limiting factors (food, limited resources, space, etc.), growth slows and reaches a limit called the carrying capacity c. In the process of solving the logistic equation for $P(t)$, we often need to decompose the expression shown into partial fractions, where $P(0)$ represents the initial population. Decompose the expression for the following values given.

$$\frac{1}{P\left(P(0) - \dfrac{P(0)}{c}P\right)}$$

47. $P(0) = 100, c = 10$ **48.** $P(0) = 80, c = 20$ **49.** $P(0) = 10, c = 100$ **50.** $P(0) = 20, c = 80$

▶ APPLICATIONS

Telescoping sums: For each function given, use the method illustrated in Example 9 to find a pattern that enables you to compute the sum shown quickly.

51. $t(x) = \dfrac{1}{x^2 + x}$;
$\dfrac{1}{1 \cdot 2} + \dfrac{1}{2 \cdot 3} + \dfrac{1}{3 \cdot 4} + \cdots + \dfrac{1}{49 \cdot 50}$

52. $t(x) = \dfrac{2}{x^2 + x}$;
$\dfrac{2}{1 \cdot 2} + \dfrac{2}{2 \cdot 3} + \dfrac{2}{3 \cdot 4} + \cdots + \dfrac{2}{19 \cdot 20}$

53. $t(x) = \dfrac{1}{(2x - 1)(2x + 1)}$;
$\dfrac{1}{1 \cdot 3} + \dfrac{1}{3 \cdot 5} + \dfrac{1}{5 \cdot 7} + \cdots + \dfrac{1}{123 \cdot 125}$

54. $t(x) = \dfrac{2x + 1}{(x^2 + 1)(x^2 + 2x + 2)}$;
$\dfrac{1}{1 \cdot 2} + \dfrac{3}{2 \cdot 5} + \dfrac{5}{5 \cdot 10} + \cdots + \dfrac{21}{101 \cdot 122}$

▶ EXTENDING THE CONCEPT

Decompose the following expressions into partial fractions.

55. $\dfrac{\ln x + 2}{(\ln x - 2)(\ln x - 1)^2}$

56. $\dfrac{1 + e^x}{(e^x - 3)(e^{2x} - 2e^x + 1)}$

57. As written, the rational expression $\dfrac{x + 2}{(x - 1)(1 - x)}$ given cannot be decomposed using the standard template (two distinct linear factors). Try to apply this template and see what happens. What can be done to decompose the expression?

58. Try to decompose the rational expression $\dfrac{3x + 1}{x^2}$ using the decomposition template $\dfrac{A}{x} + \dfrac{Bx + C}{x^2}$ (note the second rational expression in this template is a proper fraction). (a) How does this affect the decomposition process? Is the decomposition unique? (b) Next, use the standard template as outlined in this section. What do you notice?

▶ MAINTAINING YOUR SKILLS

59. (4.1) Use polynomial division to rewrite $\dfrac{2x^3 - 3x^2 + 13x - 5}{x^2 - x + 6}$ in the form $q(x) + \dfrac{r(x)}{d(x)}$.

60. (4.1) Use the remainder theorem to find $f(3)$ for $f(x) = 2x^3 - x^2 + 10$.

61. (7.2) Verify that $\dfrac{\cos^3\theta}{\sin\theta} = \cot\theta - \cos\theta\sin\theta$ is an identity.

62. (7.5) Evaluate the following expressions:

a. $\cos\left[\cos^{-1}\left(-\dfrac{\sqrt{3}}{2}\right)\right]$

b. $\cos^{-1}\left[\cos\left(-\dfrac{\pi}{6}\right)\right]$

MID-CHAPTER CHECK

1. Solve by graphing the system on a graphing calculator. State whether the system is consistent, inconsistent, or dependent.

$$\begin{cases} x - 3y = -2 \\ 2x + y = 3 \end{cases}$$

2. Solve the system using elimination. State whether the system is consistent, inconsistent, or dependent:

$$\begin{cases} x - 3y = -4 \\ 2x + y = 13 \end{cases}$$

3. Solve using a system of linear equations and any method you choose. How many ounces of a 40% acid should be mixed with 10 oz of a 64% acid to obtain a 48% acid solution?

4. Determine whether the ordered triple is a solution to the system. If not, identify which equation(s) are not satisfied.

$$\begin{cases} 5x + 2y - 4z = 22 \\ 2x - 3y + z = -1 \\ 3x - 6y + z = 2 \end{cases} \qquad (2, 0, -3)$$

5. The system given is a dependent system. Without solving, state why.

$$\begin{cases} x + 2y - 3z = 3 \\ 2x + 4y - 6z = 6 \\ x - 2y + 5z = -1 \end{cases}$$

6. Solve the system of equations:

$$\begin{cases} x + 2y - 3z = -4 \\ 2y + z = 7 \\ 5y - 2z = 4 \end{cases}$$

7. Solve using elimination:

$$\begin{cases} 2x + 3y - 4z = -4 \\ x - 2y + z = 0 \\ -3x - 2y + 2z = -1 \end{cases}$$

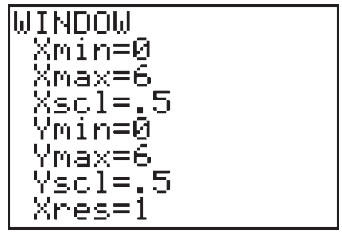
8. Decompose the expression $\dfrac{-x^2 - 4x + 15}{(x+1)(x-2)^2}$ into partial fractions.

9. Child prodigies: If you add Mozart's age when he wrote his first symphony, with the age of American chess player Paul Morphy when he began dominating the international chess scene, and the age of Blaise Pascal when he formulated his well-known *Essai pour les coniques* (Essay on Conics), the sum is 37. At the time of each event, Paul Morphy's age was 3 yr less than twice Mozart's, and Pascal was 3 yr older than Morphy. Set up a system of equations and find the age of each.

10. Candle manufacturing: David and Karen make table candles and holiday candles and sell them out of their home. Dave works 10 min and Karen works 30 min on each table candle, while Karen works 40 min and David works 20 min on each holiday candle. Dave can work at most 3 hr and 20 min (200 min) per day on the home business, while Karen can work at most 7 hr. If table candles sell for $4 and holiday candles sell for $6, how many of each should made to maximize their revenue?

REINFORCING BASIC CONCEPTS

Window Size and Graphing Technology



Since most substantial applications involve noninteger values, technology can play an important role in applying mathematical models. However, with its use comes a heavy responsibility to use it carefully. A very real effort must be made to determine the best approach and to secure a reasonable estimate. This is the only way to guard against (the inevitable) keystroke errors, or ensure a window size that properly displays the results.

Rationale

On October 1, 1999, the newspaper *USA TODAY* ran an article titled, "Bad Math added up to Doomed Mars Craft." The article told of how a $125,000,000.00 spacecraft was lost, apparently because the team of scientists that *plotted the course* for the craft used U.S. units of measurement, while the team of scientists *guiding* the craft were using metric units. NASA's space chief was later quoted, "The problem here was not the error, it was the failure of . . . the checks and balances in our process to detect the error."

No matter how powerful the technology, always try to begin your problem-solving efforts with an estimate. Begin by exploring the **context** of the problem, asking questions about the range of possibilities: How fast can a human run? How much does a new car cost? What is a reasonable price for a ticket? What is the total available to invest? There is no calculating involved in these estimates, they simply rely on "horse sense" and human experience. In many applied problems, the input and output values must be positive—which means the solution will appear in the first quadrant, narrowing the possibilities considerably. This information will be used to set the viewing window of your graphing calculator, in preparation for solving the problem using a system and graphing technology.

Illustration 1 ▶ Erin just filled both her boat and Blazer with gas, at a total cost of $211.14. She purchased 35.7 gallons of premium for her boat and 15.3 gal of regular for her Blazer. Premium gasoline cost $0.10 per gallon more than regular. What was the cost per gallon of each grade of gasoline?

Solution ▶ Asking how much *you* paid for gas the last time you filled up should serve as a fair estimate. Certainly (in 2011) a cost of $6.00 or more per gallon in the United States is too high, and a cost of $1.50 per gallon or less would be too low. Also, we can estimate a solution by assuming that both kinds of gasoline cost the same. This would mean 51 gal were purchased for about $211, and a quick division would place the estimate at near $\frac{211}{51} \approx \$4.14$ per gallon. A good viewing window would be restricted to the first quadrant (since cost > 0) with maximum values of Xmax $= 6$ and Ymax $= 6$.

Exercise 1: Solve Illustration 1 using graphing technology.

Exercise 2: Re-solve Exercises 63 and 64 from Section 9.1 using graphing technology. Verify results are identical.

9.5 Solving Linear Systems Using Matrices and Row Operations

LEARNING OBJECTIVES

In Section 9.5 you will see how we can:

- ❑ **A.** State the size of a matrix and identify its entries
- ❑ **B.** Form the augmented matrix of a system of equations
- ❑ **C.** Solve a system of equations using row operations
- ❑ **D.** Solve a system of equations using technology
- ❑ **E.** Recognize inconsistent and dependent systems
- ❑ **F.** Solve applications using matrix methods

Just as synthetic division streamlines the process of polynomial division, matrices and row operations streamline the process of solving systems using elimination. With the equations of the system in standard form, the location and order of the variable terms and constant terms are predetermined, and we simply apply the elimination process on the coefficients and constants alone.

A. Introduction to Matrices

In general terms, a **matrix** is simply a rectangular arrangement of numbers, called the **entries** of the matrix. **Matrices** (plural of matrix) are denoted by enclosing the entries between a left and right bracket, and named using a capital letter, such as $A = \begin{bmatrix} 1 & -3 & 2 \\ 5 & 1 & -1 \end{bmatrix}$ and $B = \begin{bmatrix} 2 & -1 & 3 \\ 4 & 6 & -2 \\ 1 & 0 & -1 \end{bmatrix}$. They occur in many different sizes as defined by the number of **rows** and **columns** each has, with the number of rows always given first. Matrix A is said to be a 2×3 (two by three) matrix, since it has two rows and three columns. Matrix B is a 3×3 (three by three) matrix.

EXAMPLE 1A ▶ **Identifying the Size and Entries of a Matrix**

Determine the size of each matrix and identify the entry located in the second row and first column.

a. $C = \begin{bmatrix} 3 & -2 \\ 1 & 5 \\ -4 & 3 \end{bmatrix}$ **b.** $D = \begin{bmatrix} 0.2 & -0.5 & 0.7 & 3.3 \\ -0.4 & 0.3 & 1 & 2 \\ 2.1 & -0.1 & 0.6 & 4.1 \end{bmatrix}$

Solution ▶

a. Matrix C is 3×2. The row 2, column 1 entry is 1.

b. Matrix D is 3×4. The row 2, column 1 entry is -0.4.

If a matrix has the same number of rows and columns, it's called a **square matrix.** Matrix B above is a square matrix, while matrix A is not. For square matrices, the values on a diagonal line *from the upper left to the lower right* are called the **diagonal entries** and are said to be **on the diagonal** of the matrix. When solving systems using matrices, much of our focus is on these diagonal entries.

EXAMPLE 1B ▶ **Identifying the Diagonal Entries of a Square Matrix**

Name the diagonal entries of each matrix.

a. $E = \begin{bmatrix} 1 & 4 \\ -2 & -3 \end{bmatrix}$ **b.** $F = \begin{bmatrix} 0.2 & -0.5 & 0.7 \\ -0.4 & 0.3 & 1 \\ 2.1 & -0.1 & 0.6 \end{bmatrix}$

Solution ▶

a. The diagonal entries of matrix E are 1 and -3.

b. For matrix F, the diagonal entries are 0.2, 0.3, and 0.6.

Now try Exercises 7 through 9 ▶

☑ **A.** You've just seen how we can state the size of a matrix and identify its entries

B. The Augmented Matrix of a System of Equations

A system of equations can be written in matrix form by augmenting or joining the **coefficient matrix,** formed by the variable coefficients, with the **matrix of constants.**

The coefficient matrix for the system $\begin{cases} 2x + 3y - z = 1 \\ x + z = 2 \\ x - 3y + 4z = 5 \end{cases}$ is $\begin{bmatrix} 2 & 3 & -1 \\ 1 & 0 & 1 \\ 1 & -3 & 4 \end{bmatrix}$ with column 1 for the coefficients of x, column 2 for the coefficients of y, and so on. The matrix of constants is $\begin{bmatrix} 1 \\ 2 \\ 5 \end{bmatrix}$. These two are joined to form the **augmented matrix,** with a dotted line often used to separate the two as shown here: $\left[\begin{array}{ccc:c} 2 & 3 & -1 & 1 \\ 1 & 0 & 1 & 2 \\ 1 & -3 & 4 & 5 \end{array}\right]$. It's important to note the use of a zero placeholder for the y-variable in the second row of the matrix, signifying there is no y-variable in the corresponding equation.

EXAMPLE 2 ▶ **Forming Augmented Matrices**

Form the augmented matrix for each system, and name the diagonal entries of each coefficient matrix.

a. $\begin{cases} 2x + y = 11 \\ -x + 3y = -2 \end{cases}$ **b.** $\begin{cases} \frac{1}{2}x + y = 5 \\ x + \frac{2}{3}y + \frac{5}{6}z = 11 \\ z = 6 \end{cases}$

Solution ▶

a. $\begin{cases} 2x + y = 11 \\ -x + 3y = -2 \end{cases} \longrightarrow \left[\begin{array}{cc:c} 2 & 1 & 11 \\ -1 & 3 & -2 \end{array}\right]$

Diagonal entries: 2 and 3.

b. $\begin{cases} \frac{1}{2}x + y = 5 \\ x + \frac{2}{3}y + \frac{5}{6}z = 11 \\ z = 6 \end{cases} \longrightarrow \left[\begin{array}{ccc:c} \frac{1}{2} & 1 & 0 & 5 \\ 1 & \frac{2}{3} & \frac{5}{6} & 11 \\ 0 & 0 & 1 & 6 \end{array}\right]$

Diagonal entries: $\frac{1}{2}$, $\frac{2}{3}$, and 1.

Notice that in the third row of part (b), the fact that $z = 6$ is indicated by zeroes in the x- and y-columns, 1 in the z-column, and a 6 in the column of constants.

Now try Exercises 10 through 12 ▶

This process can easily be reversed to write a system of equations from a given augmented matrix.

EXAMPLE 3 ▶ **Writing the System Corresponding to an Augmented Matrix**

Write the system of equations corresponding to each matrix, then solve the system using back-substitution.

a. $\left[\begin{array}{cc:c} 3 & -5 & -14 \\ 0 & 1 & 4 \end{array}\right]$ **b.** $\left[\begin{array}{ccc:c} 1 & 4 & -1 & -10 \\ 0 & -3 & 10 & 7 \\ 0 & 0 & 1 & 1 \end{array}\right]$

Solution ▶

a. $\left[\begin{array}{cc:c} 3 & -5 & -14 \\ 0 & 1 & 4 \end{array}\right] \longrightarrow \begin{cases} 3x - 5y = -14 \\ 1y = 4 \end{cases}$

With $y = 4$, we have

$3x - 5(4) = -14$ substitute 4 for y

$3x - 20 = -14$ multiply

$3x = 6$ add 20

$x = 2$ divide by 3

The solution is (2, 4)

b. $\left[\begin{array}{ccc|c} 1 & 4 & -1 & -10 \\ 0 & -3 & 10 & 7 \\ 0 & 0 & 1 & 1 \end{array}\right] \longrightarrow \begin{cases} 1x + 4y - 1z = -10 \\ -3y + 10z = 7 \\ 1z = 1 \end{cases}$

With $z = 1$, we first substitute 1 for z in the second equation.

$$\begin{aligned} -3y + 10(1) &= 7 && \text{substitute 1 for } z \\ -3y + 10 &= 7 && \text{multiply} \\ -3y &= -3 && \text{subtract 10} \\ y &= 1 && \text{divide by } -3 \end{aligned}$$

We then substitute 1 for z and 1 for y in the first equation.

$$\begin{aligned} x + 4(1) - 1(1) &= -10 && \text{substitute 1 for } y \text{ and 1 for } z \\ x + 3 &= -10 && \text{simplify} \\ x &= -13 && \text{subtract 3} \end{aligned}$$

The solution is $(-13, 1, 1)$.

B. You've just seen how we can form the augmented matrix of a system of equations

Now try Exercises 13 through 18 ▶

C. Solving a System Using Matrices

When a system of equations is written in augmented matrix form, we can solve the system by applying the same operations to each row of the matrix, that would be applied to the equations in the system. In this context, the operations are referred to as **elementary row operations.**

Elementary Row Operations

1. Any two rows in a matrix can be interchanged.
2. The elements of any row can be multiplied by a nonzero constant.
3. Any two rows can be added together, and the sum used to replace one of the rows.

In this section, we'll use these operations to **triangularize the augmented matrix,** employing a solution method known as **Gaussian elimination.** A square matrix is said to be in **triangular form** when all of the entries below the diagonal are zero. For example, the matrix $\left[\begin{array}{ccc|c} 1 & 4 & -1 & -10 \\ 0 & -3 & 10 & 7 \\ 0 & 0 & 1 & 1 \end{array}\right]$ is in triangular form: $\left[\begin{array}{ccc|c} 1 & 4 & -1 & -10 \\ 0 & -3 & 10 & 7 \\ 0 & 0 & 1 & 1 \end{array}\right]$.

In system form we have $\begin{cases} x + 4y - z = -10 \\ -3y + 10z = 7 \\ z = 1 \end{cases}$, meaning a matrix written in triangular form can be used to solve the system using back-substitution. We'll illustrate by solving $\begin{cases} 1x + 4y - 1z = 4 \\ 2x + 5y + 8z = 15 \\ 1x + 3y - 3z = 1 \end{cases}$, using elimination to the left, and *row operations on the augmented matrix* to the right. As before, R1 represents the first equation in the system and the first row of the matrix, R2 represents equation 2 and row 2, and so on. The calculations involved are shown for the first stage only and are designed to offer a careful comparison. In actual practice, the format shown in Example 4 is used.

Elimination (System of Equations)	Row Operations (Augmented Matrix)
$\begin{cases} 1x + 4y - 1z = 4 \\ 2x + 5y + 8z = 15 \\ 1x + 3y - 3z = 1 \end{cases}$	$\left[\begin{array}{ccc\|c} 1 & 4 & -1 & 4 \\ 2 & 5 & 8 & 15 \\ 1 & 3 & -3 & 1 \end{array}\right]$

To eliminate the x-term in R2, we use $-2R1 + R2 \rightarrow R2$. Identical operations are performed on the matrix, which begins the process of triangularizing the matrix.

System Form		Matrix Form				
$-2R1$	$-2x - 8y + 2z = -8$	$-2R1$	-2	-8	2	-8
$+$		$+$				
$R2$	$2x + 5y + 8z = 15$	$R2$	2	5	8	15
New R2	$-3y + 10z = 7$	New R2	0	-3	10	7

For R3, the operations are $-1R1 + R3 \rightarrow R3$.

$-1R1$	$-1x - 4y + 1z = -4$	$-1R1$	-1	-4	1	-4
$+$		$+$				
$R3$	$1x + 3y - 3z = 1$	$R3$	1	3	-3	1
New R3	$-1y - 2z = -3$	New R3	0	-1	-2	-3

As always, we should look for opportunities to simplify any equation in the system (and any row in the matrix). Note that $-1R3$ will make the coefficients and related matrix entries positive. Here is the new system and matrix.

New System	New Matrix
$\begin{cases} 1x + 4y - 1z = 4 \\ -3y + 10z = 7 \\ 1y + 2z = 3 \end{cases}$	$\left[\begin{array}{ccc\|c} 1 & 4 & -1 & 4 \\ 0 & -3 & 10 & 7 \\ 0 & 1 & 2 & 3 \end{array}\right]$

WORTHY OF NOTE

The procedure outlined for solving systems using matrices is virtually identical to that for solving systems by elimination. Using a 3×3 system for illustration, the "zeroes below the first diagonal entry" indicates we've eliminated the x-term from R2 and R3, the "zeroes below the second entry" indicates we've eliminated the y-term from the subsystem, and the division "to obtain a '1' in the final entry" indicates we have just solved for z.

On the left, we would finish by solving the 2×2 subsystem using $R2 + 3R3 \rightarrow R3$. In matrix form, we eliminate the corresponding entry (third row, second column) to triangularize the matrix.

$$\left[\begin{array}{ccc\|c} 1 & 4 & -1 & 4 \\ 0 & -3 & 10 & 7 \\ 0 & 1 & 2 & 3 \end{array}\right] \xrightarrow{R2 + 3R3 \rightarrow R3} \left[\begin{array}{ccc\|c} 1 & 4 & -1 & 4 \\ 0 & -3 & 10 & 7 \\ 0 & 0 & 16 & 16 \end{array}\right]$$

Dividing R3 by 16 gives $z = 1$ in the system, and entries of 0 0 1 1 in the augmented matrix. Completing the solution by back-substitution in the system gives the ordered triple (1, 1, 1). For practice using these row operations, **see Exercises 19 through 27.**

The general solution process is summarized here.

Solving Systems by Triangularizing the Augmented Matrix

1. Write the system as an augmented matrix.
2. Use row operations to obtain zeroes below the first diagonal entry.
3. Use row operations to obtain zeroes below the second diagonal entry.
4. Continue until the matrix is triangularized (entries below diagonal are zero).
5. Divide to obtain a "1" in the last diagonal entry (if it is nonzero), then convert to equation form and solve using back-substitution.

Note: At each stage, look for opportunities to simplify row entries using multiplication or division. Also, to begin the process any equation with an x-coefficient of 1 can be made R1 by interchanging the equations.

EXAMPLE 4 ▶ **Solving Systems Using the Augmented Matrix**

Solve by triangularizing the augmented matrix: $\begin{cases} 2x + y - 2z = -7 \\ x + y + z = -1 \\ -2y - z = -3 \end{cases}$

Solution ▶

$$\begin{cases} 2x + y - 2z = -7 \\ x + y + z = -1 \\ -2y - z = -3 \end{cases} \xrightarrow{\text{matrix form}} \left[\begin{array}{ccc|c} 2 & 1 & -2 & -7 \\ 1 & 1 & 1 & -1 \\ 0 & -2 & -1 & -3 \end{array}\right] \xrightarrow{R1 \leftrightarrow R2} \left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 2 & 1 & -2 & -7 \\ 0 & -2 & -1 & -3 \end{array}\right]$$

$$\left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 2 & 1 & -2 & -7 \\ 0 & -2 & -1 & -3 \end{array}\right] \xrightarrow{-2R1 + R2 \to R2} \left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 0 & -1 & -4 & -5 \\ 0 & -2 & -1 & -3 \end{array}\right] \xrightarrow{-1R2 \to R2} \left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 0 & 1 & 4 & 5 \\ 0 & -2 & -1 & -3 \end{array}\right]$$

$$\left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 0 & 1 & 4 & 5 \\ 0 & -2 & -1 & -3 \end{array}\right] \xrightarrow{2R2 + R3 \to R3} \left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 0 & 1 & 4 & 5 \\ 0 & 0 & 7 & 7 \end{array}\right] \xrightarrow{\frac{R3}{7} \to R3} \left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 0 & 1 & 4 & 5 \\ 0 & 0 & 1 & 1 \end{array}\right]$$

Converting the augmented matrix back into equation form yields $z = 1$. Back-substituting 1 for z in the second equation gives $y + 4(1) = 5$, with $y + 4 = 5$ showing $y = 1$. Back-substituting 1 for z and 1 for y in the first equation gives $x + 1 + 1 = -1$, or $x + 2 = -1$. Subtracting 2 from both sides shows $x = -3$. The solution is $(-3, 1, 1)$.

Now try Exercises 28 through 32 ▶

As mentioned, the process used in Example 4 is called **Gaussian elimination** (Carl Friedrich Gauss, 1777–1855), with the last matrix written in **row-echelon form.** It's also possible to solve a system entirely using only the augmented matrix, by continuing to use row operations until the diagonal entries are 1's, with 0's for all other entries in the coefficient matrix: $\left[\begin{array}{ccc|c} 1 & 0 & 0 & a \\ 0 & 1 & 0 & b \\ 0 & 0 & 1 & c \end{array}\right]$. The process is then called **Gauss-Jordan elimination** (Wilhelm Jordan, 1842–1899), with the final matrix written in ***reduced* row-echelon form** (see Appendix D).

Note that with Gauss-Jordan elimination, our *initial* focus is less on getting 1's along the diagonal, and more on obtaining zeroes for all entries *other than* the diagonal entries. This will enable us to work with integer values in the solution process, as shown in Example 5.

EXAMPLE 5 ▶ **Solving a System Using Gauss-Jordan Elimination**

Solve using Gauss-Jordan elimination $\begin{cases} 2x + 5z - 15 = 2y \\ 2x + 3y = -1 + z. \\ 4y + z = -7 \end{cases}$

Solution ▶

$$\begin{cases} 2x - 2y + 5z = 15 \\ 2x + 3y - 1z = -1 \\ 0x + 4y + 1z = -7 \end{cases} \xrightarrow[\text{standard form}]{\text{matrix form}} \left[\begin{array}{ccc|c} 2 & -2 & 5 & 15 \\ 2 & 3 & -1 & -1 \\ 0 & 4 & 1 & -7 \end{array}\right] \xrightarrow{-R1 + R2 \to R2} \left[\begin{array}{ccc|c} 2 & -2 & 5 & 15 \\ 0 & 5 & -6 & -16 \\ 0 & 4 & 1 & -7 \end{array}\right]$$

$$\left[\begin{array}{ccc|c} 2 & -2 & 5 & 15 \\ 0 & 5 & -6 & -16 \\ 0 & 4 & 1 & -7 \end{array}\right] \begin{array}{l} \xrightarrow{2R2 + 5R1 \to R1} \\ \xrightarrow{-4R2 + 5R3 \to R3} \end{array} \left[\begin{array}{ccc|c} 10 & 0 & 13 & 43 \\ 0 & 5 & -6 & -16 \\ 0 & 0 & 29 & 29 \end{array}\right] \xrightarrow{\frac{R3}{29} \to R3} \left[\begin{array}{ccc|c} 10 & 0 & 13 & 43 \\ 0 & 5 & -6 & -16 \\ 0 & 0 & 1 & 1 \end{array}\right]$$

$$\left[\begin{array}{ccc|c} 10 & 0 & 13 & 43 \\ 0 & 5 & -6 & -16 \\ 0 & 0 & 1 & 1 \end{array}\right] \begin{array}{l} -13R3 + R1 \to R1 \\ \\ 6R3 + R2 \to R2 \end{array} \left[\begin{array}{ccc|c} 10 & 0 & 0 & 30 \\ 0 & 5 & 0 & -10 \\ 0 & 0 & 1 & 1 \end{array}\right] \begin{array}{l} \frac{R1}{10} \to R1 \\ \\ \frac{R2}{5} \to R2 \end{array} \left[\begin{array}{ccc|c} 1 & 0 & 0 & 3 \\ 0 & 1 & 0 & -2 \\ 0 & 0 & 1 & 1 \end{array}\right]$$

The final matrix shows the solution is $x = 3, y = -2$, and $z = 1$, or $(3, -2, 1)$.

C. You've just seen how we can solve a system of equations using row operations

D. Solving Systems of Equations Using Technology

Graphing calculators offer a very efficient way to solve systems of equations using matrices. Once the system has been written in matrix form, it can easily be entered into a calculator and solved by having the calculator instantly perform the row operations needed to produce the diagonal of 1's (with zeroes for all other coefficient matrix entries). On many calculators, pressing 2nd x^{-1} **(MATRIX)** gives a screen similar to the one shown in Figure 9.41, where we begin by selecting the **EDIT** option (push the right arrow twice). Pressing ENTER places you on a screen where you can **EDIT** matrix A, changing the size as needed, then input the entries of the matrix. To use the 3×4 matrix from Example 4, we press 3 ENTER and then 4 ENTER, giving the screen shown in Figure 9.42. The dash marks to the right indicate that there is a fourth column that cannot be seen, but that comes into view as you enter the elements of the matrix. Begin entering the first row of the matrix, which is $\{2, 1, -2, -7\}$. Press ENTER after each entry and the cursor automatically goes to the next position in the matrix (note the calculator automatically shifts left and right to allow all four columns to be entered). After entering the second row $\{1, 1, 1, -1\}$ and the third row $\{0, -2, -1, -3\}$ the completed matrix should look like the one shown in Figure 9.43 (the matrix is currently shifted to the right, showing the fourth column).

Figure 9.41

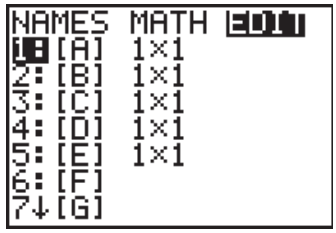

Figure 9.42

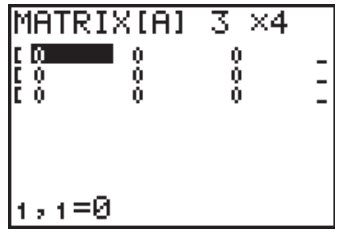

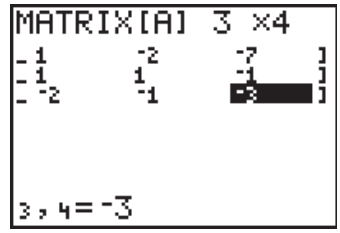

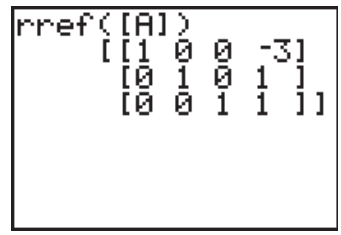

Figure 9.43

Most graphing calculators have an **rref** function, which is short for **reduced row echelon form.** To access this function, press 2nd x^{-1} **(MATRIX)** and select the **MATH** option, then scroll upward (or downward) until you get to the **B:rref** option. Pressing ENTER places this function on the home screen, where we must tell it to perform the **rref** operation on matrix [A]. Pressing the 2nd x^{-1} once again returns us to the matrix options, enabling us to select matrix **NAMES** (notice that **NAMES** is automatically highlighted). With the cursor over **1:[A] 3×4** we press ENTER and matrix [A] is placed on the home screen as the object of the **rref** function. After pressing) and ENTER the calculator quickly computes the reduced row echelon form and displays it on the screen, as in Figure 9.44. The solution is easily read as $x = -3, y = 1$, and $z = 1$, just as we found in Example 4.

Figure 9.44

EXAMPLE 6 ▶ **Solving a System of Equations Using Technology**

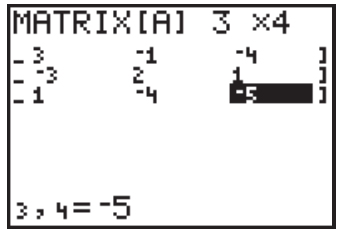
Solve the following system using a graphing calculator.

$$\begin{cases} 2x + 3y - z = -4 \\ x - 3y + 2z = 1 \\ -3x + y - 4z = -5 \end{cases}$$

Solution ▶ Entering the system as matrix [A] produces the screen shown in Figure 9.45. Using the **rref([A])** command as shown above produces the screen in Figure 9.46. The solution is the ordered triple $(-2, 1, 3)$.

Check by substituting -2 for x, 1 for y, and 3 for z in the original equations.

Figure 9.45



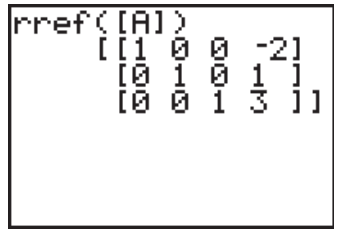


Figure 9.46

D. You've just seen how we can solve a system of equations using technology

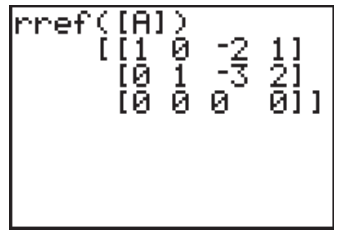
Now try Exercises 37 through 42 ▶

E. Inconsistent and Dependent Systems

Due to the strong link between a linear system and its augmented matrix, inconsistent and dependent systems can be recognized just as in Sections 9.1 and 9.2. An inconsistent system will yield an inconsistent or contradictory statement such as $0 = -12$, meaning all entries in a row of the matrix of coefficients are zero, but the constant is not. A linearly dependent system will yield an identity statement such as $0 = 0$, meaning all entries in *one* row of the matrix are zero. If the system has coincident dependence, *all* rows will be zero except one.

EXAMPLE 7 ▶ **Solving a Dependent System**

Solve the system using Gauss-Jordan elimination: $\begin{cases} x + y - 5z = 3 \\ -x + 2z = -1 \\ 2x - y - z = 0 \end{cases}$



Solution ▶

$$\begin{cases} x + y - 5z = 3 \\ -x + 2z = -1 \\ 2x - y - z = 0 \end{cases} \xrightarrow{\text{standard form}} \begin{cases} x + y - 5z = 3 \\ -x + 0y + 2z = -1 \\ 2x - y - z = 0 \end{cases} \xrightarrow{\text{matrix form}} \left[\begin{array}{ccc|c} 1 & 1 & -5 & 3 \\ -1 & 0 & 2 & -1 \\ 2 & -1 & -1 & 0 \end{array}\right]$$

$$\left[\begin{array}{ccc|c} 1 & 1 & -5 & 3 \\ -1 & 0 & 2 & -1 \\ 2 & -1 & -1 & 0 \end{array}\right] \begin{array}{l} \text{R1 + R2} \to \text{R2} \\ \\ -2\text{R1 + R3} \to \text{R3} \end{array} \left[\begin{array}{ccc|c} 1 & 1 & -5 & 3 \\ 0 & 1 & -3 & 2 \\ 0 & -3 & 9 & -6 \end{array}\right] \begin{array}{l} -1\text{R2 + R1} \to \text{R1} \\ \\ 3\text{R2 + R3} \to \text{R3} \end{array} \left[\begin{array}{ccc|c} 1 & 0 & -2 & 1 \\ 0 & 1 & -3 & 2 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

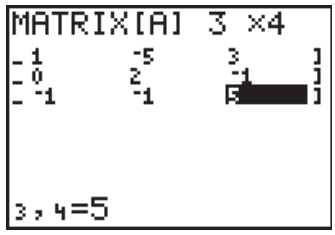
Since all entries in the last row are zeroes and it's the only row of zeroes, we conclude the system is linearly dependent and equivalent to $\begin{cases} x - 2z = 1 \\ y - 3z = 2 \end{cases}$ (a calculator solution is shown in the figure). As in Section 9.2, we demonstrate this dependence by writing the (x, y, z) solution in terms of

a parameter. Solving for y in R2 gives y in terms of z: $y = 3z + 2$. Solving for x in R1 gives x in terms of z: $x = 2z + 1$. As written, the solutions all depend on z: $x = 2z + 1$, $y = 3z + 2$, and $z = z$. Selecting p as the parameter (or some other "neutral" variable), we write the solution as $(2p + 1, 3p + 2, p)$. Two of the infinite number of solutions would be $(1, 2, 0)$ for $p = 0$, and $(-1, -1, -1)$ for $p = -1$. Test these triples in the original equations.

Now try Exercises 43 through 52 ▶

Since there was only one row of zeroes in the system from Example 7, we knew the system was *linearly* dependent. As mentioned previously, for coincident dependence the system will have only one *nonzero* row, with all other rows consisting entirely of zeroes. Note that if we change the constant in the third equation of the original system (the entry for row 3, column 4 was changed to a 5), an inconsistent system results as one equation is no longer dependent on the others (see Figures 9.47 and 9.48).

Figure 9.47



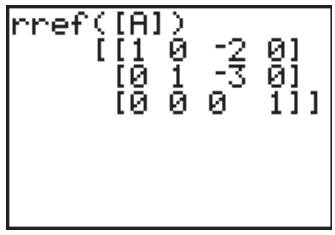


Figure 9.48

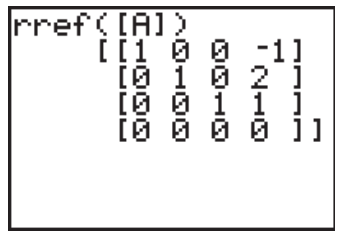

When the number of variables and equations in a system increases, solutions using technology can be particularly effective. In addition, some applications generate systems where the number of equations and number of variables are unequal, which the technology still handles efficiently.

EXAMPLE 8 ▶ **Solving a System of Equations Using Technology**

Solve the following system using a graphing calculator.

$$\begin{cases} x + 3y - z = 4 \\ -2x + y + 3z = 7 \\ -2y + 4z = 0 \\ -x + 4y + 2z = 11 \end{cases}$$

Solution ▶ After entering the system as matrix [A], using the **rref([A])** command produces the screen shown in the figure. Note that in this case, while the solution contains a row of zeroes, the system is *not linearly dependent* as there are more equations than variables, and unique values have been found for x, y, and z. The solution is $(-1, 2, 1)$.

E. You've just seen how we can recognize inconsistent and dependent systems

Now try Exercises 53 through 58 ▶

F. Solving Applications Using Matrices

As in other areas, solving applications using systems relies heavily on the ability to mathematically model information given verbally or in context. As you work through the exercises, read each problem carefully. Look for relationships that yield a system of two equations in two variables, three equations in three variables, and so on.

EXAMPLE 9 ▶ Determining the Original Value of Collector's Items

A museum purchases a famous painting, a ruby tiara, and a rare coin for its collection, spending a total of \$30,000. One year later, the painting has tripled in value, while the tiara and the coin have doubled in value. The items now have a total value of \$75,000. Find the purchase price of each if the original price of the painting was \$1000 more than twice the coin.

Solution ▶ Let P represent the price of the painting, T the tiara, and C the coin.

Total spent was \$30,000: $\rightarrow P + T + C = 30{,}000$
One year later: $\rightarrow 3P + 2T + 2C = 75{,}000$
Value of painting versus coin: $\rightarrow P = 2C + 1000$

$$\begin{cases} P + T + C = 30{,}000 \\ 3P + 2T + 2C = 75{,}000 \\ P = 2C + 1000 \end{cases} \xrightarrow{\text{standard form}} \begin{cases} 1P + 1T + 1C = 30{,}000 \\ 3P + 2T + 2C = 75{,}000 \\ 1P + 0T - 2C = 1000 \end{cases} \xrightarrow{\text{matrix form}} \left[\begin{array}{ccc|c} 1 & 1 & 1 & 30000 \\ 3 & 2 & 2 & 75000 \\ 1 & 0 & -2 & 1000 \end{array}\right]$$

$$\left[\begin{array}{ccc|c} 1 & 1 & 1 & 30000 \\ 3 & 2 & 2 & 75000 \\ 1 & 0 & -2 & 1000 \end{array}\right] \begin{array}{l} -3R1 + R2 \rightarrow R2 \\ \\ -1R1 + R3 \rightarrow R3 \end{array} \left[\begin{array}{ccc|c} 1 & 1 & 1 & 30000 \\ 0 & -1 & -1 & -15000 \\ 0 & -1 & -3 & -29000 \end{array}\right] \begin{array}{l} \\ -1R2 \rightarrow R2 \\ -1R3 \rightarrow R3 \end{array} \left[\begin{array}{ccc|c} 1 & 1 & 1 & 30000 \\ 0 & 1 & 1 & 15000 \\ 0 & 1 & 3 & 29000 \end{array}\right]$$

$$\left[\begin{array}{ccc|c} 1 & 1 & 1 & 30000 \\ 0 & 1 & 1 & 15000 \\ 0 & 1 & 3 & 29000 \end{array}\right] \begin{array}{l} \\ -1R2 + R3 \rightarrow R3 \\ \\ \end{array} \left[\begin{array}{ccc|c} 1 & 1 & 1 & 30000 \\ 0 & 1 & 1 & 15000 \\ 0 & 0 & 2 & 14000 \end{array}\right] \begin{array}{l} \\ \frac{R3}{2} \rightarrow R3 \\ \\ \end{array} \left[\begin{array}{ccc|c} 1 & 1 & 1 & 30000 \\ 0 & 1 & 1 & 15000 \\ 0 & 0 & 1 & 7000 \end{array}\right]$$

From R3 of the triangularized form, $C = \$7000$ directly. Since R2 represents $T + C = 15{,}000$, we find the tiara was purchased for $T = \$8000$. Substituting these values into the first equation shows the painting was purchased for \$15,000. The solution is (15,000, 8000, 7000). The solution found using a graphing calculator is also shown.

```
rref([A])
 [[1 0 0 15000]
  [0 1 0 8000 ]
  [0 0 1 7000 ]]
```

☑ **F.** You've just seen how we can solve applications using matrix methods

9.5 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. A matrix with the same number of rows and columns is called a(n) _____ matrix.

2. When the coefficient matrix is used with the matrix of constants, the result is a(n) _____ matrix.

3. Matrix $A = \left[\begin{array}{ccc} 2 & 4 & -3 \\ 1 & -2 & 1 \end{array}\right]$ is a ___ by ___ matrix. The entry in the second row and third column is ___.

4. Given matrix B shown here, the diagonal entries are ___, ___, and ___. $B = \left[\begin{array}{ccc} 1 & 4 & 3 \\ -1 & 5 & 2 \\ 3 & -2 & 1 \end{array}\right]$

5. The notation $-2R1 + R2 \rightarrow R2$ indicates that an equivalent matrix is formed by performing what operations/replacements?

6. Describe how to tell an inconsistent system apart from a dependent system when solving using matrix methods (row reduction).

▶ DEVELOPING YOUR SKILLS

Determine the size of each matrix and identify the third row and second column entry. If the matrix given is a square matrix, identify the diagonal entries.

7. $\begin{bmatrix} 1 & 0 \\ 2.1 & 1 \\ -3 & 5.8 \end{bmatrix}$

8. $\begin{bmatrix} 1 & 0 & 4 \\ 1 & 3 & -7 \\ 5 & -1 & 2 \end{bmatrix}$

9. $\begin{bmatrix} 1 & 0 & 4 \\ 1 & 3 & -7 \\ 5 & -1 & 2 \\ 2 & -3 & 9 \end{bmatrix}$

Form the augmented matrix, then name the diagonal entries of the coefficient matrix.

10. $\begin{cases} 2x - 3y - 2z = 7 \\ x - y + 2z = -5 \\ 3x + 2y - z = 11 \end{cases}$

11. $\begin{cases} x + 2y - z = 1 \\ x + z = 3 \\ 2x - y + z = 3 \end{cases}$

12. $\begin{cases} 2x + 3y + z = 5 \\ 2y - z = 7 \\ x - y - 2z = 5 \end{cases}$

Write the system of equations for each matrix. Then use back-substitution to find its solution.

13. $\left[\begin{array}{cc|c} 1 & 4 & 5 \\ 0 & 1 & \frac{1}{2} \end{array}\right]$

14. $\left[\begin{array}{cc|c} 1 & -5 & -15 \\ 0 & -1 & -2 \end{array}\right]$

15. $\left[\begin{array}{ccc|c} 1 & 2 & -1 & 0 \\ 0 & 1 & 2 & 2 \\ 0 & 0 & 1 & 3 \end{array}\right]$

16. $\left[\begin{array}{ccc|c} 1 & 0 & 7 & -5 \\ 0 & 1 & -5 & 15 \\ 0 & 0 & 1 & -26 \end{array}\right]$

17. $\left[\begin{array}{ccc|c} 1 & 3 & -4 & 29 \\ 0 & 1 & -\frac{3}{2} & \frac{21}{2} \\ 0 & 0 & 1 & 3 \end{array}\right]$

18. $\left[\begin{array}{ccc|c} 1 & 2 & -1 & 3 \\ 0 & 1 & \frac{1}{6} & \frac{2}{3} \\ 0 & 0 & 1 & \frac{22}{7} \end{array}\right]$

Perform the indicated row operation(s) in the order given and write the new matrix.

19. $\left[\begin{array}{cc|c} \frac{1}{2} & -3 & -1 \\ -5 & 2 & 4 \end{array}\right]$ $2R1 \to R1,$ $5R1 + R2 \to R2$

20. $\left[\begin{array}{cc|c} 7 & 4 & 3 \\ 4 & -8 & 12 \end{array}\right]$ $\frac{1}{4}R2 \to R2,$ $R1 \leftrightarrow R2$

21. $\left[\begin{array}{ccc|c} -2 & 1 & 0 & 4 \\ 5 & 8 & 3 & -5 \\ 1 & -3 & 3 & 2 \end{array}\right]$ $R1 \leftrightarrow R3,$ $-5R1 + R2 \to R2$

22. $\left[\begin{array}{ccc|c} -3 & 2 & 0 & 0 \\ 1 & 1 & 2 & 6 \\ 4 & 1 & -3 & 2 \end{array}\right]$ $R1 \leftrightarrow R2,$ $-4R1 + R3 \to R3$

23. $\left[\begin{array}{ccc|c} 3 & 1 & 1 & 8 \\ 6 & -1 & -1 & 10 \\ 4 & -2 & -3 & 22 \end{array}\right]$ $-2R1 + R2 \to R2,$ $-4R1 + 3R3 \to R3$

24. $\left[\begin{array}{ccc|c} 2 & 1 & -1 & -3 \\ 3 & 1 & 1 & 0 \\ 4 & 3 & 2 & 3 \end{array}\right]$ $-3R1 + 2R2 \to R2,$ $-2R1 + R3 \to R3$

What row operations would produce zeroes beneath the first entry in the diagonal?

25. $\left[\begin{array}{ccc|c} 1 & 3 & 0 & 2 \\ -2 & 4 & 1 & 1 \\ 3 & -1 & -2 & 9 \end{array}\right]$

26. $\left[\begin{array}{ccc|c} 1 & 1 & -4 & -3 \\ 3 & 0 & 1 & 5 \\ -5 & 3 & 2 & 3 \end{array}\right]$

27. $\left[\begin{array}{ccc|c} 1 & 2 & 0 & 10 \\ 5 & 1 & 2 & 6 \\ -4 & 3 & -3 & 2 \end{array}\right]$

Solve each system by triangularizing the augmented matrix and using back-substitution. Simplify by clearing fractions or decimals before beginning.

28. $\begin{cases} 2y = 5x + 4 \\ -5x = 2 - 4y \end{cases}$

29. $\begin{cases} 0.15g - 0.35h = -0.5 \\ -0.12g + 0.25h = 0.1 \end{cases}$

30. $\begin{cases} -\frac{1}{5}u + \frac{1}{4}v = 1 \\ \frac{1}{10}u + \frac{1}{2}v = 7 \end{cases}$

31. $\begin{cases} x - 2y + 2z = 7 \\ 2x + 2y - z = 5 \\ 3x - y + z = 6 \end{cases}$

32. $\begin{cases} 2x - 3y - 2z = 7 \\ x - y + 2z = -5 \\ 3x + 2y - z = 11 \end{cases}$

Solve using Gauss-Jordan elimination.

33. $\begin{cases} x + 2y - z = 1 \\ x + z = 3 \\ 2x - y + z = 3 \end{cases}$

34. $\begin{cases} 2x + 3y + z = 5 \\ 2y - z = 7 \\ x - y - 2z = 5 \end{cases}$

35. $\begin{cases} -x + y + 2z = 2 \\ x + y - z = 1 \\ 2x + y + z = 4 \end{cases}$

36. $\begin{cases} x + y - 2z = -1 \\ 4x - y + 3z = 3 \\ 3x + 2y - z = 4 \end{cases}$

Solve each system of equations using a graphing calculator. Verify each solution on the home screen using the ALPHA keys, as in Section 9.2.

37. $\begin{cases} x + 2y + 3z = 9 \\ -2x + y - 5z = -20 \\ 3x - 5y + z = 14 \end{cases}$

38. $\begin{cases} 3x + 5y + z = 6 \\ -4x + 7y - 2z = 24 \\ x - 10y + 3z = -40 \end{cases}$

39. $\begin{cases} 0.2x + 0.5y + z = 13 \\ -x + 0.7y - 0.4z = -9 \\ -0.5x - y + 0.8z = -4.6 \end{cases}$

40. $\begin{cases} 0.1x + 2y + 0.6z = -36.4 \\ -3x + 0.8y - 0.2z = -35 \\ 0.5x - y + 0.4z = 25 \end{cases}$

41. $\begin{cases} \frac{1}{2}x + \frac{3}{4}y + z = \frac{3}{4} \\ -x + \frac{1}{4}y + \frac{3}{2}z = -\frac{5}{8} \\ \frac{5}{4}x - y + \frac{1}{2}z = -\frac{1}{2} \end{cases}$

42. $\begin{cases} \frac{5}{4}x + \frac{1}{2}y + z = -\frac{1}{4} \\ -x + \frac{3}{2}y - \frac{7}{8}z = -\frac{3}{5} \\ \frac{1}{4}x - y + \frac{1}{4}z = \frac{2}{5} \end{cases}$

Solve each system by triangularizing the augmented matrix and using back-substitution. If the system is linearly dependent, give the solution in terms of a parameter. If the system has coincident dependence, answer in set notation as in Section 9.2.

43. $\begin{cases} 4x - 8y + 8z = 24 \\ 2x - 6y + 3z = 13 \\ 3x + 4y - z = -11 \end{cases}$

44. $\begin{cases} 3x + y + z = -2 \\ x - 2y + 3z = 1 \\ 2x - 3y + 5z = 3 \end{cases}$

45. $\begin{cases} x + 3y + 5z = 20 \\ 2x + 3y + 4z = 16 \\ x + 2y + 3z = 12 \end{cases}$

46. $\begin{cases} -x + 2y + 3z = -6 \\ x - y + 2z = -4 \\ 3x - 6y - 9z = 18 \end{cases}$

47. $\begin{cases} 3x - 4y + 2z = -2 \\ \frac{3}{2}x - 2y + z = -1 \\ -6x + 8y - 4z = 4 \end{cases}$

48. $\begin{cases} 2x - y + 3z = 1 \\ 4x - 2y + 6z = 2 \\ 10x - 5y + 15z = 5 \end{cases}$

49. $\begin{cases} 2x - y + 3z = 1 \\ 2y + 6z = 2 \\ x - \frac{1}{2}y + \frac{3}{2}z = 5 \end{cases}$

50. $\begin{cases} x - 2y + 3z = 2 \\ 3x + 4y - z = 6 \\ 4x + 2y + 2z = 7 \end{cases}$

51. $\begin{cases} x + 2y + z = 4 \\ 3x - 4y + z = 4 \\ 6x - 8y + 2z = 8 \end{cases}$

52. $\begin{cases} -2x + 4y - 3z = 4 \\ 5x - 6y + 7z = -12 \\ x + 2y + z = -4 \end{cases}$

Solve each system of equations using a graphing calculator. Verify each solution on the home screen using the ALPHA keys, as in Section 9.2.

53. $\begin{cases} 2x - 3y + z = 0 \\ x + 2y - z = 5 \\ 3x + 2z = 4 \\ x + 3y + z = 4 \end{cases}$

54. $\begin{cases} -2x + 5y = -4 \\ 3x - 4y + z = 0 \\ x + y - 3z = -8 \\ 5x - 9y + z = 4 \end{cases}$

55. $\begin{cases} x + 3y + z = 1 \\ x - 2z = 7 \\ -2y + 3z = -6 \\ 2x + 3y - z = 8 \end{cases}$

56. $\begin{cases} -2x + 3y = 4 \\ -2y + 5z = -19 \\ x - 4z = 13 \\ -x + 3y - 4z = 17 \end{cases}$

57.
$$\begin{cases} x + 2y - 3z + w = -13 \\ -2x + 3y + z - 2w = -3 \\ -x - y + 2z + 3w = 4 \\ 3x - 2y - z - w = 5 \end{cases}$$

58.
$$\begin{cases} 2x + 3y - 4z + w = -10 \\ x - 2y - 3w = 6 \\ 3x + 5z + 2w = 1 \\ -x + y + 2z - 5w = 21 \end{cases}$$

▶ WORKING WITH FORMULAS

Area of a triangle in the plane: $A = \pm\frac{1}{2}(x_1y_2 - x_2y_1 + x_2y_3 - x_3y_2 + x_3y_1 - x_1y_3)$

The area of a triangle in the plane is given by the formula shown, where the vertices of the triangle are located at the points (x_1, y_1), (x_2, y_2), and (x_3, y_3), and the sign is chosen to ensure a positive value.

59. Find the area of a triangle whose vertices are $(-1, -3)$, $(5, 2)$, and $(1, 8)$.

60. Find the area of a triangle whose vertices are $(6, -2)$, $(-5, 4)$, and $(-1, 7)$.

▶ APPLICATIONS

Model each problem using a system of linear equations. Then solve using the augmented matrix.

Descriptive Translation

61. The distance (via air travel) from Los Angeles (LA), California, to Saint Louis (STL), Missouri, to Cincinnati (CIN), Ohio, to New York City (NYC), New York, is approximately 2480 mi. Find the length of each flight if the distance from LA to STL is 50 mi more than five times the distance between STL and CIN, and 110 mi less than three times the distance from CIN to NYC.

62. In the 2006 NBA Championship Series, Dwayne Wade of the Miami Heat carried his team to the title after the first two games were lost to the Dallas Mavericks. If 187 points were scored in the title game and the Heat won by 3 points, what was the final score?

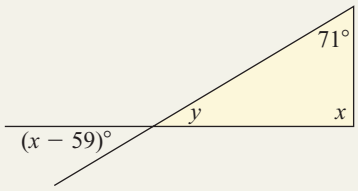
63. Moe is lecturing Larry and Curly once again (Moe, Larry, and Curly of *The Three Stooges* fame) claiming he is twice as smart as Larry and three times as smart as Curly. If he is correct and the sum of their IQs is 165, what is the IQ of each stooge?

64. A collector of rare books buys a handwritten, autographed copy of Edgar Allan Poe's *Annabel Lee,* an original advance copy of L. Frank Baum's *The Wonderful Wizard of Oz,* and a first print copy of *The Caine Mutiny* by Herman Wouk, paying a total of $100,000. Find the cost of each one, given that the cost of *Annabel Lee* and twice the cost of *The Caine Mutiny* sum to the price paid for *The Wonderful Wizard of Oz,* and *The Caine Mutiny* cost twice as much as *Annabel Lee.*

Geometry

65. A right triangle has a hypotenuse of 39 m. If the perimeter is 90 m, and the longer leg is 6 m longer than twice the shorter leg, find the dimensions of the triangle.

66. In triangle ABC, the sum of angles A and C is equal to three times angle B. Angle C is 10 degrees more than twice angle B. Find the measure of each angle.



Investment and Finance

67. Suppose $10,000 is invested in three different investment vehicles paying 5%, 7%, and 9% annual interest. Find the amount invested at each rate if the interest earned after 1 yr is $760 and the amount invested at 9% is equal to the sum of the amounts invested at 5% and 7%.

68. The trustee of a union's pension fund has invested funds in three ways: a savings fund paying 4% annual interest, a money market fund paying 7%, and government bonds paying 8%. Find the amount invested in each if the interest earned after one year is $0.178 million and the amount in government bonds is $0.3 million more than twice the amount in money market funds. The total amount invested is $2.5 million dollars.

▶ EXTENDING THE CONCEPT

69. Given the drawing shown, use a system of equations and the matrix method to find the measure of the angles labeled as x and y. Recall that vertical angles are equal and that the sum of the angles in a triangle is 180°.

70. The system given here has a solution of $(1, -2, 3)$. Find the value of a and b.

$$\left[\begin{array}{ccc|c} 1 & a & b & 1 \\ 2b & 2a & 5 & 13 \\ 2a & 7 & 3b & -8 \end{array}\right]$$

▶ MAINTAINING YOUR SKILLS

71. (8.5) **a.** Convert $z_1 = -1 - 3i$ to trigonometric form.

b. Convert $z_2 = 5 \text{ cis}\left(\frac{2\pi}{3}\right)$ to rectangular form.

72. (6.2) State the exact value of the following trig functions:

a. $\sin\left(-\frac{\pi}{6}\right)$ **b.** $\cos\left(\frac{5\pi}{4}\right)$

c. $\tan\left(\frac{2\pi}{3}\right)$ **d.** $\csc\left(\frac{3\pi}{2}\right)$

73. (5.6) Since 2005, cable installations for an Internet company have been modeled by the function $C(t) = 15 \ln(t + 1)$, where $C(t)$ represents cable installations in thousands, t yr after 2005. In what year will the number of installations be greater than 30,000?

74. (5.6) If a set amount of money p is deposited regularly (daily, weekly, monthly, etc.) n times per year at a fixed interest rate r, the amount of money A accumulated in t years is given by the formula shown. If a parent deposits $250 per month for 18 yr at 4.6% beginning when her first child was born, how much has been accumulated to help pay for college expenses?

$$A = \frac{p\left[\left(1 + \frac{r}{n}\right)^{nt} - 1\right]}{\frac{r}{n}}$$

9.6 The Algebra of Matrices

LEARNING OBJECTIVES

In Section 9.6 you will see how we can:

- ❑ **A.** Determine if two matrices are equal
- ❑ **B.** Add and subtract matrices
- ❑ **C.** Compute the product of two matrices

Matrices serve a much wider purpose than just a convenient method for solving systems. To understand their broader application, we need to know more about matrix theory, the various ways matrices can be combined, and some of their more practical uses. The common operations of addition, subtraction, multiplication, and division are all defined for matrices, as are other operations. Practical applications of matrix theory can be found in the social sciences, inventory management, genetics, operations research, engineering, and many other fields.

A. Equality of Matrices

To effectively study matrix algebra, we first give matrices a more general definition. For the *general* matrix A, all entries will be denoted using the lowercase letter "a," with their position in the matrix designated by the dual subscript a_{ij}. The letter "i" gives the *row* and the letter "j" gives the *column* of the entry's location. The general $m \times n$ matrix A is written

$$\begin{array}{l} \\ \text{row } 1 \rightarrow \\ \text{row } 2 \rightarrow \\ \text{row } 3 \rightarrow \\ \\ \text{row } i \rightarrow \\ \\ \text{row } m \rightarrow \end{array} \begin{array}{c} \begin{array}{ccccccc} \text{col } 1 & \text{col } 2 & \text{col } 3 & & \text{col } j & & \text{col } n \end{array} \\ \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1j} & \cdots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2j} & \cdots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \cdots & a_{3j} & \cdots & a_{3n} \\ \vdots & \vdots & \vdots & & \vdots & & \vdots \\ a_{i1} & a_{i2} & a_{i3} & \cdots & \boldsymbol{a_{ij}} & \cdots & a_{in} \\ \vdots & \vdots & \vdots & & \vdots & & \vdots \\ a_{m1} & a_{m2} & a_{m3} & \cdots & a_{mj} & \cdots & a_{mn} \end{bmatrix} \end{array}$$

a_{ij} is a general matrix element

The size of a matrix is also referred to as its **order,** and we say the order of general matrix A is $m \times n$. Note that diagonal entries have the same row and column number, a_{ij}, where $i = j$. Also, where the general entry of matrix A is a_{ij}, the general entry of matrix B is b_{ij}, of matrix C is c_{ij}, and so on.

EXAMPLE 1 ▶ Identifying the Order and Entries of a Matrix

State the order of each matrix and name the entries corresponding to a_{22}, a_{31}; b_{22}, b_{31}; and c_{22}, c_{31}.

a. $A = \begin{bmatrix} 1 & 4 \\ -2 & -3 \end{bmatrix}$ **b.** $B = \begin{bmatrix} 3 & -2 \\ 1 & 5 \\ -4 & 3 \end{bmatrix}$ **c.** $C = \begin{bmatrix} 0.2 & -0.5 & 0.7 \\ -1 & 0.3 & 1 \\ 2.1 & -0.1 & 0.6 \end{bmatrix}$

Solution ▶

a. matrix A: order 2×2. Entry $a_{22} = -3$ (the row 2, column 2 entry is -3). There is no a_{31} entry (A is only 2×2).

b. matrix B: order 3×2. Entry $b_{22} = 5$, entry $b_{31} = -4$.

c. matrix C: order 3×3. Entry $c_{22} = 0.3$, entry $c_{31} = 2.1$.

Now try Exercises 7 through 12 ▶

Equality of Matrices

Two matrices are equal if they have the same order and their corresponding entries are equal. In symbols, this means that $A = B$ if $a_{ij} = b_{ij}$ for all i and j.

EXAMPLE 2 ▶ Determining If Two Matrices Are Equal

Determine whether the following statements are true, false, or conditional. If false, explain why. If conditional, find values that will make the statement true.

a. $\begin{bmatrix} 1 & 4 \\ -2 & -3 \end{bmatrix} = \begin{bmatrix} -3 & -2 \\ 4 & 1 \end{bmatrix}$ **b.** $\begin{bmatrix} 3 & -2 \\ 1 & 5 \\ -4 & 3 \end{bmatrix} = \begin{bmatrix} 3 & -2 & 1 \\ 5 & -4 & 3 \end{bmatrix}$

c. $\begin{bmatrix} 1 & 4 \\ -2 & -3 \end{bmatrix} = \begin{bmatrix} a-2 & 2b \\ c & -3 \end{bmatrix}$

Solution ▶

a. $\begin{bmatrix} 1 & 4 \\ -2 & -3 \end{bmatrix} = \begin{bmatrix} -3 & -2 \\ 4 & 1 \end{bmatrix}$ is false. The matrices have the same order and entries, but corresponding entries are not equal.

b. $\begin{bmatrix} 3 & -2 \\ 1 & 5 \\ -4 & 3 \end{bmatrix} = \begin{bmatrix} 3 & -2 & 1 \\ 5 & -4 & 3 \end{bmatrix}$ is false. Their orders are not equal.

c. $\begin{bmatrix} 1 & 4 \\ -2 & -3 \end{bmatrix} = \begin{bmatrix} a-2 & 2b \\ c & -3 \end{bmatrix}$ is conditional. The statement is true when $a - 2 = 1$ $(a = 3)$, $2b = 4$ $(b = 2)$, $c = -2$, and is false otherwise.

A. You've just seen how we can determine if two matrices are equal

Now try Exercises 13 through 16 ▶

B. Addition and Subtraction of Matrices

A sum or difference of matrices is found by combining the corresponding entries. This limits the operations to matrices of like orders, so that every entry in one matrix has a "corresponding entry" in the other. This also means the result is a new matrix of *like order,* whose entries are the corresponding sums or differences. If you attempt to add matrices of unlike size on a graphing calculator, an error message is displayed: ERR: DIM MISMATCH. Note that since a_{ij} represents a general entry of matrix A, $[a_{ij}]$ represents the entire matrix.

Addition and Subtraction of Matrices

Given matrices A, B, and C having like orders.

The sum $A + B = C$, where $[a_{ij} + b_{ij}] = [c_{ij}]$.

The difference $A - B = C$, where $[a_{ij} - b_{ij}] = [c_{ij}]$.

EXAMPLE 3 ▶ **Adding and Subtracting Matrices**

Compute the sum or difference of the matrices indicated.

$$A = \begin{bmatrix} 2 & 6 \\ 1 & 0 \\ 1 & -3 \end{bmatrix} \qquad B = \begin{bmatrix} -3 & 2 & -1 \\ -5 & 4 & 3 \end{bmatrix} \qquad C = \begin{bmatrix} 3 & -2 \\ 1 & 5 \\ -4 & 3 \end{bmatrix}$$

a. $A + C$ **b.** $A + B$ **c.** $C - A$

Solution ▶

a. $A + C = \begin{bmatrix} 2 & 6 \\ 1 & 0 \\ 1 & -3 \end{bmatrix} + \begin{bmatrix} 3 & -2 \\ 1 & 5 \\ -4 & 3 \end{bmatrix}$ sum of A and C

$= \begin{bmatrix} 2+3 & 6+(-2) \\ 1+1 & 0+5 \\ 1+(-4) & -3+3 \end{bmatrix} = \begin{bmatrix} 5 & 4 \\ 2 & 5 \\ -3 & 0 \end{bmatrix}$ add corresponding entries

b. $A + B = \begin{bmatrix} 2 & 6 \\ 1 & 0 \\ 1 & -3 \end{bmatrix} + \begin{bmatrix} -3 & 2 & -1 \\ -5 & 4 & 3 \end{bmatrix}$ Addition and subtraction are not defined for matrices of unlike order.

c. $C - A = \begin{bmatrix} 3 & -2 \\ 1 & 5 \\ -4 & 3 \end{bmatrix} - \begin{bmatrix} 2 & 6 \\ 1 & 0 \\ 1 & -3 \end{bmatrix}$ difference of C and A

$= \begin{bmatrix} 3-2 & -2-6 \\ 1-1 & 5-0 \\ -4-1 & 3-(-3) \end{bmatrix} = \begin{bmatrix} 1 & -8 \\ 0 & 5 \\ -5 & 6 \end{bmatrix}$ subtract corresponding entries

Now try Exercises 17 through 20 ▶

Operations on matrices can be very laborious for larger matrices and for matrices with noninteger or large entries. For these, we can turn to available technology for assistance. This shifts our focus from a meticulous computation of entries, to carefully entering each matrix into the calculator, double-checking each entry, and appraising results to see if they're reasonable.

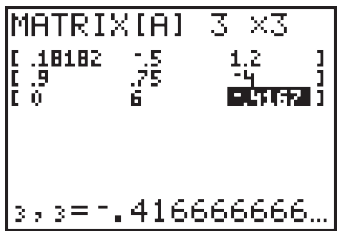
EXAMPLE 4 ▶ **Using Technology for Matrix Operations**

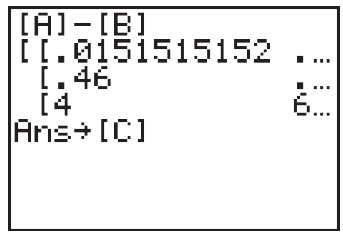
Use a calculator to compute the difference $A - B$ for the matrices given.

$$A = \begin{bmatrix} \frac{2}{11} & -0.5 & \frac{6}{5} \\ 0.9 & \frac{3}{4} & -4 \\ 0 & 6 & -\frac{5}{12} \end{bmatrix} \quad B = \begin{bmatrix} \frac{1}{6} & \frac{-7}{10} & 0.75 \\ \frac{11}{25} & 0 & -5 \\ -4 & \frac{-5}{9} & \frac{-5}{12} \end{bmatrix}$$

Solution ▶ The entries for matrix A are shown in Figure 9.49. After entering matrix B, exit to the home screen **[2nd MODE (QUIT)]**, call up matrix A, press the $-$ (subtract) key, then call up matrix B and press ENTER. The calculator quickly finds the difference and displays the results shown in Figure 9.50. The last line on the screen shows the result can be stored for future use in a new matrix C by pressing the STO▸ key, calling up matrix C, and pressing ENTER.

Figure 9.49





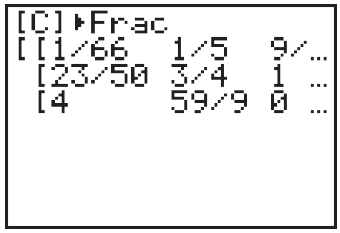


Figure 9.50

Now try Exercises 21 through 24 ▶

Figure 9.51

In Figure 9.50 the dots to the right on the calculator screen indicate there are additional digits or matrix columns that can't fit on the display, as often happens with larger matrices or decimal numbers. Sometimes, converting entries to fraction form will provide a display that's easier to read. Here, this is done by calling up the matrix C, and using the MATH **1: ▶ Frac** option. After pressing ENTER, all entries are converted to fractions in simplest form (where possible), as in Figure 9.51. The third column can be viewed by pressing the right arrow.

Since the addition of two matrices is defined as the sum of corresponding entries, we find the properties of matrix addition closely resemble those of real number addition. Similar to standard algebraic properties, $-A$ represents the product $-1 \cdot A$ and any subtraction can be rewritten as an algebraic sum: $A - B = A + (-B)$. As noted in the properties box, for any matrix A, the sum $A + (-A)$ will yield the **zero matrix *Z*,** a matrix of like size whose entries are all zeroes. Also note that matrix $-A$ is the **additive inverse** for A, while Z is the **additive identity.**

Properties of Matrix Addition

Given matrices A, B, C, and Z are $m \times n$ matrices, with Z the zero matrix. Then,

I. $A + B = B + A$ ⟶ matrix addition is commutative

II. $(A + B) + C = A + (B + C)$ ⟶ matrix addition is associative

III. $A + Z = Z + A = A$ ⟶ Z is the additive identity

IV. $A + (-A) = (-A) + A = Z$ ⟶ $-A$ is the additive inverse of A

☑ **B.** You've just seen how we can add and subtract matrices

C. Matrices and Multiplication

The algebraic terms $2a$ and ab have counterparts in matrix algebra. The product $2A$ represents a constant times a matrix and is called **scalar multiplication.** The product AB represents the product of two matrices.

Scalar Multiplication

Scalar multiplication is defined by taking the product of the constant with *each entry* in the matrix, forming a new matrix of like size. In symbols, for any real number k and matrix A, $kA = [ka_{ij}]$.

EXAMPLE 5 ▶ **Computing Operations on Matrices**

Given $A = \begin{bmatrix} 4 & 3 \\ \frac{1}{2} & 1 \\ 0 & -3 \end{bmatrix}$ and $B = \begin{bmatrix} 3 & -2 \\ 0 & 6 \\ -4 & 0.4 \end{bmatrix}$, compute the following:

a. $\frac{1}{2}B$ **b.** $-4A - \frac{1}{2}B$

Solution ▶

a. $\frac{1}{2}B = \left(\frac{1}{2}\right)\begin{bmatrix} 3 & -2 \\ 0 & 6 \\ -4 & 0.4 \end{bmatrix}$

$= \begin{bmatrix} (\frac{1}{2})(3) & (\frac{1}{2})(-2) \\ (\frac{1}{2})(0) & (\frac{1}{2})(6) \\ (\frac{1}{2})(-4) & (\frac{1}{2})(0.4) \end{bmatrix} = \begin{bmatrix} \frac{3}{2} & -1 \\ 0 & 3 \\ -2 & 0.2 \end{bmatrix}$

b. $-4A - \frac{1}{2}B = -4A + \left(-\frac{1}{2}\right)B$ rewrite using algebraic addition

$= \begin{bmatrix} (-4)(4) & (-4)(3) \\ (-4)(\frac{1}{2}) & (-4)(1) \\ (-4)(0) & (-4)(-3) \end{bmatrix} + \begin{bmatrix} (-\frac{1}{2})(3) & (-\frac{1}{2})(-2) \\ (-\frac{1}{2})(0) & (-\frac{1}{2})(6) \\ (-\frac{1}{2})(-4) & (-\frac{1}{2})(0.4) \end{bmatrix}$

$= \begin{bmatrix} -16 & -12 \\ -2 & -4 \\ 0 & 12 \end{bmatrix} + \begin{bmatrix} -\frac{3}{2} & 1 \\ 0 & -3 \\ 2 & -0.2 \end{bmatrix}$ simplify

$= \begin{bmatrix} -16 + (-\frac{3}{2}) & -12 + 1 \\ -2 + 0 & -4 + (-3) \\ 0 + 2 & 12 + (-0.2) \end{bmatrix} = \begin{bmatrix} -\frac{35}{2} & -11 \\ -2 & -7 \\ 2 & 11.8 \end{bmatrix}$ result

Now try Exercises 25 through 28 ▶

Matrix Multiplication

Consider a cable company offering three different levels of Internet service: Bronze—fast, Silver—very fast, and Gold—lightning fast. Table 9.3 shows the number and types of programs sold to households and businesses for the week. Each program has an incentive package consisting of a rebate and a certain number of free weeks, as shown in Table 9.4.

Table 9.3 Matrix A

	Bronze	Silver	Gold
Homes	40	20	**25**
Businesses	10	15	45

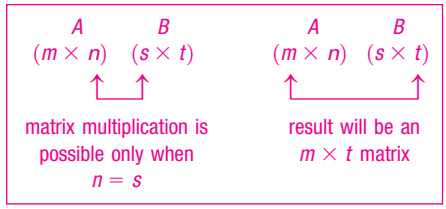

Table 9.4 Matrix B

	Rebate	Free Weeks
Bronze	$15	2
Silver	$25	4
Gold	**$35**	**6**

To compute the amount of rebate money the cable company paid to households for the week, we would take the first row (R1) in Table 9.3 and multiply by the

corresponding entries (bronze with bronze, silver with silver, and so on) in the first column (C1) of Table 9.4 and add these products. In matrix form, we have $[40\ \ 20\ \ \mathbf{25}] \cdot \begin{bmatrix} 15 \\ 25 \\ \mathbf{35} \end{bmatrix} = 40 \cdot 15 + 20 \cdot 25 + \mathbf{25} \cdot \mathbf{35} = \$1975$. Using R1 of Table 9.3 with C2 from Table 9.4 gives the number of free weeks awarded to homes: $[40\ \ 20\ \ \mathbf{25}] \cdot \begin{bmatrix} 2 \\ 4 \\ \mathbf{6} \end{bmatrix} = 40 \cdot 2 + 20 \cdot 4 + \mathbf{25} \cdot \mathbf{6} = 310$. Using the second row (R2) of Table 9.3 with the two columns from Table 9.4 will give the amount of rebate money and the number of free weeks, respectively, awarded to business customers. When all computations are complete, the result is a product matrix P with order 2×2. This is because the product of R1 from matrix A, with C1 from matrix B, *gives the entry in position* P_{11} *of the product matrix:* $\begin{bmatrix} 40 & 20 & \mathbf{25} \\ 10 & 15 & 45 \end{bmatrix} \cdot \begin{bmatrix} 15 & 2 \\ 25 & 4 \\ \mathbf{35} & 6 \end{bmatrix} = \begin{bmatrix} 1975 & 310 \\ 2100 & 350 \end{bmatrix}$.

Likewise, the product R1 · C2 will give entry P_{12} (310), the product of R2 with C1 will give P_{21} (2100), and so on. This "row × column" multiplication can be generalized, and leads to the following. Given $m \times n$ matrix A and $s \times t$ matrix B,

In more formal terms, we have the following definition of matrix multiplication.

Matrix Multiplication

Given the $m \times n$ matrix $A = [a_{ij}]$ and the $s \times t$ matrix $B = [b_{ij}]$. If $n = s$, then matrix multiplication is possible and the product AB is an $m \times t$ matrix $P = [p_{ij}]$, where p_{ij} is product of the ith row of A with the jth column of B.

In less formal terms, matrix multiplication involves multiplying the row entries of the first matrix with the corresponding column entries of the second, and adding them together. In Example 6, two of the matrix products [parts (a) and (b)] are shown in full detail, with the first entry of the product matrix color-coded.

EXAMPLE 6 ▶ Multiplying Matrices

Given the matrices A through E shown here, compute the following products:

a. AB **b.** CD **c.** DC **d.** AE **e.** EA

$$A = \begin{bmatrix} -2 & 1 \\ 3 & 4 \end{bmatrix} \quad B = \begin{bmatrix} 4 & 3 \\ 6 & 1 \end{bmatrix} \quad C = \begin{bmatrix} -2 & 1 & 3 \\ 1 & 0 & 2 \\ 4 & 1 & -1 \end{bmatrix} \quad D = \begin{bmatrix} 2 & 5 & 1 \\ 4 & -1 & 1 \\ 0 & 3 & -2 \end{bmatrix} \quad E = \begin{bmatrix} -2 & -1 \\ 3 & 0 \\ 1 & 2 \end{bmatrix}$$

Solution ▶ **a.** $AB = \begin{bmatrix} -2 & 1 \\ 3 & 4 \end{bmatrix}\begin{bmatrix} 4 & 3 \\ 6 & 1 \end{bmatrix} = \begin{bmatrix} -2 & -5 \\ 36 & 13 \end{bmatrix}$

Computation: $\begin{bmatrix} (-2)(4) + (1)(6) & (-2)(3) + (1)(1) \\ (3)(4) + (4)(6) & (3)(3) + (4)(1) \end{bmatrix}$

A B (2×2) (2×2) — multiplication is possible since $2 = 2$

A B (2×2) (2×2) — result will be a 2×2 matrix

b. $CD = \begin{bmatrix} -2 & 1 & 3 \\ 1 & 0 & 2 \\ 4 & 1 & -1 \end{bmatrix}\begin{bmatrix} 2 & 5 & 1 \\ 4 & -1 & 1 \\ 0 & 3 & -2 \end{bmatrix} = \begin{bmatrix} 0 & -2 & -7 \\ 2 & 11 & -3 \\ 12 & 16 & 7 \end{bmatrix}$

C D (3×3) (3×3) — multiplication is possible since $3 = 3$

C D (3×3) (3×3) — result will be a 3×3 matrix

Computation: $\begin{bmatrix} (-2)(2) + (1)(4) + \mathbf{(3)(0)} & (-2)(5) + (1)(-1) + \mathbf{(3)}(3) & (-2)(1) + (1)(1) + \mathbf{(3)}(-2) \\ (1)(2) + (0)(4) + (2)\mathbf{(0)} & (1)(5) + (0)(-1) + (2)(3) & (1)(1) + (0)(1) + (2)(-2) \\ (4)(2) + (1)(4) + (-1)\mathbf{(0)} & (4)(5) + (1)(-1) + (-1)(3) & (4)(1) + (1)(1) + (-1)(-2) \end{bmatrix}$

c. $DC = \begin{bmatrix} 2 & 5 & 1 \\ 4 & -1 & 1 \\ 0 & 3 & -2 \end{bmatrix}\begin{bmatrix} -2 & 1 & 3 \\ 1 & 0 & 2 \\ 4 & 1 & -1 \end{bmatrix} = \begin{bmatrix} 5 & 3 & 15 \\ -5 & 5 & 9 \\ -5 & -2 & 8 \end{bmatrix}$

D C (3×3) (3×3) — multiplication is possible since $3 = 3$

D C (3×3) (3×3) — result will be a 3×3 matrix

d. $AE = \begin{bmatrix} -2 & 1 \\ 3 & 4 \end{bmatrix}\begin{bmatrix} -2 & -1 \\ 3 & 0 \\ 1 & 2 \end{bmatrix}$

A E (2×2) (3×2) — multiplication is not possible since $2 \neq 3$

e. $EA = \begin{bmatrix} -2 & -1 \\ 3 & 0 \\ 1 & 2 \end{bmatrix}\begin{bmatrix} -2 & 1 \\ 3 & 4 \end{bmatrix} = \begin{bmatrix} 1 & -6 \\ -6 & 3 \\ 4 & 9 \end{bmatrix}$

E A (3×2) (2×2) — multiplication is possible since $2 = 2$

E A (3×2) (2×2) — result will be a 3×2 matrix

Now try Exercises 29 through 40 ▶

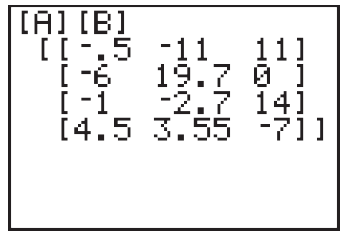
Example 6 shows that in general, matrix multiplication is not commutative. Parts (b) and (c) show $CD \neq DC$ since we get different results, and parts (d) and (e) show $AE \neq EA$, since AE is not defined while EA *is*.

As with the addition and subtraction of matrices, matrix multiplication becomes cumbersome and time consuming for larger matrices, and we will often turn to the technology available in such cases.

EXAMPLE 7 ▶ Using Technology for Matrix Operations

Use a calculator to compute the product AB.

$$A = \begin{bmatrix} 2 & -3 & 0 \\ -1 & 5 & 4 \\ 6 & 0 & 2 \\ 3 & 2 & -1 \end{bmatrix} \quad B = \begin{bmatrix} \frac{1}{2} & -0.7 & 1 \\ 0.5 & 3.2 & -3 \\ -2 & \frac{3}{4} & 4 \end{bmatrix}$$



Solution ▶ Carefully enter matrices A and B into the calculator, then press 2nd MODE **(QUIT)** to get to the home screen. Use [A][B] ENTER, and the calculator finds the product shown in the figure. Just for "fun," we'll

A B (4×3) (3×3) — multiplication is possible since $3 = 3$

A B (4×3) (3×3) — result will be a 4×3 matrix

double check the first entry of the product matrix:
$(2)(\frac{1}{2}) + (-3)(0.5) + (0)(-2) = -0.5$. ✓

$$AB = \begin{bmatrix} 2 & -3 & 0 \\ -1 & 5 & 4 \\ 6 & 0 & 2 \\ 3 & 2 & -1 \end{bmatrix} \begin{bmatrix} \frac{1}{2} & -0.7 & 1 \\ 0.5 & 3.2 & -3 \\ -2 & \frac{3}{4} & 4 \end{bmatrix}$$

Now try Exercises 41 through 52 ▶

Properties of Matrix Multiplication

Earlier, Example 6 demonstrated that matrix multiplication is not commutative. Here is a group of properties that *do* hold for matrices. You are asked to check these properties in the Exercise Set using various matrices. **See Exercises 53 through 56.**

Properties of Matrix Multiplication

Given matrices A, B, and C for which the products are defined:

I. $A(BC) = (AB)C$ ⟶ matrix multiplication is associative
II. $A(B + C) = AB + AC$ ⟶ matrix multiplication is distributive from the left
III. $(B + C)A = BA + CA$ ⟶ matrix multiplication is distributive from the right
IV. $k(A + B) = kA + kB$ ⟶ a constant k can be distributed over addition

We close this section with an application of matrix multiplication. There are many other interesting applications in the Exercise Set.

EXAMPLE 8 ▶ Using Matrix Multiplication to Track Volunteer Enlistments

In a certain country, the number of males and females that will join the military depends on their age. This information is stored in matrix A (Table 9.5). The likelihood a volunteer will join a *particular branch* of the military also depends on their age, with this information stored in matrix B (Table 9.6). (a) Compute the product $P = AB$ and discuss/interpret what is indicated by the entries P_{11}, P_{13}, and P_{24} of the product matrix. (b) How many males are expected to join the Navy this year?

Table 9.5 Matrix *A*

A	Age Group		
Sex	**18–19**	**20–21**	**22–23**
Female	1000	1500	500
Male	2500	3000	2000

Table 9.6 Matrix *B*

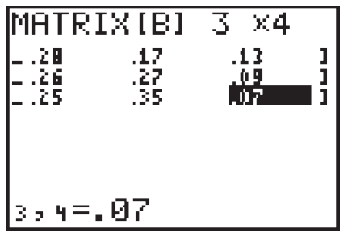
B	Likelihood of Joining			
Age Group	**Army**	**Navy**	**Air Force**	**Marines**
18–19	0.42	0.28	0.17	0.13
20–21	0.38	0.26	0.27	0.09
22–23	0.33	0.25	0.35	0.07

Solution ▶ **a.** Matrix A has order 2×3 and matrix B has order 3×4. The product matrix P can be found and is a 2×4 matrix. Carefully enter the matrices in your calculator. Figure 9.52 shows the entries of matrix B. Using $[A][B]$ ENTER, the calculator finds the product matrix shown in Figure 9.53. Pressing the right arrow shows the complete product matrix is

$$P = \begin{bmatrix} 1155 & 795 & 750 & 300 \\ 2850 & 1980 & 1935 & 735 \end{bmatrix}.$$

The entry P_{11} is the product of R1 from A and C1 from B, and indicates that for the year, 1155 females are projected to join the Army. In like manner, entry P_{13} shows that 750 females are projected to join the Air Force. Entry P_{24} indicates that 735 males are projected to join the Marines.

Figure 9.52



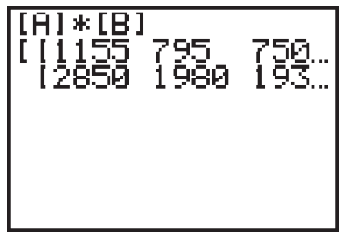


Figure 9.53

b. The product R2 (males) · C2 (Navy) gives $P_{22} = 1980$, meaning 1980 males are expected to join the Navy.

☑ **C.** You've just seen how we can compute the product of two matrices

Now try Exercise 59 through 66 ▶

9.6 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. Two matrices are equal if they are like size and the corresponding entries are equal. In symbols, $A = B$ if ____ = ____.

2. The sum of two matrices (of like size) is found by adding the corresponding entries. In symbols, $A + B =$ _____.

3. The product of a constant times a matrix is called _____ multiplication.

4. The size of a matrix is also referred to as its _____. The order of $A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}$ is _____.

5. Give two reasons why matrix multiplication is generally not commutative. Include several examples using matrices of various sizes.

6. Discuss the conditions under which matrix multiplication is defined. Include several examples using matrices of various sizes.

▶ DEVELOPING YOUR SKILLS

State the order of each matrix and name the entries in positions a_{12} and a_{23} if they exist. Then name the position a_{ij} of the "5" in each.

7. $\begin{bmatrix} 1 & -3 \\ \mathbf{5} & -7 \end{bmatrix}$

8. $\begin{bmatrix} 19 \\ -11 \\ \mathbf{5} \end{bmatrix}$

9. $\begin{bmatrix} 2 & -3 & 0.5 \\ 0 & \mathbf{5} & 6 \end{bmatrix}$

10. $\begin{bmatrix} 2 & 0.4 \\ -0.1 & \mathbf{5} \\ 0.3 & -3 \end{bmatrix}$

11. $\begin{bmatrix} -2 & 1 & -7 \\ 0 & 8 & 1 \\ \mathbf{5} & -1 & 4 \end{bmatrix}$

12. $\begin{bmatrix} 89 & 55 & 34 & 21 \\ 13 & 8 & \mathbf{5} & 3 \\ 2 & 1 & 1 & 0 \end{bmatrix}$

Determine if the following statements are true, false, or conditional. If false, explain why. If conditional, find values of a, b, c, p, q, and r that will make the statement true.

13. $\begin{bmatrix} \sqrt{1} & \sqrt{4} & \sqrt{8} \\ \sqrt{16} & \sqrt{32} & \sqrt{64} \end{bmatrix} = \begin{bmatrix} 1 & 2 & 2\sqrt{2} \\ 4 & 4\sqrt{2} & 8 \end{bmatrix}$

14. $\begin{bmatrix} \frac{3}{2} & \frac{-7}{5} & \frac{13}{10} \\ \frac{-1}{2} & \frac{-2}{5} & \frac{1}{3} \end{bmatrix} = \begin{bmatrix} 1.5 & -1.4 & 1.3 \\ -0.5 & -0.4 & 0.\overline{3} \end{bmatrix}$

15. $\begin{bmatrix} -2 & 3 & a \\ 2b & -5 & 4 \\ 0 & -9 & 3c \end{bmatrix} = \begin{bmatrix} c & 3 & -4 \\ 6 & -5 & -a \\ 0 & -3b & -6 \end{bmatrix}$

16. $\begin{bmatrix} 2p+1 & -5 & 9 \\ 1 & 12 & 0 \\ q+5 & 9 & -2r \end{bmatrix} = \begin{bmatrix} 7 & -5 & 2-q \\ 1 & 3r & 0 \\ -2 & 3p & -8 \end{bmatrix}$

For matrices A through J as given, perform the indicated operation(s), if possible. If an operation cannot be completed, state why. Use a calculator only for those exercises designated by an icon.

$$A = \begin{bmatrix} 2 & 3 \\ 5 & 8 \end{bmatrix} \qquad B = \begin{bmatrix} 2 \\ 1 \\ -3 \end{bmatrix}$$

$$C = \begin{bmatrix} 2 & 0.5 \\ 0.2 & 5 \\ -1 & 3 \end{bmatrix} \qquad D = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$E = \begin{bmatrix} 1 & -2 & 0 \\ 0 & -1 & 2 \\ 4 & 3 & -6 \end{bmatrix} \qquad F = \begin{bmatrix} 6 & -3 & 9 \\ 12 & 0 & -6 \end{bmatrix}$$

$$G = \begin{bmatrix} -1 & 2 & 0 \\ 0 & 1 & -2 \\ -4 & -3 & 6 \end{bmatrix} \qquad H = \begin{bmatrix} 8 & -3 \\ -5 & 2 \end{bmatrix}$$

$$I = \begin{bmatrix} \frac{1}{2} & -\frac{3}{8} & -\frac{1}{4} \\ \frac{1}{4} & \frac{3}{2} & -\frac{5}{8} \\ \frac{1}{8} & \frac{3}{4} & -\frac{5}{2} \end{bmatrix} \qquad J = \begin{bmatrix} \frac{7}{32} & \frac{5}{8} \\ -\frac{5}{16} & \frac{3}{16} \end{bmatrix}$$

17. $A + H$

18. $E + G$

19. $F + H$

20. $G + D$

21. $H + J$

22. $A - J$

23. $G + I$

24. $I - G$

25. $3H - 2A$

26. $2E + 3G$

27. $\frac{1}{2}E - 3D$

28. $F - \frac{2}{3}F$

52. AF

For Exercises 53 through 56, use a calculator and matrices A, B, and C to verify each statement.

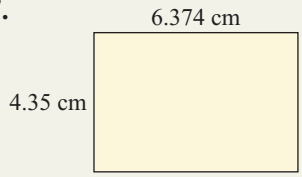
$$A = \begin{bmatrix} -1 & 3 & 5 \\ 2 & 7 & -1 \\ 4 & 0 & 6 \end{bmatrix} \qquad B = \begin{bmatrix} 0.3 & -0.4 & 1.2 \\ -2.5 & 2 & 0.9 \\ 1 & -0.5 & 0.2 \end{bmatrix}$$

$$C = \begin{bmatrix} 45 & -1 & 3 \\ -6 & 10 & -15 \\ 21 & -28 & 36 \end{bmatrix}$$

53. Matrix multiplication is not generally commutative: (a) $AB \neq BA$, (b) $AC \neq CA$, and (c) $BC \neq CB$.

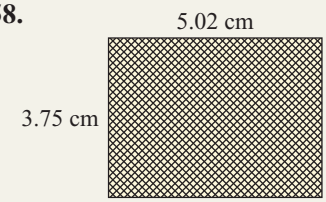
54. Matrix multiplication is distributive from the left: $A(B + C) = AB + AC$.

55. Matrix multiplication is distributive from the right: $(B + C)A = BA + CA$.



56. Matrix multiplication is associative: $(AB)C = A(BC)$.

▶ WORKING WITH FORMULAS



$$\begin{bmatrix} 2 & 2 \\ W & 0 \end{bmatrix} \cdot \begin{bmatrix} L \\ W \end{bmatrix} = \begin{bmatrix} \text{Perimeter} \\ \text{Area} \end{bmatrix}$$

The perimeter and area of a rectangle can be simultaneously calculated using the matrix formula shown, where L represents the length and W represents the width of the rectangle. Use the matrix formula and your calculator to find the perimeter and area of the rectangles shown, then check the results using $P = 2L + 2W$ and $A = LW$.

57.

58.

▶ APPLICATIONS

59. Custom T's designs and sells specialty T-shirts and sweatshirts, with factories in Verdi and Minsk. The company offers this apparel in three quality levels: standard, deluxe, and premium. Last fall the Verdi plant produced 3820 standard, 2460 deluxe, and 1540 premium T-shirts, along with 1960 standard, 1240 deluxe, and 920 premium sweatshirts. The Minsk plant produced 4220 standard, 2960 deluxe, and 1640 premium T-shirts, along with 2960 standard, 3240 deluxe, and 820 premium sweatshirts in the same time period.

a. Write a 3×2 "production matrix" for each plant [$V \rightarrow$ Verdi, $M \rightarrow$ Minsk], with a *T-shirt* column, a *sweatshirt* column, and three rows showing how many of the different types of apparel were manufactured.

b. Use the matrices from part (a) to determine how many more or fewer articles of clothing were produced by Minsk than Verdi.

c. Use scalar multiplication to find how many shirts of each type will be made at Verdi and Minsk next fall, if each is expecting a 4% increase in business.

d. Write a matrix that shows Custom T's total production next fall (from both plants), for each type of apparel.

60. Terry's Tire Store sells automobile and truck tires through three retail outlets. Sales at the Cahokia store for the months of January, February, and March broke down as follows: 350, 420, and 530 auto tires and 220, 180, and 140 truck tires. The Shady Oak branch sold 430, 560, and 690 auto tires and 280, 320, and 220 truck tires during the same 3 months. Sales figures for the downtown store were 864, 980, and 1236 auto tires and 535, 542, and 332 truck tires.

a. Write a 2×3 "sales matrix" for each store [$C \rightarrow$ Cahokia, $S \rightarrow$ Shady Oak, $D \rightarrow$ Downtown], with *January, February,* and *March* columns, and two rows showing the sales of auto and truck tires respectively.

b. Use the matrices from part (a) to determine how many more or fewer tires of each type the downtown store sold (each month) over the other two stores combined.

c. Market trends indicate that for the same three months in the following year, the Cahokia store will likely experience a 10% increase in sales, the Shady Oak store a 3% decrease, with sales at the downtown store remaining level (no change). Write a matrix that shows the combined monthly sales from all three stores next year, for each type of tire.

61. Home improvements: Dream-Makers Home Improvements specializes in replacement windows, replacement doors, and new siding. During the peak season, the number of contracts that came from various parts of the city (North, South, East, and West) are shown in matrix C. The average profit per contract is shown in matrix P. Compute the product PC and discuss what each entry of the product matrix represents.

$$\begin{array}{r} \\ \text{Windows} \\ \text{Doors} \\ \text{Siding} \end{array} \begin{array}{c} \begin{array}{cccc} \text{N} & \text{S} & \text{E} & \text{W} \end{array} \\ \begin{bmatrix} 9 & 6 & 5 & 4 \\ 7 & 5 & 7 & 6 \\ 2 & 3 & 5 & 2 \end{bmatrix} \end{array} = C$$

$$\begin{array}{c} \begin{array}{ccc} \text{Windows} & \text{Doors} & \text{Siding} \end{array} \\ \begin{bmatrix} 1500 & 500 & 2500 \end{bmatrix} \end{array} = P$$

62. Classical music: Station 90.7—*The Home of Classical Music*—is having their annual fund drive. Being a loyal listener, Mitchell decides that for the next 3 days he will donate money according to his favorite composers, by the number of times their music comes on the air: \$3 for every piece by Mozart (M), \$2.50 for every piece by Beethoven (B), and \$2 for every piece by Vivaldi (V).

This information is displayed in matrix D. The number of pieces he heard from each composer is displayed in matrix C. Compute the product DC and discuss what each entry of the product matrix represents.

$$\begin{array}{c} \\ M \\ B \\ V \end{array}\begin{array}{c}\text{Mon.}\\ \\ \\ \end{array}\begin{array}{c}\text{Tue.}\\ \\ \\ \end{array}\begin{array}{c}\text{Wed.}\\ \\ \\ \end{array}\begin{bmatrix} 4 & 3 & 5 \\ 3 & 2 & 4 \\ 2 & 3 & 3 \end{bmatrix} = C$$

$$\begin{array}{c} M \\ \\ \\ \end{array}\begin{array}{c} B \\ \\ \\ \end{array}\begin{array}{c} V \\ \\ \\ \end{array}\begin{bmatrix} 3 & 2.5 & 2 \end{bmatrix} = D$$

63. Pizza and salad: The science department and math department of a local college are at a pre-semester retreat, and decide to have pizza, salads, and soft drinks for lunch. The quantity of food ordered by each department is shown in matrix Q. The cost of the food item at each restaurant is shown in matrix C using the published prices from three popular restaurants: Pizza Home (PH), Papa Jeff's (PJ), and Dynamos (D).

a. What is the total cost to the math department if the food is ordered from Pizza Home?

b. What is the total cost to the science department if the food is ordered from Papa Jeff's?

c. Compute the product QC and discuss the meaning of each entry in the product matrix.

$$\begin{array}{r} \\ \text{Science} \\ \text{Math} \end{array}\begin{array}{c}\text{Pizza}\\ \\ \\ \end{array}\begin{array}{c}\text{Salad}\\ \\ \\ \end{array}\begin{array}{c}\text{Drink}\\ \\ \\ \end{array}\begin{bmatrix} 8 & 12 & 20 \\ 10 & 8 & 18 \end{bmatrix} = Q$$

$$\begin{array}{r} \\ \text{Pizza} \\ \text{Salad} \\ \text{Drink} \end{array}\begin{array}{c}\text{PH}\\ \\ \\ \end{array}\begin{array}{c}\text{PJ}\\ \\ \\ \end{array}\begin{array}{c}\text{D}\\ \\ \\ \end{array}\begin{bmatrix} 8 & 7.5 & 10 \\ 1.5 & 1.75 & 2 \\ 0.90 & 1 & 0.75 \end{bmatrix} = C$$

64. Manufacturing pool tables: Cue Ball Incorporated makes three types of pool tables, for homes, commercial use, and professional use. The amount of time required to pack, load, and install each is summarized in matrix T, with all times in hours. The cost of these components in dollars per hour, is summarized in matrix C for two of its warehouses, one on the west coast and the other in the midwest.

a. What is the cost to package, load, and install a commercial pool table from the coastal warehouse?

b. What is the cost to package, load, and install a commercial pool table from the warehouse in the midwest?

c. Compute the product TC and discuss the meaning of each entry in the product matrix.

$$\begin{array}{r} \\ \text{Home} \\ \text{Comm} \\ \text{Prof} \end{array}\begin{array}{c}\text{Pack}\\ \\ \\ \end{array}\begin{array}{c}\text{Load}\\ \\ \\ \end{array}\begin{array}{c}\text{Install}\\ \\ \\ \end{array}\begin{bmatrix} 1 & 0.2 & 1.5 \\ 1.5 & 0.5 & 2.2 \\ 1.75 & 0.75 & 2.5 \end{bmatrix} = T$$

$$\begin{array}{r} \\ \text{Pack} \\ \text{Load} \\ \text{Install} \end{array}\begin{array}{c}\text{Coast}\\ \\ \\ \end{array}\begin{array}{c}\text{Midwest}\\ \\ \\ \end{array}\begin{bmatrix} 10 & 8 \\ 12 & 10.5 \\ 13.5 & 12.5 \end{bmatrix} = C$$

65. Joining a club: Each school year, among the students planning to join a club, the likelihood a student joins a particular club depends on their class standing. This information is stored in matrix C. The number of males and females from each class that are projected to join a club each year is stored in matrix J. Compute the product JC and use the result to answer the following:

a. Approximately how many females joined the chess club?

b. Approximately how many males joined the writing club?

c. What does the entry p_{13} of the product matrix tells us?

$$\begin{array}{r} \\ \text{Female} \\ \text{Male} \end{array}\begin{array}{c}\text{Fresh}\\ \\ \\ \end{array}\begin{array}{c}\text{Soph}\\ \\ \\ \end{array}\begin{array}{c}\text{Junior}\\ \\ \\ \end{array}\begin{bmatrix} 25 & 18 & 21 \\ 22 & 19 & 18 \end{bmatrix} = J$$

$$\begin{array}{r} \\ \text{Fresh} \\ \text{Soph} \\ \text{Junior} \end{array}\begin{array}{c}\text{Spanish}\\ \\ \\ \end{array}\begin{array}{c}\text{Chess}\\ \\ \\ \end{array}\begin{array}{c}\text{Writing}\\ \\ \\ \end{array}\begin{bmatrix} 0.6 & 0.1 & 0.3 \\ 0.5 & 0.2 & 0.3 \\ 0.4 & 0.2 & 0.4 \end{bmatrix} = C$$

66. Designer shirts: The SweatShirt Shoppe sells three types of designs on its products: stenciled (S), embossed (E), and applique (A). The quantity of each size sold is shown in matrix Q. The retail price of each sweatshirt depends on its size and whether it was finished by hand or machine. Retail prices are shown in matrix C. Assuming all stock is sold, compute the product QC and use the result to answer the following.

a. How much revenue was generated by the large sweatshirts?

b. How much revenue was generated by the extra-large sweatshirts?

c. What does the entry p_{11} of the product matrix QC tell us?

$$\begin{array}{r} \\ \text{med} \\ \text{large} \\ \text{x-large} \end{array}\begin{array}{c}\text{S}\\ \\ \\ \end{array}\begin{array}{c}\text{E}\\ \\ \\ \end{array}\begin{array}{c}\text{A}\\ \\ \\ \end{array}\begin{bmatrix} 30 & 30 & 15 \\ 60 & 50 & 20 \\ 50 & 40 & 30 \end{bmatrix} = Q \qquad \begin{array}{r} \\ \text{S} \\ \text{E} \\ \text{A} \end{array}\begin{array}{c}\text{Hand}\\ \\ \\ \end{array}\begin{array}{c}\text{Machine}\\ \\ \\ \end{array}\begin{bmatrix} 40 & 25 \\ 60 & 40 \\ 90 & 60 \end{bmatrix} = C$$

▶ EXTENDING THE CONCEPT

67. For the matrix A shown, use your calculator to compute A^2, A^3, A^4, and A^5. Do you notice a pattern? Try to write a "matrix formula" for A^n, where n is a positive integer, then use your formula to find A^6. Check results using a calculator.

$$A = \begin{bmatrix} 1 & 0 & 1 \\ 1 & 1 & 1 \\ 1 & 0 & 1 \end{bmatrix}$$

68. The matrix $M = \begin{bmatrix} 2 & 1 \\ -3 & -2 \end{bmatrix}$ has some very interesting properties. Compute the powers M^2, M^3, M^4, and M^5, then discuss what you find. Try to find/create another 2×2 matrix that has similar properties.

▶ MAINTAINING YOUR SKILLS

69. **(9.2)** Solve the system using elimination.

$$\begin{cases} x + 2y - z = 3 \\ -2x - y + 3z = -5 \\ 5x + 3y - 2z = 2 \end{cases}$$

70. **(7.5)** Evaluate $\cos(\cos^{-1}0.3211)$.

71. **(8.6)** Solve $z^4 - 81i = 0$ using the nth roots theorem. Leave your answer in trigonometric form.

72. **(4.1)** Find the quotient using synthetic division, then check using multiplication.

$$\frac{x^3 - 9x + 10}{x - 2}$$

9.7 Solving Linear Systems Using Matrix Equations

LEARNING OBJECTIVES

In Section 9.7 you will see how we can:

- ❑ **A.** Recognize the identity matrix for multiplication
- ❑ **B.** Find the inverse of a square matrix
- ❑ **C.** Solve systems using matrix equations
- ❑ **D.** Use determinants to find whether a matrix is invertible

While using matrices and row operations offers a degree of efficiency in solving systems, we are still required to solve for each variable *individually*. Using matrix multiplication we can actually rewrite a given system as a single *matrix equation,* in which the solutions are computed *simultaneously*. As with other kinds of equations, the use of identities and inverses are involved, which we now develop in the context of matrices.

A. Multiplication and Identity Matrices

From the properties of real numbers, 1 is the identity for multiplication since $n \cdot 1 = 1 \cdot n = n$. A similar identity exists for matrix multiplication. Consider the 2×2 matrix $A = \begin{bmatrix} 1 & 4 \\ -2 & 3 \end{bmatrix}$. While matrix multiplication is not *generally* commutative, if we can find a matrix B where $AB = BA = A$, then B is a prime candidate for the identity matrix, which is denoted I. For the products AB and BA to be possible and have the same order as A, we note B must also be a 2×2 matrix. Using the arbitrary matrix $B = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$, we have the following.

EXAMPLE 1A ▶ **Solving $AB = A$ to Find the Identity Matrix**

For $\begin{bmatrix} 1 & 4 \\ -2 & 3 \end{bmatrix}\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} 1 & 4 \\ -2 & 3 \end{bmatrix}$, use matrix multiplication, the equality of matrices, and systems of equations to find the value of a, b, c, and d.

Solution ▶ The product on the left gives $\begin{bmatrix} a + 4c & b + 4d \\ -2a + 3c & -2b + 3d \end{bmatrix} = \begin{bmatrix} 1 & 4 \\ -2 & 3 \end{bmatrix}$.

Since corresponding entries must be equal (shown by matching colors), we can find a, b, c, and d by solving the systems $\begin{cases} a + 4c = 1 \\ -2a + 3c = -2 \end{cases}$ and $\begin{cases} b + 4d = 4 \\ -2b + 3d = 3 \end{cases}$. For the first system, 2R1 + R2 shows $a = 1$ and $c = 0$. Using 2R1 + R2 for the second shows $b = 0$ and $d = 1$. It appears $\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$ is a candidate for the identity matrix.

Before we name B as the identity matrix, we must show that $AB = BA = A$.

EXAMPLE 1B ▶ **Verifying $AB = BA = A$**

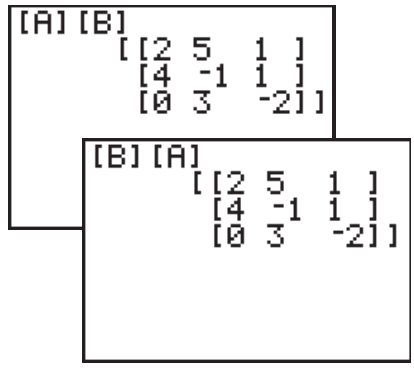
Given $A = \begin{bmatrix} 1 & 4 \\ -2 & 3 \end{bmatrix}$ and $B = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$, determine if $AB = A$ and $BA = A$.

Solution ▶

$$AB = \begin{bmatrix} 1 & 4 \\ -2 & 3 \end{bmatrix}\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 1(1) + 4(0) & 1(0) + 4(1) \\ -2(1) + 3(0) & -2(0) + 3(1) \end{bmatrix} = \begin{bmatrix} 1 & 4 \\ -2 & 3 \end{bmatrix} = A \checkmark$$

$$BA = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\begin{bmatrix} 1 & 4 \\ -2 & 3 \end{bmatrix} = \begin{bmatrix} 1(1) + 0(-2) & 1(4) + 0(3) \\ 0(1) + 1(-2) & 0(4) + 1(3) \end{bmatrix} = \begin{bmatrix} 1 & 4 \\ -2 & 3 \end{bmatrix} = A \checkmark$$

Since $AB = A = BA$, B is the identity matrix I.



Now try Exercises 7 through 10 ▶

By replacing the entries of $A = \begin{bmatrix} 1 & 4 \\ -2 & -3 \end{bmatrix}$ with those of the general matrix $\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$, we can show that $I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$ is the identity for *all* 2×2 matrices. In considering the identity for larger matrices, we find that only *square matrices* have inverses, since $AI = IA$ is the primary requirement (the multiplication must be possible in both directions). This is commonly referred to as *multiplication from the right* and *multiplication from the left*. Using the same procedure as before we can show $\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$ is the identity for 3×3 matrices (denoted I_3). The $n \times n$ identity matrix I_n consists of 1's down the main diagonal and 0's for all other entries. Also, the identity I_n for a square matrix is unique.

A. You've just seen how we can recognize the identity matrix for multiplication

As in Section 9.6, a graphing calculator can be used to investigate operations on matrices and matrix properties. For the 3×3 matrix $A = \begin{bmatrix} 2 & 5 & 1 \\ 4 & -1 & 1 \\ 0 & 3 & -2 \end{bmatrix}$ and $I_3 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$, a calculator will confirm that $AI_3 = A = I_3A$. Carefully enter A into your calculator as matrix A, and I_3 as matrix B. Figure 9.54 shows $AB = A$ and $BA = A$. **See Exercises 11 through 14.**

Figure 9.54

B. The Inverse of a Matrix

Again from the properties of real numbers, we know the multiplicative inverse for a is $a^{-1} = \frac{1}{a}$ $(a \neq 0)$, since the products $a \cdot a^{-1}$ and $a^{-1} \cdot a$ yield the identity 1. To show that a similar inverse exists for matrices, consider the square matrix $A = \begin{bmatrix} 6 & 5 \\ 2 & 2 \end{bmatrix}$ and an arbitrary matrix $B = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$. If we can find a matrix B, where $AB = BA = I$, then B is a prime candidate for the inverse matrix of A, which is denoted A^{-1}. In an attempt to find such a matrix B, we proceed as in Examples 1A and 1B.

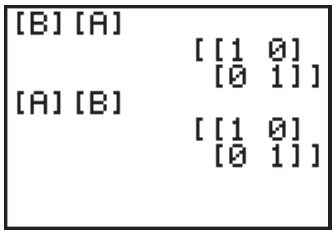
EXAMPLE 2A ▶ Solving $AB = I$ to find A^{-1}

For $\begin{bmatrix} 6 & 5 \\ 2 & 2 \end{bmatrix}\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$, use matrix multiplication, the equality of matrices, and systems of equations to find the entries of B.

Solution ▶ The product on the left gives $\begin{bmatrix} 6a + 5c & 6b + 5d \\ 2a + 2c & 2b + 2d \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$. Since corresponding entries must be equal (shown by matching colors), we find the values of a, b, c, and d by solving the systems $\begin{cases} 6a + 5c = 1 \\ 2a + 2c = 0 \end{cases}$ and $\begin{cases} 6b + 5d = 0 \\ 2b + 2d = 1 \end{cases}$. Using $-3R2 + R1$ for the first system shows $a = 1$ and $c = -1$, while $-3R2 + R1$ for the second system shows $b = -2.5$ and $d = 3$. Matrix $B = \begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} 1 & -2.5 \\ -1 & 3 \end{bmatrix}$ is the prime candidate for A^{-1}.

It may have occurred to you that the systems used in Example 2A have *exactly the same coefficients.* In matrix form, these systems are $\left[\begin{array}{cc|c} 6 & 5 & 1 \\ 2 & 2 & 0 \end{array}\right]$ and $\left[\begin{array}{cc|c} 6 & 5 & 0 \\ 2 & 2 & 1 \end{array}\right]$. Instead of solving these two systems separately, we can solve them *simultaneously* by simply using the coefficient matrix augmented with the identity matrix: $\left[\begin{array}{cc|cc} 6 & 5 & 1 & 0 \\ 2 & 2 & 0 & 1 \end{array}\right]$. Row operations are then used to transform the given matrix into the identity: $\left[\begin{array}{cc|cc} 1 & 0 & e & f \\ 0 & 1 & g & h \end{array}\right]$, in a sense "preserving" the inverse operations needed. The inverse matrix is then $\begin{bmatrix} e & f \\ g & h \end{bmatrix}$.

EXAMPLE 2B ▶ Finding a 2 × 2 Inverse Using the Augmented Matrix



Use the augmented matrix method to find A^{-1} for $A = \begin{bmatrix} 6 & 5 \\ 2 & 2 \end{bmatrix}$. Then use a calculator to verify $A^{-1}A = AA^{-1} = I$.

Solution ▶ First we augment the given matrix with the identity: $\left[\begin{array}{cc|cc} 6 & 5 & 1 & 0 \\ 2 & 2 & 0 & 1 \end{array}\right]$. Then we use row operations to transform A into the identity matrix.

$$\left[\begin{array}{cc|cc} 6 & 5 & 1 & 0 \\ 2 & 2 & 0 & 1 \end{array}\right] \quad -3\text{R2} + \text{R1} \to \text{R2} \quad \left[\begin{array}{cc|cc} 6 & 5 & 1 & 0 \\ 0 & -1 & 1 & -3 \end{array}\right]$$

$$\left[\begin{array}{cc|cc} 6 & 5 & 1 & 0 \\ 0 & -1 & 1 & -3 \end{array}\right] \quad 5\text{R2} + \text{R1} \to \text{R1} \quad \left[\begin{array}{cc|cc} 6 & 0 & 6 & -15 \\ 0 & -1 & 1 & -3 \end{array}\right]$$

$$\left[\begin{array}{cc|cc} 6 & 0 & 6 & -15 \\ 0 & -1 & 1 & -3 \end{array}\right] \quad \begin{array}{c} \frac{\text{R1}}{6} \to \text{R1} \\ -1\text{R2} \to \text{R2} \end{array} \quad \left[\begin{array}{cc|cc} 1 & 0 & 1 & -2.5 \\ 0 & 1 & -1 & 3 \end{array}\right]$$

As in Example 2A, a prime candidate for A^{-1} is $\begin{bmatrix} 1 & -2.5 \\ -1 & 3 \end{bmatrix}$. Using a calculator with $A = [\text{A}]$ and $A^{-1} = [\text{B}]$ confirms that $A^{-1}A = AA^{-1} = I$ (see figure).

Now try Exercises 15 through 22 ▶

These observations guide us to the following definition of an inverse matrix.

The Inverse of a Matrix

Given an $n \times n$ matrix A, if there exists an $n \times n$ matrix A^{-1} such that $AA^{-1} = A^{-1}A = I_n$, then A^{-1} is the inverse of matrix A.

We will soon discover that while only square matrices have inverses, not every square matrix has an inverse. If an inverse exists, the matrix is said to be **invertible.** For 2×2 matrices that are invertible, a simple formula exists for computing the inverse. The formula is derived in the *Strengthening Core Skills* feature at the end of Chapter 9.

The Inverse of a 2 × 2 Matrix

$$\text{If } A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}, \text{ then } A^{-1} = \frac{1}{ad - bc}\begin{bmatrix} d & -b \\ -c & a \end{bmatrix} \text{ provided } ad - bc \neq 0$$

To "test" the formula, again consider the matrix $A = \begin{bmatrix} 6 & 5 \\ 2 & 2 \end{bmatrix}$, where $a = 6$, $b = 5$, $c = 2$, and $d = 2$:

$$A^{-1} = \frac{1}{(6)(2) - (5)(2)}\begin{bmatrix} 2 & -5 \\ -2 & 6 \end{bmatrix}$$

$$= \frac{1}{2}\begin{bmatrix} 2 & -5 \\ -2 & 6 \end{bmatrix} = \begin{bmatrix} 1 & -2.5 \\ -1 & 3 \end{bmatrix} \checkmark$$

See Exercises 63 through 66 for more practice with this formula.

Almost without exception, real-world applications involve much larger matrices, with entries that are not integer-valued. Although the augmented matrix method from Example 2 can be extended to find the inverse of larger matrices, the process becomes very tedious and too time consuming to be useful. The process for a 3×3 matrix is discussed in the *Strengthening Core Skills* feature at the end of Chapter 9. But for practical reasons, we will rely on a calculator to produce these larger inverse matrices. This is done by (1) carefully entering a square matrix A into the calculator, (2) returning to the home screen, and (3) calling up matrix A and pressing the x^{-1} key and ENTER to find A^{-1}. In the context of matrices, calculators are programmed to compute an inverse matrix using this key, rather than to somehow find a reciprocal. **See Exercises 23 through 26.**

☑ **B.** You've just seen how we can find the inverse of a square matrix

C. Solving Systems Using Matrix Equations

One reason matrix multiplication has its row $\times$ column definition is to assist in writing a linear system of equations as a single matrix equation. The equation consists of the matrix of constants B on the right, and a product of the coefficient matrix A with the matrix of variables X on the left: $AX = B$. For $\begin{cases} x + 4y - z = 10 \\ 2x + 5y - 3z = 7, \\ 8x + y - 2z = 11 \end{cases}$ the matrix equation is $\begin{bmatrix} 1 & 4 & -1 \\ 2 & 5 & -3 \\ 8 & 1 & -2 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 10 \\ 7 \\ 11 \end{bmatrix}$. Note that computing the product on the left will yield the original system.

Once written as a matrix equation, the system can be solved using an inverse matrix and the following sequence. If A represents the matrix of coefficients, X the matrix of variables, B the matrix of constants, and I the appropriate identity, the sequence is

(1)	$AX = B$	matrix equation
(2)	$A^{-1}(AX) = A^{-1}B$	multiply from the left by the inverse of A
(3)	$(A^{-1}A)X = A^{-1}B$	associative property
(4)	$IX = A^{-1}B$	$A^{-1}A = I$
(5)	$X = A^{-1}B$	$IX = X$

Lines 1 through 5 illustrate the steps that make the method work. In actual practice, after carefully entering the matrices, only step 5 is used when solving matrix equations using technology. Once matrix A is entered, the calculator will automatically *find* and *use* A^{-1} as we enter $A^{-1}B$.

EXAMPLE 3 ▶ Using Technology to Solve a Matrix Equation

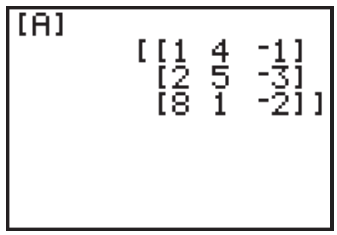
Use a calculator and a matrix equation to solve the system

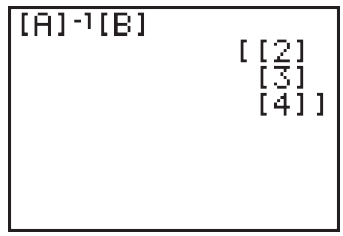
$$\begin{cases} x + 4y - z = 10 \\ 2x + 5y - 3z = 7. \\ 8x + y - 2z = 11 \end{cases}$$

Solution ▶ As before, the matrix equation is $\begin{bmatrix} 1 & 4 & -1 \\ 2 & 5 & -3 \\ 8 & 1 & -2 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 10 \\ 7 \\ 11 \end{bmatrix}$.

Carefully enter (and double-check) the matrix of coefficients as matrix A in your calculator, and the matrix of constants as matrix B (see Figure 9.55). The product $A^{-1}B$ shows the solution is $x = 2, y = 3, z = 4$ (see Figure 9.56). Verify by substitution.

Figure 9.55





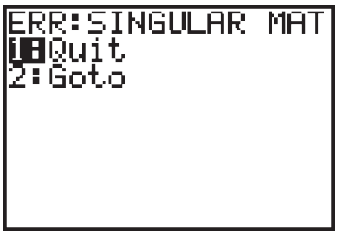


Figure 9.56

Now try Exercises 27 through 44 ▶

Figure 9.57

The matrix equation method does have a few shortcomings. Consider the system whose corresponding matrix equation is $\begin{bmatrix} 4 & -10 \\ -2 & 5 \end{bmatrix}\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} -8 \\ 13 \end{bmatrix}$. After entering the matrix of coefficients A and matrix of constants B, attempting to compute $A^{-1}B$ results in the error message shown in Figure 9.57. The calculator is unable to return a solution due to something called a **"singular matrix."** To investigate further, we attempt to find A^{-1} for $\begin{bmatrix} 4 & -10 \\ -2 & 5 \end{bmatrix}$ using the formula for a 2×2 matrix. With $a = 4$, $b = -10$, $c = -2$, and $d = 5$, we have

$$A^{-1} = \frac{1}{ad - bc}\begin{bmatrix} d & -b \\ -c & a \end{bmatrix} = \frac{1}{(4)(5) - (-10)(-2)}\begin{bmatrix} 5 & 10 \\ 2 & 4 \end{bmatrix} = \frac{1}{0}\begin{bmatrix} 5 & 10 \\ 2 & 4 \end{bmatrix}$$

C. You've just seen how we can solve systems using matrix equations

Since division by zero is undefined, we conclude that matrix A has no inverse. A matrix having no inverse is said to be **singular** or **noninvertible.** Solving systems using matrix equations is only possible when the matrix of coefficients is **nonsingular.**

D. Determinants and Singular Matrices

As a practical matter, it becomes important to know ahead of time whether a particular matrix has an inverse. To help with this, we introduce one additional operation on a square matrix, that of calculating its **determinant.** For a 1×1 matrix the determinant is the entry itself. For a 2×2 matrix $A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$, the determinant of A, written as $\det(A)$ or denoted with vertical bars as $|A|$, is computed as *a difference of diagonal products* beginning with the upper-left entry:

$$\det(A) = \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = a_{11}a_{22} - a_{21}a_{12}$$

2nd diagonal product

1st diagonal product

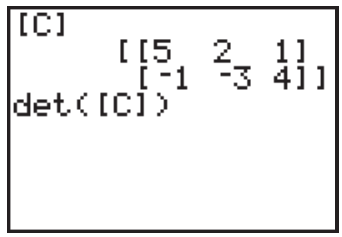
The Determinant of a 2 × 2 Matrix

Given any 2×2 matrix $A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$,

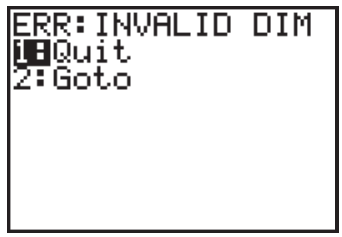
$$\det(A) = |A| = a_{11}a_{22} - a_{21}a_{12}$$

EXAMPLE 4 ▶ **Calculating Determinants**

Compute the determinant of each matrix.



a. $B = \begin{bmatrix} 3 & 2 \\ 1 & -6 \end{bmatrix}$ **b.** $C = \begin{bmatrix} 5 & 2 & 1 \\ -1 & -3 & 4 \end{bmatrix}$ **c.** $D = \begin{bmatrix} 4 & -10 \\ -2 & 5 \end{bmatrix}$



Solution ▶

a. $\det(B) = \begin{vmatrix} 3 & 2 \\ 1 & -6 \end{vmatrix} = (3)(-6) - (1)(2) = -20$

b. Determinants are only defined for square matrices (see figure).

c. $\det(D) = \begin{vmatrix} 4 & -10 \\ -2 & 5 \end{vmatrix} = (4)(5) - (-2)(-10) = 20 - 20 = 0$

Now try Exercises 45 through 48 ▶

Notice from Example 4(c), the determinant of $\begin{bmatrix} 4 & -10 \\ -2 & 5 \end{bmatrix}$ is zero, and this is the same matrix we earlier found had no inverse. This observation can be extended to larger matrices and offers the connection we seek between a given matrix, its inverse, and matrix equations.

Singular Matrices

If A is a square matrix and $\det(A) = 0$, the inverse matrix *does not exist* and A is said to be *singular* or *noninvertible.*

In summary, inverses exist only for square matrices, but not every square matrix has an inverse. If the determinant of a square matrix is zero, an inverse does not exist and the method of matrix equations cannot be used to solve the system.

WORTHY OF NOTE

For the determinant of a general $n \times n$ matrix using cofactors, see Appendix D.

To use the determinant test for a 3×3 system, we need to compute a 3×3 determinant. At first glance, our experience with 2×2 determinants appears to be of little help. However, every entry in a 3×3 matrix is associated with a smaller 2×2 matrix, formed by *deleting the row and column* of that entry and using the entries that remain. These 2×2's are called the **associated minor matrices** or simply the **minors.** Using a general matrix of coefficients, we'll identify the minors associated with the entries in the first row.

$$\begin{bmatrix} \boxed{a_{11}} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \qquad \begin{bmatrix} a_{11} & \boxed{a_{12}} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \qquad \begin{bmatrix} a_{11} & a_{12} & \boxed{a_{13}} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$$

Entry: a_{11} associated minor $\begin{bmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{bmatrix}$

Entry: a_{12} associated minor $\begin{bmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{bmatrix}$

Entry: a_{13} associated minor $\begin{bmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{bmatrix}$

To illustrate, consider the system shown, and (1) form the matrix of coefficients, (2) identify the minor matrices associated with the entries in the first row, and (3) compute the determinant of each *minor*.

$$\begin{cases} 2x + 3y - z = 1 \\ x - 4y + 2z = -3 \\ 3x + y = -1 \end{cases}$$

(1) Matrix of coefficients $\begin{bmatrix} 2 & 3 & -1 \\ 1 & -4 & 2 \\ 3 & 1 & 0 \end{bmatrix}$

(2) $\begin{bmatrix} \textcircled{2} & 3 & -1 \\ 1 & -4 & 2 \\ 3 & 1 & 0 \end{bmatrix}$ $\begin{bmatrix} 2 & \textcircled{3} & -1 \\ 1 & -4 & 2 \\ 3 & 1 & 0 \end{bmatrix}$ $\begin{bmatrix} 2 & 3 & \textcircled{-1} \\ 1 & -4 & 2 \\ 3 & 1 & 0 \end{bmatrix}$

Entry a_{11}: 2 associated minor	**Entry a_{12}: 3 associated minor**	**Entry a_{13}: -1 associated minor**
$\begin{bmatrix} -4 & 2 \\ 1 & 0 \end{bmatrix}$	$\begin{bmatrix} 1 & 2 \\ 3 & 0 \end{bmatrix}$	$\begin{bmatrix} 1 & -4 \\ 3 & 1 \end{bmatrix}$
(3) **Determinant of minor**	**Determinant of minor**	**Determinant of minor**
$(-4)(0) - (1)(2) = -2$	$(1)(0) - (3)(2) = -6$	$(1)(1) - (3)(-4) = 13$

For computing a 3×3 determinant, we illustrate a technique called **expansion by minors.**

The Determinant of a 3 × 3 Matrix—Expansion by Minors

For the matrix M shown, $\det(M)$ is the unique number computed as follows:

matrix M

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$$

1. Select any row or column and form the product of each entry with its minor matrix. The illustration here uses the entries in row 1:

$$\det(M) = +a_{11}\begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix} - a_{12}\begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix} + a_{13}\begin{vmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{vmatrix}$$

Sign Chart

$$\begin{bmatrix} + & - & + \\ - & + & - \\ + & - & + \end{bmatrix}$$

2. The *signs used between terms* of the expansion depends on the row or column chosen, according to the *sign chart* shown.

The determinant of a matrix is unique and *any* row or column can be used. For this reason, it's helpful to select the row or column having the most zero, positive, and/or smaller entries.

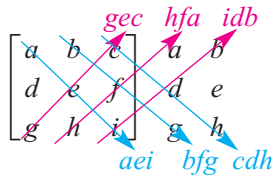
EXAMPLE 5 ▶ Calculating a 3 × 3 Determinant

Compute the determinant of $M = \begin{bmatrix} 2 & 1 & -3 \\ 1 & -1 & 0 \\ -2 & 1 & 4 \end{bmatrix}$.

Solution ▶ Since the second row has the "smallest" entries as well as a zero entry, we compute the determinant using this row. According to the sign chart, the signs of the terms will be negative–positive–negative, giving

$$\begin{aligned} \det(M) &= -(1)\begin{vmatrix} 1 & -3 \\ 1 & 4 \end{vmatrix} + (-1)\begin{vmatrix} 2 & -3 \\ -2 & 4 \end{vmatrix} - (0)\begin{vmatrix} 2 & 1 \\ -2 & 1 \end{vmatrix} \\ &= -1(4 + 3) + (-1)(8 - 6) - (0)(2 + 2) \\ &= -7 + (-2) - 0 \\ &= -9 \end{aligned}$$

The value of $\det(M)$ is -9.



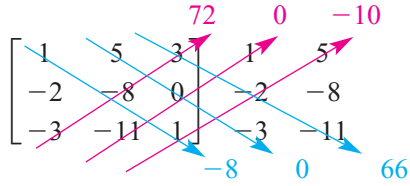
Now try Exercises 49 through 52 ▶

Try computing the determinant of M two more times, using a different row or column each time. Since the determinant is unique, you should obtain the same result.

There are actually other alternatives for computing a 3×3 determinant. The first is called **determinants by column rotation,** and takes advantage of patterns generated from the expansion of minors. This method is applied to the matrix shown, which uses alphabetical entries for simplicity.

$$\det\begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix} \begin{aligned} &= a(ei - fh) - b(di - fg) + c(dh - eg) && \text{expansion using R1} \\ &= aei - afh - bdi + bfg + cdh - ceg && \text{distribute} \\ &= aei + bfg + cdh - afh - bdi - ceg && \text{rewrite result} \end{aligned}$$

Although history is unsure of who should be credited, notice that if you repeat the first two columns to the right of the given matrix ("rotation of columns"), identical products are obtained using the six diagonals formed—three in the downward direction using addition, three in the upward direction using subtraction.



Adding the products in **blue** (regardless of sign) and subtracting the products in **red** (regardless of sign) gives the determinant. This method is more efficient than expansion by minors, *but can only be used for* 3×3 *matrices!*

EXAMPLE 6 ▶ Calculating det(A) Using Column Rotation

Use the column rotation method to find the determinant of $A = \begin{bmatrix} 1 & 5 & 3 \\ -2 & -8 & 0 \\ -3 & -11 & 1 \end{bmatrix}$.

Solution ▶ Rotate columns 1 and 2 to the right, and compute the diagonal products.

Adding the products in **blue** (regardless of sign) and subtracting the products in **red** (regardless of sign) shows $\det(A) = -4$:

$$-8 + 0 + 66 - 72 - 0 - (-10) = -4.$$

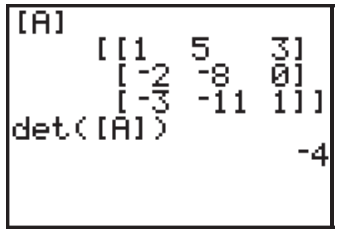
Now try Exercises 53 through 56 ▶

The final method is presented in the *Extending the Concept* feature of the Exercise Set, and shows that if certain conditions are met, the determinant of a matrix can be found using its triangularized form.

As with the operations studied in Section 9.6, the process of computing a determinant becomes very cumbersome for larger matrices, or those with rational or radical entries. Most graphing calculators are programmed to handle these computations easily. After accessing the matrix menu (2nd x^{-1}), calculating a determinant is the first option under the **MATH** submenu (Figure 9.58). The calculator results for det([A]) and det([B]) as defined are shown in Figures 9.59 and 9.60. **See Exercises 57 and 58.**

Figure 9.58

Figure 9.59



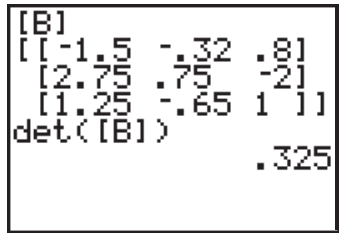


Figure 9.60

EXAMPLE 7 ▶ **Solving a System after Verifying *A* is Invertible**

Given the system shown here, (1) form the matrix equation $AX = B$; (2) compute the determinant of the coefficient matrix and determine if you can proceed; and (3) if so, solve the system using a matrix equation.

$$\begin{cases} 2x + 1y - 3z = 11 \\ 1x - 1y \quad\quad = 1 \\ -2x + 1y + 4z = -8 \end{cases}$$

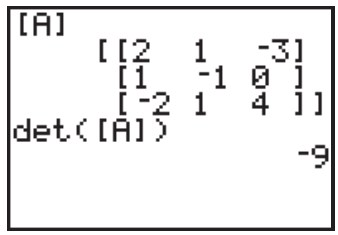
Solution ▶

1. Form the matrix equation $AX = B$:

$$\begin{bmatrix} 2 & 1 & -3 \\ 1 & -1 & 0 \\ -2 & 1 & 4 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 11 \\ 1 \\ -8 \end{bmatrix}$$

2. Since $\det(A)$ is nonzero (from Example 5 and Figure 9.61), we can proceed.
3. For $X = A^{-1}B$, input $A^{-1}B$ on your calculator and press ENTER (Figure 9.62). Notice that matrix name [B] has scrolled out of view.

Figure 9.61



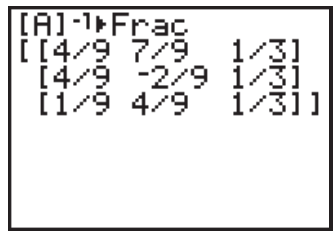


Figure 9.62

The solution is the ordered triple $(3, 2, -1)$.

Now try Exercises 59 through 62 ▶

We close this section with an application involving a 4×4 system. There is a large variety of additional applications in the Exercise Set.

EXAMPLE 8 ▶ **Solving an Application Using Technology and Matrix Equations**

A local theater sells four sizes of soft drinks: 32 oz @ \$2.25; 24 oz @ \$1.90; 16 oz @ \$1.50; and 12 oz @ \$1.20/each. As part of a "free guest pass" promotion, the manager asks employees to try and determine the number of each size sold, given the following information: (1) the total revenue from soft drinks was \$719.80; (2) there were 9096 oz of soft drink sold; (3) there was a total of 394 soft drinks sold; and (4) the number of 24-oz and 12-oz drinks sold was 12 more than the number of 32-oz and 16-oz drinks sold. Write a system of equations that models this information, then solve the system using a matrix equation.

Solution ▶ If we let x, l, m, and s represent the number of 32-oz, 24-oz, 16-oz, and 12-oz soft drinks sold, the following system is produced:

$$\begin{array}{rl} \text{revenue:} & 2.25x + 1.90l + 1.50m + 1.20s = 719.8 \\ \text{ounces sold:} & 32x + 24l + 16m + 12s = 9096 \\ \text{quantity sold:} & x + l + m + s = 394 \\ \text{amounts sold:} & l + s = x + m + 12 \end{array}$$

When written as a matrix equation the system becomes:

$$\begin{bmatrix} 2.25 & 1.9 & 1.5 & 1.2 \\ 32 & 24 & 16 & 12 \\ 1 & 1 & 1 & 1 \\ -1 & 1 & -1 & 1 \end{bmatrix} \begin{bmatrix} x \\ l \\ m \\ s \end{bmatrix} = \begin{bmatrix} 719.8 \\ 9096 \\ 394 \\ 12 \end{bmatrix}$$

To solve, carefully enter the matrix of coefficients as matrix A (see Figure 9.63), and the matrix of constants as matrix B, then compute $A^{-1}B = X$ [since $\det(A) \neq 0$]. This gives a solution of $(x, l, m, s) = (112, 151, 79, 52)$ (Figure 9.64).

Figure 9.63

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. The $n \times n$ identity matrix I_n consists of 1's down the _____ and _____ for all other entries.
2. The product of a square matrix A and its inverse A^{-1} yields the _____ matrix.
3. Given square matrices A and B of like size, B is the inverse of A if ___ = ___ = ___. Notationally we write B = ___.
4. If the determinant of a matrix is zero, the matrix is said to be _____ or _____, meaning no inverse exists.
5. Explain why inverses exist only for square matrices, then discuss why some square matrices do not have an inverse. Illustrate each point with an example.
6. What is the connection between the determinant of a 2×2 matrix and the formula for finding its inverse? Use the connection to create a 2×2 matrix that is invertible, and another that is not.

▶ DEVELOPING YOUR SKILLS

Use matrix multiplication, equality of matrices, and the arbitrary matrix given to show that $\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$.

7. $A = \begin{bmatrix} 2 & 5 \\ -3 & -7 \end{bmatrix}\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} 2 & 5 \\ -3 & -7 \end{bmatrix}$

8. $A = \begin{bmatrix} 9 & -7 \\ -5 & 4 \end{bmatrix}\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} 9 & -7 \\ -5 & 4 \end{bmatrix}$

9. $A = \begin{bmatrix} 0.4 & 0.6 \\ 0.3 & 0.2 \end{bmatrix}\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} 0.4 & 0.6 \\ 0.3 & 0.2 \end{bmatrix}$

10. $A = \begin{bmatrix} \frac{1}{2} & \frac{1}{4} \\ \frac{1}{3} & \frac{1}{8} \end{bmatrix}\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} \frac{1}{2} & \frac{1}{4} \\ \frac{1}{3} & \frac{1}{8} \end{bmatrix}$

For $I_2 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$, $I_3 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$, and $I_4 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$, show $AI = IA = A$ for the matrices of like size. Use a calculator for Exercise 14.

11. $\begin{bmatrix} -3 & 8 \\ -4 & 10 \end{bmatrix}$

12. $\begin{bmatrix} 0.5 & -0.2 \\ -0.7 & 0.3 \end{bmatrix}$

13. $\begin{bmatrix} -4 & 1 & 6 \\ 9 & 5 & 3 \\ 0 & -2 & 1 \end{bmatrix}$

14. $\begin{bmatrix} 9 & 1 & 3 & -1 \\ 2 & 0 & -5 & 3 \\ 4 & 6 & 1 & 0 \\ 0 & -2 & 4 & 1 \end{bmatrix}$

Find the inverse of each 2 × 2 matrix using matrix multiplication, equality of matrices, and a system of equations.

15. $\begin{bmatrix} 5 & -4 \\ 2 & 2 \end{bmatrix}$

16. $\begin{bmatrix} 1 & -5 \\ 0 & -4 \end{bmatrix}$

Find the inverse of each matrix by augmenting of the the identity matrix and using row operations.

17. $\begin{bmatrix} 1 & -3 \\ 4 & -10 \end{bmatrix}$

18. $\begin{bmatrix} -2 & 0.4 \\ 1 & 0.8 \end{bmatrix}$

Demonstrate that $B = A^{-1}$, by showing $AB = BA = I$. Do not use a calculator.

19. $A = \begin{bmatrix} 1 & 5 \\ -2 & -9 \end{bmatrix}$ $B = \begin{bmatrix} -9 & -5 \\ 2 & 1 \end{bmatrix}$

20. $A = \begin{bmatrix} -2 & -6 \\ 4 & 11 \end{bmatrix}$ $B = \begin{bmatrix} 5.5 & 3 \\ -2 & -1 \end{bmatrix}$

21. $A = \begin{bmatrix} 4 & -5 \\ 0 & 2 \end{bmatrix}$ $B = \begin{bmatrix} \frac{1}{4} & \frac{5}{8} \\ 0 & \frac{1}{2} \end{bmatrix}$

22. $A = \begin{bmatrix} -2 & 5 \\ 3 & -4 \end{bmatrix}$ $B = \begin{bmatrix} \frac{4}{7} & \frac{5}{7} \\ \frac{3}{7} & \frac{2}{7} \end{bmatrix}$

Use a calculator to find $A^{-1} = B$, then confirm the inverse by showing $AB = BA = I$.

23. $A = \begin{bmatrix} -2 & 3 & 1 \\ 5 & 2 & 4 \\ 2 & 0 & -1 \end{bmatrix}$

24. $A = \begin{bmatrix} 0.5 & 0.2 & 0.1 \\ 0 & 0.3 & 0.6 \\ 1 & 0.4 & -0.3 \end{bmatrix}$

25. $A = \begin{bmatrix} -7 & 5 & -3 \\ 1 & 9 & 0 \\ 2 & -2 & -5 \end{bmatrix}$

26. $A = \frac{1}{12}\begin{bmatrix} 12 & -6 & 3 & 0 \\ 0 & -4 & 8 & -12 \\ 12 & -12 & 0 & 0 \\ 0 & 12 & 0 & -12 \end{bmatrix}$

Write each system in the form of a matrix equation. Do not solve.

27. $\begin{cases} 2x - 3y = 9 \\ -5x + 7y = 8 \end{cases}$

28. $\begin{cases} 0.5x - 0.6y = 0.6 \\ -0.7x + 0.4y = -0.375 \end{cases}$

29. $\begin{cases} x + 2y - z = 1 \\ x + z = 3 \\ 2x - y + z = 3 \end{cases}$

30. $\begin{cases} 2x - 3y - 2z = 4 \\ \frac{1}{4}x - \frac{2}{5}y + \frac{3}{4}z = \frac{-1}{3} \\ -2x + 1.3y - 3z = 5 \end{cases}$

31. $\begin{cases} -2w + x - 4y + 5z = -3 \\ 2w - 5x + y - 3z = 4 \\ -3w + x + 6y + z = 1 \\ w + 4x - 5y + z = -9 \end{cases}$

32. $\begin{cases} 1.5w + 2.1x - 0.4y + z = 1 \\ 0.2w - 2.6x + y = 5.8 \\ 3.2x + z = 2.7 \\ 1.6w + 4x - 5y + 2.6z = -1.8 \end{cases}$

Write each system as a matrix equation and solve (if possible) using inverse matrices and your calculator. If the coefficient matrix is singular, write *no solution.*

33. $\begin{cases} 0.05x - 3.2y = -15.8 \\ 0.02x + 2.4y = 12.08 \end{cases}$

34. $\begin{cases} 0.3x + 1.1y = 3.5 \\ -0.5x - 2.9y = -10.1 \end{cases}$

35. $\begin{cases} \frac{-1}{6}u + \frac{1}{4}v = 1 \\ \frac{1}{2}u - \frac{2}{3}v = -2 \end{cases}$

36. $\begin{cases} \sqrt{2}a + \sqrt{3}b = 2\sqrt{6} \\ \sqrt{6}a + b = 4\sqrt{2} \end{cases}$

37. $\begin{cases} \frac{-5}{2}a + \frac{3}{5}b = -\frac{3}{10} \\ \frac{5}{16}a - \frac{3}{2}b = -\frac{7}{16} \end{cases}$

38. $\begin{cases} 3\sqrt{2}a + 2\sqrt{3}b = 12 \\ 5\sqrt{2}a - 3\sqrt{3}b = 1 \end{cases}$

39. $\begin{cases} 0.2x - 1.6y + 2z = -1.9 \\ -0.4x - y + 0.6z = -1 \\ 0.8x + 3.2y - 0.4z = 0.2 \end{cases}$

40. $\begin{cases} 1.7x + 2.3y - 2z = 41.5 \\ 1.4x - 0.9y + 1.6z = -10 \\ -0.8x + 1.8y - 0.5z = 16.5 \end{cases}$

41. $\begin{cases} x - 2y + 2z = 9 \\ 2x - 1.5y + 1.8z = 12 \\ \frac{-2}{3}x + \frac{1}{2}y - \frac{3}{5}z = -4 \end{cases}$

42. $\begin{cases} 4x - 5y - 6z = 33 \\ \frac{1}{8}x - \frac{3}{5}y + \frac{5}{4}z = 9 \\ -0.5x + 2.4y - 4z = -32 \end{cases}$

43. $\begin{cases} -2w + 3x - 4y + 5z = -3 \\ 0.2w - 2.6x + y - 0.4z = 2.4 \\ -3w + 3.2x + 2.8y + z = 6.1 \\ 1.6w + 4x - 5y + 2.6z = -9.8 \end{cases}$

44. $\begin{cases} 2w - 5x + 3y - 4z = 7 \\ 1.6w + 4.2y - 1.8z = 5.4 \\ 3w + 6.7x - 9y + 4z = -8.5 \\ 0.7x - 0.9z = 0.9 \end{cases}$

Compute the determinant of each matrix and state whether an inverse matrix exists. Do not use a calculator.

45. $\begin{bmatrix} 4 & -7 \\ 3 & -5 \end{bmatrix}$

46. $\begin{bmatrix} 0.6 & 0.3 \\ 0.4 & 0.5 \end{bmatrix}$

47. $\begin{bmatrix} 1.2 & -0.8 \\ 0.3 & -0.2 \end{bmatrix}$

48. $\begin{bmatrix} -2 & 6 \\ -3 & 9 \end{bmatrix}$

Compute the determinant of each matrix without using a calculator. If the determinant is zero, write *singular matrix.*

49. $A = \begin{bmatrix} 1 & 0 & -2 \\ 0 & -1 & -1 \\ 2 & 1 & -4 \end{bmatrix}$ **50.** $B = \begin{bmatrix} -2 & 2 & 1 \\ 0 & -1 & 2 \\ 4 & -4 & 0 \end{bmatrix}$

51. $C = \begin{bmatrix} -2 & 3 & 4 \\ 0 & 6 & 2 \\ 1 & -1.5 & -2 \end{bmatrix}$

52. $D = \begin{bmatrix} 1 & 2 & -0.8 \\ 2.5 & 5 & -2 \\ 3 & 0 & -2.5 \end{bmatrix}$

Compute the determinant of each matrix using the column rotation method.

53. $\begin{bmatrix} 2 & -3 & 1 \\ 4 & -1 & 5 \\ 1 & 0 & -2 \end{bmatrix}$

54. $\begin{bmatrix} -3 & 2 & 4 \\ -1 & -2 & 0 \\ 3 & 1 & 5 \end{bmatrix}$

55. $\begin{bmatrix} 1 & -1 & 2 \\ 3 & -2 & 4 \\ 4 & 3 & 1 \end{bmatrix}$

56. $\begin{bmatrix} 5 & 6 & 2 \\ -2 & 1 & -2 \\ 3 & 4 & -1 \end{bmatrix}$

Use a calculator to compute the determinant of each matrix. If the determinant is zero, write *singular matrix.* If the determinant is nonzero, find A^{-1} and store the result as matrix B (STO▸ 2nd x^{-1} 2: [B] ENTER). Then verify the inverse by showing $AB = BA = I$.

57. $A = \begin{bmatrix} 1 & 0 & 3 & -4 \\ 2 & 5 & 0 & 1 \\ 8 & 15 & 6 & -5 \\ 0 & 8 & -4 & 1 \end{bmatrix}$

58. $M = \begin{bmatrix} 1 & 2 & 1 & 1 \\ 0 & 1 & -3 & 2 \\ -1 & 0 & 2 & -3 \\ 2 & -1 & 1 & 4 \end{bmatrix}$

For each system shown, form the matrix equation $AX = B$; compute the determinant of the coefficient matrix and determine if you can proceed; and if possible, solve the system using the matrix equation.

59. $\begin{cases} x - 2y + 2z = 7 \\ 2x + 2y - z = 5 \\ 3x - y + z = 6 \end{cases}$

60. $\begin{cases} 2x - 3y - 2z = 7 \\ x - y + 2z = -5 \\ 3x + 2y - z = 11 \end{cases}$

61. $\begin{cases} x - 3y + 4z = -1 \\ 4x - y + 5z = 7 \\ 3x + 2y + z = -3 \end{cases}$

62. $\begin{cases} 5x - 2y + z = 1 \\ 3x - 4y + 9z = -2 \\ 4x - 3y + 5z = 6 \end{cases}$

▶ WORKING WITH FORMULAS

The inverse of a 2 × 2 matrix: $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \rightarrow A^{-1} = \dfrac{1}{ad - bc} \cdot \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}$

The inverse of a 2 × 2 matrix can be found using the formula shown, as long as $ad - bc \neq 0$. Use the formula to find inverses for the matrices here (if possible), then verify by showing $A \cdot A^{-1} = A \cdot A^{-1} = I$.

63. $A = \begin{bmatrix} 3 & -5 \\ 2 & 1 \end{bmatrix}$ **64.** $B = \begin{bmatrix} 2 & 3 \\ -5 & -4 \end{bmatrix}$ **65.** $C = \begin{bmatrix} 0.3 & -0.4 \\ -0.6 & 0.8 \end{bmatrix}$ **66.** $\begin{bmatrix} 0.2 & 0.3 \\ -0.4 & -0.6 \end{bmatrix}$

▶ APPLICATIONS

Solve each application using a matrix equation.

Descriptive Translation

67. Convenience store sales: The local Moto-Mart sells four different sizes of Slushies—behemoth, 60 oz @ $2.59; gargantuan, 48 oz @ $2.29; mammoth, 36 oz @ $1.99; and jumbo, 24 oz @ $1.59. As part of a promotion, the owner offers free gas to any customer who can tell how many of each size were sold last week, given the following information: (1) The total revenue for the Slushies was $402.29; (2) 7884 ounces were sold; (3) a total of 191 Slushies were sold; and (4) the number of behemoth Slushies sold was one more than the number of jumbo. How many of each size were sold?

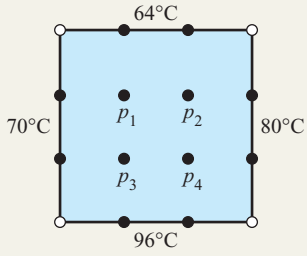
68. Cartoon characters: In America, four of the most beloved cartoon characters are Foghorn Leghorn, Elmer Fudd, Bugs Bunny, and Tweety Bird. Suppose that Bugs Bunny is four times as tall as Tweety Bird. Elmer Fudd is as tall as the combined height of Bugs Bunny and Tweety Bird. Foghorn Leghorn is 20 cm taller than the combined height of Elmer Fudd and Tweety Bird. The combined height of all four characters is 500 cm. How tall is each one?

69. Rolling Stones music: One of the most prolific and popular rock-and-roll bands of all time is the Rolling Stones. Four of their many great hits include: *Jumpin' Jack Flash, Tumbling Dice, You Can't Always Get What You Want,* and *Wild Horses.* The total playing time of all four songs is 20.75 min. The combined playing time of *Jumpin' Jack Flash* and *Tumbling Dice* equals that of *You Can't Always Get What You Want. Wild Horses* is 2 min longer than *Jumpin' Jack Flash,* and *You Can't Always Get What You Want* is twice as long as *Tumbling Dice.* Find the playing time of each song.

70. Mozart's arias: Mozart wrote some of vocal music's most memorable arias in his operas, including *Tamino's Aria, Papageno's Aria,* the *Champagne Aria,* and the *Catalogue Aria.* The total playing time of all four arias is 14.3 min. *Papageno's Aria* is 3 min shorter than the *Catalogue Aria.* The *Champagne Aria* is 2.7 min shorter than *Tamino's Aria.* The combined time of *Tamino's Aria* and *Papageno's Aria* is five times that of the *Champagne Aria.* Find the playing time of all four arias.

Manufacturing

71. Resource allocation: Time Pieces Inc. manufactures four different types of grandfather clocks. Each clock requires these four stages: (1) assembly, (2) installing the clockworks, (3) inspection and testing, and (4) packaging for delivery. The time required for each stage is shown in the table, for each of the four clock types. At the end of a busy week, the owner determines that personnel on the assembly line worked for 262 hr, the installation crews for 160 hr, the testing department for 29 hr, and the packaging department for 68 hr. How many clocks of each type were made?



Dept.	Clock A	Clock B	Clock C	Clock D
Assemble	2.2	2.5	2.75	3
Install	1.2	1.4	1.8	2
Test	0.2	0.25	0.3	0.5
Pack	0.5	0.55	0.75	1.0

72. Resource allocation: Figurines Inc. makes and sells four sizes of metal figurines, mostly historical figures and celebrities. Each figurine goes through four stages of development: (1) casting, (2) trimming, (3) polishing, and (4) painting. The time required for each stage is shown in the table, for each of the four sizes. At the end of a busy week, the manager finds that the casting department put in 62 hr, and

the trimming department worked for 93.5 hr, with the polishing and painting departments logging 138 hr and 358 hr, respectively. How many figurines of each type were made?

Dept.	Small	Medium	Large	X-Large
Casting	0.5	0.6	0.75	1
Trimming	0.8	0.9	1.1	1.5
Polishing	1.2	1.4	1.7	2
Painting	2.5	3.5	4.5	6

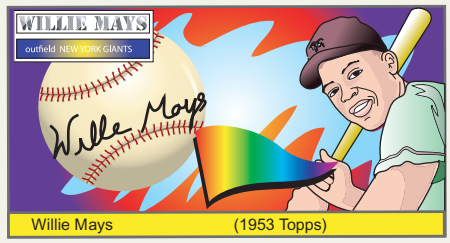
73. Thermal conductivity: In lab experiments designed to measure the heat conductivity of a square metal plate of uniform density, the edges are held at four different (constant) temperatures. The *mean-value principle* from physics tells us that the temperature at a given point p_i on the plate is equal to the average temperature of nearby points. Use this information to form a system of four equations in four variables, and determine the temperature at interior points p_1, p_2, p_3, and p_4 on the plate shown. (*Hint:* Use the temperature of the four points closest to each.)

74. Thermal conductivity: Repeat Exercise 73 if (a) the temperatures at the top and bottom of the plate were *increased* by 10°, with the temperatures at the left and right edges *decreased* by 10° (what do you notice?); (b) the temperature at the top and the temperature to the left were *decreased* by 10°, with the temperatures at the bottom and right held at their original temperature.

Curve Fitting

75. Quadratic fit: Use a matrix equation to find a quadratic function of the form $y = ax^2 + bx + c$ such that $(-4, -5)$, $(0, -5)$, and $(2, 7)$ are on the graph of the function.

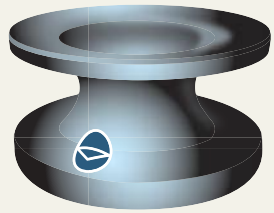
76. Quadratic fit: Use a matrix equation to find a quadratic function of the form $y = ax^2 + bx + c$ such that $(-4, -0)$, $(1, 5)$, and, $(2, -6)$ are on the graph of the function.



77. Cubic fit: Use a matrix equation to find a cubic function of the form $y = ax^3 + bx^2 + cx + d$ such that $(-4, -6)$, $(-1, 0)$, $(1, -16)$, and $(3, 8)$ are on the graph of the function.

78. Cubic fit: Use a matrix equation to find a cubic function of the form $y = ax^3 + bx^2 + cx + d$ such that $(-2, 5)$, $(0, 1)$, $(2, -3)$, and $(3, 25)$ are on the graph of the function.

Investing



79. Wise investing: Morgan received an $800 gift from her grandfather, and showing wisdom beyond her years, decided to place the money in a certificate of deposit (CD) and a money market fund (MM). At the time, CDs were earning 3.5% and MMs were earning 2.5%. At the end of 1 yr, she cashed both in and received a total of $824.50. How much was deposited in each?

80. Baseball cards: Gary has a passion for baseball, which includes a collection of rare baseball cards. His most prized cards feature Willie Mays (1953 Topps) and Mickey Mantle (1959 Topps). The Willie Mays card has appreciated 28% and the Mickey Mantle card 25% since he purchased them, and together they are now worth $17,100. If he paid a total of $13,507.50 at auction for both cards, what was the original price of each?

81. Retirement planning: Using payroll deduction, Jeanette was able to put aside $4800 per month last year for her impending retirement. Last year, her company retirement fund paid 4.2% and her mutual funds returned 5.75%, but her stock fund actually decreased 2.5% in value. If her net gain for the year was $104.50 and $300 more was placed in stocks than in mutual funds, how much was placed in each investment vehicle?

82. Charitable giving: The hyperbolic funnels seen at many shopping malls are primarily used by nonprofit organizations to raise funds for worthy causes. A coin is launched down a ramp into the funnel and seemingly makes endless circuits before finally disappearing down a "black hole" (the collection bin). During one such collection, the bin was found to hold $112.89, and 1450 coins consisting of pennies, nickels, dimes, and quarters. How many of each denominator were there, if the number of quarters and dimes was equal to the number of nickels, and the number of pennies was twice the number of quarters.

Nutrition

83. Animal diets: A zoo dietician needs to create a specialized diet that regulates an animal's intake of fat, carbohydrates, and protein during a meal. The table given shows three different foods and the amount of these nutrients (in grams) that each ounce of food provides. How many ounces of each should the dietician recommend to supply 20 g of fat, 30 g of carbohydrates, and 44 g of protein?

Nutrient	Food I	Food II	Food III
Fat	2	4	3
Carb.	4	2	5
Protein	5	6	7

84. Training diet: A physical trainer is designing a workout diet for one of her clients, and wants to supply him with 24 g of fat, 244 g of carbohydrates, and 40 g of protein for the noontime meal. The table given shows three different foods and the amount of these nutrients (in grams) that each ounce of food provides. How many ounces of each should the trainer recommend?

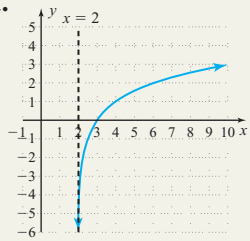
Nutrient	Food I	Food II	Food III
Fat	2	5	0
Carb.	10	15	18
Protein	2	10	0.75

▶ EXTENDING THE CONCEPT

85. Some matrix applications require that you solve a matrix equation of the form $AX + B = C$, where A, B, and C are matrices with the appropriate number of rows and columns and A^{-1} exists. Investigate the solution process for such equations using $A = \begin{bmatrix} 2 & 3 \\ -5 & -4 \end{bmatrix}$, $B = \begin{bmatrix} 4 \\ 9 \end{bmatrix}$, $C = \begin{bmatrix} 12 \\ -4 \end{bmatrix}$, and $X = \begin{bmatrix} x \\ y \end{bmatrix}$, then solve $AX + B = C$ for X *symbolically* (using A^{-1}, I, and so on).

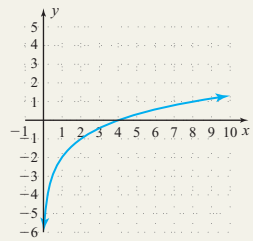
86. Another alternative for finding determinants uses the triangularized form of a matrix and is offered without proof: *If nonsingular matrix A is written in triangularized form using standard row operations but without exchanging any rows and without using the operation kR_i to replace any row (k a constant), then det(A) is equal to the product of resulting diagonal entries*. Compute the determinant of each matrix using this method. Be careful not to interchange rows and do not replace any row by a multiple of that row in the process.

a. $\begin{bmatrix} 1 & -2 & 3 \\ -4 & 5 & -6 \\ 2 & 5 & 3 \end{bmatrix}$ **b.** $\begin{bmatrix} 2 & 5 & -1 \\ -2 & -3 & 4 \\ 4 & 6 & 5 \end{bmatrix}$ **c.** $\begin{bmatrix} -2 & 4 & 1 \\ 5 & 7 & -2 \\ 3 & -8 & -1 \end{bmatrix}$ **d.** $\begin{bmatrix} 3 & -1 & 4 \\ 0 & -2 & 6 \\ -2 & 1 & -3 \end{bmatrix}$



▶ MAINTAINING YOUR SKILLS

87. **(6.3)** Find the amplitude and period of $y = -125\cos(3t)$.



88. **(2.2/5.3)** Match each equation to its related graph. Justify your answers.

___ $y = \log_2(x - 2)$ ___ $y = \log_2 x - 2$

a.

b.

89. **(2.3)** Solve the absolute value inequality: $-3|2x + 5| - 7 \leq -19$.

90. **(7.6)** Find all solutions of $-7\tan^2 x = -21$ in $[0, 2\pi)$.

9.8 Applications of Matrices and Determinants: Cramer's Rule, Geometry, and More

LEARNING OBJECTIVES

In Section 9.8 you will see how we can:

- ❑ **A.** Solve a system using determinants and Cramer's rule
- ❑ **B.** Use determinants in applications involving geometry in the coordinate plane
- ❑ **C.** Decompose a rational expression into partial fractions using matrices and technology
- ❑ **D.** Use matrices to solve static systems
- ❑ **E.** Use matrices for encryption/decryption

In addition to solving systems, matrices can be used to accomplish such diverse things as finding the volume of a three-dimensional solid or establishing certain geometrical relationships in the coordinate plane. Numerous uses are also found in higher mathematics, such as checking whether solutions to a differential equation are linearly independent.

A. Solving Systems Using Determinants and Cramer's Rule

In addition to identifying singular matrices, determinants can actually be used to *develop a formula* for the solution of a system. Consider the following solution to a *general* 2×2 system, which parallels the solution to a specific 2×2 system. With a view toward a solution involving determinants, the coefficients of x are written as a_{11} and a_{21} in the general system, and the coefficients of y are a_{12} and a_{22}.

Specific System	**General System**
$\begin{cases} 2x + 5y = 9 \\ 3x + 4y = 10 \end{cases}$	$\begin{cases} a_{11}x + a_{12}y = c_1 \\ a_{21}x + a_{22}y = c_2 \end{cases}$
eliminate the x-term: $-3R1 + 2R2$	eliminate the x-term: $-a_{21}R1 + a_{11}R2$
sums to zero: $\begin{cases} -3 \cdot 2x - 3 \cdot 5y = -3 \cdot 9 \\ 2 \cdot 3x + 2 \cdot 4y = 2 \cdot 10 \end{cases}$	sums to zero: $\begin{cases} -a_{21}a_{11}x - a_{21}a_{12}y = -a_{21}c_1 \\ a_{11}a_{21}x + a_{11}a_{22}y = a_{11}c_2 \end{cases}$
$2 \cdot 4y - 3 \cdot 5y = 2 \cdot 10 - 3 \cdot 9$	$a_{11}a_{22}y - a_{21}a_{12}y = a_{11}c_2 - a_{21}c_1$

Notice the x-terms sum to zero in both systems. We are deliberately leaving the solution on the left unsimplified to show the pattern developing on the right. Next we solve for y.

Factor Out y	**Factor Out y**
$(2 \cdot 4 - 3 \cdot 5)y = 2 \cdot 10 - 3 \cdot 9$	$(a_{11}a_{22} - a_{21}a_{12})y = a_{11}c_2 - a_{21}c_1$
$y = \dfrac{2 \cdot 10 - 3 \cdot 9}{2 \cdot 4 - 3 \cdot 5}$ divide	divide $y = \dfrac{a_{11}c_2 - a_{21}c_1}{a_{11}a_{22} - a_{21}a_{12}}$

On the left we find $y = \frac{-7}{-7} = 1$ and back-substitution shows $x = 2$. But more important, on the right we obtain a formula for the y-value of *any* 2×2 system: $y = \dfrac{a_{11}c_2 - a_{21}c_1}{a_{11}a_{22} - a_{21}a_{12}}$. If we had chosen to solve for x, the solution would be $x = \dfrac{a_{22}c_1 - a_{12}c_2}{a_{11}a_{22} - a_{21}a_{12}}$. Note these formulas are defined only if $a_{11}a_{22} - a_{21}a_{12} \neq 0$. You may have already noticed, but this denominator is the *determinant of the matrix of coefficients* $\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$ from the previous section! Since the numerator is also a difference of two products, we investigate the possibility that it too can be expressed as a determinant. Working backward, we're able to reconstruct the numerator for x in determinant form as $\begin{bmatrix} c_1 & a_{12} \\ c_2 & a_{22} \end{bmatrix}$, where it is apparent this matrix was formed by *replacing the coefficients of the x-variables with the constant terms.*

$$\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} \quad \begin{vmatrix} \text{(removed)} & a_{12} \\ & a_{22} \end{vmatrix} \quad \begin{vmatrix} c_1 & a_{12} \\ c_2 & a_{22} \end{vmatrix}$$

remove coefficients of x — replace with constants

It is also apparent the numerator for y can be also written in determinant form as $\begin{vmatrix} a_{11} & c_1 \\ a_{21} & c_2 \end{vmatrix}$, or the determinant formed by *replacing the coefficients of the y-variables with the constant terms*:

$$\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} \quad \begin{vmatrix} a_{11} & \text{(removed)} \\ a_{21} & \end{vmatrix} \quad \begin{vmatrix} a_{11} & c_1 \\ a_{21} & c_2 \end{vmatrix}$$

remove coefficients of y — replace with constants

If we use the notation D_y for this determinant, D_x for the determinant where x coefficients were replaced by the constants, and D as the determinant for the matrix of coefficients—the solution of the system can be written as shown next, with the result known as **Cramer's rule.**

Cramer's Rule for 2 × 2 Systems

Given a 2×2 system of linear equations

$$\begin{cases} a_{11}x + a_{12}y = c_1 \\ a_{21}x + a_{22}y = c_2 \end{cases}$$

the solution is the ordered pair (x, y), where

$$x = \frac{D_x}{D} = \frac{\begin{vmatrix} c_1 & a_{12} \\ c_2 & a_{22} \end{vmatrix}}{\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix}} \quad \text{and} \quad y = \frac{D_y}{D} = \frac{\begin{vmatrix} a_{11} & c_1 \\ a_{21} & c_2 \end{vmatrix}}{\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix}}$$

provided $D \neq 0$.

EXAMPLE 1 ▶ **Solving a System Using Cramer's Rule**

Use Cramer's rule to solve the system $\begin{cases} 2x - 5y = 9 \\ -3x + 4y = -10 \end{cases}$.

Solution ▶ Begin by finding the value of D, D_x, and D_y.

$$D = \begin{vmatrix} 2 & -5 \\ -3 & 4 \end{vmatrix} = (2)(4) - (-3)(-5) = -7$$

$$D_x = \begin{vmatrix} 9 & -5 \\ -10 & 4 \end{vmatrix} = (9)(4) - (-10)(-5) = -14$$

$$D_y = \begin{vmatrix} 2 & 9 \\ -3 & -10 \end{vmatrix} = (2)(-10) - (-3)(9) = 7$$

This gives $x = \frac{D_x}{D} = \frac{-14}{-7} = 2$ and $y = \frac{D_y}{D} = \frac{7}{-7} = -1$. The solution is $(2, -1)$. Check by substituting these values into the original equations.

Now try Exercises 7 through 14 ▶

Regardless of the method used to solve a system, always be aware that a consistent, inconsistent, or dependent system is possible. The system $\begin{cases} y - 2x = -3 \\ 4x + 6 = 2y \end{cases}$ yields $\begin{cases} -2x + y = -3 \\ 4x - 2y = -6 \end{cases}$ in standard form, with $D = \begin{vmatrix} -2 & 1 \\ 4 & -2 \end{vmatrix} = (-2)(-2) - (4)(1) = 0$. Since $D = 0$, Cramer's rule cannot be applied, and the system is either inconsistent or dependent. To find out which, we write the equations in function form (solve

for y). The result is $\begin{cases} y = 2x - 3 \\ y = 2x + 3 \end{cases}$, showing the system consists of two parallel lines and has no solutions.

Cramer's Rule for 3 × 3 Systems

Cramer's rule can be extended to a 3×3 system of linear equations, using the same pattern as for 2×2 systems. Given the general 3×3 system

$$\begin{cases} a_{11}x + a_{12}y + a_{13}z = c_1 \\ a_{21}x + a_{22}y + a_{23}z = c_2 \\ a_{31}x + a_{32}y + a_{33}z = c_3 \end{cases}$$

the solutions are $x = \dfrac{D_x}{D}$, $y = \dfrac{D_y}{D}$, and $z = \dfrac{D_z}{D}$, where D_x, D_y, and D_z are again formed by replacing the coefficients of the indicated variable with the constants, and D is the determinant of the matrix of coefficients ($D \neq 0$).

Cramer's Rule Applied to 3 × 3 Systems

Given a 3×3 system of linear equations

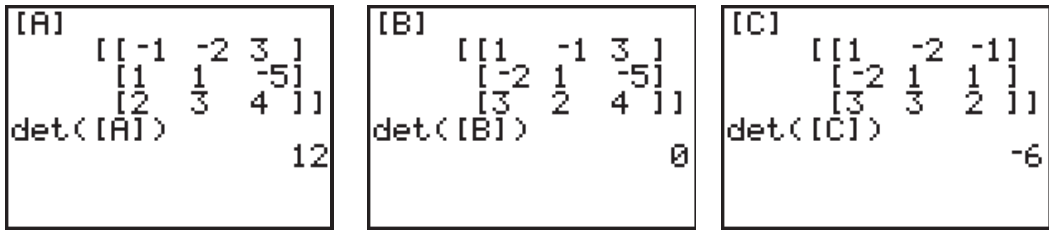
$$\begin{cases} a_{11}x + a_{12}y + a_{13}z = c_1 \\ a_{21}x + a_{22}y + a_{23}z = c_2 \\ a_{31}x + a_{32}y + a_{33}z = c_3 \end{cases}$$

The solution is an ordered triple (x, y, z), where

$$x = \frac{\begin{vmatrix} c_1 & a_{12} & a_{13} \\ c_2 & a_{22} & a_{23} \\ c_3 & a_{32} & a_{33} \end{vmatrix}}{\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix}} \quad y = \frac{\begin{vmatrix} a_{11} & c_1 & a_{13} \\ a_{21} & c_2 & a_{23} \\ a_{31} & c_3 & a_{33} \end{vmatrix}}{\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix}} \quad z = \frac{\begin{vmatrix} a_{11} & a_{12} & c_1 \\ a_{21} & a_{22} & c_2 \\ a_{31} & a_{32} & c_3 \end{vmatrix}}{\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix}},$$

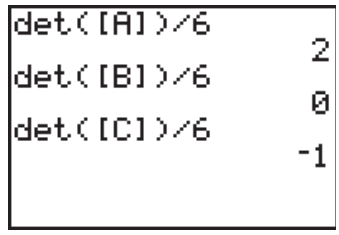
provided $D \neq 0$.

EXAMPLE 2 ▶ Solving a 3 × 3 System Using Cramer's Rule



Solve using Cramer's rule: $\begin{cases} x - 2y + 3z = -1 \\ -2x + y - 5z = 1 \\ 3x + 3y + 4z = 2 \end{cases}$

Solution ▶ Begin by computing the determinant of the matrix of coefficients, to ensure that Cramer's rule can be applied. Using the third row, we have



$$D = \begin{vmatrix} 1 & -2 & 3 \\ -2 & 1 & -5 \\ 3 & 3 & 4 \end{vmatrix} = +3\begin{vmatrix} -2 & 3 \\ 1 & -5 \end{vmatrix} - 3\begin{vmatrix} 1 & 3 \\ -2 & -5 \end{vmatrix} + 4\begin{vmatrix} 1 & -2 \\ -2 & 1 \end{vmatrix}$$
$$= 3(7) - 3(1) + 4(-3) = 6$$

Since $D \neq 0$ we continue, electing to compute the remaining determinants using a calculator (see figures).

$$D_x = \begin{vmatrix} -1 & -2 & 3 \\ 1 & 1 & -5 \\ 2 & 3 & 4 \end{vmatrix} = 12 \quad D_y = \begin{vmatrix} 1 & -1 & 3 \\ -2 & 1 & -5 \\ 3 & 2 & 4 \end{vmatrix} = 0 \quad D_z = \begin{vmatrix} 1 & -2 & -1 \\ -2 & 1 & 1 \\ 3 & 3 & 2 \end{vmatrix} = -6$$

As the final screen shows, the solution is $x = \frac{D_x}{D} = \frac{12}{6} = 2$, $y = \frac{D_y}{D} = \frac{0}{6} = 0$, and $z = \frac{D_z}{D} = \frac{-6}{6} = -1$, or $(2, 0, -1)$ in triple form. Check this solution in the original equations.

Now try Exercises 15 through 22 ▶

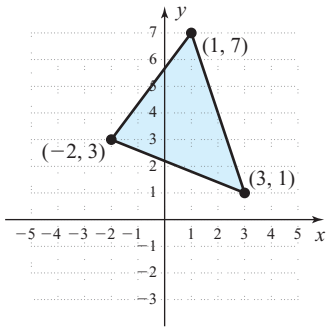
A. You've just seen how we can solve a system using determinants and Cramer's rule

B. Determinants, Geometry, and the Coordinate Plane

As mentioned in the introduction, the use of determinants extends far beyond solving systems of equations. Here, we'll demonstrate how determinants can be used to find the area of a triangle whose vertices are given as three points in the coordinate plane.

The Area of a Triangle in the *xy*-Plane

Given a triangle with vertices at (x_1, y_1), (x_2, y_2), and (x_3, y_3),



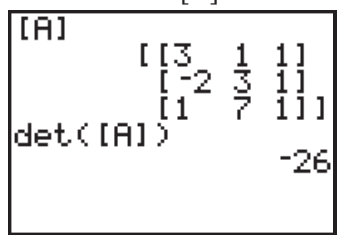
$$\text{Area} = \left|\frac{\det(T)}{2}\right| \text{ where } T = \begin{bmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{bmatrix}$$

EXAMPLE 3 ▶ **Finding the Area of a Triangle Using Determinants**

Find the area of a triangle with vertices at (3, 1), (−2, 3), and (1, 7) (see Figure 9.65).

Solution ▶ Begin by forming matrix T and computing $\det(T)$ (see Figure 9.66):

Figure 9.65



$$\det(T) = \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix} = \begin{vmatrix} 3 & 1 & 1 \\ -2 & 3 & 1 \\ 1 & 7 & 1 \end{vmatrix}$$
$$= 3(3 - 7) - 1(-2 - 1) + 1(-14 - 3)$$
$$= -12 + 3 + (-17) = -26$$

Compute the area: $A = \left|\frac{\det(T)}{2}\right| = \left|\frac{-26}{2}\right|$
$$= 13$$

The area of this triangle is 13 units^2.

Figure 9.66

T = [A]

Now try Exercises 25 through 32 ▶

As an extension of this formula, what if the three points were collinear? After a moment, it may occur to you that the formula would give an area of 0 units^2, since no triangle could be formed. This gives rise to a **test for collinear points.**

Test for Collinear Points

Three points (x_1, y_1), (x_2, y_2), and (x_3, y_3) are collinear if

$$\det(A) = \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix} = 0.$$

B. You've just seen how we can use determinants in applications involving geometry in the coordinate plane

See Exercises 33 through 38.

C. More on Partial Fraction Decomposition

Occasionally, the decomposition template for a rational expression becomes rather extensive. Instead of attempting a solution using convenient values or row operations as in Section 9.4, solutions can more readily be found using a matrix equation and technology.

EXAMPLE 4 ▶ **Decomposing a Rational Expression Using Matrices and Technology**

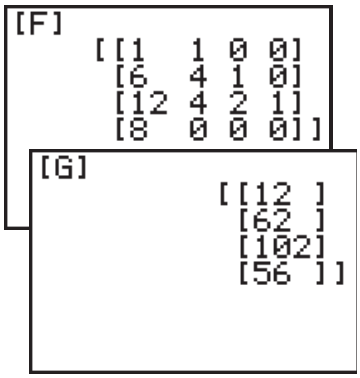
Use matrix equations and a graphing calculator to decompose the given expression into partial fractions: $\dfrac{12x^3 + 62x^2 + 102x + 56}{x^4 + 6x^3 + 12x^2 + 8x}$.

Solution ▶ The degree of the numerator is less than that of the denominator, so we begin by factoring the denominator. After removing the common factor of x and applying the rational roots theorem with synthetic division ($c = -2$), the completely factored form is $\dfrac{12x^3 + 62x^2 + 102x + 56}{x(x+2)^3}$. The decomposed form will be

$$\frac{12x^3 + 62x^2 + 102x + 56}{x(x+2)^3} = \frac{A}{x} + \frac{B}{(x+2)^1} + \frac{C}{(x+2)^2} + \frac{D}{(x+2)^3}.$$

Clearing denominators and simplifying yields

$$12x^3 + 62x^2 + 102x + 56 = A(x+2)^3 + Bx(x+2)^2 + Cx(x+2) + Dx \qquad \text{clear denominators}$$



After expanding the powers on the right, grouping like terms, and factoring, we obtain

$$12x^3 + 62x^2 + 102x + 56 = (A+B)x^3 + (6A + 4B + C)x^2 + (12A + 4B + 2C + D)x + 8A$$

By equating the coefficients of like terms, the following system and matrix equation are obtained:

$$\begin{cases} A + B = 12 \\ 6A + 4B + C = 62 \\ 12A + 4B + 2C + D = 102 \\ 8A = 56 \end{cases} \rightarrow \begin{bmatrix} 1 & 1 & 0 & 0 \\ 6 & 4 & 1 & 0 \\ 12 & 4 & 2 & 1 \\ 8 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} A \\ B \\ C \\ D \end{bmatrix} = \begin{bmatrix} 12 \\ 62 \\ 102 \\ 56 \end{bmatrix}.$$

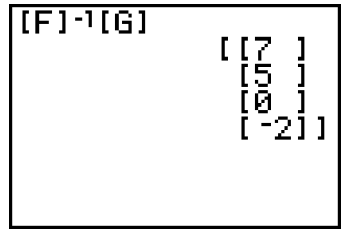


Figure 9.67

After carefully entering the matrices F (coefficients) and G (constants) (see Figure 9.67), we obtain the solution $A = 7$, $B = 5$, $C = 0$, and $D = -2$ as shown in Figure 9.68. The decomposed form is

$$\frac{12x^3 + 62x^2 + 102x + 56}{x(x+2)^3} = \frac{7}{x} + \frac{5}{(x+2)^1} - \frac{2}{(x+2)^3}.$$

Figure 9.68

C. You've just seen how we can decompose a rational expression into partial fractions using matrices and technology

Now try Exercises 39 through 42 ▶

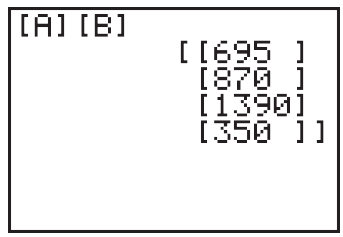
D. Solving Static Systems with Varying Constraints

When the considerations of a business or industry involve more than two variables, solutions using matrix methods have a distinct advantage over other methods. Companies often have to perform calculations using basic systems weekly, daily, or even hourly, to keep up with trends, market changes, changes in cost of raw materials, and so on. In many situations, the basic requirements remain the same, but the frequently changing inputs require a recalculation each time they change.

EXAMPLE 5 ▶ Determining Supply Inventories Using Matrices

BNN Soft Drinks receives new orders daily for its most popular drink, Saratoga Cola. It can deliver the carbonated beverage in a twelve-pack of 12-ounce (oz) cans, a six-pack of 20-oz bottles, or in a 2-L bottle. The ingredients required to produce a twelve-pack include 1 gallon (gal) of carbonated water, 1.25 pounds (lb) of sugar, 2 cups (c) of flavoring, and 0.5 grams (g) of caffeine. For the six-pack, 0.8 gal of carbonated water, 1 lb of sugar, 1.6 c of flavoring, and 0.4 g of caffeine are needed. The 2-L bottle contains 0.47 gal of carbonated water, 0.59 lb of sugar, 0.94 c of flavoring, and 0.24 g of caffeine. How much of each ingredient must be on hand for Monday's order of 300 twelve-packs, 200 six-packs, and 500 2-L bottles? What quantities must be on hand for Tuesday's order: 410 twelve-packs, 320 six-packs, and 275 2-L bottles?

Solution ▶ Begin by setting up a general system of equations, letting x represent the number of twelve-packs, y the number of six-packs, and z the number of 2-L bottles:



$$\begin{cases} 1x + 0.8y + 0.47z = \text{gallons of carbonated water} \\ 1.25x + 1y + 0.59z = \text{pounds of sugar} \\ 2x + 1.6y + 0.94z = \text{cups of flavoring} \\ 0.5x + 0.4y + 0.24z = \text{grams of caffeine} \end{cases}$$

As a matrix equation we have

$$\begin{bmatrix} 1 & 0.8 & 0.47 \\ 1.25 & 1 & 0.59 \\ 2 & 1.6 & 0.94 \\ 0.5 & 0.4 & 0.24 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} w \\ s \\ f \\ c \end{bmatrix}$$

Enter the 4×3 matrix as matrix A, and the size of the order as matrix as B. Using a calculator, we find

$$AB = \begin{bmatrix} 1 & 0.8 & 0.47 \\ 1.25 & 1 & 0.59 \\ 2 & 1.6 & 0.94 \\ 0.5 & 0.4 & 0.24 \end{bmatrix} \begin{bmatrix} 300 \\ 200 \\ 500 \end{bmatrix} = \begin{bmatrix} 695 \\ 870 \\ 1390 \\ 350 \end{bmatrix},$$

and BNN Soft Drinks will need 695 gal of carbonated water, 870 lb of sugar, 1390 c of flavoring, and 350 g of caffeine for Monday's order. After entering $C = \begin{bmatrix} 410 \\ 320 \\ 275 \end{bmatrix}$ for Tuesday's orders, computing the product AC shows 795.25 gal of carbonated water, 994.75 lb of sugar, 1590.5 c of flavoring, and 399 g of caffeine are needed for Tuesday.

Now try Exercises 43 through 46 ▶

Example 5 showed how the creation of a static matrix can help track and control inventory requirements. In Example 6, we use a static matrix to solve a system that will identify the amount of data traffic used by a company during various hours of the day.

EXAMPLE 6 ▶ **Identifying the Source of Data Traffic Using Matrices**

Mariño Imports is a medium-size company that is considering upgrading from a 1.544 megabytes per sec (Mbps) T1 Internet line to a fractional T3 line with a bandwidth of 7.72 Mbps. They currently use their bandwidth for phone traffic, office data, and Internet commerce. The IT (Information Technology) director devises a plan to monitor how much data traffic each resource uses on an hourly basis. Because of the physical arrangement of the hardware, she cannot monitor each resource individually. The table shows the information she collected for the first 3 hr. Determine how many gigabytes (GB) each resource used individually during these 3 hr.

	Phone, Data, and Commerce	Phone and Data	Data and Commerce
9–10:00 A.M.	5.4 GB	4.0 GB	4.2 GB
10–11:00 A.M.	5.3 GB	3.8 GB	4.2 GB
11–12:00 P.M.	5.1 GB	3.5 GB	3.6 GB

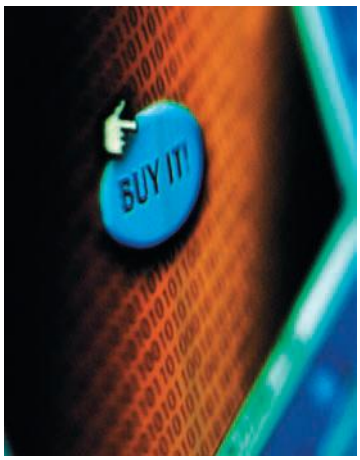
Solution ▶ Using p to represent the phone traffic, d for office data, and c for Internet commerce, we create the system shown, which models data use for the 9:00 o'clock hour. Since we actually need to solve two more systems whose only difference is the constant terms (for the 10 and 11 o'clock hours), using a matrix equation to solve the system (Section 9.7) will be most convenient. Begin by writing the related matrix equation for this system:

$$\begin{cases} p + d + c = 5.4 \\ p + d \quad\quad = 4.0 \\ \quad\quad d + c = 4.2 \end{cases}$$

$$AX = B: \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} p \\ d \\ c \end{bmatrix} = \begin{bmatrix} 5.4 \\ 4.0 \\ 4.2 \end{bmatrix}$$

Using $X = A^{-1}B$ to solve the system (see figure), we find there was 1.2 GB of phone traffic, 2.8 GB of office data, and 1.4 GB of Internet commerce during this hour. Note that the IT director may make this calculation 10 or more times a day (once for every hour of business). While we *could* solve for the 10 and 11 o'clock hours

using $C = \begin{bmatrix} 5.3 \\ 3.8 \\ 4.2 \end{bmatrix}$ and $D = \begin{bmatrix} \mathbf{5.1} \\ \mathbf{3.5} \\ \mathbf{3.6} \end{bmatrix}$, then calculate $A^{-1}C$ and $A^{-1}D$, these calculations *can all be performed simultaneously* by combining the matrices B, C, and D into one 3×3 matrix and multiplying by A^{-1}. Due to the properties of matrix multiplication, each column of the product will represent the data information for a given hour, as shown here:



$$[A^{-1}] \begin{bmatrix} 5.4 & 5.3 & \mathbf{5.1} \\ 4.0 & 3.8 & \mathbf{3.5} \\ 4.2 & 4.2 & \mathbf{3.6} \end{bmatrix} = \begin{bmatrix} 1.2 & 1.1 & 1.5 \\ 2.8 & 2.7 & 2.0 \\ 1.4 & 1.5 & 1.6 \end{bmatrix}$$

In the second hour, there was 1.1 GB of phone traffic, 2.7 GB of office data, and 1.5 GB of Internet commerce. In the third hour, 1.5 GB of phone traffic, 2.0 GB of office data, and 1.6 GB of Internet commerce bandwidth was used.

☑ **D.** You've just seen how we can use matrix equations to solve static systems

Now try Exercises 47 through 50 ▶

E. Using Matrices to Encrypt Messages

In *The Gold-Bug,* by Edgar Allan Poe, the narrator deciphers the secret message on a treasure map by accounting for the frequencies of specific letters and words. The coding used was a simple substitution cipher, which today can be broken with relative ease. In modern times where information wields great power, a simple cipher like the one used there will not suffice. When you pay your tuition, register for classes, make on-line purchases, and so on, you are publicly transmitting very private data, which needs to be protected. While there are many complex encryption methods available (including the now famous symmetric-key and public-key techniques), we will use a matrix-based technique. The nature of matrix multiplication makes it very difficult to determine the exact matrices that yield a given product, and we'll use this fact to our advantage. Beginning with a fixed, invertible matrix A, we will develop a matrix B such that the product AB is possible, and our secret message is encrypted in AB. At the receiving end, they will need to know A^{-1} to decipher the message, since $A^{-1}(AB) = (A^{-1}A)B = B$, which is the original message. Note that in case an intruder were to find matrix A (perhaps purchasing the information from a disgruntled employee), we must be able to change it easily. This means we should develop a method for generating a matrix A, with integer entries, where A is invertible and A^{-1} also has integer entries.

EXAMPLE 7 ▶ Finding an Invertible Matrix A Where Both A and A^{-1} Have Integer Entries

Find an invertible 3×3 matrix A as just described, and its inverse A^{-1}.

Solution ▶ Begin with any 3×3 matrix that has only 1s or -1s on its main diagonal, and 0s below the diagonal. The upper triangle can consist of any integer values you choose, as in

$$\begin{bmatrix} -1 & 5 & -1 \\ 0 & 1 & 8 \\ 0 & 0 & 1 \end{bmatrix}.$$

WORTHY OF NOTE

Performing row operations is explained in more detail in the graphing calculator manual accompanying this text.

Now, use **any** of the elementary row operations to make the matrix more complex. For instance, we'll use a calculator to create a new matrix by (1) using R1 + R2 → R2 to create matrix [C], then (2) using R1 + R3 → R3 to create matrix [D], then (3) using R3 + R2 → R2 to create matrix [E], and finally (4) −2 R1 + R3 → R3 to obtain our final matrix [A]. To begin, enter the initial matrix as matrix [B]. For (1) R1 + R2 → R2, go to the (MATRIX) **MATH** submenu, select option **D:row+(** and press ENTER to bring this option to the home screen. This feature requires us to name the matrix we're using, and to indicate what rows to add, so we enter **D:row+([B], 1, 2).** The screen shown in Figure 9.69 indicates we've placed the result in matrix [C]. For R1 + R3 → R3, recall **D:row+([B], 1, 2)** using 2nd ENTER and change it to **D:row+([C], 1, 3)** STO▸ [D] (Figure 9.70). Repeat this process for (3) R3 + R2 → R2 to create matrix [E]: **D:row+([D], 3, 2)** STO▸ [E] (Figure 9.71). Finally, we compute (4) −2R1 + R3 → R3 using the (new) option **F:*row+(−2, [E], 1, 3)** STO▸ [A]

Figure 9.69

```
row+([B],1,2)→[C
]
      [[-1  5  -1]
       [-1  6  7 ]
       [0   0  1 ]]
```

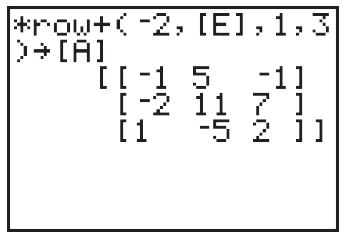
Figure 9.70

```
row+([C],1,3)→[D
]
      [[-1  5  -1]
       [-1  6  7 ]
       [-1  5  0 ]]
```

Figure 9.71

```
row+([D],3,2)→[E
]
     [[-1  5   -1]
      [-2  11  7 ]
      [-1  5   0 ]]
```

Figure 9.72



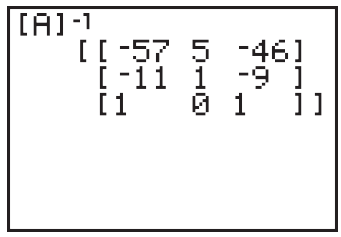


Figure 9.73

and the process is complete (Figure 9.72). The entries of matrix A are all integers, and A^{-1} exists and also has integer entries (Figure 9.73). This will always be the case for matrices created in this way.

Now try Exercises 51 through 56 ▶

EXAMPLE 8 ▶ Using Matrices to Encrypt Messages

Set up a substitution cipher to encode the message MATH IS SWEET, and then use the matrix A from Example 7 to encrypt it.

Solution ▶ For the cipher, we will associate a unique number to every letter in the alphabet. This can be done randomly or using a systematic approach. Here we choose to associate 0 with a blank space, and assign 1 to A, −1 to B, 2 to C, −2 to D, and so on.

Blank	A	B	C	D	E	F	G	H	I	J	K	L	M
0	1	−1	2	−2	3	−3	4	−4	5	−5	6	−6	7

N	O	P	Q	R	S	T	U	V	W	X	Y	Z
−7	8	−8	9	−9	10	−10	11	−11	12	−12	13	−13

Now encode the secret message as shown:

M	A	T	H		I	S		S	W	E	E	T
7	1	−10	−4	0	5	10	0	10	12	3	3	−10

We next enter the coded message into a new matrix B, by entering it letter by letter *into the columns* of B. Note that since the encrypting matrix A is 3×3, B must have 3 rows for multiplication to be possible. The result is

$$B = \begin{bmatrix} M & H & S & W & T \\ A & * & * & E & * \\ T & I & S & E & * \end{bmatrix} = \begin{bmatrix} 7 & -4 & 10 & 12 & -10 \\ 1 & 0 & 0 & 3 & 0 \\ -10 & 5 & 10 & 3 & 0 \end{bmatrix}$$

Since the message is too short to fill matrix B, we use blank spaces to complete the final column. Computing the product AB encrypts the message, and only someone with access to A^{-1} will be able to read it:

$$AB = \begin{bmatrix} -1 & 5 & -1 \\ -2 & 11 & 7 \\ 1 & -5 & 2 \end{bmatrix} \begin{bmatrix} 7 & -4 & 10 & 12 & -10 \\ 1 & 0 & 0 & 3 & 0 \\ -10 & 5 & 10 & 3 & 0 \end{bmatrix}$$

$$= \begin{bmatrix} 8 & -1 & -20 & 0 & 10 \\ -73 & 43 & 50 & 30 & 20 \\ -18 & 6 & 30 & 3 & -10 \end{bmatrix}$$

The encrypted message is 8, −73, −18, −1, 43, 6, −20, 50, 30, 0, 30, 3, 10, 20, −10.

Now try Exercises 57 through 62 ▶

EXAMPLE 9 ▶ **Deciphering Encrypted Messages Using an Inverse Matrix**

Decipher the encrypted message from Example 8 using A^{-1} from Example 7.

Solution ▶ The received message is 8, −73, −18, −1, 43, 6, −20, 50, 30, 0, 30, 3, 10, 20, −10, and is the result of the product AB. To find matrix B, we apply A^{-1} since $A^{-1}(AB) = (A^{-1}A)B = B$. Writing the received message in matrix form we have

$$AB = \begin{bmatrix} 8 & -1 & -20 & 0 & 10 \\ -73 & 43 & 50 & 30 & 20 \\ -18 & 6 & 30 & 3 & -10 \end{bmatrix}$$

Next multiply AB by A^{-1} on the left, to determine matrix B:

$$A^{-1}(AB) = \begin{bmatrix} -57 & 5 & -46 \\ -11 & 1 & -9 \\ 1 & 0 & 1 \end{bmatrix} \begin{bmatrix} 8 & -1 & -20 & 0 & 10 \\ -73 & 43 & 50 & 30 & 20 \\ -18 & 6 & 30 & 3 & -10 \end{bmatrix}$$

$$= \begin{bmatrix} 7 & -4 & 10 & 12 & -10 \\ 1 & 0 & 0 & 3 & 0 \\ -10 & 5 & 10 & 3 & 0 \end{bmatrix} = B$$

Writing matrix B in sentence form gives 7, 1, −10, −4, 0, 5, 10, 0, 10, 12, 3, 3, −10, 0, 0, and using the substitution cipher to replace numbers with letters, reveals the message MATH IS SWEET.

☑ **E.** You've just seen how we can use matrices for encryption/decryption

1. The determinant $\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix}$ is evaluated as: _____.

2. _____ rule uses a ratio of determinants to solve for the unknowns in a system.

3. Given the matrix of coefficients D, the matrix D_x is formed by replacing the coefficients of x with the _____ terms.

4. The three points (x_1, y_1), (x_2, y_2), and (x_3, y_3) are collinear if $|T| = \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}$ has a value of ____.

5. Discuss/Explain the process of writing $\dfrac{8x-3}{x^2-x}$ as a sum of partial fractions.

6. Discuss/Explain why Cramer's rule cannot be applied if $D = 0$. Use an example to illustrate.

▶ DEVELOPING YOUR SKILLS

Write the determinants D, D_x, and D_y for the systems given. Do not solve.

7. $\begin{cases} 2x + 5y = 7 \\ -3x + 4y = 1 \end{cases}$

8. $\begin{cases} -x + 5y = 12 \\ 3x - 2y = -8 \end{cases}$

Solve each system of equations using Cramer's rule, if possible. Do not use a calculator.

9. $\begin{cases} 4x + y = -11 \\ 3x - 5y = -60 \end{cases}$

10. $\begin{cases} x = -2y - 11 \\ y = 2x - 13 \end{cases}$

11. $\begin{cases} \frac{x}{8} + \frac{y}{4} = 1 \\ \frac{y}{5} = \frac{x}{2} + 6 \end{cases}$

12. $\begin{cases} \frac{2}{3}x - \frac{3}{8}y = \frac{7}{5} \\ \frac{5}{6}x + \frac{3}{4}y = \frac{11}{10} \end{cases}$

13. $\begin{cases} 0.6x - 0.3y = 8 \\ 0.8x - 0.4y = -3 \end{cases}$

14. $\begin{cases} -2.5x + 6y = -1.5 \\ 0.5x - 1.2y = 3.6 \end{cases}$

The two systems given in Exercises 15 and 16 are identical except for the third equation. For the first system given, (a) write the determinants D, D_x, D_y, and D_z then (b) determine if a solution using Cramer's rule is possible by computing $|D|$ without the use of a calculator (do not solve the system). Then (c) compute $|D|$ for the second system and try to determine how the equations in the second system are related.

15. $\begin{cases} 4x - y + 2z = -5 \\ -3x + 2y - z = 8 \\ x - 5y + 3z = -3 \end{cases}$ **16.** $\begin{cases} 2x + 3z = -2 \\ -x + 5y + z = 12 \\ 3x - 2y + z = -8 \end{cases}$

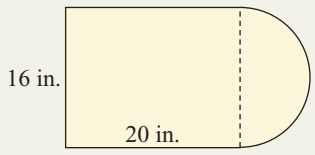
$\begin{cases} 4x - y + 2z = -5 \\ -3x + 2y - z = 8 \\ x + y + z = 3 \end{cases}$ $\begin{cases} 2x + 3z = -2 \\ -x + 5y + z = 12 \\ 3x + 5y + 4z = 10 \end{cases}$

Use Cramer's rule to solve each system of equations. Verify computations using a graphing calculator.

17. $\begin{cases} x + 2y + 5z = 10 \\ 3x + 4y - z = 10 \\ x - y - z = -2 \end{cases}$ **18.** $\begin{cases} x + 3y + 5z = 6 \\ 2x - 4y + 6z = 14 \\ 9x - 6y + 3z = 3 \end{cases}$

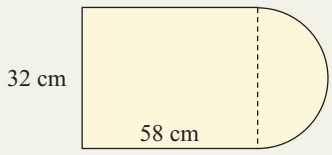
19. $\begin{cases} y + 2z = 1 \\ 4x - 5y + 8z = -8 \\ 8x - 9z = 9 \end{cases}$

20. $\begin{cases} x + 2y + 5z = 10 \\ 3x - z = 8 \\ -y - z = -3 \end{cases}$



21. $\begin{cases} w + 2x - 3y = -8 \\ x - 3y + 5z = -22 \\ 4w - 5x = 5 \\ -y + 3z = -11 \end{cases}$

22. $\begin{cases} w - 2x + 3y - z = 11 \\ 3w - 2y + 6z = -13 \\ 2x + 4y - 5z = 16 \\ 3x - 4z = 5 \end{cases}$



▶ WORKING WITH FORMULAS

Area of a Norman window: $A = \begin{vmatrix} L & r^2 \\ -\frac{\pi}{2} & W \end{vmatrix}$. **The determinant shown can be used to find the area of a Norman window (rectangle + half-circle) with length L, width W, and radius $r = \frac{W}{2}$. Find the area of the following windows.**

23.

24.

▶ APPLICATIONS

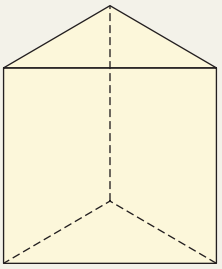
Area of a triangle: Find the area of the triangle with the vertices given. Assume units are in centimeters.

25. (2, 1), (3, 7), and (5, 3)

26. (−2, 3), (−3, −4), and (−6, 1)

Area of a parallelogram: Find the area of the parallelogram with vertices given (*Hint:* Use two triangles.) Assume units are in feet.

27. (−4, 2), (−6, −1), (3, −1), and (5, 2)



28. (−5, −6), (5, 0), (5, 4), and (−5, −2)

Volume of a pyramid: The volume of a triangular pyramid is given by the formula $V = \frac{1}{3}Bh$, where B represents the area of the triangular base and h is the height of the pyramid. Find the volume of a triangular pyramid whose height is given and whose base has the coordinates shown. Assume units are in meters.

29. $h = 6$ m; vertices (3, 5), (−4, 2), and (−1, 6)

30. $h = 7.5$ m; vertices (−2, 3), (−3, −4), and (−6, 1)

Volume of a prism: The volume of a right prism is given by the formula $V = Bh$, where B represents the area of the base and h is the height of the prism. Find the volume of a triangular prism whose height is given and whose base has the coordinates shown. Assume units are in inches.

31. (3, 0), (9, 0), (6, 4), $h = 8$

32. (2, 3), (9, 5), (0, 6), $h = 5$

Determine if the following sets of points are collinear.

33. (1, 5), (−2, −1), and (4, 11)

34. (1, 1), (3, −5), and (−2, 9)

35. (−2.5, 5.2), (1.2, −5.6), and (2.2, −8.5)

36. (−0.5, 2.55), (−2.8, 1.63), and (3, 3.95)

For each linear equation given, substitute the first two points to verify they are solutions. Then use the test for collinear points to determine if the third point is also a solution.

37. $2x - 3y = 7$; (2, −1), (−1.3, −3.2), (−3.1, −4.4)

38. $5x + 2y = 4$; (2, −3), (3.5, −6.75), (−2.7, 8.75)

Decompose each rational expressing using a matrix equation and a graphing calculator.

39. $\dfrac{x^4 - x^2 - 2x + 1}{x^5 - 2x^3 + x}$

40. $\dfrac{-3x^4 + 13x^2 + x - 12}{x^5 - 4x^3 + 4x}$

41. $\dfrac{x^3 - 17x^2 + 76x - 98}{(x^2 - 6x + 9)(x^2 - 2x - 3)}$

42. $\dfrac{16x^3 - 66x^2 + 98x - 54}{(2x^2 - 3x)(4x^2 - 12x + 9)}$

43. Slammin' Drums manufactures several different types of drums. Its most popular drums are the 22″ bass drum, the 12″ tom, and the 14″ snare drum. The 22″ bass drum requires 7 ft^2 of skin, 8.5 ft^2 of wood veneer, 8 tension rods, and 11.5 ft of hoop. The 12″ tom requires 2 ft^2 of skin, 3 ft^2 of wood veneer, 6 tension rods, and 6.5 ft of hoop. The 14″ snare requires 2.5 ft^2 of skin, 1.5 ft^2 of wood veneer, 10 tension rods, and 7 ft of hoop. In February, Slammin' Drums received orders for 15 bass drums, 21 toms, and 27 snares. Use your calculator and a matrix equation to determine how much of each raw material they need to have on hand to fill these orders.

44. In March, Slammin' Drums' orders consisted of 19 bass drums, 19 toms, and 25 snares. Use your calculator and a matrix equation to determine how much of each raw material they need to have on hand to fill their orders. (See Exercise 43.)

45. The following table represents Slammin's orders for the months of April through July. Use your calculator and a matrix equation to determine how much of each raw material they need to have on hand to fill these orders. (See Exercise 43.) (*Hint:* Using a clever 4 × 3 and 3 × 1 matrix can reduce this problem to a single step.)

	April	May	June	July
Bass drum	23	21	17	14
Tom	20	18	15	17
Snare drum	29	35	27	25

46. The following table represents Slammin's orders for the months of August through November. Use your calculator and a matrix equation to determine how much of each raw material they need to have on hand to fill their orders (see Exercise 43). (*Hint:* Using a clever 4 × 3 and 3 × 1 matrix can reduce this problem to a single step.)

	August	September	October	November
Bass drum	17	22	16	12
Tom	15	14	13	11
Snare drum	32	28	27	21

47. Roll-X Watches makes some of the finest wristwatches in the world. Their most popular model is the Clam. It comes in three versions: Silver, Gold, and Platinum. Management thinks there might be a thief in the production line, so they decide to closely monitor the precious metal consumption. A Silver Clam contains 1.2 oz of silver and 0.2 oz of gold. A Gold Clam contains 0.5 oz of silver, 0.8 oz of gold, and 0.1 oz of platinum. A Platinum Clam contains 0.2 oz of silver, 0.5 oz of gold, and 0.7 oz of platinum. During the first week of monitoring, the production team used 10.9 oz of silver, 9.2 oz of gold, and 2.3 oz of platinum. Use your calculator and a matrix equation to determine the number of each type of watch that should have been produced.

48. The following table contains the precious metal consumption of the Roll-X Watch production line

during the next five weeks (see Exercise 47). Use your graphing calculator to determine the number of each type of watch that should have been produced each week. For which week does the data seem to indicate a possible theft of precious metal?

Ounces	Week 1	Week 2	Week 3	Week 4	Week 5
Silver	13.1	9	12.9	11.9	11.2
Gold	11	7.7	8.6	8.4	9.5
Platinum	2.5	1.5	0.9	2.8	1.7

49. There are three classes of grain, of which three bundles from the first class, two from the second, and one from the third make 39 measures. Two of the first, three of the second, and one of the third make 34 measures. And one of the first, two of the second, and three of the third make 26 measures. How many measures of grain are contained in one bundle of each class? *(This is the historic problem from the Chiu chang suan shu.)*

50. During a given week, the measures of grain that make up the bundles in Exercise 49 can vary slightly. Three local Chinese bakeries always buy the same numbers of bundles, as outlined in Exercise 49. That is to say, bakery 1 buys three bundles of the first class, two of the second, and one of the third. Bakery 2 buys two of the first, three of the second, and one of the third. And finally, bakery 3 buys one of the first, two of the second, and three of the third. The following table outlines how many measures of grain each bakery received each day. How many measures of grain were contained in one bundle of each class, on each day?

	Mon	Tues	Wed	Thurs	Fri
Bakery 1 (measures)	39	38	38	37.75	39.75
Bakery 2 (measures)	34	33	33.5	32.5	35
Bakery 3 (measures)	26	26	27	26.25	27.25

For Exercises 51–56, use the criteria indicated to find 3×3 matrices A and A^{-1}, where the entries of both are all integers.

51. The lower triangle is all zeroes.

52. The upper triangle is all zeroes.

53. $a_{2,1} = 5$

54. $a_{3,2} = -2$

55. $a_{3,1} = 1$ and $a_{2,3} = 2$

56. $a_{2,1} = -3$ and $a_{1,3} = 1$

57. Use the matrix A you created in Exercise 51 and the substitution cipher from Example 8 to encrypt your full name.

58. Use the matrix A you created in Exercise 52 and the substitution cipher from Example 8 to encrypt your school's name.

59. Design your own substitution cipher. Then use it and the matrix A you created in Exercise 53 to encrypt the title of your favorite movie.

60. Design your own substitution cipher. Then use it and the matrix A you created in Exercise 54 to encrypt the title of your favorite snack food.

61. Design your own substitution cipher. Then use it and the matrix A you created in Exercise 55 to encrypt the White House switchboard phone number, 202-456-1414.

62. Design your own substitution cipher. Then use it and the matrix A you created in Exercise 56 to encrypt the Casa Rosada switchboard phone number 54-11-4344-3600. The Casa Rosada, or Pink House, consists of the offices of the president of Argentina.

63. Use the matrix A^{-1} from Exercise 51, and the appropriate substitution cipher to decrypt the message from Exercise 57.

64. Use the matrix A^{-1} from Exercise 52, and the appropriate substitution cipher to decrypt the message from Exercise 58.

65. Use the matrix A^{-1} from Exercise 53, and the appropriate substitution cipher to decrypt the message from Exercise 59.

66. Use the matrix A^{-1} from Exercise 54, and the appropriate substitution cipher to decrypt the message from Exercise 60.

67. Use the matrix A^{-1} from Exercise 55, and the appropriate substitution cipher to decrypt the message from Exercise 61.

68. Use the matrix A^{-1} from Exercise 56, and the appropriate substitution cipher to decrypt the message from Exercise 62.

Use a linear system to model each application. Then solve using Cramer's rule.

69. Return on investments: If \$15,000 is invested at a certain interest rate and \$25,000 is invested at another interest rate, the total return was \$2900. If the investments were reversed the return would be \$2700. What was the interest rate paid on each investment?

70. CD and DVD clearance sale: To generate interest in a music store clearance sale, the manger sets out a large box full of \$2 CDs and \$7 DVDs, with an advertised price of \$800 for the lot. When asked how many of each are in the box, the manager will only say the box holds a total of 200 disks. How many CDs and DVDs are in the box?

71. Cost of fruit: Many years ago, two pounds of apples, 2 lb of kiwi, and 10 lb of pears cost \$3.26. Three pounds of apples, 2 lb of kiwi, and 7 lb of pears cost \$2.98. Two pounds of apples, 3 lb of kiwi, and 6 lb of pears cost \$2.89. Find the cost of a pound of each fruit.

72. Vending machine receipts: The vending machines at an amusement park are stocked with various candies that sell for 5¢, 10¢, and 25¢. At week's end, the park collected \$54.30 from one of the machines. How many of each type of candy were sold, if 484 total sales were made and the machine vended twice as many 5¢ candies as 25¢ candies?

73. Coffee blends: To make its morning coffees, a coffee shop uses three kinds of beans costing \$1.90/lb, \$2.25/lb, and \$3.50/lb, respectively. By the end of the week, the shop went through 24 lb of coffee beans, having a total value of \$58. Find how many pounds of each type of bean were used, given that the number of pounds used of the cheapest beans was four more than the most expensive beans.

74. Manufacturing ball bearings: A ball bearing producer makes three sizes of bearings, half-inch-diameter size weighing 30 grams (g), a three-quarter-inch-diameter size weighing 105 g, and a 1-in.-diameter size weighing 250 g. A large storage container holds ball bearings that have been rejected due to small defects. If the net weight of the container's contents is 95.6 kilograms (95,600 g), and automated tallies show 920 bearings have been rejected, how many of each size is in the reject bin, given that statistical studies show there are twice as many rejects of the smallest bearing, as compared to the largest?

▶ EXTENDING THE CONCEPT

75. Solve the given system four different ways: (1) elimination, (2) row reduction, (3) Cramer's rule, and (4) using a matrix equation. Which method seems to be the least error-prone? Which method seems most efficient (takes the least time)? Discuss the advantages and drawbacks of each method.

$$\begin{cases} x + 3y + 5z = 6 \\ 2x - 4y + 6z = 14 \\ 9x - 6y + 3z = 3 \end{cases}$$

76. Find the area of the pentagon whose vertices are: $(-5, -5)$, $(5, -5)$, $(8, 6)$, $(-8, 6)$, and $(0, 12.5)$.

77. The polynomial form for the equation of a circle is $x^2 + y^2 + Dx + Ey + F = 0$. Find the equation of the circle that contains the points $(-1, 7)$, $(2, 8)$, and $(5, -1)$.

78. For square matrix A, calculating A^2 is a simple matter of matrix multiplication. But what of those applications that require higher powers?

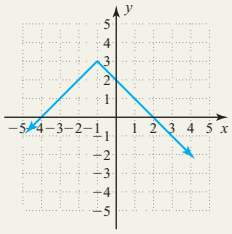
For any matrix $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$, we define the **characteristic polynomial** of A to be

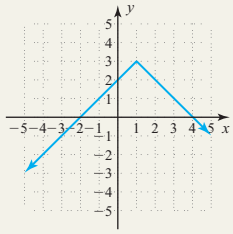
$$p(\lambda) = \begin{vmatrix} \lambda - a & -b \\ -c & \lambda - d \end{vmatrix} = (\lambda - a)(\lambda - d) + cb.$$

The **Cayley-Hamilton theorem** states that if the original matrix A is substituted for λ, the result must be zero, or in other words, every square matrix satisfies its own characteristic equation. This fact is often used to compute higher powers of a square matrix, since all higher powers can then be expressed in terms of A. Specifically, for

$$A = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}, p(\lambda) = \begin{vmatrix} \lambda - 1 & -2 \\ -3 & \lambda - 4 \end{vmatrix} =$$

$(\lambda - 1)(\lambda - 4) - (-3)(-2) = \lambda^2 - 5\lambda - 2$, with the theorem stating that $A^2 - 5A - 2I_2 = 0$ (note I_2 is used to ensure we remain in the context of 2×2 matrices). For $A^2 = 5A + 2I_2$, we have the follow sequence for any power of A:





$$\begin{aligned} A^3 &= A^2A \\ &= (5A + 2I_2)A \\ &= 5A^2 + 2A \\ &= 5(5A + 2I_2) + 2A \\ &= 27A + 10I_2 \end{aligned} \qquad \begin{aligned} A^4 &= A^3A \\ &= (27A + 10I_2)A \\ &= 27A^2 + 10A \\ &= 27(5A + 2I_2) + 10A \\ &= 145A + 54I_2 \end{aligned}$$

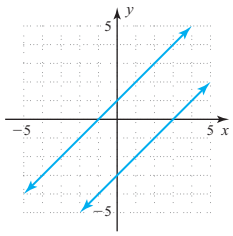
For $A = \begin{bmatrix} 2 & -1 \\ 4 & 1 \end{bmatrix}$, find A^2 in terms of A and I_2, then use the Cayley-Hamilton theorem to find A^3, A^4, and A^5. Verify A^3 using scalar multiplication and matrix addition.

▶ MAINTAINING YOUR SKILLS

79. (4.3) Graph the polynomial using information about end-behavior, y-intercept, x-intercept(s), and midinterval points: $f(x) = x^3 - 2x^2 - 7x + 6$.

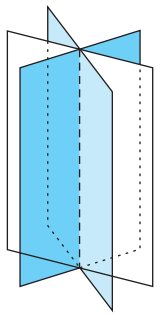
80. **(2.2)** Which is the graph (left or right) of $g(x) = -|x + 1| + 3$? Justify your answer.

81. **(8.1)** Solve the triangle:
side $a = 8.7$ in.
side $b = 11.2$ in.
$\angle A = 49.0°$



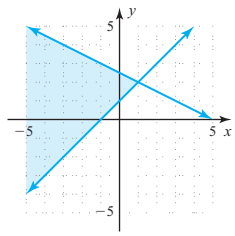
82. **(6.4)** Graph $y = 3\tan(2\pi t)$ over the interval $[-\frac{1}{2}, \frac{1}{2}]$. Note the period, asymptotes, zeroes and value of A.

MAKING CONNECTIONS

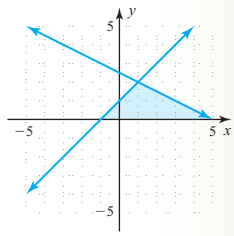


Making Connections: Graphically, Symbolically, Numerically, and Verbally

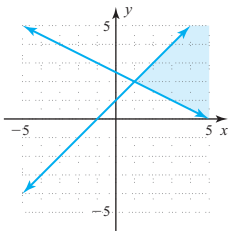
Eight graphs (a) through (h) are given. Match the characteristics shown in 1 through 16 to one of the eight graphs.



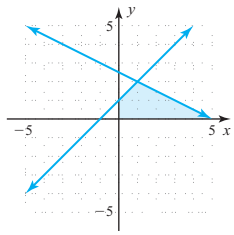
(a)



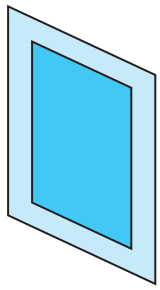
(b)



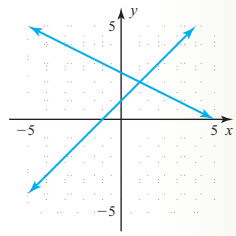
(c)



(d)



(e)



(f)

(g)

(h)

1. ____ $\left|\begin{array}{cc|c} 1 & -1 & -1 \\ 1 & 2 & 5 \end{array}\right|$

2. ____ $\begin{cases} x \geq y - 1 \\ x + 2y \geq 5 \end{cases}$

3. ____ $\begin{cases} y \leq x + 1 \\ y \geq 0 \\ y \leq -\frac{1}{2}x + \frac{5}{2} \end{cases}$

4. ____ coincident dependence

5. ____ inconsistent

6. ____ linear dependence

7. ____ vertices: (1, 2), (5, 0), (0, 0), (0, 1)

8. ____ independent and consistent

9. ____ three equations in three variables

10. ____ (3, 2) does not satisfy any inequality

11. ____ $\begin{cases} y \leq x + 1 \\ x + 2y \leq 5 \\ x \geq 0, y \geq 0 \end{cases}$

12. ____ $\left|\begin{array}{cc|c} -1 & 1 & 1 \\ 1 & -1 & 3 \end{array}\right|$

13. ____ (1, 2) is the solution

14. ____ (3, 2) is a solution

15. ____ $\begin{cases} y \geq x + 1 \\ x + 2y \leq 5 \end{cases}$

16. ____ $\mathcal{A} = \frac{1}{2}\begin{vmatrix} -1 & 0 & 1 \\ 1 & 2 & 1 \\ 5 & 0 & 1 \end{vmatrix}$

SUMMARY AND CONCEPT REVIEW

SECTION 9.1 Linear Systems in Two Variables with Applications

KEY CONCEPTS

- A *solution* to a linear system in two variables is any ordered pair (x, y) that makes all equations in the system true.
- Since every point on the graph of a line satisfies the equation of that line, a point where two lines intersect must satisfy both equations and is a solution of the system.
- A system with at least one solution is called a *consistent system.*
- If the lines have different slopes, there is a unique solution to the system (they intersect at a single point). The system is called a *consistent* and *independent system.*
- If the lines have equal slopes and the same y-intercept, they form identical or *coincident lines.* Since one line is right atop the other, they intersect at all points with an infinite number of solutions. The system is called a *consistent* and *dependent system.*
- If the lines have equal slopes but different y-intercepts, they will never intersect. The system has no solution and is called an *inconsistent system.*

EXERCISES

Solve each system by graphing manually. Verify your answer by graphing on a graphing calculator. If the system is inconsistent or dependent, so state.

1. $\begin{cases} 3x - 2y = 4 \\ -x + 3y = 8 \end{cases}$ **2.** $\begin{cases} 0.2x + 0.5y = -1.4 \\ x - 0.3y = 1.4 \end{cases}$ **3.** $\begin{cases} 2x + y = 2 \\ x - 2y = 4 \end{cases}$

Solve using substitution. Indicate whether each system is consistent, inconsistent, or dependent. Write unique solutions as an ordered pair. Check your answer using a graphing calculator.

4. $\begin{cases} y = 5 - x \\ 2x + 2y = 13 \end{cases}$ **5.** $\begin{cases} x + y = 4 \\ 0.4x + 0.3y = 1.7 \end{cases}$ **6.** $\begin{cases} x - 2y = 3 \\ x - 4y = -1 \end{cases}$

Solve using elimination. Indicate whether each system is consistent, inconsistent, or dependent. Write unique solutions as an ordered pair. Check your answer using a graphing calculator.

7. $\begin{cases} 2x - 4y = 10 \\ 3x + 4y = 5 \end{cases}$ **8.** $\begin{cases} 2x = 3y + 6 \\ 2.4x + 3.6y = 6 \end{cases}$

9. When it was first constructed in 1968, the John Hancock building in Chicago, Ilinois, was the tallest structure in the world. In 1974, the Willis Tower in Chicago (formerly known as the Sears Tower) became the world's tallest structure. The Willis Tower is 323 ft taller than the John Hancock Building, and the sum of their heights is 2577 ft. How tall is each structure?

10. The manufacturer of a revolutionary automobile spark plug finds that demand for the plug can be modeled by the function $D(p) = -0.8p + 110$, where $D(p)$ represents the number of plugs bought (demanded, in tens of thousands) at price p in cents. The supply of these spark plugs is modeled by $S(p) = 0.24p - 14.8$, where $S(p)$ represents the number of plugs manufactured/supplied (in tens of thousands) at price p. Find the price for market equilibrium using a graphing calculator.

SECTION 9.2 Linear Systems in Three Variables with Applications

KEY CONCEPTS

- The graph of a linear equation in three variables is a *plane.*
- A linear system in three variables has the following possible solution sets:
  - If the planes intersect at a point, the system could have one *unique solution* (x, y, z).
  - If the planes intersect at a line, the system has *linear dependence* and the solution (x, y, z) can be written as linear combinations of a single variable (*a parameter*).

- If the planes are *coincident,* the equations in the system differ by a constant multiple, meaning they are all "disguised forms" of the *same equation.* The solutions have *coincident dependence,* and the solution set can be represented by any one of the equations.
- In all other cases, the system has *no solutions* and is an inconsistent system.

EXERCISES

Solve using elimination. If a system is inconsistent or dependent, so state. For systems with linear dependence, give the answer as an ordered triple using a parameter. Verify solutions on the home screen using the ALPHA keys.

11. $\begin{cases} x + y - 2z = -1 \\ 4x - y + 3z = 3 \\ 3x + 2y - z = 4 \end{cases}$ **12.** $\begin{cases} -x + y + 2z = 2 \\ x + y - z = 1 \\ 2x + y + z = 4 \end{cases}$ **13.** $\begin{cases} 3x + y + 2z = 3 \\ x - 2y + 3z = 1 \\ 4x - 8y + 12z = 7 \end{cases}$

Solve using a system of three equations in three variables.

14. A large coin jar is full of nickels, dimes, and quarters. There are 217 coins in all. The number of nickels is 12 more than the number of quarters. The value of the dimes is \$4.90 more than the value of the nickels. How many coins of each type are in the bank?

15. If the point (x, y) is on the graph of a parabola, it must satisfy the equation $y = ax^2 + bx + c$. Use a system of three equations in three variables to find the equation of the parabola containing the points $(0, -9)$, $(2, 7)$, and $(6, 15)$.

SECTION 9.3 Systems of Inequalities and Linear Programming

KEY CONCEPTS

- To solve a *system of inequalities,* we find the intersecting or *overlapping regions* of the solution regions from the individual inequalities. The common area is called the *solution region* for the system.
- The process known as *linear programming* seeks to *maximize* or *minimize* the value of a given quantity under certain *constraints* or restrictions.
- The quantity we attempt to maximize or minimize is called the *objective function.*
- The solution(s) to a linear programming problem *occur at one of the corner points of the feasible (solution) region.*
- The process of solving a linear programming application contains these six steps:
  - Identify the main objective and the decision variables.
  - Write the objective function in terms of these variables.
  - Organize all information in a table, using the decision variables and constraints.
  - Fill in the table with the information given and write the constraint inequalities.
  - Graph the constraint inequalities and determine the feasible region.
  - Identify all corner points of the feasible region and test these points in the objective function.

EXERCISES

Graph the solution region for each system of linear inequalities by first solving equation for y. Verify each solution using a test point. Solve Exercise 18 using a graphing calculator.

16. $\begin{cases} -x - y > -2 \\ -x + y < -4 \end{cases}$ **17.** $\begin{cases} x - 4y \le 5 \\ -x + 2y \le 0 \end{cases}$ **18.** $\begin{cases} x + 2y \ge 1 \\ 2x - y \le -2 \end{cases}$

19. Carefully graph the feasible region for the system of inequalities shown, then maximize the objective function: $f(x, y) = 30x + 45y$

$$\begin{cases} 2x + y \le 10 \\ 2x + 3y \le 18 \\ x \ge 0, y \ge 0 \end{cases}$$

20. After retiring, Oliver and Lisa Douglas buy and work a small farm (near Hooterville) that consists mostly of milk cows and egg-laying chickens. Although the price of a commodity is rarely stable, suppose that milk sales bring in an average of \$85 per cow and egg sales an average of \$50 per chicken over a period of time. During this time period, the new ranchers estimate that care and feeding of the animals took about 3 hr per cow and 2 hr per

chicken, while maintaining the related equipment took 2 hr per cow and 1 hr per chicken. How many animals of each type should be maintained in order to maximize profits, if at most 1000 hr can be spent on care and feeding, and at most 525 hr on equipment maintenance?

SECTION 9.4 Partial Fraction Decomposition

KEY CONCEPTS

- Partial fraction decomposition is an attempt to reverse the process of adding rational expressions.
- The process begins by factoring the denominator and setting up a "decomposition template."
- For each linear factor $(x + c)$ of the denominator, the template will have a term of the form $\frac{A_1}{x + c}$, A_1 a constant.
- For each irreducible quadratic factor $(ax^2 + bx + c)$ of the denominator, the template will have a term of the form $\frac{A_1x + B_1}{ax^2 + bx + c}$ for constants A_1 and B_1.
- If the factor $(x + c)$ is repeated n times the template will have n terms of the form $\frac{A_i}{(x + c)^i}$ for $i = 1$ to n.
- If the irreducible quadratic factor is repeated n times, the template will have n terms of the form $\frac{A_ix + B_i}{(ax^2 + bx + c)^i}$, for $i = 1$ to n.
- After the template has been set (original expression = decomposition template), multiply both sides by the LCD and (1) use convenient values or (2) simplify the right-hand side and equate coefficients to find the constants A_i and B_i needed. Note that some of the coefficients found may be zero.
- If the degree of the numerator is greater than the degree of the denominator, divide using long division and decompose the remainder portion.

EXERCISES

Decompose each of the following expressions into partial fractions.

21. $\frac{6x + 14}{x^2 + 2x - 15}$

22. $\frac{16x + 1}{2x^2 - 5x - 3}$

23. $\frac{x^2 + 2x + 9}{x^3 + 4x^2 + x + 4}$

24. $\frac{-2x^2 - 3x - 19}{x^3 - 5x^2 + 3x - 15}$

25. $\frac{-2x^2 + 13x - 24}{x^3 + 27}$

26. $\frac{6x^2 + 2x + 7}{x^3 - 1}$

27. $\frac{2x^2 - 8x + 33}{x^3 - x^2 - 8x + 12}$

28. $\frac{-x^2 - 15x + 22}{x^3 + 3x^2 - 9x + 5}$

29. $\frac{2x^2 - x + 1}{x^4 + 6x^2 + 9}$

SECTION 9.5 Solving Linear Systems Using Matrices and Row Operations

KEY CONCEPTS

- A *matrix* is a rectangular arrangement of numbers. An $m \times n$ matrix has m rows and n columns.
- The matrix derived from a system of linear equations is called the *augmented matrix.* It is created by augmenting the *coefficient matrix* (formed by the variable coefficients) with the *matrix of constants.*
- One matrix method for solving systems involves the augmented matrix and *row-reduction.*
  - If possible, interchange equations so that the coefficient of x is a "1" in R1.
  - Write the system in augmented matrix form (coefficient matrix with matrix of constants).
  - Use row operations to obtain zeroes below the first entry of the diagonal.
  - Use row operations to obtain zeroes below the second entry of the diagonal.
  - Continue until the matrix is triangularized (all entries below the diagonal are zero).
  - Convert the augmented matrix back into equation form and solve for z.
  - Graphing calculators can quickly and accurately perform row-reduction.

EXERCISES

Solve by triangularizing the augmented matrix. Use a calculator for Exercise 32.

30. $\begin{cases} x - 2y = 6 \\ 4x - 3y = 4 \end{cases}$

31. $\begin{cases} x - 2y + 2z = 7 \\ 2x + 2y - z = 5 \\ 3x - y + z = 6 \end{cases}$

32. $\begin{cases} 2w + x + 2y - 3z = -19 \\ w - 2x - y + 4z = 15 \\ x + 2y - z = 1 \\ 3w - 2x - 5z = -60 \end{cases}$

SECTION 9.6 The Algebra of Matrices

KEY CONCEPTS

- The entries of a matrix are denoted a_{ij}, where i gives the row and j gives the column of its location.
- The $m \times n$ size of a matrix is also referred to as its *order.*
- Two matrices A and B are equal if corresponding entries are equal: $A = B$ if $a_{ij} = b_{ij}$.
- The sum or difference of two matrices is found by combining corresponding entries: $A + B = [a_{ij} + b_{ij}]$.
- The *identity matrix* for addition is an $m \times n$ matrix whose entries are all zeroes.
- The product of a constant times a matrix is called *scalar multiplication,* and is found by taking the product of the scalar with each entry, forming a new matrix of like size. For matrix A: $kA = ka_{ij}$.
- Matrix multiplication is performed as row entry $\times$ column entry according to the following procedure: For an $m \times n$ matrix $A = [a_{ij}]$ and a $p \times q$ matrix $B = [b_{ij}]$, matrix multiplication is possible if $n = p$, and the result will be an $m \times q$ matrix P. In symbols $A \cdot B = [p_{ij}]$, where p_{ij} is product of the ith row of A with the jth column of B.
- When technology is used to perform operations on matrices, the focus shifts from a meticulous computation of new entries, to carefully entering each matrix into the calculator, double checking that each entry is correct, and appraising the results to see if they are reasonable.

EXERCISES

Compute the operations indicated below (if possible), using the following matrices.

$A = \begin{bmatrix} \frac{-1}{4} & \frac{-3}{4} \\ \frac{-1}{8} & \frac{-7}{8} \end{bmatrix}$ $B = \begin{bmatrix} -7 & 6 \\ 1 & -2 \end{bmatrix}$ $C = \begin{bmatrix} -1 & 3 & 4 \\ 5 & -2 & 0 \\ 6 & -3 & 2 \end{bmatrix}$ $D = \begin{bmatrix} 2 & -3 & 0 \\ 0.5 & 1 & -1 \\ 4 & 0.1 & 5 \end{bmatrix}$

33. $A + B$ **34.** $B - A$ **35.** $C - B$ **36.** $8A$ **37.** BA

38. $C + D$ **39.** $D - C$ **40.** BC **41.** $-4D$ **42.** CD

SECTION 9.7 Solving Linear Systems Using Matrix Equations

KEY CONCEPTS

- The *identity matrix* I for multiplication has 1's on the main diagonal and 0's for all other entries. For any $n \times n$ matrix A, the identity matrix is also an $n \times n$ matrix I_n, where $AI_n = I_nA = A$.
- For an $n \times n$ (square) matrix A, the *inverse matrix* for multiplication is a matrix B such that $AB = BA = I$. Only square matrices have inverses. For matrix A the inverse is denoted A^{-1}.
- Any $n \times n$ system of equations can be written as a matrix equation and solved (if solutions exist) using an inverse matrix. For $\begin{cases} 2x + 3y - z = 5 \\ -3x + 2y + 4z = 13 \\ x - 5y + 2z = -3 \end{cases}$, the matrix equation is $\begin{bmatrix} 2 & 3 & -1 \\ -3 & 2 & 4 \\ 1 & -5 & 2 \end{bmatrix} \cdot \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 5 \\ 13 \\ -3 \end{bmatrix}$.
- Every square matrix has a real number associated with it called its determinant. For a 2×2 matrix $A = \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix}$, $\det(A) = a_{11}a_{22} - a_{21}a_{12}$.
- If the determinant of a matrix is zero, the matrix is said to be *singular* or *noninvertible.*
- For matrix equations, if the coefficient matrix is noninvertible, the system has no unique solution.

EXERCISES

Complete Exercises 43 through 45 using the following matrices:

$$A = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad B = \begin{bmatrix} 0.2 & 0.2 \\ -0.6 & 0.4 \end{bmatrix} \quad C = \begin{bmatrix} 2 & -1 \\ 3 & 1 \end{bmatrix} \quad D = \begin{bmatrix} 10 & -6 \\ -15 & 9 \end{bmatrix}$$

43. Exactly one of the matrices given is singular. Compute each determinant to identify it.

44. Show that $AB = BA = B$. What can you conclude about matrix A?

45. Show that $BC = CB = I$. What can you conclude about matrix C?

Use a graphing calculator to complete Exercises 46 through 49, using these matrices:

$$E = \begin{bmatrix} 1 & -2 & 3 \\ -2 & 1 & -5 \\ -1 & -1 & -2 \end{bmatrix} \quad F = \begin{bmatrix} 1 & -1 & 1 \\ 0 & 1 & 0 \\ -2 & 1 & -1 \end{bmatrix} \quad G = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad H = \begin{bmatrix} -1 & 0 & -1 \\ 0 & 1 & 0 \\ 2 & 1 & 1 \end{bmatrix}$$

46. Exactly one of the matrices above is singular. Determine which one.

47. Show that $GF = FG = F$. What can you conclude about the matrix G?

48. Show that $FH = HF = I$. What can you conclude about the matrix H?

49. Verify that $EH \neq HE$ and $EF \neq FE$ and comment.

Solve manually using a matrix equation.

50. $\begin{cases} 2x - 5y = 14 \\ -3y + 4x = -14 \end{cases}$

Solve using a matrix equation and your calculator.

51. $\begin{cases} 0.5x - 2.2y + 3z = -8 \\ -0.6x - y + 2z = -7.2 \\ x + 1.5y - 0.2z = 2.6 \end{cases}$

SECTION 9.8 Applications of Matrices and Determinants: Cramer's Rule, Geometry, and More

KEY CONCEPTS

- Cramer's rule uses a ratio of determinants to solve systems of equations (if they exist).
- To compute the value of 3×3 and larger determinants, a calculator is generally used.
- Determinants can be used to find the area of a triangle in the plane if the vertices are known, and as a test to see if three points are collinear.
- A system of equations can be used to write a rational expression as a sum of its partial fractions.

EXERCISES

Solve using Cramer's rule. Use a graphing calculator for Exercise 54.

52. $\begin{cases} 5x + 6y = 8 \\ 10x - 2y = -9 \end{cases}$

53. $\begin{cases} 2x + y - z = -1 \\ x - 2y + z = 5 \\ 3x - y + 2z = 8 \end{cases}$

54. $\begin{cases} 2x + y = -2 \\ -x + y + 5z = 12 \\ 3x - 2y + z = -8 \end{cases}$

55. Find the area of a triangle whose vertices have the coordinates $(6, 1)$, $(-1, -6)$, and $(-6, 2)$.

56. Use a matrix equation and a graphing calculator to find the partial fraction decomposition for $\dfrac{7x^2 - 5x + 17}{x^3 - 2x^2 + 3x - 6}$.

57. Midwest Petroleum (MP) produces three types of combustibles using common refined gasoline and vegetable products. The first is E10 (also known as gasohol), the second is E85, and the third is biodiesel. One gallon of E10 requires 0.90 gal of gasoline, 2 lb of corn, 1 oz of yeast, and 0.5 gal of water. One gallon of E85 requires 0.15 gal of gasoline, 17 lb of corn, 8.5 oz of yeast, and 4.25 gal of water. One gallon of biodiesel requires 20 lb of corn and 3 gal of water. One week's production at MP consisted of 100,000 gal of E10, 15,000 gal of E85, and 7000 gal of biodiesel. Use your calculator and a matrix equation to determine how much of each raw material they used to fill their orders.

58. The following table represents Midwest Petroleum's production for the next 3 weeks. Use your calculator and a matrix equation to determine the total amount of raw material they used to fill their orders. See Exercise 57.

	Week 2	Week 3	Week 4
E10	110,000	95,000	105,000
E85	17,000	18,000	20,000
Biodiesel	6000	8000	10,000

59. In addition to being one of the world's first celebrity chefs, Marie-Antoine Carême (1784–1833) was a master pastry chef. Had he used matrices to encode his favorite culinary math secret, perhaps his message would have been:

$$11, 10, 25, -25, -6, -59, 33, 13, 76, 34, 43, 69, -3, 0, -6$$

If Carême used the cipher on page 941 (Example 8) and the matrix $A = \begin{bmatrix} 1 & 2 & 3 \\ 1 & 3 & 1 \\ 2 & 4 & 7 \end{bmatrix}$ for the encoding process, decode the message to find the unconventional culinary secret that is actually familiar to students of mathematics.

PRACTICE TEST

Solve each system and state whether the system is consistent, inconsistent, or dependent. Verify solutions using a graphing calculator.

1. Solve graphically:

$$\begin{cases} 3x + 2y = 12 \\ -x + 4y = 10 \end{cases}$$

2. Solve using substitution:

$$\begin{cases} 3x - y = 2 \\ -7x + 4y = -6 \end{cases}$$

3. Solve using elimination:

$$\begin{cases} 5x + 8y = 1 \\ 3x + 7y = 5 \end{cases}$$

4. Solve using elimination:

$$\begin{cases} x + 2y - z = -4 \\ 2x - 3y + 5z = 27 \\ -5x + y - 4z = -27 \end{cases}$$

5. Given matrices A and B, compute:

a. $A - B$ **b.** $\frac{2}{5}B$ **c.** AB

d. A^{-1} **e.** $|A|$

$$A = \begin{bmatrix} -3 & -2 \\ 5 & 4 \end{bmatrix} \qquad B = \begin{bmatrix} 3 & 3 \\ -3 & -5 \end{bmatrix}$$

6. Given matrices C and D, use a calculator to find:

a. $C - D$ **b.** $-0.6D$ **c.** DC

d. D^{-1} **e.** $|D|$

$$C = \begin{bmatrix} 0.5 & 0 & 0.2 \\ 0.4 & -0.5 & 0 \\ 0.1 & -0.4 & -0.1 \end{bmatrix} \qquad D = \begin{bmatrix} 0.5 & 0.1 & 0.2 \\ -0.1 & 0.1 & 0 \\ 0.3 & 0.4 & 0.8 \end{bmatrix}$$

7. Solve using matrices and row reduction:

$$\begin{cases} 4x - 5y - 6z = 5 \\ 2x - 3y + 3z = 0 \\ x + 2y - 3z = 5 \end{cases}$$

8. Solve using Cramer's rule:

$$\begin{cases} 2x + 3y + z = 3 \\ x - 2y - z = 4 \\ x - y - 2z = -1 \end{cases}$$

9. Solve using a matrix equation and your calculator:

$$\begin{cases} 2x - 5y = 11 \\ 4x + 7y = 4 \end{cases}$$

10. Solve using a matrix equation and your calculator:

$$\begin{cases} x - 2y + 2z = 7 \\ 2x + 2y - z = 5 \\ 3x - y + z = 6 \end{cases}$$

Use a system of equations to model each exercise, then solve using the method of your choice.

11. The perimeter of a "legal-size" paper is 114.3 cm. The length of the paper is 7.62 cm less than twice the width. Find the dimensions of a legal-size sheet of paper.

12. The island nations of Tahiti and Tonga have a combined land area of 692 mi^2. Tahiti's land area is 112 mi^2 more than Tonga's. What is the land area of each island group?

13. After inheriting $30,000 from a rich aunt, David decides to place the money in three different investments: a savings account paying 5%, a bond account paying 7%, and a stock account paying 9%. After 1 yr he earned $2080 in interest. Find how much was invested at each rate if $8000 less was invested at 9% than at 7%.

14. The company from Exercise 10 of the *Summary and Concept Review*, hired a market research firm to collect data about the next-generation spark plug that will increase fuel efficiency by over 20%. The data they collected are shown in the table. Enter the data into a graphing calculator, calculate the regression line for each set of data, then (a) display the lines and scatterplot on a single screen, and (b) use the lines to find the estimated price and quantity at which market equilibrium is achieved.

Price (cents)	Demand (10,000s)	Supply (10,000s)
135	2.9	19.7
90	37.2	8.0
62	59.6	0.45
112	19.7	12.7
75	46.0	3.69
121	12.4	15.9

Using a radar gun placed in a protective cage beneath a falling baseball, the following data points are taken: (1, 128), (2, 80), (2.5, 44). Assume the data are of the form (time in seconds, distance from radar gun).

15. Use the data to set up a system of three equations in three variables to find the quadratic equation that models the ball's height at time t.

16. From what height is the baseball being released? In how many seconds will it strike the cage protecting the radar gun?

17. Solve the system of inequalities by graphing.

$$\begin{cases} x - y \le 2 \\ x + 2y \ge 8 \end{cases}$$

18. Maximize the objective function: $P = 50x - 12y$

$$\begin{cases} x + 2y \le 8 \\ 8x + 5y \ge 40 \\ x \ge 0, y \ge 0 \end{cases}$$

Solve the linear programming problem.

19. A company manufactures two types of T-shirts, a plain T-shirt and a deluxe monogrammed T-shirt. To produce a plain shirt requires 1 hr of working time on machine A and 2 hr on machine B. To produce a deluxe shirt requires 1 hr on machine A and 3 hr on machine B. Machine A is available for at most 50 hr/week, while machine B is available for at most 120 hr/week. If a plain shirt can be sold at a profit of $4.25 each and a deluxe shirt can be sold at a profit of $5.00 each, how many of each should be manufactured to maximize the profit?

20. Decompose the expression into partial fractions:

$$\frac{4x^2 - 4x + 3}{x^3 - 27}.$$

CALCULATOR EXPLORATION AND DISCOVERY

Cramer's Rule

In Section 9.8, we saw that one interesting application of matrices is Cramer's rule. You may have noticed that when technology is used with Cramer's rule, the chances of making an error are fairly high, as we need to input the entries for numerous matrices. However, as we mentioned in the chapter introduction, one of the advantages of matrices is that they *are easily programmable,* and we can actually write a very simple program that will make Cramer's rule a more efficient method.

To begin, press the PRGM key, and then the right arrow twice and ENTER to create a name for our program. At the prompt, we'll enter **CRAMER2.** As we write the program, note that the needed commands **(ClrHome, Disp, Pause, Prompt, Stop)** are all located in the submenus of the PRGM key, and the = sign is found under the **TEST** menu, accessed using the 2nd MATH keys (the arrows "→" are used to indicate the STO key.

The following program takes the coefficients and constants of a 2 × 2 linear system, and returns the ordered pair solution in the form of $x = h$ and $y = k$ (for constants h and k). Even with minimal programming experience, reading through the program will help you identify that Cramer's rule is being used.

Exercise 1: Use the program to check the answers to Exercises 1, 2, and 3 of the Practice Test.

Exercise 2: Create 2×2 systems of your own that are (a) consistent, (b) inconsistent, and (c) dependent. Then verify results using the program.

Exercise 3: Use the box on page 935 of Section 9.8 to write a similar program for 3×3 systems. Call the program CRAMER3, and repeat parts (a), (b), and (c) from Exercise 2.

STRENGTHENING CORE SKILLS

Augmented Matrices and Matrix Inverses

The formula for finding the inverse of a 2×2 matrix has its roots in the more general method of computing the inverse of an $n \times n$ matrix. This involves augmenting a square matrix M with its corresponding identity I_n on the right (forming an $n \times 2n$ matrix), and using row operations to *transform M into the identity.* In some sense, as the original matrix is transformed, the "identity part" keeps track of the operations we used to convert M and we can use the results to "get back home," so to speak. We'll illustrate with the 2×2 matrix from Section 9.7, Example 2B, where we found that $\begin{bmatrix} 1 & -2.5 \\ -1 & 3 \end{bmatrix}$ was the inverse matrix for $\begin{bmatrix} 6 & 5 \\ 2 & 2 \end{bmatrix}$. We begin by augmenting $\begin{bmatrix} 6 & 5 \\ 2 & 2 \end{bmatrix}$ with the 2×2 identity matrix.

$$\left[\begin{array}{cc|cc} 6 & 5 & 1 & 0 \\ 2 & 2 & 0 & 1 \end{array}\right] \xrightarrow{-3R2 + R1 \to R2} \left[\begin{array}{cc|cc} 6 & 5 & 1 & 0 \\ 0 & -1 & 1 & -3 \end{array}\right] \xrightarrow{-1R2 \to R2} \left[\begin{array}{cc|cc} 6 & 5 & 1 & 0 \\ 0 & 1 & -1 & 3 \end{array}\right]$$

$$\left[\begin{array}{cc|cc} 6 & 5 & 1 & 0 \\ 0 & 1 & -1 & 3 \end{array}\right] \xrightarrow{-5R2 + R1 \to R1} \left[\begin{array}{cc|cc} 6 & 0 & 6 & -15 \\ 0 & 1 & -1 & 3 \end{array}\right] \xrightarrow{\frac{R1}{6} \to R1} \left[\begin{array}{cc|cc} 1 & 0 & 1 & -2.5 \\ 0 & 1 & -1 & 3 \end{array}\right]$$

As you can see, the identity is automatically transformed into the inverse matrix when this method is applied. Performing similar row operations on the general matrix $\begin{bmatrix} a & b \\ c & d \end{bmatrix}$ results in the formula given earlier. As you might imagine, attempting this on a general 3×3 matrix is problematic at best, and instead we simply apply the augmented matrix method to find A^{-1} for the 3×3 matrix shown in blue.

$$\left[\begin{array}{ccc|ccc} 2 & 1 & 0 & 1 & 0 & 0 \\ -1 & 3 & -2 & 0 & 1 & 0 \\ 3 & -1 & 2 & 0 & 0 & 1 \end{array}\right] \xrightarrow[-3R1 + 2R3 \to R3]{R1 + 2R2 \to R2} \left[\begin{array}{ccc|ccc} 2 & 1 & 0 & 1 & 0 & 0 \\ 0 & 7 & -4 & 1 & 2 & 0 \\ 0 & -5 & 4 & -3 & 0 & 2 \end{array}\right]$$

$$\xrightarrow[5R2 + 7R3 \to R3]{R2 - 7R1 \to R1} \left[\begin{array}{ccc|ccc} -14 & 0 & -4 & -6 & 2 & 0 \\ 0 & 7 & -4 & 1 & 2 & 0 \\ 0 & 0 & 8 & -16 & 10 & 14 \end{array}\right] \xrightarrow{\frac{R3}{8} \to R3} \left[\begin{array}{ccc|ccc} -14 & 0 & -4 & -6 & 2 & 0 \\ 0 & 7 & -4 & 1 & 2 & 0 \\ 0 & 0 & 1 & -2 & 1.25 & 1.75 \end{array}\right]$$

$$\xrightarrow[4R3 + R1 \to R1]{4R3 + R2 \to R2} \left[\begin{array}{ccc|ccc} -14 & 0 & 0 & -14 & 7 & 7 \\ 0 & 7 & 0 & -7 & 7 & 7 \\ 0 & 0 & 1 & -2 & 1.25 & 1.75 \end{array}\right] \xrightarrow[\frac{R2}{7} \to R2]{\frac{R1}{-14} \to R1} \left[\begin{array}{ccc|ccc} 1 & 0 & 0 & 1 & -0.5 & -0.5 \\ 0 & 1 & 0 & -1 & 1 & 1 \\ 0 & 0 & 1 & -2 & 1.25 & 1.75 \end{array}\right].$$

To verify, we show $AA^{-1} = I$: $\begin{bmatrix} 2 & 1 & 0 \\ -1 & 3 & -2 \\ 3 & -1 & 2 \end{bmatrix}\begin{bmatrix} 1 & -0.5 & -0.5 \\ -1 & 1 & 1 \\ -2 & 1.25 & 1.75 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$ ✓ ($A^{-1}A = I$ also checks).

Exercise 1: Use the preceding inverse and a matrix equation to solve the system

$$\begin{cases} 2x + y = -2 \\ -x + 3y - 2z = -15. \\ 3x - y + 2z = 9 \end{cases}$$

CUMULATIVE REVIEW CHAPTERS 1–9

1. Solve each equation by factoring.
- **a.** $9x^2 - 12x = -4$
- **b.** $x^2 - 7x = 0$
- **c.** $3x^3 - 15x^2 + 6x = 30$
- **d.** $x^3 = 4x + 3x^2$

2. Solve for x.

$$\frac{-3}{x-3} + \frac{3x}{x^2 - x - 6} = \frac{1}{x+2}$$

3. A torus is a donut-shaped solid figure. Its surface area is given by the formula $A = \pi^2(R^2 - r^2)$, where R is the outer radius of the donut, and r is the inner radius. Solve the formula for R in terms of r and A.

4. State the value of all six trig functions given (21, −28) is a point on the terminal side of θ.

5. Sketch the graph of $y = 4\cos\left(\frac{\pi}{6}x - \frac{\pi}{3}\right)$ using transformations of $y = \cos x$.

6. A jai alai player in an open-air court becomes frustrated and flings the pelota out and beyond the court. If the initial velocity of the ball is 136 mph and it is released at height of 5 ft, (a) how high is the ball after 3 sec? (b) What is the maximum height of the ball? (c) How long until the ball hits the ground (hopefully in an unpopulated area)? Recall the projectile equation is $h(t) = -16t^2 + v_0t + k$.

7. For a complex number $a + bi$, (a) verify the sum of a complex number and its conjugate is a real number. (b) Verify the product of a complex number and its conjuate is a real number.

8. Solve using the quadratic formula: $5x^2 + 8x + 2 = 0$.

9. Solve by completing the square: $3x^2 - 72x + 427 = 0$.

10. Given $\cos 53° \approx 0.6$ and $\cos 72° \approx 0.3$, approximate the value of $\cos 19°$ and $\cos 125°$ without using a calculator.

11. Given $\left(\frac{\sqrt{3}}{4}, y\right)$ is a point on the unit circle, find the value of $\sin\theta$, $\cos\theta$, and $\tan\theta$ if $y > 0$.

12. State the domain of each function:
- **a.** $f(x) = \sqrt{2x - 3}$
- **b.** $g(x) = \log_b(x + 3)$
- **c.** $h(x) = \dfrac{x+3}{x^2 - 5}$

13. Write the following formulas from memory:
- **a.** slope formula
- **b.** midpoint formula
- **c.** quadratic formula
- **d.** distance formula
- **e.** interest formula (compounded continuously)

14. Find the equation of the line perpendicular to the line $4x + 5y = -20$, that contains the point (0, 1).

15. For the force vectors $\mathbf{F}_1$ and $\mathbf{F}_2$ given, find a third force vector $\mathbf{F}_3$ that will bring these vectors into equilibrium: $\mathbf{F}_1\langle -5, 12\rangle$, $\mathbf{F}_2\langle 8, 6\rangle$

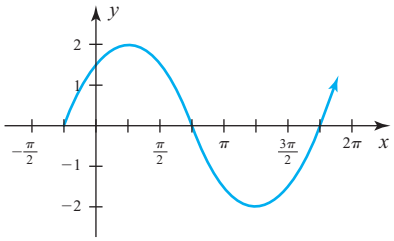
16. A commercial fishery stocks a lake with 250 fish. Based on previous experience, the population of fish is expected to grow according to the model $P(t) = \dfrac{12{,}000}{1 + 25e^{-0.2t}}$, where t is the time in months. From on this model, (a) how many months are required for the population to grow to 7500 fish? (b) If the fishery expects to harvest three-fourths of the fish population in 2 yr, approximately how many fish will be taken?

17. Evaluate each expression by drawing a right triangle and labeling the sides.
- **a.** $\sec\left[\sin^{-1}\left(\dfrac{x}{\sqrt{121 + x^2}}\right)\right]$
- **b.** $\sin\left[\csc^{-1}\left(\dfrac{\sqrt{9 + x^2}}{x}\right)\right]$

18. An luxury ship is traveling at 15 mph on a heading of 10°. There is a strong, 12 mph ocean current flowing from the southeast, at a heading of 330°. What is the true course and speed of the ship?

19. Use the *Guidelines for Graphing* to sketch the graph of function f given, then use it to solve $f(x) < 0$: $f(x) = x^3 - 4x^2 + x + 6$

20. Use the *Guidelines for Graphing* to sketch the graph of function g given, then use it to name the intervals where $g(x)\downarrow$ and $g(x)\uparrow$: $g(x) = \dfrac{x^2 - 4}{x^2 - 1}$



21. Find $(1 - i\sqrt{3})^8$ using De Moivre's theorem.

22. Solve $\ln(x + 2) + \ln(x - 3) = \ln(4x)$.

23. If I deposited \$200 each month into an annuity program that paid 8% annual interest compounded monthly, how long would it take to save \$10,000?

24. Mount Tortolas lies on the Argentine-Chilean border. When viewed from a distance of 5 mi, the angle of elevation to the top of the peak is 38°. How tall is Mount Tortolas? State the answer in feet.

25. The graph given is of the form $y = A\sin(Bx + C)$. Find the values of A, B, and C.

Exercises 26 through 30 require the use of a graphing calculator.

26. At Leroy's Butcher Shop, last week's specials were boneless chuck steaks, chicken breasts, and chorizo sausages. Pamela spent a total of \$17.81 on 3.21 lb of chuck, 2.45 lb of chicken, and 1.15 lb of chorizo. Shannon purchased 1.57 lb of chuck, 4.21 lb of chicken, and 0.89 lb of chorizo with \$15.24, while the 2.41 lb of chuck, 1.39 lb of chicken, and 1.46 lb of chorizo Dusty took home cost a total of \$14.05. To the nearest cent, how much did each type of meat cost per pound?

27. Apply long division to find the quotient and remainder for $v(x) = \dfrac{\pi^2x^2 + \pi x}{x^2 + \pi}$. Determine where the graph of the function crosses the horizontal asymptote.

28. Find all real solutions of the equation: $\tan t + \cos t = \cos t$.

29. Find the local minimum value of $y = x^3 - 3x^2$.

30. In New Zealand's Abel Tasman National Park, the depth of the water in one particular tidal pool can be modeled by the function $d(t) = 1.9\sin\left(\dfrac{\pi}{6}t\right) + 2.2$, where $d(t)$ is the depth in feet and t is the time of the day (using a 24-hr clock). Determine the times of the day when there is at most 2 ft of water in this pool. Round your answers to the nearest minute.

As mentioned in the chapter opener, in calculus as well as algebra we often look for expressions that fit a special form, then apply a general formula to all expressions of that form. Here this general idea is applied to partial fraction decomposition, a technique we studied in Section 9.4 and an important part of integral calculus.

More on Partial Fraction Decomposition

To rewrite the expression $\frac{10}{x^2 - 25}$ as a sum of its partial fractions, we would use the template $\frac{10}{(x + 5)(x - 5)} = \frac{A}{x + 5} + \frac{B}{x - 5}$ and proceed as in Section 9.4. Using the ideas developed there, we'll attempt to develop a decomposition formula that works for *all* rational expressions of the form $\frac{2k}{x^2 - k^2}$, a form that certainly applies to the expression at hand.

EXAMPLE 1 ▶ **Decomposing Special Forms**

Use the techniques from Section 9.4 to rewrite the expression $\frac{2k}{x^2 - k^2}$ as the sum of its partial fractions.

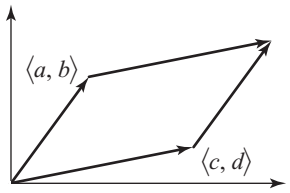
Solution ▶ After factoring the denominator, we obtain the following template:

$$\begin{aligned} \frac{2k}{(x + k)(x - k)} &= \frac{A}{x + k} + \frac{B}{x - k} && \text{decomposition template} \\ 2k &= A(x - k) + B(x + k) && \text{clear denominators} \\ &= Ax - Ak + Bx + Bk && \text{distribute} \\ &= (A + B)x + (B - A)k && \text{collect like terms} \end{aligned}$$

This gives the system $\begin{cases} A + B = 0 \\ B - A = 2 \end{cases}$, yielding the solutions $B = 1$ and $A = -1$. As it turns out, any rational expression of the form $\frac{2k}{x^2 - k^2}$ can be written in decomposed form as $\frac{-1}{x + k} + \frac{1}{x - k}$.

Now try Exercises 1 and 2 ▶

EXAMPLE 2 ▶ **Decomposing Special Forms**



Use the "formula" from Example 1 to decompose the expression $\frac{10}{x^2 - 25}$ as the sum of its partial fractions, then verify the result.

Solution ▶ By comparing $\frac{2k}{x^2 - k^2}$ with $\frac{10}{x^2 - 25}$, we note $2k = 10$ and $k = 5$, so $\frac{10}{x^2 - 25}$ must be equal to $\frac{-1}{x + 5} + \frac{1}{x - 5}$. To check, we combine the fractions using the LCD $(x + 5)(x - 5)$, giving $\frac{-1(x - 5) + 1(x + 5)}{(x + 5)(x - 5)} = \frac{-x + 5 + x + 5}{(x + 5)(x - 5)}$ or $\frac{10}{x^2 - 25}$ ✓.

Now try Exercises 3 through 8 ▶

The Geometry of Vectors and Determinants

Figure 9.74

Although vectors (Section 8.3) and determinants (Section 9.8) are studied in two separate chapters in *Precalculus,* in a calculus course you'll see there is an intriguing connection between the two. In Section 8.3 we noted the tip-to-tail addition of vectors **u** and **v** form a parallelogram, and used the parallelogram to illustrate a vector sum. In a calculus course, we say the vectors *span* the parallelogram, and in certain applications we need to know the area of this figure. Using the vectors $\mathbf{u} = \langle a, b\rangle$ and $\mathbf{v} = \langle c, d\rangle$ and relation $\cos\theta = \dfrac{\mathbf{u}\cdot\mathbf{v}}{|\mathbf{u}||\mathbf{v}|}$ for the angle θ between them, it can be shown that the area of the parallelogram is the absolute value of the determinant $\begin{vmatrix} a & b \\ c & d \end{vmatrix}$ (see Figure 9.74). For a complete proof, see Appendix B.

EXAMPLE 3 ▶ Using Determinants to Find Area

For the vectors $\mathbf{u} = \langle 12, 5\rangle$ and $\mathbf{v} = \langle 8, 15\rangle$,

a. Compute the vector sum $\mathbf{w} = \mathbf{u} + \mathbf{v}$ using the parallelogram (tail-to-tip) method.

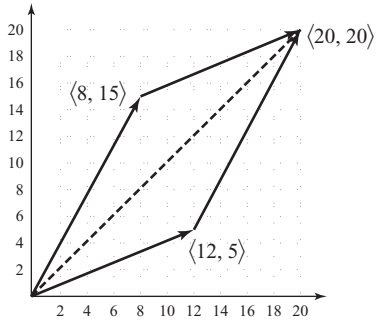
b. Compute $|\mathbf{w}|$ and find the angle θ between **u** and **w**.

c. Use the formula $A = \frac{1}{2}|\mathbf{u}||\mathbf{w}|\sin\theta$ from Section 8.2 to find the area of the triangle formed.

d. Use the determinant $\begin{vmatrix} a & b \\ c & d \end{vmatrix} = \begin{vmatrix} 12 & 5 \\ 8 & 15 \end{vmatrix}$ to find the area of the parallelogram spanned by these vectors, then verify the area is twice as large as the triangle found in part (c).

Solution ▶

a. The vector sum is $\langle 12, 5\rangle + \langle 8, 15\rangle = \langle 20, 20\rangle = \mathbf{w}$.



b. $|\mathbf{w}| = \sqrt{20^2 + 20^2} = \sqrt{800} = 20\sqrt{2}$. For $\mathbf{u}\cdot\mathbf{w} = 12(20) + 5(20) = 340$, and $|\mathbf{u}| = 13$ (verify this), we have $\cos\theta = \dfrac{340}{(13)(20\sqrt{2})}$ and $\theta = \cos^{-1}\left(\dfrac{17}{13\sqrt{2}}\right)$. This indicates $\theta \approx 22.38°$.

c. $A = \frac{1}{2}|\mathbf{u}||\mathbf{w}|\sin\theta$ area formula

$\approx \frac{1}{2}(13)(20\sqrt{2})\sin 22.38°$ substitute

$\approx 70 \text{ units}^2$ result

d. For $\mathbf{u} = \langle 12, 5\rangle$ and $\mathbf{v} = \langle 8, 15\rangle$, the determinant $\begin{vmatrix} a & b \\ c & d \end{vmatrix} = \begin{vmatrix} 12 & 5 \\ 8 & 15 \end{vmatrix} = (12)(15) - (8)(5) = 140 \text{ units}^2$✓, and the area of the parallelogram is indeed twice the area of the triangle.

Now try Exercises 9 through 14 ▶

Connections to Calculus Exercises

Use the techniques from Section 9.4 to complete Exercises 1 and 2.

1. A common form of partial fraction decomposition involves a constant over a factorable quadratic expression. (a) Rewrite the expression $\frac{k}{(x+a)(x+b)}$ as the sum of partial fractions to show the system obtained is $\begin{cases} A+B=0 \\ Ab+Ba=k \end{cases}$. (b) Use the fact that $A+B=0$ to show the system can be rewritten as $\begin{cases} A+B=0 \\ A(b-a)=k \end{cases}$. (c) Solve for A in the second equation and use the result to quickly write $\frac{16}{(x+3)(x-5)}$ as the sum of its partial fractions.

2. Another common form involves a linear expression $x+k$ over a factorable quadratic expression. (a) Rewrite the expression $\frac{x+k}{(x+a)(x+b)}$ as the sum of partial fractions to show the system obtained is $\begin{cases} A+B=1 \\ Ab+Ba=k \end{cases}$. (b) Use the fact that $A+B=1$ to show that system can be written as $\begin{cases} A+B=1 \\ A(b-a)+a=k \end{cases}$. (c) Solve for A in the second equation, and use the result to write $\frac{x+10}{(x+3)(x+4)}$ as the sum of its partial fractions.

Use the "formulas" developed in Example 1 and Exercises 1 and 2 to decompose each expression into a sum of partial fractions.

3. $\frac{6}{x^2-9}$

4. $\frac{18}{x^2-81}$

5. $\frac{-22}{x^2+3x-28}$

6. $\frac{15}{x^2-3x-4}$

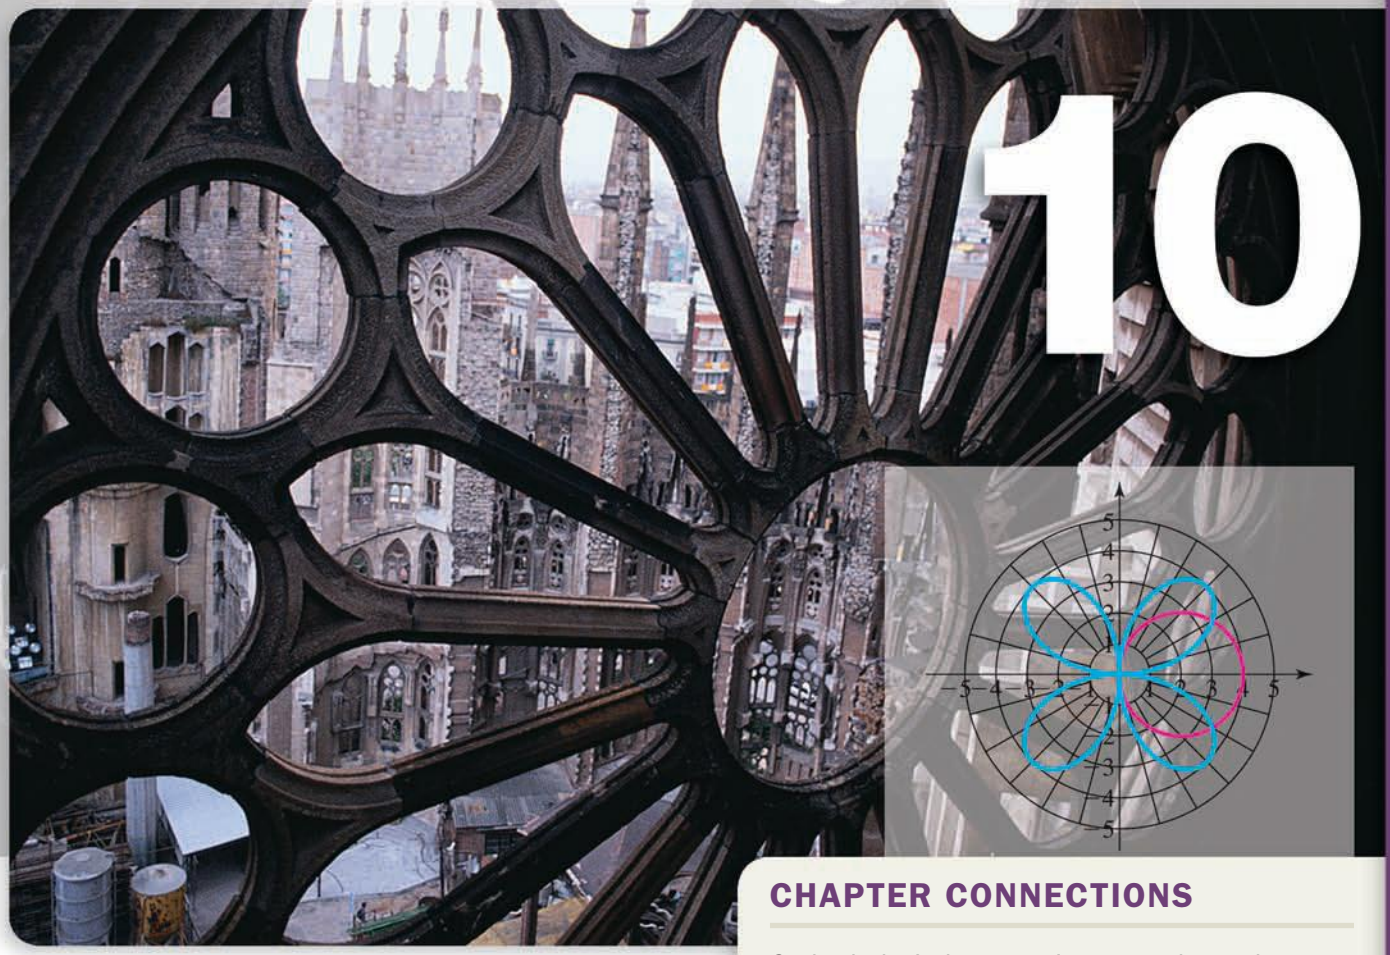
7. $\frac{x+11}{x^2+13x+40}$

8. $\frac{x-17}{x^2-9x+14}$

Find the area of the parallelogram spanned by the vectors given, then verify your answer using the method shown in Example 3.

9. $\mathbf{u}=\langle 2, 8\rangle$ and $\mathbf{v}=\langle 15, 3\rangle$

10. $\mathbf{u}=\langle -4, 1\rangle$ and $\mathbf{v}=\langle 4, 4\rangle$



11. $6\mathbf{i}+3\mathbf{j}$ and $6\mathbf{i}-3\mathbf{j}$

12. $9\mathbf{i}$ and $7\mathbf{j}$

Similar to how the absolute value of $\begin{vmatrix} a & b \\ c & d \end{vmatrix}$ gives the *area* of a parallelogram spanned by $\langle a, b\rangle$ and $\langle c, d\rangle$, the absolute value of the determinant $\begin{vmatrix} a & b & c \\ d & e & f \\ g & h & i \end{vmatrix}$ gives the *volume* of a parallelepiped spanned by $\langle a, b, c,\rangle$, $\langle d, e, f\rangle$, and $\langle g, h, i\rangle$ in three dimensions.

13. Find the volume of the parallelepiped spanned by $\langle 5, 0, 0\rangle$, $\langle 0, 6, 0\rangle$, and $\langle 0, 0, 8\rangle$ using the determinant formula, then verify your answer using a more familiar formula.

14. Find the volume of the parallelepiped spanned by $\mathbf{u}=\langle 2, 5, -8\rangle$, $\langle 3, 0, 4\rangle$, and $\langle 0, 10, -7\rangle$.

CHAPTER CONNECTIONS

Cathedral windows are just one place where we can appreciate the beauty and intricacy of polar graphs. The characteristics and features of these graphs are explored in this chapter, and introduce a historic alternative to graphing relations by simply computing points (x, y). While graphing relations using a rectangular coordinate system is much more widely known, both polar graphs and rectangular graphs seemed to have matured simultaneously, in the early 1600s.

▶ The graphs shown appear as Exercises 73 and 81 in Section 10.6.

Connections to Calculus

When using polar curves in the design of windows or other forms of architechture, finding where two graphs intersect aids in the calculation of the area between curves and in determining the arclength of certain portions of the graph. These are important considerations in a study of calculus, and techniques for working with systems of polar equations are explored in the *Connections to Calculus* for Chapter 10.

10.1 A Brief Introduction to Analytical Geometry

LEARNING OBJECTIVES

In Section 10.1 you will see how we can:

- ❑ **A.** Verify theorems from basic geometry involving the distance between two points
- ❑ **B.** Verify that points (x, y) are an equal distance from a given point and a given line
- ❑ **C.** Use the defining characteristics of a conic section to find its equation

Generally speaking, **analytical geometry** is a study of geometry using the tools of algebra and a coordinate system. These tools include the midpoint and distance formulas; the algebra of parallel, perpendicular, and intersecting lines; and other tools that help establish geometric concepts. In this section, we'll use these tools to verify certain relationships, then use these relationships to introduce a family of curves known as the **conic sections.**

A. Verifying Relationships from Plane Geometry

For the most part, the algebraic tools used in this study were introduced in previous chapters. As the midpoint and distance formulas play a central role, they are restated here for convenience.

Algebraic Tools Used in Analytical Geometry

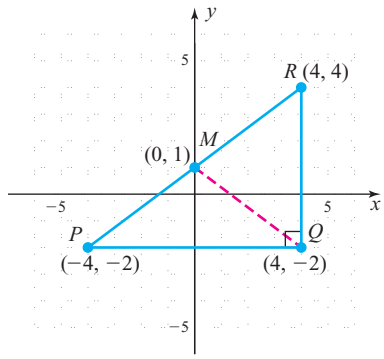
Given two points $P_1 = (x_1, y_1)$ and $P_2 = (x_2, y_2)$ in the xy-plane.

Midpoint Formula

The midpoint of line segment P_1P_2 is

$$(x, y) = \left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2}\right)$$

Distance Formula



The distance from P_1 to P_2 is

$$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

These formulas can be used to verify the conclusion of many theorems from Euclidean geometry, while providing important links to an understanding of the conic sections.

EXAMPLE 1 ▶ **Verifying a Theorem from Basic Geometry**

A theorem from basic geometry states: *The midpoint of the hypotenuse of a right triangle is an equal distance from all three vertices.* Verify this statement for the right triangle formed by $(-4, -2)$, $(4, -2)$, and $(4, 4)$.

Solution ▶ After the plotting points and drawing a triangle, we note the hypotenuse has endpoints $(-4, -2)$ and $(4, 4)$, with midpoint

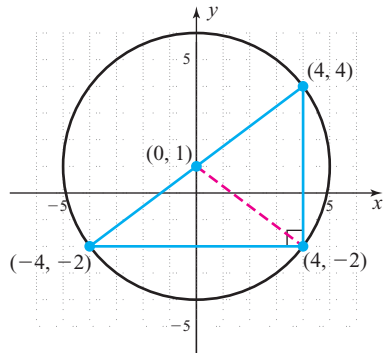
$$\left(\frac{4 + (-4)}{2}, \frac{4 + (-2)}{2}\right) = (0, 1).$$

Using the distance formula to find the distance from $(0, 1)$ to $(4, 4)$ gives

$$\begin{aligned} d &= \sqrt{(4 - 0)^2 + (4 - 1)^2} \\ &= \sqrt{(4)^2 + (3)^2} \\ &= \sqrt{25} \\ &= 5 \end{aligned}$$

From the definition of midpoint, $(0, 1)$ is also 5 units from $(-4, -2)$.

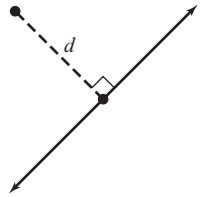
Checking the distance from $(0, 1)$ to the vertex $(4, -2)$ gives



$$\begin{aligned} d &= \sqrt{(4 - 0)^2 + (-2 - 1)^2} \\ &= \sqrt{4^2 + (-3)^2} \\ &= \sqrt{25} \\ &= 5 \end{aligned}$$

The midpoint of the hypotenuse *is* an equal distance from all three vertices (see the figure).

Now try Exercises 7 through 12 ▶



Recall from Section 1.1 that a circle is the set of all points that are an equal distance (called the radius) from a given point (called the center). If all three vertices of a triangle lie on the circumference of a circle, we say the circle **circumscribes** the triangle. Based on our earlier work, it appears we could also state the theorem in Example 1 as: *For any circle in the xy-plane whose center (h, k) is the midpoint of the hypotenuse L of a right triangle, the circle defined by* $(x - h)^2 + (y - k)^2 = (\frac{L}{2})^2$ *circumscribes the triangle.* The circle and triangle from Example 1 illustrate this theorem in Figure 10.1, where the equation of the circle is $(x - 0)^2 + (y - 1)^2 = (\frac{10}{2})^2$. **See Exercises 13 through 20.**

Figure 10.1

☑ **A.** You've just seen how we can verify theorems from basic geometry involving the distance between two points

Figure 10.2

B. The Distance Between a Point and a Line

In a study of analytical geometry, we are also interested in the distance d between a point and a *line*. This is always defined as the **perpendicular distance,** or the length of a line segment perpendicular to the given line, with the given point and the point of intersection as endpoints (see Figure 10.2).

EXAMPLE 2 ▶ **Locating Points That Are an Equal Distance from a Given Point and Line**

In Figure 10.3, the origin (0, 0) is seen to be an equal distance from the point (0, 2) and the line $y = -2$. Show that the following points are also an equal distance from (0, 2) and $y = -2$:

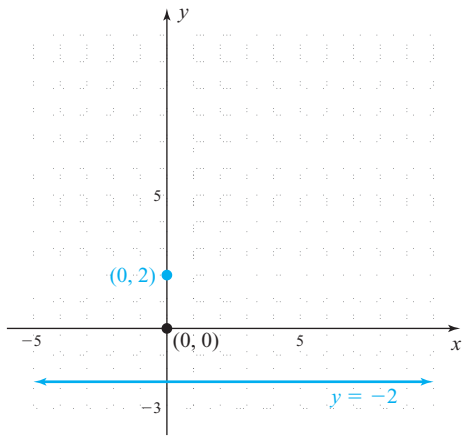
a. $(2, \frac{1}{2})$ **b.** (4, 2) **c.** (8, 8)

Solution ▶ Since the given line is horizontal, the perpendicular distance from the line to each point can be found by vertically counting the units. It remains to show that this is also the distance from the given point to (0, 2) (see Figure 10.4).

a. The distance from $(2, \frac{1}{2})$ to $y = -2$ is **2.5 units**. The distance from $(2, \frac{1}{2})$ to (0, 2) is

$$\begin{aligned} d &= \sqrt{(0 - 2)^2 + (2 - 0.5)^2} \\ &= \sqrt{(-2)^2 + (1.5)^2} \\ &= \sqrt{6.25} \\ &= 2.5 \checkmark \end{aligned}$$

Figure 10.3



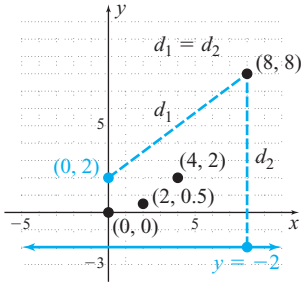


Figure 10.4

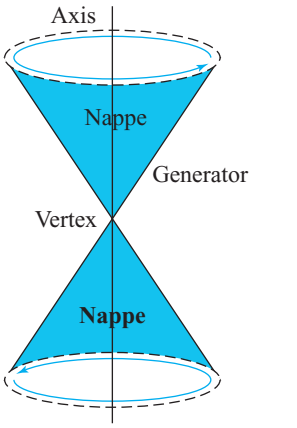
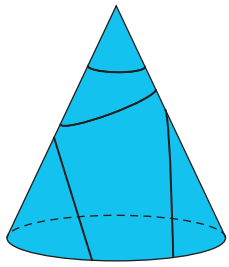
b. The distance from (4, 2) to $y = -2$ is **4 units**. The distance from (4, 2) to (0, 2) is

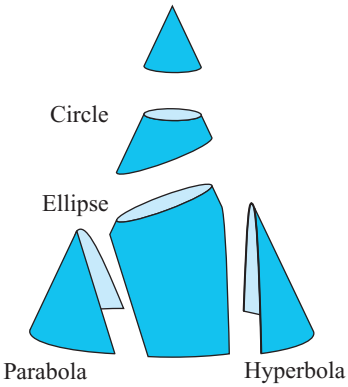
$$\begin{aligned} d &= \sqrt{(0 - 4)^2 + (2 - 2)^2} \\ &= \sqrt{(-4)^2 + (0)^2} \\ &= \sqrt{16} \\ &= 4 \checkmark \end{aligned}$$



c. The distance d_2 from (8, 8) to $y = -2$ is **10 units**. The distance d_1 from (8, 8) to (0, 2) is



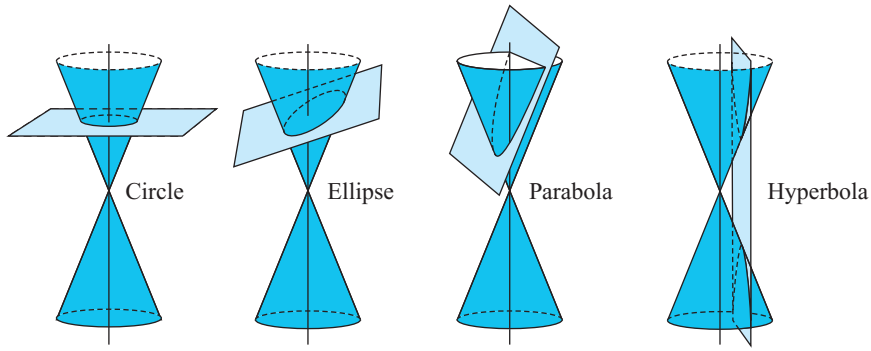
$$\begin{aligned} d_1 &= \sqrt{(0 - 8)^2 + (2 - 8)^2} \\ &= \sqrt{(-8)^2 + (-6)^2} \\ &= \sqrt{100} \\ &= 10 \checkmark \end{aligned}$$



☑ **B.** You've just seen how we can verify that points (*x*, *y*) are an equal distance from a given point and a given line

Now try Exercises 23 through 26 ▶

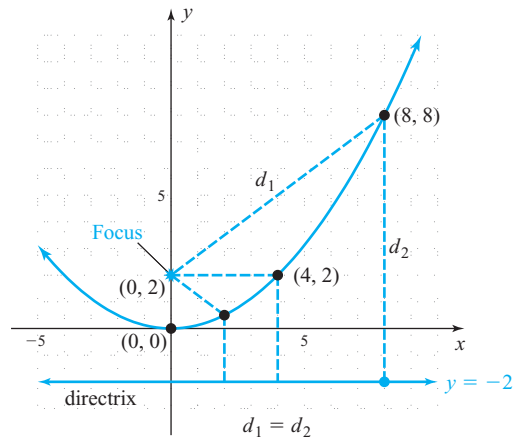
Figure 10.5



C. Characteristics of the Conic Sections

Examples 1 and 2 bring us one step closer to the wider application of these ideas in a study of the conic sections. But before the connection is clearly made, we'll introduce some background on this family of curves. In common use, a cone might bring to mind the conical paper cups found at a water cooler. The point of the cone is called the **vertex** and the sheet of paper forming the sides is called a **nappe.** In mathematical terms, a cone has two nappes, formed by rotating a nonvertical line (called the generator), about a vertical line (called the axis), at their point of intersection—the vertex (see Figure 10.5). The conic sections are so named because all curves in the family can be formed by a *section* of the *cone,* or more precisely the intersection of a plane and a cone. Figure 10.6 shows that if the plane does not go through the vertex, the intersection will produce a circle, ellipse, parabola, or hyperbola.

Figure 10.6



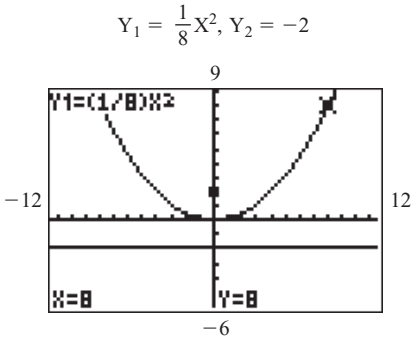
If the plane *does* go through the vertex, the result is a single point, a single line (if the plane contains the generator), or a pair of intersecting lines (if the plane contains the axis).

The connection we seek to make is that each conic section can be defined in terms of the distance between points in the plane, as in Example 1, or the distance between a given point and a line, as in Example 2. In Example 1, we noted the points $(-4, -2)$, $(4, -2)$, and $(4, 4)$ were all on a circle of radius 5 with center $(0, 1)$, in line with the analytic definition of a circle: *A circle is the set of all points that are an equal distance (called the radius) from a given point (called the center).*

In Example 2, you may have noticed that the points seemed to form the right branch of a parabola (see Figure 10.7), and in fact, this example illustrates the analytic definition of a parabola: *A parabola is the set of all points that are an equal distance from a given point (called the **focus**), and a given line (called the **directrix**).*

The focus and directrix are not actually part of the graph, they are simply used to locate points on the graph. For this reason all foci (plural of focus) will be represented by a "✷" symbol rather than a point.

Figure 10.7



EXAMPLE 3 ▶ **Finding an Equation for All Points That Form a Certain Parabola**

With Example 2 as a pattern, use the analytic definition to find a formula (equation) for the set of all points that form the parabola.

Solution ▶ Use the ordered pair (x, y) to represent an arbitrary point on the parabola. Since any point on the line $y = -2$ has coordinates $(x, -2)$, we set the distance from $(x, -2)$ to (x, y) equal to the distance from $(0, 2)$ to (x, y). The result is

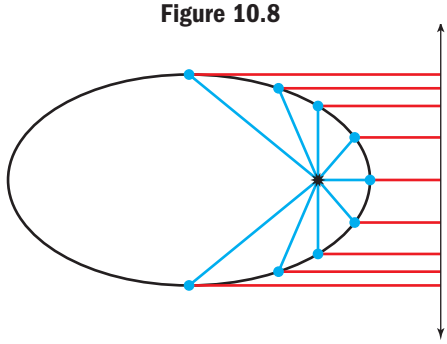
$$\sqrt{(x - x)^2 + [y - (-2)]^2} = \sqrt{(x - 0)^2 + (y - 2)^2} \quad \text{distances are equal}$$
$$\sqrt{(y + 2)^2} = \sqrt{x^2 + (y - 2)^2} \quad \text{simplify}$$
$$(y + 2)^2 = x^2 + (y - 2)^2 \quad \text{power property}$$
$$y^2 + 4y + 4 = x^2 + y^2 - 4y + 4 \quad \text{expand binomials}$$
$$8y = x^2 \quad \text{simplify}$$
$$y = \frac{1}{8}x^2 \quad \text{result}$$

All points satisfying these conditions are on the parabola defined by $y = \frac{1}{8}x^2$. See the figure.

Now try Exercises 27 and 28 ▶

At this point, it seems reasonable to ask what happens when the distance from the focus to (x, y) is *less than* the distance from the directrix to (x, y). For example, what if the distance is only two-thirds as long? As you might guess, the result is one of the other conic sections, in this case an ellipse. If the distance from the focus to a point (x, y) is *greater than* the distance from the directrix to (x, y), one branch of a hyperbola is formed. While we will defer a development of their general equations until later in the chapter, the following diagrams serve to illustrate this relationship for the ellipse, and show why we refer to the conic sections as a *family of curves*. In Figure 10.8, the line segment from the focus to each point on the graph (shown in blue), is exactly two-thirds the length of the line segment from the directrix to the same point (shown in red). Note the graph of these points forms the right half of an ellipse. In Figure 10.9, the lines and points forming the first half are removed to more clearly show the remaining points that form the complete graph.

Figure 10.8



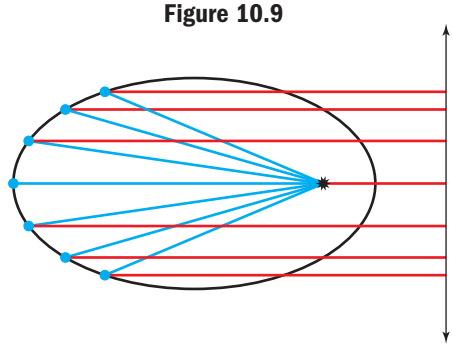


Figure 10.9

EXAMPLE 4 ▶ **Finding an Equation for All Points That Form a Certain Ellipse**

Suppose we arbitrarily select the point $(1, 0)$ as a focus and the (vertical) line $x = 4$ as the directrix. Use these to find an equation for the set of all points where the distance from the focus to a point (x, y) is $\frac{1}{2}$ the distance from the directrix to (x, y).

Solution ▶ Since any point on the line $x = 4$ has coordinates $(4, y)$, we have:

$$\text{Distance from } (1, 0) \text{ to } (x, y) = \frac{1}{2}[\text{distance from } (4, y) \text{ to } (x, y)] \quad \text{in words}$$

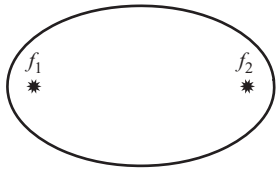
$$\sqrt{(x-1)^2 + [y-(0)]^2} = \frac{1}{2}\sqrt{(x-4)^2 + (y-y)^2} \quad \text{resulting equation}$$

$$\sqrt{(x-1)^2 + y^2} = \frac{1}{2}\sqrt{(x-4)^2} \quad \text{simplify}$$

$$(x-1)^2 + y^2 = \frac{1}{4}(x-4)^2 \quad \text{power property}$$

$$x^2 - 2x + 1 + y^2 = \frac{1}{4}(x^2 - 8x + 16) \quad \text{expand binomials}$$

$$x^2 - 2x + 1 + y^2 = \frac{1}{4}x^2 - 2x + 4 \quad \text{distribute}$$



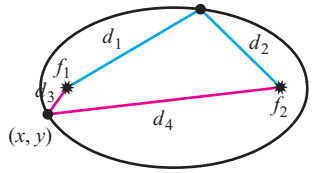
$$\frac{3}{4}x^2 + y^2 = 3 \quad \text{simplify: } 1x^2 - \frac{1}{4}x^2 = \frac{3}{4}x^2$$

$$3x^2 + 4y^2 = 12 \quad \text{polynomial form}$$

All points satisfying these conditions are on the ellipse defined by $3x^2 + 4y^2 = 12$.

Now try Exercises 29 and 30 ▶

Figure 10.10



Actually, any given ellipse has two foci (see Figure 10.10) and the equation from Example 4 could also have been developed using the left focus (with the directrix also on the left). This symmetrical relationship leads us to an *alternative definition* for the ellipse, which we will explore further in Section 10.2:

For foci f_1 and f_2, an ellipse is the set of all points (x, y) where the sum of the distances from f_1 to (x, y) and f_2 to (x, y) is constant.

See Figure 10.11 and **Exercises 31 and 32.** Both the focus/directrix definition and the two foci definition have merit, and simply tend to call out different characteristics and applications of the ellipse. The hyperbola also has a focus/directrix definition and a two foci definition. **See Exercises 33 and 34.**

Figure 10.11

$d_1 + d_2 = d_3 + d_4$

☑ **C.** You've just seen how we can use the defining characteristics of a conic section to find its equation

10.1 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. Analytical geometry is a study of _____ using the tools of _____.
2. The distance formula is $d =$ _____; the midpoint formula is $M =$ _____.
3. The distance between a point and a line always refers to the _____ distance.
4. The conic sections are formed by the intersection of a _____ and a _____.
5. If a plane intersects a cone at its vertex, the result is a _____, a line, or a pair of _____ lines.
6. A circle is defined relative to an equal distance between two _____. A parabola is defined relative to an equal distance between a _____ and a _____.

▶ DEVELOPING YOUR SKILLS

The three points given form a right triangle. Find the midpoint of the hypotenuse and verify that the midpoint is an equal distance from all three vertices.

7. $P_1 = (-5, 2)$, $P_2 = (1, 2)$, $P_3 = (-5, -6)$

8. $P_1 = (3, 2)$, $P_2 = (3, 14)$, $P_3 = (8, 2)$

9. $P_1 = (-2, 1)$, $P_2 = (6, -5)$, $P_3 = (2, -7)$

10. $P_1 = (0, -5)$, $P_2 = (-6, 4)$, $P_3 = (6, -1)$

11. $P_1 = (10, -21)$, $P_2 = (-6, -9)$, $P_3 = (3, 3)$

12. $P_1 = (6, -6)$, $P_2 = (-12, 18)$, $P_3 = (20, 42)$

13. Find an equation of the circle that circumscribes the triangle in Exercise 7.

14. Find an equation of the circle that circumscribes the triangle in Exercise 8.

15. Find an equation of the circle that circumscribes the triangle in Exercise 9.

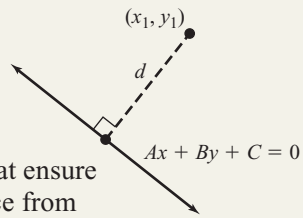
16. Find an equation of the circle that circumscribes the triangle in Exercise 10.

17. Find an equation of the circle that circumscribes the triangle in Exercise 11.

18. Find an equation of the circle that circumscribes the triangle in Exercise 12.

19. Of the following six points, identify which four are an equal distance from the point $A(2, 3)$.

$B(7, 15)$ $C(-10, 8)$ $D(9, 14)$ $E(-3, -9)$ $F(5, 4 + 3\sqrt{10})$ $G(2 - 2\sqrt{30}, 10)$



20. Of the following six points, identify which four are an equal distance from the point $P(-1, 4)$.

$Q(-9, 10)$ $R(5, 12)$ $S(-7, 11)$ $T(4, 4 + 5\sqrt{3})$ $U(-1 + 4\sqrt{6}, 6)$ $V(-7, 4 + \sqrt{51})$

▶ WORKING WITH FORMULAS

The Perpendicular Distance from a Point to a Line: $d = \dfrac{|Ax_1 + By_1 + C|}{\sqrt{A^2 + B^2}}$. The perpendicular distance from a point (x_1, y_1) to a given line can be found using the formula shown, where $Ax + By + C = 0$ is the equation of the line in standard form (A, B, and C are integers).

Exercise 21

21. Use the formula to verify that $P(-6, 2)$ and $Q(6, 4)$ are an equal distance from the line $y = -\frac{1}{2}x + 3$.

22. Find the value(s) for y that ensure $(1, y)$ is this same distance from $y = -\frac{1}{2}x + 3$.

▶ APPLICATIONS

23. Of the following four points, identify which three are an equal distance from the point $A(0, 1)$ and the line $y = -1$.

$B(-6, 9)$ $C(4, 4)$ $D(-2\sqrt{2}, 6)$ $E(4\sqrt{2}, 8)$

24. Of the following four points, identify which three are an equal distance from the point $P(2, 4)$ and the line $y = -4$.

$Q(-10, 9)$ $R(2 + 4\sqrt{2}, 3)$ $S(10, 4)$ $T(2 - 4\sqrt{5}, 5)$

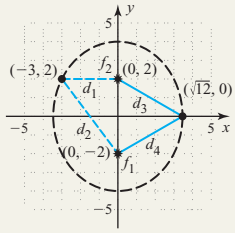
25. Consider the fixed *point* $(0, -4)$ and the fixed *line* $y = 4$. Verify that the distance from each point given to $(0, -4)$, is equal to the distance from the point to the line $y = 4$.

$A(4, -1)$ $B\left(10, -\frac{25}{4}\right)$ $C(4\sqrt{2}, -2)$ $D(8\sqrt{5}, -20)$

26. Consider the fixed *point* $(0, -2)$ and the fixed *line* $y = 2$. Verify that the distance from each point given to $(0, -2)$, is equal to the distance from the point to the line $y = 2$.

$P(12, -18)$ $Q\left(6, -\frac{9}{2}\right)$ $R(4\sqrt{5}, -10)$ $S(4\sqrt{6}, -12)$

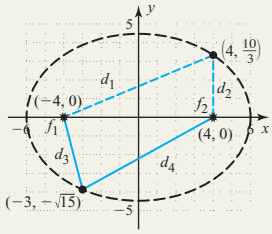
27. The points from Exercise 25 are on the graph of a parabola. Find an equation of the parabola.



28. The points from Exercise 26 are on the graph of a parabola. Find an equation of the parabola.

29. Using $(0, -2)$ as the focus and the horizontal line $y = -8$ as the directrix, find an equation for the set of all points (x, y) where the distance from the focus to (x, y) is one-half the distance from the directrix to (x, y).

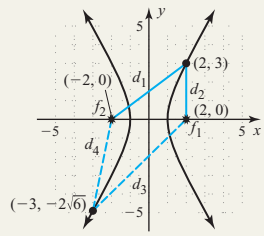
30. Using (4, 0) as the focus and the vertical line $x = 9$ as the directrix, find an equation for the set of all points (x, y) where the distance from the focus to (x, y) is two-thirds the distance from the directrix to (x, y).



31. From Exercise 29, verify the points $(-3, 2)$ and $(\sqrt{12}, 0)$ are on the ellipse defined by $4x^2 + 3y^2 = 48$. Then verify that $d_1 + d_2 = d_3 + d_4$.

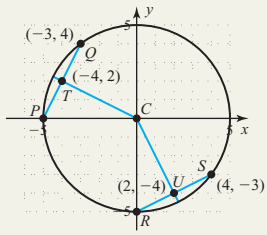
Exercise 31

32. From Exercise 30, verify the points $(4, \frac{10}{3})$ and $(-3, -\sqrt{15})$ are on the ellipse defined by $5x^2 + 9y^2 = 180$. Then verify that $d_1 + d_2 = d_3 + d_4$.



Exercise 32

33. From the focus/directrix definition of a hyperbola: *If the distance from the focus to a point (x, y) is* ***greater than*** *the distance from the directrix to (x, y), one branch of a hyperbola is formed.* Using (2, 0) as the focus and the vertical line $x = \frac{1}{2}$ as the directrix, find an equation for the set of all points (x, y) where the distance from the focus to (x, y), is twice the distance from the directrix to (x, y).



34. From the two foci definition of a hyperbola: *For foci f_1 and f_2, a hyperbola is the set of all points (x, y) where the difference of the distances from f_1 to (x, y) and f_2 to (x, y) is constant.* Verify the points (2, 3) and $(-3, -2\sqrt{6})$ are on the graph of the hyperbola from Exercise 33. Then verify $d_1 - d_2 = d_3 - d_4$.

Exercise 34

▶ EXTENDING THE CONCEPT

35. Properties of a circle: A theorem from elementary geometry states: *If a radius is perpendicular to a chord, it bisects the chord.* Verify this is true for the circle, radii, and chords shown.

36. Verify that points $C(-2, 3)$ and $D(2\sqrt{2}, \sqrt{6})$ are points on the ellipse with foci at $A(-2, 0)$ and $B(2, 0)$, by verifying $d(AC) + d(BC) = d(AD) + d(BD)$. The expression that results has the form $\sqrt{U + V} + \sqrt{U - V}$, which prior to the common use of technology, had to be simplified using the formula $\sqrt{U + V} + \sqrt{U - V} = \sqrt{a + \sqrt{b}}$, where $a = 2U$ and $b = 4(U^2 - V^2)$. Use this relationship to simplify the equation above.

▶ MAINTAINING YOUR SKILLS

37. **(7.4)** Verify the following is an identity:

$$\frac{\cos(2x) + \sin^2 x}{1 - \cos^2 x} = \cot^2(x)$$

38. **(7.7)** Find all solutions in $[0, 2\pi)$

$$-225 = 600 + 825 \sin\left(x + \frac{\pi}{6}\right)$$

39. **(5.5)** Solve for x in both exact and approximate form:

a. $5 = \dfrac{10}{1 + 9e^{-0.5x}}$

b. $345 = 5e^{0.4x} + 75$

40. **(4.4)** Sketch a complete graph of $h(x) = \dfrac{x^2 - 9}{x^2 - 4}$. Clearly label all intercepts and asymptotes.

10.2 The Circle and the Ellipse

LEARNING OBJECTIVES

In Section 10.2 you will see how we can:

- ❑ **A.** Use the characteristics of a circle and its graph to understand the equation of an ellipse
- ❑ **B.** Use the equation of an ellipse to graph central and noncentral ellipses
- ❑ **C.** Locate the foci of an ellipse and use the foci and other features to write the equation
- ❑ **D.** Solve applications involving the foci

In Section 10.1, we introduced the equation of an ellipse using analytical geometry and the focus-directrix definition. Here we'll take a different approach, and use the equation of a circle to demonstrate that a circle is simply a special ellipse. In doing so, we'll establish a relationship between the foci and vertices of the ellipse, that enables us to apply these characteristics in context.

A. The Equation and Graph of a Circle

Recall that the equation of a circle with radius r and center at (h, k) is

$$(x - h)^2 + (y - k)^2 = r^2.$$

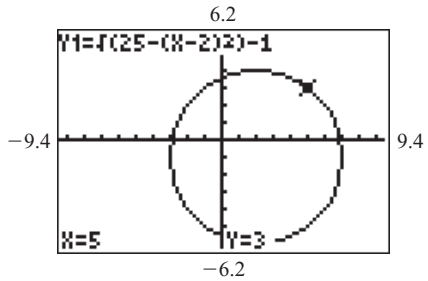
As in Section 1.1, the standard form can be used to construct the equation of the circle given the center and radius as in Example 1, or to graph the circle as in Example 2.

EXAMPLE 1 ▶ **Determining the Equation of a Circle Given Its Center and Radius**

Find an equation of the circle with radius 5 and center at $(2, -1)$, then graph the relation on a calculator.

Solution ▶ With a center of $(2, -1)$, we have $h = 2$, $k = -1$, and $\boldsymbol{r = 5}$. Making the corresponding substitutions into the standard form we obtain

$$\begin{aligned} (x - h)^2 + (y - k)^2 &= \boldsymbol{r}^2 && \text{standard form} \\ (x - 2)^2 + [y - (-1)]^2 &= \boldsymbol{5}^2 && \text{substitute 2 for } h, -1 \text{ for } k, \text{ and 5 for } r \\ (x - 2)^2 + (y + 1)^2 &= 25 && \text{simplify} \end{aligned}$$



The equation of this circle is $(x - 2)^2 + (y + 1)^2 = 25$.

Recall from Section 1.1 that circles (and other relations) can be graphed by solving for y, then graphing the upper and lower halves of the circle.

$$\begin{aligned} (x - 2)^2 + (y + 1)^2 &= 25 && \text{original equation} \\ (y + 1)^2 &= 25 - (x - 2)^2 && \text{isolate term containing } y \\ y + 1 &= \pm\sqrt{25 - (x - 2)^2} && \text{take square roots} \\ y &= \pm\sqrt{25 - (x - 2)^2} - 1 && \text{subtract 1} \end{aligned}$$

$$Y_1 = +\sqrt{25 - (X - 2)^2} - 1,\ Y_2 = -\sqrt{25 - (X - 2)^2} - 1$$

The graph is shown in the figure using a square window. Note the point $(5, 3)$ satisfies the original equation and is a point on the graph and that $(5, -5)$, $(-1, -5)$, and $(-1, 3)$ must also be on the graph due to symmetry.

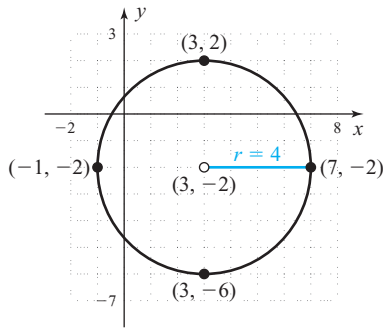
Now try Exercises 7 through 12 ▶

If the equation is given in polynomial form, recall that we first complete the square in x and y to identify the center and radius.

EXAMPLE 2 ▶ **Completing the Square to Graph a Circle**

Find the center and radius of the circle whose equation is given, then sketch its graph: $x^2 + y^2 - 6x + 4y - 3 = 0$.

Solution ▶ Begin by completing the square in both x and y.



$$(x^2 - 6x + __) + (y^2 + 4y + __) = 3 \qquad \text{group } x\text{- and } y\text{-terms; add 3}$$

$$(x^2 - 6x + 9) + (y^2 + 4y + 4) = 3 + 9 + 4 \qquad \text{complete the square}$$

adds 9 to left side; adds 4 to left side; add 9 + 4 to right side

$$(x - 3)^2 + (y + 2)^2 = 16 \qquad \text{factor and simplify}$$

The center is at $(3, -2)$, with radius $r = \sqrt{16} = 4$.

Circle

Center at $(3, -2)$

Radius: $r = 4$

Diameter: $2r = 8$

Endpoints of horizontal diameter
$(-1, -2)$ and $(7, -2)$

Endpoints of vertical diameter
$(3, 2)$ and $(3, -6)$

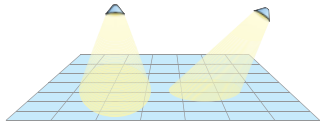
Now try Exercises 13 through 18 ▶

The equation of a circle in **standard form** provides a useful link to some of the other conic sections, and is obtained by *setting the equation equal to 1.* In the case of a circle, this means we simply divide by r^2.

$$(x - h)^2 + (y - k)^2 = r^2 \qquad \text{standard form}$$

$$\frac{(x - h)^2}{r^2} + \frac{(y - k)^2}{r^2} = 1 \qquad \text{divide by } r^2$$

A. You've just seen how we can use the characteristics of a circle and its graph to understand the equation of an ellipse



In this form, the value of r in each denominator gives the *horizontal* and *vertical* distances, respectively, from the center to the graph. This is not so important in the case of a circle, since this distance is the same in *any* direction. But for other conics, these horizontal and vertical distances are *not* the same, making the new form a valuable tool for graphing. To distinguish the horizontal from the vertical distance, r^2 is replaced by a^2 in the "x-term" (horizontal distance), and by b^2 in the "y-term" (vertical distance). This distinction leads us directly into our study of the ellipse.

B. The Equation of an Ellipse

It then seems reasonable to ask, "What happens to the graph when $a \neq b$?" To answer, consider the equation from Example 2. We have $\dfrac{(x - 3)^2}{4^2} + \dfrac{(y + 2)^2}{4^2} = 1$ (after dividing by 16), which we now compare to $\dfrac{(x - 3)^2}{4^2} + \dfrac{(y + 2)^2}{3^2} = 1$, where $a = 4$ and $b = 3$. The center of the graph is still at $(3, -2)$, since $h = 3$ and $k = -2$ remain unchanged. Substituting $y = -2$ to find additional points, eliminates the y-term and gives two values for x:

WORTHY OF NOTE

If you point a flashlight at the floor keeping it perpendicular to the ground, a circle is formed with the bulb pointing directly at the center and every point along the outer edge of the beam an equal distance from this center. If you hold the flashlight at an angle, the circle is elongated and becomes an ellipse, with the bulb pointing directly at one focus.

$$\frac{(x-3)^2}{4^2}+\frac{(-2+2)^2}{3^2}=1 \qquad \text{substitute } -2 \text{ for } y$$

$$\frac{(x-3)^2}{4^2}+0=1 \qquad \text{simplify}$$

$$(x-3)^2=16 \qquad \text{multiply by } 4^2=16$$

$$x-3=\pm 4 \qquad \text{property of square roots}$$

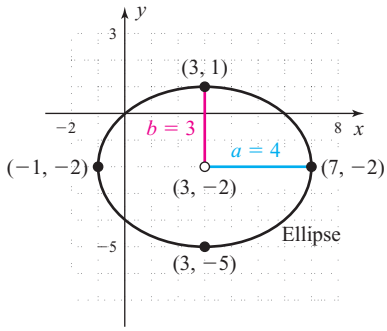
$$x=3\pm 4 \qquad \text{add 3}$$

$$x=7 \text{ and } x=-1$$

This shows the horizontal distance from the center to the graph is still $a=4$, and the points $(-1,-2)$ and $(7,-2)$ are on the graph (see Figure 10.12). Similarly, for $x=3$ we have $(y+2)^2=9$, giving $y=-5$ and $y=1$, and showing the vertical distance from the center to the graph is now $b=3$, with points $(3,1)$ and $(3,-5)$ on the graph. Using this information to sketch the curve reveals the "circle" is elongated and has become a **horizontal ellipse.**

For this ellipse, the line segment through the center, parallel to the x-axis, and with endpoints on the ellipse is called the **major axis,** with the endpoints of the major axis called **vertices.** The segment perpendicular to and bisecting the major axis (with its endpoints on the ellipse) is called the **minor axis,** as shown in Figure 10.13.

Figure 10.12



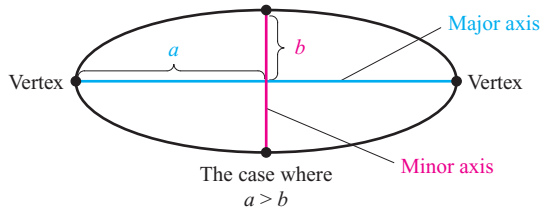


Figure 10.13

- If $a^2>b^2$, the major axis is horizontal (parallel to the x-axis) with length $2a$, and the minor axis is vertical with length $2b$ (see Example 3).
- If $a^2<b^2$ the major axis is vertical (parallel to the y-axis) with length $2b$, and the minor axis is horizontal with length $2a$ (see Example 4).

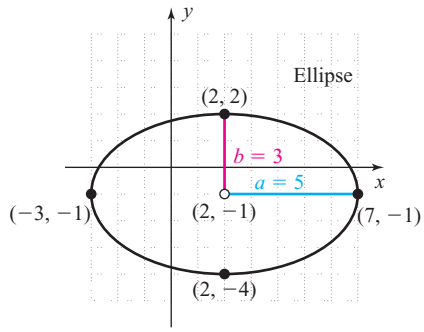
Generalizing this observation we obtain the equation of an ellipse in standard form.

The Equation of an Ellipse in Standard Form

Given $\dfrac{(x-h)^2}{a^2}+\dfrac{(y-k)^2}{b^2}=1.$

If $a\neq b$ the equation represents the graph of an ellipse with center at (h,k).

- $|a|$ gives the horizontal distance from center to graph.
- $|b|$ gives the vertical distance from center to graph.



Finally, note the line segment from center to vertex is called the **semimajor axis,** with the perpendicular line segment from center to graph called the **semiminor axis.**

EXAMPLE 3 ▶ Graphing a Horizontal Ellipse

Sketch the graph of the ellipse defined by

$$\frac{(x-2)^2}{25}+\frac{(y+1)^2}{9}=1.$$

Solution ▶ Noting $a \neq b$, we have an ellipse with center $(h, k) = (2, -1)$. The horizontal distance from the center to the graph is $a = 5$, and the vertical distance from the center to the graph is $b = 3$. After plotting the corresponding points and connecting them with a smooth curve, we obtain the graph shown.

Now try Exercises 19 through 24 ▶

WORTHY OF NOTE
In general, for the equation $Ax^2 + By^2 = F$ ($A, B, F > 0$), the equation represents a circle if $A = B$, and an ellipse if $A \neq B$.

As with the circle, the equation of an ellipse can be given in polynomial form, and here our knowledge of circles is helpful. For the equation $25x^2 + 4y^2 = 100$, we know the graph cannot be a circle since the coefficients are unequal, and the center of the graph must be at the origin since $h = k = 0$. To actually draw the graph, we convert the equation to standard form. Note that a circle whose center is at (0, 0) is called a **central circle,** and an ellipse with center at (0, 0) is called a **central ellipse.**

EXAMPLE 4 ▶ **Graphing a Vertical Ellipse**

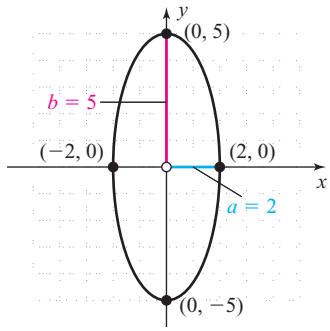
For $25x^2 + 4y^2 = 100$,

a. Write the equation in standard form and identify the center and the values of a and b.

b. Identify the major and minor axes and name the vertices.

c. Sketch the graph.

d. Graph the relation on a graphing calculator using a "friendly" window, then use the TRACE feature to find four additional points on the graph whose coordinates are rational.



Solution ▶ The coefficients of x^2 and y^2 are unequal, and 25, 4, and 100 have like signs. The equation represents an ellipse with center at (0, 0). To obtain standard form:

a.
$$25x^2 + 4y^2 = 100 \quad \text{given equation}$$
$$\frac{25x^2}{100} + \frac{4y^2}{100} = 1 \quad \text{divide by 100}$$
$$\frac{x^2}{4} + \frac{y^2}{25} = 1 \quad \text{standard form}$$
$$\frac{x^2}{2^2} + \frac{y^2}{5^2} = 1 \quad \text{write denominators in squared form; } a = 2,\ b = 5$$

b. The result shows $a = 2$ and $b = 5$, indicating the major axis will be vertical and the minor axis will be horizontal. With the center at the origin, the x-intercepts will be $(-2, 0)$ and $(2, 0)$, with the vertices (and y-intercepts) at $(0, -5)$ and $(0, 5)$.

c. Plotting these intercepts and sketching the ellipse results in the graph shown in Figure 10.14.

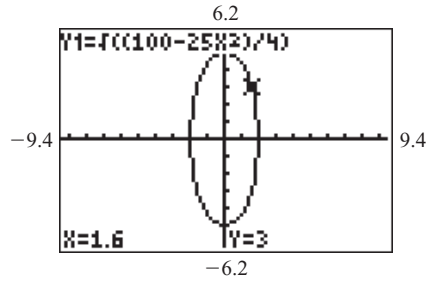
Figure 10.14

Vertical ellipse

Center at (0, 0)

Endpoints of major axis (vertices)
(0, −5) and (0, 5)

Endpoints of minor axis
(−2, 0) and (2, 0)



Length of major axis $2b$: $2(5) = 10$
Length of minor axis $2a$: $2(2) = 4$

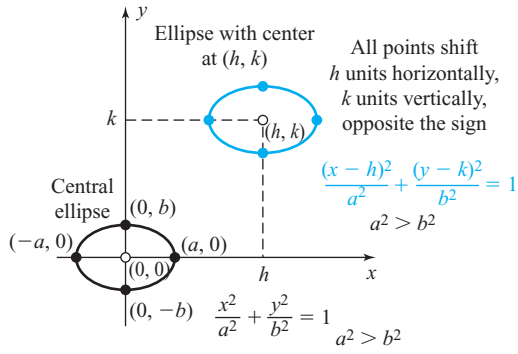
d. As with the circle, we begin by solving for y.

$$25x^2 + 4y^2 = 100 \quad \text{original equation}$$
$$4y^2 = 100 - 25x^2 \quad \text{isolate term containing } y$$
$$y^2 = \frac{100 - 25x^2}{4} \quad \text{divide by 4}$$
$$y = \pm\sqrt{\frac{100 - 25x^2}{4}} \quad \text{take square roots}$$

$$Y_1 = +\sqrt{\frac{100 - 25X^2}{4}},\ Y_2 = -\sqrt{\frac{100 - 25X^2}{4}}$$

Figure 10.15

The graph is shown in Figure 10.15, where we note that (1.6, 3) is a point on the graph. Due to the symmetry of the ellipse, $(-1.6, 3)$, $(-1.6, -3)$, and $(1.6, -3)$ are also on the graph.



Now try Exercises 25 through 36 ▶

WORTHY OF NOTE

After writing the equation in standard form, it is possible to end up with a constant that is zero or negative. In the first case, the graph is a single point. In the second case, no graph is possible since roots of the equation will be complex numbers. These are called *degenerate cases*. **See Exercise 84.**

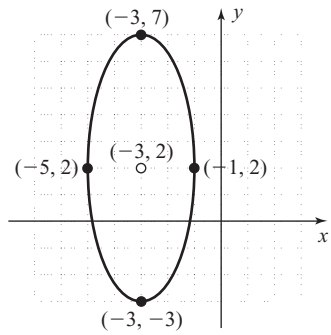
If the center of the ellipse is not at the origin, the polynomial form has additional linear terms and we must first complete the square in x and y, then write the equation in standard form to sketch the graph (see the *Reinforcing Basic Concepts* feature for more on completing the square). Figure 10.16 illustrates how the central ellipse and the shifted ellipse are related.

Figure 10.16

EXAMPLE 5 ▶ Completing the Square to Graph an Ellipse

Sketch the graph of $25x^2 + 4y^2 + 150x - 16y + 141 = 0$, then state the domain and range of the relation.

Solution ▶ The coefficients of x^2 and y^2 are unequal and have like signs, and we assume the equation represents an ellipse but wait until we have the factored form to be certain (it could be a degenerate ellipse).



$$25x^2 + 4y^2 + 150x - 16y + 141 = 0 \quad \text{given equation (polynomial form)}$$
$$25x^2 + 150x + 4y^2 - 16y = -141 \quad \text{group like terms; subtract 141}$$
$$25(x^2 + 6x + __) + 4(y^2 - 4y + __) = -141 \quad \text{factor out leading coefficient from each group}$$
$$25(x^2 + 6x + 9) + 4(y^2 - 4y + 4) = -141 + 225 + 16 \quad \text{complete the square}$$

adds $25(9) = 225$; adds $4(4) = 16$; add $225 + 16$ to right

$$25(x+3)^2 + 4(y-2)^2 = 100 \quad \text{factor}$$
$$\frac{25(x+3)^2}{100} + \frac{4(y-2)^2}{100} = \frac{100}{100} \quad \text{divide both sides by 100}$$
$$\frac{(x+3)^2}{4} + \frac{(y-2)^2}{25} = 1 \quad \text{simplify (standard form)}$$
$$\frac{(x+3)^2}{2^2} + \frac{(y-2)^2}{5^2} = 1 \quad \text{write denominators in squared form}$$

The result is a vertical ellipse with center at $(-3, 2)$, with $a = 2$ and $b = 5$. The vertices are a vertical distance of 5 units from center, and the endpoints of the minor axis are a horizontal distance of 2 units from center. Note this is the same ellipse as in Example 4, but shifted 3 units left and 2 up.

The domain of this relation is $x \in [-5, -1]$, and the range is $y \in [-3, 7]$.

Vertical ellipse

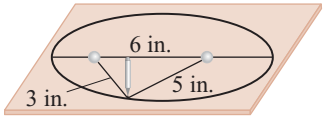
Center at $(-3, 2)$

Endpoints of major axis (vertices)
$(-3, -3)$ and $(-3, 7)$

Endpoints of minor axis
$(-5, 2)$ and $(-1, 2)$

Length of major axis $2b$: $2(5) = 10$
Length of minor axis $2a$: $2(2) = 4$

Now try Exercises 37 through 44 ▶



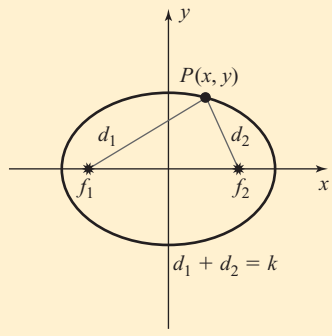
B. You've just seen how we can use the equation of an ellipse to graph central and noncentral ellipses

C. The Foci of an Ellipse

In Section 10.1, we noted that an ellipse could also be defined in terms of two special points called the **foci.** The Museum of Science and Industry in Chicago, Illinois (http://www.msichicago.org), has a permanent exhibit called the *Whispering Gallery.* The construction of the room is based on some of the reflective properties of an ellipse. If two people stand at designated points in the room and one of them whispers very softly, the other person can hear the whisper quite clearly—even though they are over 40 ft apart! The point where each person stands is a **focus** of an ellipse. This reflective property also applies to light and radiation, giving the ellipse some powerful applications in science, medicine, acoustics, and other areas. To understand and appreciate these applications, we introduce the analytic definition of an ellipse.

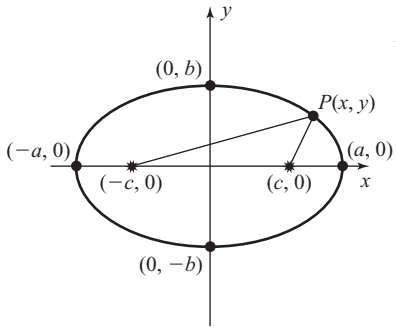
WORTHY OF NOTE

You can easily draw an ellipse that satisfies the definition. Press two pushpins (these form the foci of the ellipse) halfway down into a piece of heavy cardboard about 6 in. apart. Take an 8-in. piece of string and loop each end around the pins. Use a pencil to draw the string taut and keep it taut as you move the pencil in a circular motion—and the result is an ellipse! A different length of string or a different distance between the foci will produce a different ellipse.



Definition of an Ellipse

Given two fixed points f_1 and f_2 in a plane, an ellipse is the set of all points (x, y) where the distance from f_1 to (x, y) added to the distance from f_2 to (x, y) remains constant.



$$d_1 + d_2 = k$$

The fixed points f_1 and f_2 are called the *foci* of the ellipse, and the points $P(x, y)$ are on the graph of the ellipse.

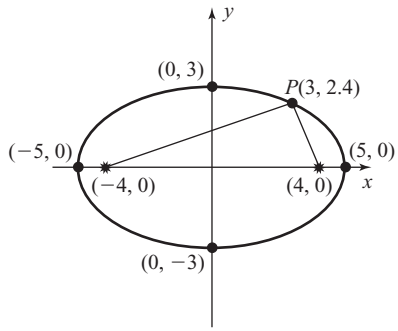
To find the equation of an ellipse in terms of a and b we combine the definition just given with the distance formula. Consider the ellipse shown in Figure 10.17 (for

Figure 10.17

calculating ease we use a central ellipse). Note the vertices have coordinates $(-a, 0)$ and $(a, 0)$, and the endpoints of the minor axis have coordinates $(0, -b)$ and $(0, b)$ as before. It is customary to assign foci the coordinates $f_1 \rightarrow (-c, 0)$ and $f_2 \rightarrow (c, 0)$. We can calculate the distance between $(c, 0)$ and any point $P(x, y)$ on the ellipse using the distance formula:

$$\sqrt{(x - c)^2 + (y - 0)^2}$$

Likewise the distance between $(-c, 0)$ and any point (x, y) is



$$\sqrt{(x + c)^2 + (y - 0)^2}$$

According to the definition, the sum must be constant:

$$\sqrt{(x - c)^2 + y^2} + \sqrt{(x + c)^2 + y^2} = k$$

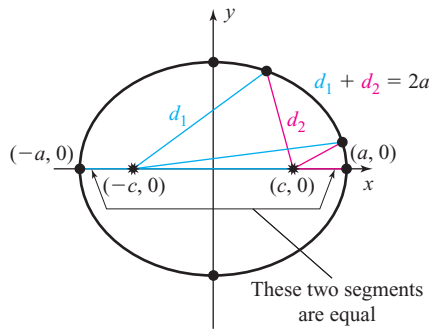
EXAMPLE 6 ▶ Finding the Value of *k* from the Definition of an Ellipse

Use the definition of an ellipse and the diagram given to determine the constant k used for this ellipse (also see the following *Worthy of Note*). Note that $a = 5$, $b = 3$, and $c = 4$.

Solution ▶

$$\sqrt{(x - c)^2 + (y - 0)^2} + \sqrt{(x + c)^2 + (y - 0)^2} = k \quad \text{given}$$
$$\sqrt{(3 - 4)^2 + (2.4 - 0)^2} + \sqrt{(3 + 4)^2 + (2.4 - 0)^2} = k \quad \text{substitute}$$
$$\sqrt{(-1)^2 + 2.4^2} + \sqrt{7^2 + 2.4^2} = k \quad \text{add}$$
$$\sqrt{6.76} + \sqrt{54.76} = k \quad \text{simplify radicals}$$
$$2.6 + 7.4 = k \quad \text{compute square roots}$$
$$10 = k \quad \text{result}$$

The constant value for this ellipse is 10 units.



Now try Exercises 45 through 48 ▶

WORTHY OF NOTE

Note that if the foci are coincident (both at the origin) the "ellipse" will actually be a circle with radius $\frac{k}{2}$; $\sqrt{x^2 + y^2} + \sqrt{x^2 + y^2} = k$ leads to $x^2 + y^2 = \frac{k^2}{4}$. In Example 6 we found $k = 10$, giving $\frac{10}{2} = 5$, and if we used the "string" to draw the circle, the pencil would be 5 units from the center, creating a circle of radius 5.

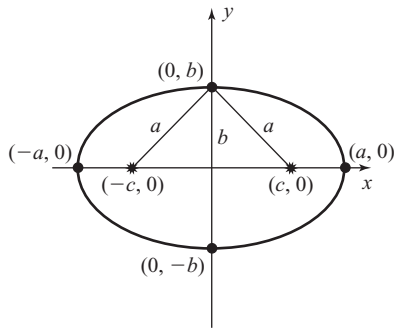
In Example 6, the sum of the distances could also be found by moving the point (x, y) to the location of a vertex $(a, 0)$, then using the symmetry of the ellipse. The sum is identical to the length of the major axis, since the overlapping part of the string from $(c, 0)$ to $(a, 0)$ is the same length as from $(-a, 0)$ to $(-c, 0)$ (see Figure 10.18). This shows the constant k is equal to $2a$ *regardless of the distance between foci.*

Figure 10.18

As we noted, the result is

$$\sqrt{(x - c)^2 + y^2} + \sqrt{(x + c)^2 + y^2} = 2a \quad \text{substitute } 2a \text{ for } k$$

The details for simplifying this expression are given in Appendix E, and the result is very close to the standard form seen previously:



$$\frac{x^2}{a^2} + \frac{y^2}{a^2 - c^2} = 1$$

By comparing the standard form $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ with $\frac{x^2}{a^2} + \frac{y^2}{a^2 - c^2} = 1$, we might suspect that $b^2 = a^2 - c^2$, and this is indeed the case. Note from Example 6 the relationship yields

$$\begin{aligned} b^2 &= a^2 - c^2 \\ 3^2 &= 5^2 - 4^2 \\ 9 &= 25 - 16 \end{aligned}$$

Additionally, when we consider that $(0, b)$ is a point on the ellipse, the distance from $(0, b)$ to $(c, 0)$ must be equal to a due to symmetry (the "constant distance" used to form the ellipse is always $2a$). We then see in Figure 10.19, that $b^2 + c^2 = a^2$ (Pythagorean Theorem), yielding $b^2 = a^2 - c^2$ as above.

Figure 10.19

With this development, we now have the ability to *locate the foci of any ellipse*—an important step toward using the ellipse in practical applications. Because we're often asked to find the location of the foci, it's best to rewrite the relationship in terms of c^2, using absolute value bars to allow for a major axis that is vertical: $c^2 = |a^2 - b^2|$.

EXAMPLE 7 ▶ Completing the Square to Graph an Ellipse and Locate the Foci

For the ellipse defined by $25x^2 + 9y^2 - 100x - 54y - 44 = 0$, find the coordinates of the center, vertices, foci, and endpoints of the minor axis. Then sketch the graph.

Solution ▶

$$25x^2 + 9y^2 - 100x - 54y - 44 = 0 \qquad \text{given}$$

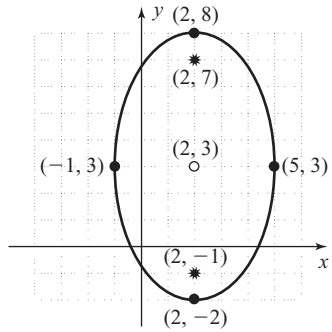
$$25x^2 - 100x + 9y^2 - 54y = 44 \qquad \text{group terms; add 44}$$

$$25(x^2 - 4x + __) + 9(y^2 - 6y + __) = 44 \qquad \text{factor out lead coefficients}$$

$$25(x^2 - 4x + 4) + 9(y^2 - 6y + 9) = 44 + 100 + 81$$

adds $25(4) = 100$; adds $9(9) = 81$; add $100 + 81$ to right-hand side

$$25(x - 2)^2 + 9(y - 3)^2 = 225 \qquad \text{factored form}$$



$$\frac{25(x - 2)^2}{225} + \frac{9(y - 3)^2}{225} = \frac{225}{225} \qquad \text{divide by 225}$$

$$\frac{(x - 2)^2}{9} + \frac{(y - 3)^2}{25} = 1 \qquad \text{simplify (standard form)}$$

$$\frac{(x - 2)^2}{3^2} + \frac{(y - 3)^2}{5^2} = 1 \qquad \text{write denominators in squared form}$$

The result shows a vertical ellipse with $a = 3$ and $b = 5$. The center of the ellipse is at $(2, 3)$. The vertices are a vertical distance of $b = 5$ units from center at $(2, 8)$ and $(2, -2)$. The endpoints of the minor axis are a horizontal distance of $a = 3$ units from center at $(-1, 3)$ and $(5, 3)$. To locate the foci, we use the foci formula

for an ellipse: $c^2 = |a^2 - b^2|$, giving $c^2 = |3^2 - 5^2| = 16$. This shows the foci "✷" are located a vertical distance of 4 units from center at (2, 7) and (2, −1).

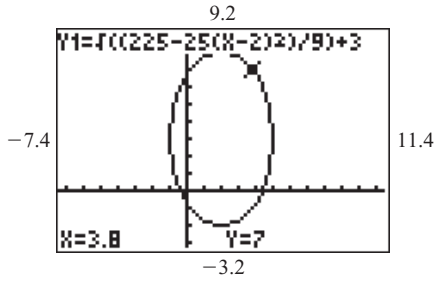
Vertical ellipse

Center at (2, 3)

Endpoints of major axis (vertices)
(2, 8) and (2, −2)

Endpoints of minor axis
(−1, 3) and (5, 3)

Location of foci
(2, 7) and (2, −1)



Length of major axis: $2b = 2(5) = 10$

Length of minor axis: $2a = 2(3) = 6$

Now try Exercises 49 through 54 ▶

For an ellipse, a **focal chord** is a line segment perpendicular to the major axis, through a focus and with endpoints on the ellipse. In the Exercise Set, you are asked to verify that the focal chord of an ellipse has length $L = \dfrac{2m^2}{n}$, where m is the length of the semiminor axis and n is the length of the semimajor axis. This means the distance from the foci to the graph (along a focal chord) is $\dfrac{m^2}{n}$, a fact that can often be used to help graph an ellipse. For Example 7, $m = 3$ and $n = 5$, so the horizontal distance from focus to graph (in either direction) is $\dfrac{3^2}{5} = \dfrac{9}{5}$. From the upper focus (2, 7), we can now graph the additional points $(2 - 1.8, 7) = (0.2, 7)$ and $(2 + 1.8, 7) = (3.8, 7)$, and from the lower focus $(2, -1)$ we obtain $(0.2, -1)$ and $(3.8, -1)$ without having to evaluate the original equation. Graphical verification is provided in Figure 10.20. Also **see Exercises 83 and 85.**

Figure 10.20

For future reference, remember the foci of an ellipse always occur on the major axis, with $a > c$ and $a^2 > c^2$ for a horizontal ellipse, and $b > c$ and $b^2 > c^2$ for a vertical ellipse. This makes it easier to remember the **foci formula** for ellipses: $c^2 = |a^2 - b^2|$. If any two of the values for a, b, and c are known, the relationship between them can be used to construct the equation of the ellipse.

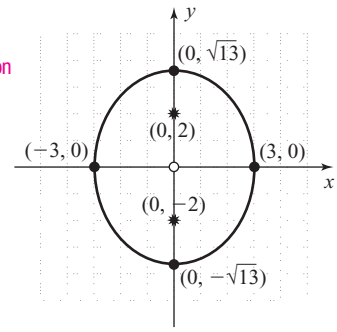
EXAMPLE 8 ▶ **Finding the Equation of an Ellipse**

Find the equation of the ellipse (in standard form) that has foci at (0, −2) and (0, 2), with a minor axis 6 units in length. Then graph the ellipse

a. By hand.

b. On a graphing calculator.

c. Find the distance from foci to graph along a focal chord $\left(\text{using } \dfrac{m^2}{n}\right)$, and use the result to verify that the endpoints of both focal chords are all on the graph.



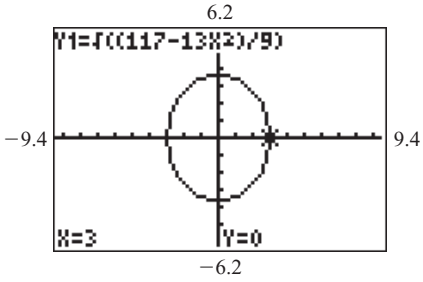
Solution ▶ Since the foci are on the y-axis and an equal distance from (0, 0), we know this is a vertical and central ellipse with $c = 2$ and $c^2 = 4$. The minor axis has a length of $2a = 6$ units, meaning $a = 3$ and $a^2 = 9$. To find b^2, use the foci equation and solve.

LOOKING AHEAD
For the hyperbola, we'll find that $c > a$, and the formula for the foci of a hyperbola will be $c^2 = a^2 + b^2$.

$$c^2 = |a^2 - b^2| \qquad \text{foci equation (ellipse)}$$
$$4 = |9 - b^2| \qquad \text{substitute}$$
$$-4 = 9 - b^2 \quad \text{or} \quad 4 = 9 - b^2 \qquad \text{solve the absolute value equation}$$
$$b^2 = 13 \quad \text{or} \quad b^2 = 5 \qquad \text{result}$$

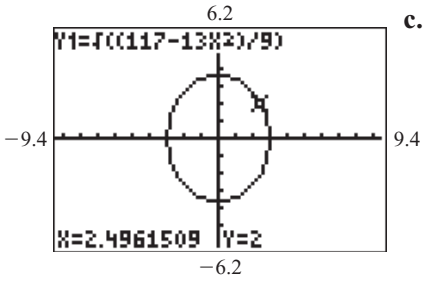
Since we know b^2 must be greater than a^2 (the major axis is always longer), $b^2 = 5$ can be discarded. The standard form is $\dfrac{x^2}{3^2} + \dfrac{y^2}{(\sqrt{13})^2} = 1$.

Figure 10.21



a. The graph is shown in Figure 10.21.

b. For a calculator generated graph, begin by solving for y.



$$\frac{x^2}{9} + \frac{y^2}{13} = 1 \qquad \text{original equation}$$
$$13x^2 + 9y^2 = 117 \qquad \text{clear denominators}$$
$$9y^2 = 117 - 13x^2 \qquad \text{isolate } y\text{-term}$$
$$y^2 = \frac{117 - 13x^2}{9} \qquad \text{divide by 9}$$
$$y = \pm\sqrt{\frac{117 - 13x^2}{9}} \qquad \text{take square roots}$$
$$Y_1 = +\sqrt{\frac{117 - 13X^2}{9}},\ Y_2 = -\sqrt{\frac{117 - 13X^2}{9}}$$

Figure 10.22

The graph is shown in Figure 10.22.

Figure 10.23

c. From the discussion prior to Example 8, the horizontal distance from foci to graph must be $\dfrac{m^2}{n} = \dfrac{9}{\sqrt{13}}$. Using the TRACE feature and entering $X = 9/\sqrt{13}$ verifies that $\left(\dfrac{9}{\sqrt{13}}, 2\right)$ is a point on the graph (Figure 10.23), and that $\left(-\dfrac{9}{\sqrt{13}}, 2\right)$, $\left(-\dfrac{9}{\sqrt{13}}, -2\right)$, and $\left(\dfrac{9}{\sqrt{13}}, -2\right)$ must also be on the graph due to symmetry.

Now try Exercises 55 through 62 ▶

C. You've just seen how we can locate the foci of an ellipse and use the foci and other features to write the equation

D. Applications Involving Foci

Applications involving the foci of a conic section can take various forms. In many cases, only partial information about the conic section is available and the ideas from Example 8 must be used to "fill in the gaps." In other applications, we must rewrite a known or given equation to find information related to the values of a, b, and c.

EXAMPLE 9 ▶ **Solving Applications Using the Characteristics of an Ellipse**

In Washington, D.C., there is a park called the *Ellipse* located between the White House and the Washington Monument. The park is surrounded by a path that forms an ellipse with the length of the major axis being about 1502 ft and the minor axis having a length of 1280 ft. Suppose the park manager wants to install water fountains at the location of the foci. Find the distance between the fountains rounded to the nearest foot.

Solution ▶ Since the major axis has length $2a = 1502$, we know $a = 751$ and $a^2 = 564{,}001$. The minor axis has length $2b = 1280$, meaning $b = 640$ and $b^2 = 409{,}600$. To find c, use the foci equation:

$$\begin{aligned} c^2 &= a^2 - b^2 && \text{since we know } a > b \\ &= 564{,}001 - 409{,}600 && \text{substitute} \\ &= 154{,}401 && \text{subtract} \\ c \approx -393 \text{ and } c &\approx 393 && \text{square root property} \end{aligned}$$

The distance between the water fountains would be $2(393) = 786$ ft.

D. You've just seen how we can solve applications involving the foci

Now try Exercises 65 through 80 ▶

10.2 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. For an ellipse, the relationship between a, b, and c is given by the foci equation _____, since $c < a$ or $c < b$.
2. The greatest distance across an ellipse is called the _____ _____ and the endpoints are called _____.
3. For a vertical ellipse, the length of the minor axis is _____ and the length of the major axis is _____.
4. To write the equation $2x^2 + y^2 - 6x = 7$ in standard form, _____ the _____ in x.
5. Explain/Discuss how the relations $a > b$, $a = b$ and $a < b$ affect the graph of a conic section with equation $\dfrac{(x-h)^2}{a^2} + \dfrac{(y-k)^2}{b^2} = 1$.
6. Suppose foci are located at $(-3, 2)$ and $(5, 2)$. Discuss/Explain the conditions necessary for the graph to be an ellipse.

▶ DEVELOPING YOUR SKILLS

Find an equation of the circle satisfying the conditions given, then graph the result on a graphing calculator and locate two additional points on the graph.

7. center $(0, 0)$, radius 7
8. center $(0, 0)$, radius 9
9. center $(5, 0)$, radius $\sqrt{3}$
10. center $(0, 4)$, radius $\sqrt{5}$
11. diameter has endpoints $(4, 9)$ and $(-2, 1)$
12. diameter has endpoints $(-2, -3)$, and $(3, 9)$

Write each equation in standard form to identify the center and radius of the circle, then sketch its graph.

13. $x^2 + y^2 - 12x - 10y + 52 = 0$
14. $x^2 + y^2 + 8x - 6y - 11 = 0$
15. $x^2 + y^2 - 4x + 10y + 4 = 0$
16. $x^2 + y^2 + 4x + 6y - 3 = 0$
17. $x^2 + y^2 + 6x - 5 = 0$
18. $x^2 + y^2 - 8y - 5 = 0$

Sketch the graph of each ellipse.

19. $\dfrac{(x-1)^2}{9} + \dfrac{(y-2)^2}{16} = 1$
20. $\dfrac{(x-3)^2}{4} + \dfrac{(y-1)^2}{25} = 1$
21. $\dfrac{(x-2)^2}{25} + \dfrac{(y+3)^2}{4} = 1$
22. $\dfrac{(x+5)^2}{1} + \dfrac{(y-2)^2}{16} = 1$

23. $\dfrac{(x+1)^2}{16} + \dfrac{(y+2)^2}{9} = 1$

24. $\dfrac{(x+1)^2}{36} + \dfrac{(y+3)^2}{9} = 1$

For each exercise, (a) write the equation in standard form, then identify the center and the values of *a* and *b*, (b) state the coordinates of the vertices and the coordinates of the endpoints of the minor axis, (c) sketch the graph, and (d) for 25–28 (only) graph the relations on a graphing calculator and identify four additional points on the graph whose coordinates are rational.

25. $x^2 + 4y^2 = 16$

26. $9x^2 + y^2 = 36$

27. $16x^2 + 9y^2 = 144$

28. $25x^2 + 9y^2 = 225$

29. $2x^2 + 5y^2 = 10$

30. $3x^2 + 7y^2 = 21$

Identify each equation as that of an ellipse or circle, then sketch its graph.

31. $(x+1)^2 + 4(y-2)^2 = 16$

32. $9(x-2)^2 + (y+3)^2 = 36$

33. $2(x-2)^2 + 2(y+4)^2 = 18$

34. $(x-6)^2 + y^2 = 49$

35. $4(x-1)^2 + 9(y-4)^2 = 36$

36. $25(x-3)^2 + 4(y+2)^2 = 100$

Complete the square in both *x* and *y* to write each equation in standard form. Then draw a complete graph of the relation and identify all important features, including the domain and range.

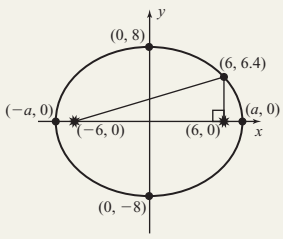
37. $4x^2 + y^2 + 6y + 5 = 0$

38. $x^2 + 3y^2 + 8x + 7 = 0$

39. $x^2 + 4y^2 - 8y + 4x - 8 = 0$

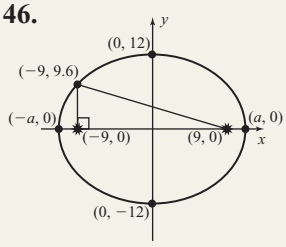
40. $3x^2 + y^2 - 8y + 12x - 8 = 0$

41. $5x^2 + 2y^2 + 20y - 30x + 75 = 0$



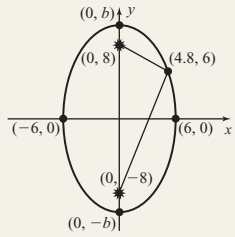
42. $4x^2 + 9y^2 - 16x + 18y - 11 = 0$

43. $2x^2 + 5y^2 - 12x + 20y - 12 = 0$

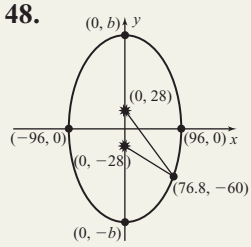


44. $6x^2 + 3y^2 - 24x + 18y - 3 = 0$

Use the definition of an ellipse to find the constant *k* for each ellipse (figures are not drawn to scale).



45.



46.

47.

48.

Find the coordinates of the (a) center, (b) vertices, (c) foci, and (d) endpoints of the minor axis. Then (e) sketch the graph.

49. $4x^2 + 25y^2 - 16x - 50y - 59 = 0$

50. $9x^2 + 16y^2 - 54x - 64y + 1 = 0$

51. $25x^2 + 16y^2 - 200x + 96y + 144 = 0$

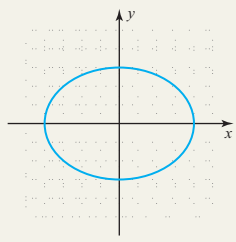
52. $49x^2 + 4y^2 + 196x - 40y + 100 = 0$

53. $6x^2 + 24x + 9y^2 + 36y + 6 = 0$

54. $5x^2 - 50x + 2y^2 - 12y + 93 = 0$

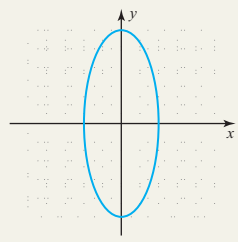
Find the equation of the ellipse (in standard form) that satisfies the following conditions. Then (a) graph the ellipse by hand, (b) confirm your graph by graphing the ellipse on a graphing calculator, and (c) find the length of the focal chords and verify the endpoints of the chords are on the graph.

55. vertices at $(-6, 0)$ and $(6, 0)$; foci at $(-4, 0)$ and $(4, 0)$



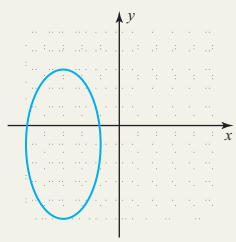
56. vertices at $(-8, 0)$ and $(8, 0)$; foci at $(-5, 0)$ and $(5, 0)$

57. foci at $(3, -6)$ and $(3, 2)$; length of minor axis: 6 units

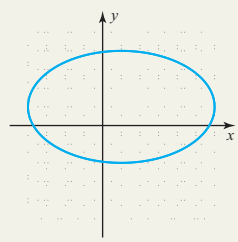


58. foci at $(-4, -3)$ and $(8, -3)$; length of minor axis: 8 units

Use the characteristics of an ellipse and the graph given to write the related equation and find the location of the foci.



59.



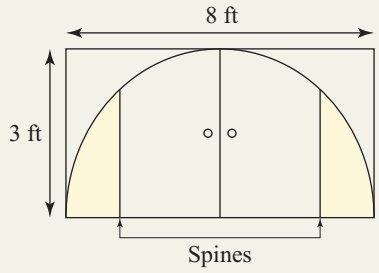
60.

61.

62.

▶ WORKING WITH FORMULAS

63. Area of an Ellipse: $A = \pi ab$



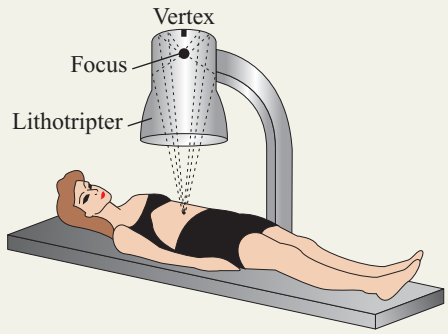
The area of an ellipse is given by the formula shown, where a is the distance from the center to the graph in the horizontal direction and b is the distance from center to graph in the vertical direction. Find the area of the ellipse defined by $16x^2 + 9y^2 = 144$.

64. The Perimeter of an Ellipse: $P = 2\pi\sqrt{\dfrac{a^2 + b^2}{2}}$

The perimeter of an ellipse can be *approximated* by the formula shown, where a represents the length of the semimajor axis and b represents the length of the semiminor axis. Find the perimeter of the ellipse defined by the equation $\dfrac{x^2}{49} + \dfrac{y^2}{4} = 1$.

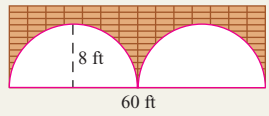
▶ APPLICATIONS

65. Decorative fireplaces: A bricklayer intends to build an elliptical fireplace 3 ft high and 8 ft wide, with two glass doors that open at the middle. The hinges to these doors are to be screwed onto a spine that is perpendicular to the hearth and goes through the foci of the ellipse. How far from center will the spines be located? How tall will each spine be?



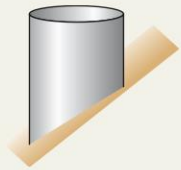
66. Decorative gardens: A retired math teacher decides to present her husband with a beautiful elliptical garden to help celebrate their 50th anniversary. The ellipse is to be 8 m long and 5 m across, with decorative fountains located at the foci. How far from the center of the ellipse should the fountains be located (round to the nearest 100th of a meter)? How far apart are the fountains?

67. Attracting attention to art: As part of an art show, a gallery owner asks a student from the local university to design a unique exhibit that will highlight one of the more significant pieces in the collection, an ancient sculpture. The student decides to create an elliptical showroom with reflective walls, with a rotating laser light on a stand at one focus, and the sculpture placed at the other focus on a stand of equal height. The laser light then points continually at the sculpture as it rotates. If the elliptical room is 24 ft long and 16 ft wide, how far from the center of the ellipse should the stands be located (round to the nearest 10th of a foot)? How far apart are the stands?



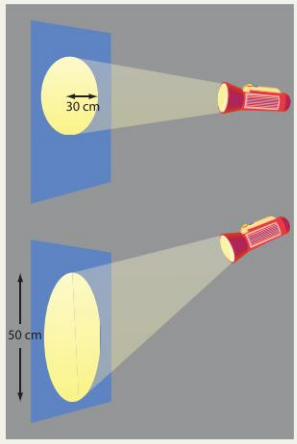
68. Medical procedures: The medical procedure called *lithotripsy* is a noninvasive medical procedure that is used to break up kidney and bladder stones in the body. A machine called a *lithotripter* uses its three-dimensional semielliptical shape and the foci properties of an ellipse to concentrate shock waves generated at one focus, on a kidney stone located at the other focus (see diagram—not drawn to scale). If the lithotripter has a length (semimajor axis) of 16 cm and a radius (semiminor axis) of 10 cm, how far from the vertex should a kidney stone be located for the best result? Round to the nearest hundredth.

Exercise 68



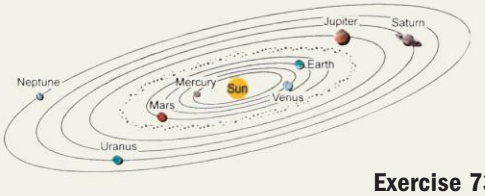
69. Elliptical arches: In some situations, bridges are built using uniform elliptical archways as shown in the figure given. Find the equation of the ellipse forming each arch if it has a total width of 30 ft and a maximum center height (above level ground) of 8 ft. What is the height of a point 9 ft to the right of the center of each arch?

Exercise 69



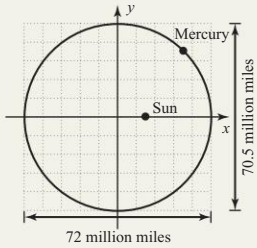
70. Elliptical arches: An elliptical arch bridge is built across a one-lane highway. The arch is 20 ft across and has a maximum center height of 12 ft. Will a farm truck hauling a load 10 ft wide with a clearance height of 11 ft be able to go under the bridge without damage? (*Hint:* See Exercise 69.)

71. Plumbing: By allowing the free flow of air, a properly vented home enables water to run freely throughout its plumbing system, while helping to prevent sewage gases from entering the home.

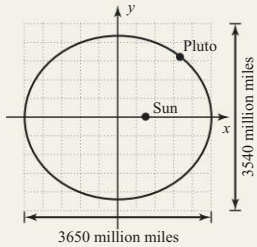


Find the equation of the elliptical hole cut in a roof in order to allow a 3-in. vent pipe to exit, if the roof has a slope of $\frac{4}{3}$.

72. Light projection: Standing a short distance from a wall, Kymani's flashlight projects a circle of radius 30 cm. When holding the flashlight at an angle, a vertical ellipse 50 cm long is formed, with the focus 10 cm from the vertex (see *Worthy of Note,* page 971). Find the equation of the circle and ellipse, and the area of the wall that each illuminates.



As a planet orbits around the Sun, it traces out an ellipse. If the center of the ellipse were placed at (0, 0) on a coordinate grid, the Sun would be actually off-centered (located at the *focus* of the ellipse). Use this information and the graphs provided to complete Exercises 73 through 78.



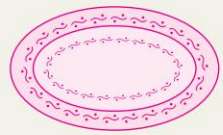
Exercise 73

73. Orbit of Mercury: The approximate orbit of the planet Mercury is shown in the figure given. Find an equation that models this orbit.

Exercise 74

74. Orbit of Pluto: The approximate orbit of the Kuiper object formerly known as Pluto is shown in the figure given. Find an equation that models this orbit.

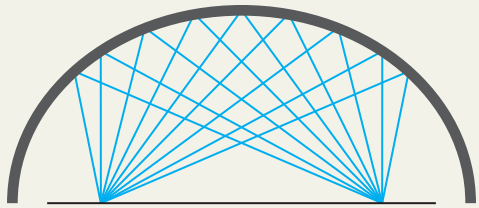
75. Planetary orbits: Except for small variations, a planet's orbit around the Sun is elliptical with the Sun at one focus. The aphelion (maximum distance from the Sun) of the planet Mars is approximately 156 million miles, while the perihelion (minimum distance from the Sun) of Mars is about 128 million miles. Use this information to find the lengths of the semimajor and semiminor axes, rounded to the nearest million. If Mars has an orbital velocity of 54,000 miles per hour (1.296 million miles per day), how many days does it take Mars to orbit the Sun? (*Hint:* Use the formula from Exercise 64.)



76. Planetary orbits: The aphelion (maximum distance from the Sun) of the planet Saturn is approximately 940 million miles, while the perihelion (minimum distance from the Sun) of Saturn is about 840 million miles. Use this information to find the lengths of the semimajor and semiminor axes, rounded to the nearest million. If Saturn has an orbital velocity of 21,650 miles per hour (about 0.52 million miles per day), how many days does it take Saturn to orbit the Sun? How many years?

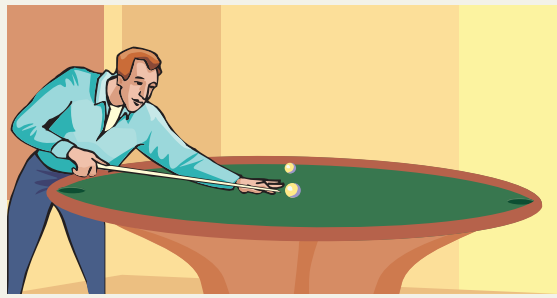
77. Orbital velocity of Earth: The planet Earth has a perihelion (minimum distance from the Sun) of about 91 million mi, an aphelion (maximum distance from the Sun) of close to 95 million mi, and completes one orbit in about 365 days. Use this information and the formula from Exercise 64 to find Earth's orbital speed around the Sun in miles per hour.

78. Orbital velocity of Jupiter: The planet Jupiter has a perihelion of 460 million mi, an aphelion of 508 million mi, and completes one orbit in about 4329 days. Use this information and the formula from Exercise 64 to find Jupiter's orbital speed around the Sun in miles per hour.



79. Area of a race track: Suppose the *Toronado 500* is a car race that is run on an elliptical track. The track is bounded by two ellipses with equations of $4x^2 + 9y^2 = 900$ and $9x^2 + 25y^2 = 900$, where x and y are in hundreds of yards. Use the formula given in Exercise 63 to find the area of the race track.

Exercise 80



80. Area of a border: The tablecloth for a large oval table is elliptical in shape. It is designed with two concentric ellipses (one within the other) as shown in the figure. The equation of the outer ellipse is $9x^2 + 25y^2 = 225$, and the equation of the inner ellipse is $4x^2 + 16y^2 = 64$ with x and y in feet. Use the formula given in Exercise 63 to find the area of the border of the tablecloth.

81. Whispering galleries: Due to their unique properties, ellipses are used in the construction of *whispering galleries* like those in St. Paul's Cathedral (London) and Statuary Hall in the U.S. Capitol. Regarding the latter, it is known that John Quincy Adams (1767–1848), while a member of the House of Representatives, situated his desk at a focal point of the elliptical ceiling, easily eavesdropping on the private conversations of other House members located near the other focal point. Suppose a whispering gallery was built using the equation $\frac{x^2}{2809} + \frac{y^2}{2025} = 1$, with the dimensions in feet. (a) How tall is the ceiling at its highest point? (b) How wide is the gallery vertex to vertex? (c) How far from the base of the doors at either end, should a young couple stand so that one can clearly hear the other whispering, "I love you."?

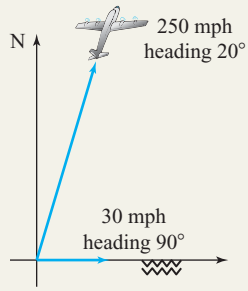
82. Elliptical billiards: While an elliptical billiard table has little practical value, it offers an excellent illustration of elliptical properties. A ball placed at one focus and hit with the cue stick from any angle, will hit the cushion and immediately rebound to the other focus and continue through each focus until coming to rest. Suppose one such table was constructed using the equation $\frac{x^2}{9} + \frac{y^2}{4} = 1$ as a model, with the dimensions in feet. (a) How far apart are the vertices? (b) How far apart are the foci? As a side note, Lewis Carroll (1832–1898) did invent a game of circular billiards, complete with rules.

▶ EXTENDING THE CONCEPT

83. For $6x^2 + 36x + 3y^2 - 24y + 74 = -28$, does the equation appear to be that of a circle, ellipse, or parabola? Write the equation in factored form. What do you notice? What can you say about the graph of this equation?

84. Algebraically verify that for the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ with $b > a$, the length of the focal chord is still $\frac{2a^2}{b}$.

▶ MAINTAINING YOUR SKILLS



85. **(5.4)** Evaluate the expression using the change-of-base formula: $\log_3 20$.

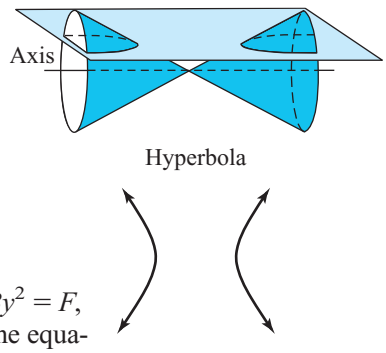
86. **(2.6)** The resistance R to current flow in an electrical wire varies directly as the length L of the wire and inversely as the square of its diameter d. (a) Write the equation of variation; (b) find the constant of variation if a wire 2 m long with diameter $d = 0.005$ m has a resistance of 240 ohms (Ω); and (c) find the resistance in a similar wire 3 m long and 0.006 m in diameter.

87. **(8.6)** Use De Moivre's theorem to compute the value of $z = (1 - i\sqrt{3})^6$.

88. **(8.3)** Find the true direction and groundspeed of the airplane shown, given the direction and speed of the wind (indicated in blue).

Exercise 88

10.3 The Hyperbola



LEARNING OBJECTIVES

In Section 10.3 you will see how we can:

- ❑ **A.** Use the equation of a hyperbola to graph central and noncentral hyperbolas
- ❑ **B.** Distinguish between the equations of circles, ellipses, and hyperbolas
- ❑ **C.** Locate the foci of a hyperbola and use the foci and other features to write its equation
- ❑ **D.** Solve applications involving foci

As seen in Section 10.1 (see Figure 10.24), a hyperbola is a conic section formed by a plane that cuts both nappes of a right circular cone. A hyperbola has two symmetric parts called **branches,** which open in opposite directions. Although the branches appear to resemble parabolas, we will soon discover they are actually a very different curve.

Figure 10.24

A. The Equation of a Hyperbola

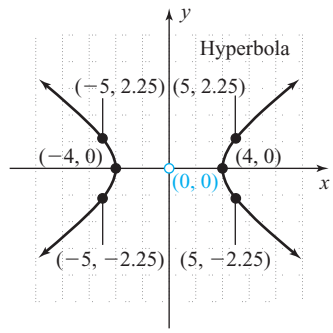
In Section 10.2, we noted that for the equation $Ax^2 + By^2 = F$, if $A = B$, the equation is that of a circle, if $A \neq B$, the equation represents an ellipse. Both cases contain a *sum* of second-degree terms. Perhaps driven by curiosity, we might wonder what happens if the equation has a *difference* of second-degree terms. Consider the equation $9x^2 - 16y^2 = 144$. It appears the graph will be centered at $(0, 0)$ since no shifts are applied (h and k are both zero). Using the intercept method to graph this equation reveals an entirely new curve, called a *hyperbola*.

EXAMPLE 1 ▶ **Graphing a Central Hyperbola**

Graph the equation $9x^2 - 16y^2 = 144$ using intercepts and additional points as needed.

Solution ▶

$$\begin{aligned} 9x^2 - 16y^2 &= 144 && \text{given} \\ 9(0)^2 - 16y^2 &= 144 && \text{substitute 0 for } x \\ -16y^2 &= 144 && \text{simplify} \\ y^2 &= -9 && \text{divide by } -16 \end{aligned}$$



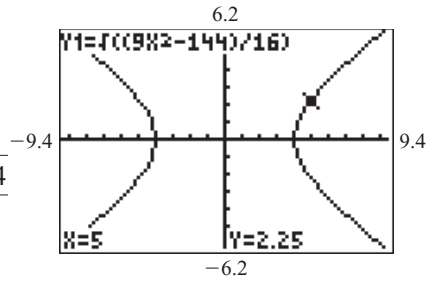
Since y^2 can never be negative, we conclude that the graph has *no y-intercepts.* Substituting $y = 0$ to find the x-intercepts gives

$$\begin{aligned} 9x^2 - 16y^2 &= 144 && \text{given} \\ 9x^2 - 16(0)^2 &= 144 && \text{substitute 0 for } y \\ 9x^2 &= 144 && \text{simplify} \\ x^2 &= 16 && \text{divide by 9} \\ x = \sqrt{16} \quad \text{and} \quad x &= -\sqrt{16} && \text{square root property} \\ x = 4 \quad \text{and} \quad x &= -4 && \text{simplify} \\ (4, 0) \quad \text{and} \quad (-4, 0) & && x\text{-intercepts} \end{aligned}$$

Knowing the graph has no y-intercepts, we select inputs greater than 4 and less than -4 to help sketch the graph. Using $x = 5$ and $x = -5$ yields

$9x^2 - 16y^2 = 144$	given	$9x^2 - 16y^2 = 144$
$9(5)^2 - 16y^2 = 144$	substitute for x	$9(-5)^2 - 16y^2 = 144$
$9(25) - 16y^2 = 144$	$5^2 = (-5)^2 = 25$	$9(25) - 16y^2 = 144$
$225 - 16y^2 = 144$	simplify	$225 - 16y^2 = 144$
$-16y^2 = -81$	subtract 225	$-16y^2 = -81$
$y^2 = \frac{81}{16}$	divide by -16	$y^2 = \frac{81}{16}$
$y = \frac{9}{4} \quad y = -\frac{9}{4}$	square root property	$y = \frac{9}{4} \quad y = -\frac{9}{4}$
$y = 2.25 \quad y = -2.25$	decimal form	$y = 2.25 \quad y = -2.25$
$(5, 2.25) \quad (5, -2.25)$	ordered pairs	$(-5, 2.25) \quad (-5, -2.25)$

Plotting these points and connecting them with a smooth curve, while *knowing there are no y-intercepts,* produces the graph in the figure. The point at the origin (in blue) is not a part of the graph, and is given only to indicate the "center" of the hyperbola. The points $(-4, 0)$ and $(4, 0)$ are called **vertices,** and the **center** of the hyperbola is always the point halfway between them.



Now try Exercises 7 through 22 ▶

As with the circle and ellipse, the hyperbola fails the vertical line test and we must graph the relation on a calculator by writing its equation in two parts, each of which is a function. For the hyperbola in Example 1, this gives

$$9x^2 - 16y^2 = 144 \qquad \text{original equation}$$
$$-16y^2 = 144 - 9x^2 \qquad \text{isolate } y\text{-term}$$
$$16y^2 = 9x^2 - 144 \qquad \text{multiply by } -1$$
$$y^2 = \frac{9x^2 - 144}{16} \qquad \text{divide by 16}$$
$$y = \pm\sqrt{\frac{9x^2 - 144}{16}} \qquad \text{take square roots}$$

$$Y_1 = +\sqrt{\frac{9X^2 - 144}{16}}, \quad Y_2 = -\sqrt{\frac{9X^2 - 144}{16}}$$

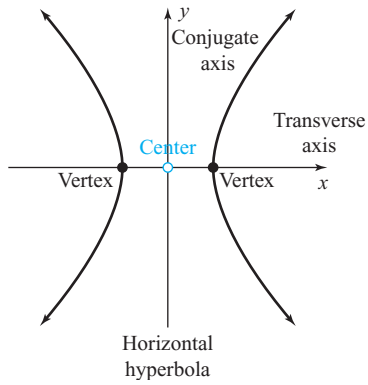
Figure 10.25

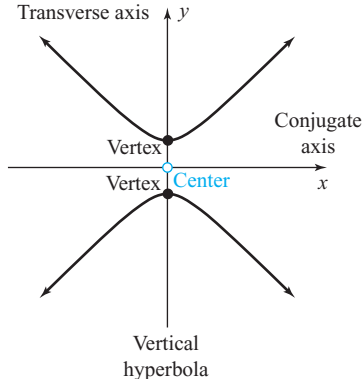
The graph is shown in Figure 10.25.

Since the hyperbola in Example 1 crosses a horizontal line of symmetry, it is referred to as a **horizontal hyperbola.** If the center is at the origin, we have a **central hyperbola.** The line passing through the center and both vertices is called the **transverse axis** (vertices are always on the transverse axis), and the line passing through the center and perpendicular to this axis is called the **conjugate axis** (see Figure 10.26).

In Example 1, the coefficient of x^2 was positive and we were subtracting $16y^2$: $9x^2 - 16y^2 = 144$. The result was a horizontal hyperbola. If the y^2-term is positive and we subtract the term containing x^2, the result is a **vertical hyperbola** (Figure 10.27).

Figure 10.26





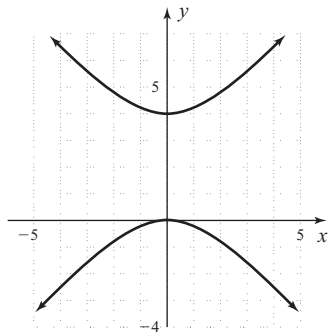


Figure 10.27

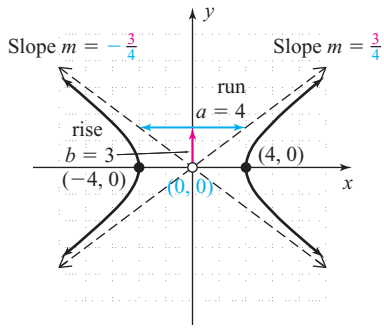
EXAMPLE 2 ▶ Identifying the Axes, Vertices, and Center of a Hyperbola from Its Graph

For the hyperbola shown, state the location of the vertices and the equation of the transverse axis. Then identify the location of the center and the equation of the conjugate axis.

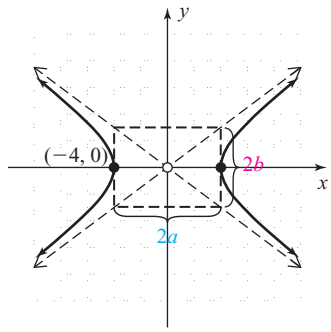
Solution ▶ By inspection we locate the vertices at (0, 0) and (0, 4). The equation of the transverse axis is $x = 0$. The center is halfway between the vertices at (0, 2), meaning the equation of the conjugate axis is $y = 2$.



Now try Exercises 23 through 26 ▶

Standard Form

As with the ellipse, the polynomial form of the equation is helpful for *identifying* hyperbolas, but not very helpful when it comes to *graphing* a hyperbola (since we still must go through the laborious process of finding additional points). For graphing, standard form is once again preferred. Consider the hyperbola $9x^2 - 16y^2 = 144$ from Example 1. To write the equation in standard form, we divide by 144 and obtain $\frac{x^2}{4^2} - \frac{y^2}{3^2} = 1$. By comparing the standard form to the graph, we note $a = 4$ represents the distance from center to vertices, similar to the way we used a previously. But since the graph has no y-intercepts, what could $b = 3$ represent? The answer lies in the fact that branches of a hyperbola are **asymptotic,** meaning they will approach and become very close to imaginary lines that can be used to sketch the graph. For a central hyperbola, the slopes of the asymptotic lines are given by the ratios $\frac{b}{a}$ and $-\frac{b}{a}$, with the related equations being $y = \frac{b}{a}x$ and $y = -\frac{b}{a}x$. The graph from Example 1 is repeated in Figure 10.28, with the asymptotes drawn. For a clearer understanding of how the equations for the asymptotes were determined, **see Exercise 87.**



A second method of drawing the asymptotes involves drawing a **central rectangle** with dimensions $2a$ by $2b$, as shown in Figure 10.29. The asymptotes will be the *extended diagonals* of this rectangle. This brings us to the equation of a hyperbola in standard form.

Figure 10.28

Slope method

Figure 10.29

Central rectangle method

The Equation of a Hyperbola in Standard Form

The equation

$$\frac{(x-h)^2}{a^2} - \frac{(y-k)^2}{b^2} = 1$$

represents a *horizontal* hyperbola with center (h, k)

- *transverse* axis $y = k$
- *conjugate* axis $x = h$
- $|a|$ gives the distance from center to vertices.

The equation

$$\frac{(y-k)^2}{b^2} - \frac{(x-h)^2}{a^2} = 1$$

represents a *vertical* hyperbola with center (h, k)

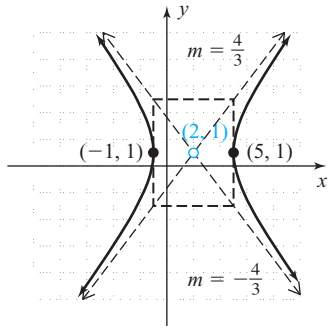
- *transverse* axis $x = h$
- *conjugate* axis $y = k$
- $|b|$ gives the distance from center to vertices.

- Asymptotes can be drawn by starting at (h, k) and using slopes $m = \pm\frac{b}{a}$.

EXAMPLE 3 ▶ **Graphing a Hyperbola Using Its Equation in Standard Form**

Sketch the graph of $16(x-2)^2 - 9(y-1)^2 = 144$, and label the center, vertices, and asymptotes.

Solution ▶ Begin by noting a difference of the second-degree terms, with the x^2-term occurring first. This means we'll be graphing a horizontal hyperbola whose center is at (2, 1). Continue by writing the equation in standard form.



$$16(x-2)^2 - 9(y-1)^2 = 144 \quad \text{given equation}$$

$$\frac{16(x-2)^2}{144} - \frac{9(y-1)^2}{144} = \frac{144}{144} \quad \text{divide by 144}$$

$$\frac{(x-2)^2}{9} - \frac{(y-1)^2}{16} = 1 \quad \text{simplify}$$

$$\frac{(x-2)^2}{3^2} - \frac{(y-1)^2}{4^2} = 1 \quad \text{write denominators in squared form}$$

Since $a = 3$ the vertices are a horizontal distance of 3 units from the center (2, 1), giving $(2+3, 1) \rightarrow (5, 1)$ and $(2-3, 1) \rightarrow (-1, 1)$. After plotting the center and vertices, we can begin at the center and count off slopes of $m = \pm\frac{b}{a} = \pm\frac{4}{3}$, or draw a rectangle centered at (2, 1) with dimensions $2(3) = 6$ (horizontal dimension) by $2(4) = 8$ (vertical dimension) to sketch the asymptotes. The complete graph is shown here.

Horizontal hyperbola

Center at (2, 1)

Vertices at (−1, 1) and (5, 1)

Transverse axis: $y = 1$
Conjugate axis: $x = 2$

Width of rectangle
(horizontal dimension and distance between vertices)
$2a = 2(3) = 6$

Length of rectangle
(vertical dimension)
$2b = 2(4) = 8$

Now try Exercises 27 through 44 ▶

If the hyperbola in Example 3 were a central hyperbola, the equations of the asymptotes would be $y = \frac{4}{3}x$ and $y = -\frac{4}{3}x$. But the center of this graph has been shifted 2 units right and 1 unit up. Using our knowledge of shifts and translations, the equations for the asymptotes of the shifted hyperbola must be

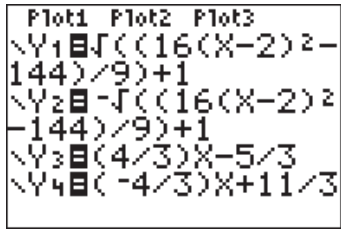
1. $(y - 1) = +\frac{4}{3}(x - 2)$, or $y = \frac{4}{3}x - \frac{5}{3}$ in simplified form, and

2. $(y - 1) = -\frac{4}{3}(x - 2)$ or $y = -\frac{4}{3}x + \frac{11}{3}$.

Using $Y_1 = +\sqrt{\frac{16(X-2)^2 - 144}{9}} + 1$, and $Y_2 = -\sqrt{\frac{16(X-2)^2 - 144}{9}} + 1$

(obtained by solving for y in the original equation), a calculator generated graph of the hyperbola and its asymptotes is shown here (Figures 10.30 and 10.31).

Figure 10.30



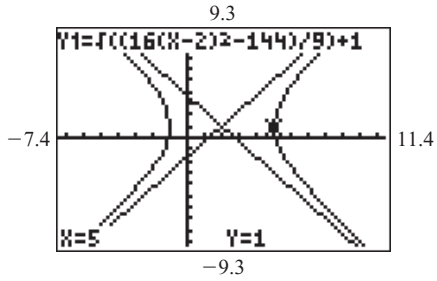


Figure 10.31

Polynomial Form

If the equation is given as a polynomial in expanded form, complete the square in x and y, then write the equation in standard form.

EXAMPLE 4 ▶ Graphing a Hyperbola by Completing the Square

Graph the equation $9y^2 - x^2 + 54y + 4x + 68 = 0$ by completing the square. Label the center and vertices and sketch the asymptotes. Then graph the hyperbola on a graphing calculator and use the TRACE feature with a "friendly" window to locate four additional points whose coordinates are rational.

Solution ▶ Since the y^2-term occurs first, we assume the equation represents a vertical hyperbola, but wait for the factored form to be sure (**see Exercise 91**).

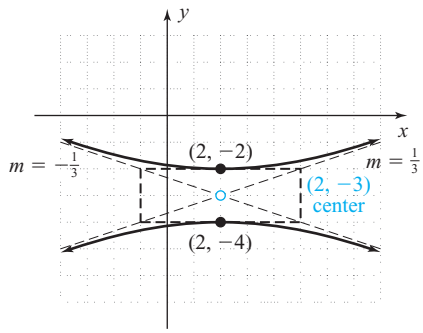
$$9y^2 - x^2 + 54y + 4x + 68 = 0 \qquad \text{given}$$

$$9y^2 + 54y - x^2 + 4x = -68 \qquad \text{collect like-variable terms; subtract 68}$$

$$9(y^2 + 6y + ___) - 1(x^2 - 4x + ___) = -68 \qquad \text{factor out 9 from } y\text{-terms and } -1 \text{ from } x\text{-terms}$$

$$9(y^2 + 6y + 9) - 1(x^2 - 4x + 4) = -68 + 81 + (-4) \qquad \text{complete the square}$$

adds $9(9) = 81$; adds $-1(4) = -4$; add $81 + (-4)$ to right



$$9(y + 3)^2 - 1(x - 2)^2 = 9 \qquad \text{factor} \rightarrow \text{vertical hyperbola}$$

$$\frac{(y + 3)^2}{1} - \frac{(x - 2)^2}{9} = 1 \qquad \text{divide by 9 (standard form)}$$

$$\frac{(y + 3)^2}{1^2} - \frac{(x - 2)^2}{3^2} = 1 \qquad \text{write denominators in squared form}$$

The center of the hyperbola is $(2, -3)$ with $a = 3$, $b = 1$, and a transverse axis of $x = 2$. The vertices are at $(2, -3 + 1)$ and $(2, -3 - 1) \rightarrow (2, -2)$ and $(2, -4)$. After plotting the center and vertices, we draw a rectangle centered at $(2, -3)$ with a horizontal "width" of $2(3) = 6$ and a vertical "length" of $2(1) = 2$ to sketch the asymptotes. The completed graph is given in Figure 10.32.

Figure 10.32

Vertical hyperbola

Center at $(2, -3)$
Vertices at $(2, -2)$ and $(2, -4)$

Transverse axis: $x = 2$
Conjugate axis: $y = -3$

Width of rectangle (horizontal dimension)
$2a = 2(3) = 6$

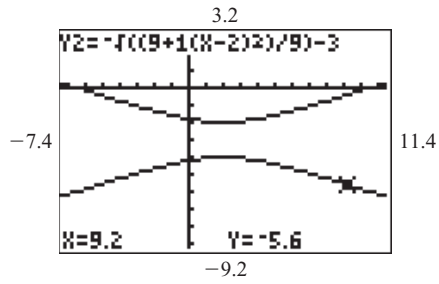
Length of rectangle (vertical dimension and distance between vertices)
$2b = 2(1) = 2$

To graph the hyperbola on a calculator, we again solve for y.

$$9(y + 3)^2 - (x - 2)^2 = 9 \qquad \text{factored form}$$

$$9(y + 3)^2 = 9 + (x - 2)^2 \qquad \text{isolate term containing } y$$

$$(y + 3)^2 = \frac{9 + (x - 2)^2}{9} \qquad \text{divide by 9}$$



$$y + 3 = \pm\sqrt{\frac{9 + (x - 2)^2}{9}} \qquad \text{take square roots}$$

$$y = \pm\sqrt{\frac{9 + (x - 2)^2}{9}} - 3 \qquad \text{subtract 3}$$

$$Y_1 = +\sqrt{\frac{9 + (X - 2)^2}{9}} - 3,\ Y_2 = -\sqrt{\frac{9 + (X - 2)^2}{9}} - 3$$

Using the "friendly" window shown, we can use the arrow keys to TRACE though x-values and find the points $(-5.2, -0.4)$ and $(9.2, -0.4)$ on the upper branch, with $(-5.2, -5.6)$ and $(9.2, -5.6)$ on the lower branch. Note how these points show that a hyperbola is symmetric to its center, as well as the horizontal line and vertical line through its center. The graph is shown in Figure 10.33.

Figure 10.33

Now try Exercises 45 through 48 ▶

A. You've just seen how we can use the equation of a hyperbola to graph central and noncentral hyperbolas

B. Distinguishing Between the Equations of Circles, Ellipses, and Hyperbolas

So far we've explored numerous graphs of circles, ellipses, and hyperbolas. In Example 5 we'll attempt to identify a given conic section from its equation alone (without graphing the equation). As you've seen, the corresponding equations have unique characteristics that can help distinguish one from the other.

EXAMPLE 5 ▶ **Identifying a Conic Section from Its Equation**

Identify each equation as that of a circle, ellipse, or hyperbola. Justify your choice and name the center, but do not draw the graphs.

a. $y^2 = 36 + 9x^2$ **b.** $4x^2 = 16 - 4y^2$

c. $x^2 = 225 - 25y^2$ **d.** $25x^2 = 100 + 4y^2$

e. $3(x - 2)^2 + 4(y + 3)^2 = 12$ **f.** $4(x + 5)^2 = 36 + 9(y - 4)^2$

Solution ▶

a. Writing the equation as $y^2 - 9x^2 = 36$ shows $h = 0$ and $k = 0$. Since the equation contains a difference of second-degree terms, it is the equation of a (vertical) hyperbola (A and B have opposite signs). The center is at (0, 0).

b. Rewriting the equation as $4x^2 + 4y^2 = 16$ and dividing by 4 gives $x^2 + y^2 = 4$. The equation represents a circle of radius 2 ($A = B$), with the center at (0, 0).

c. Writing the equation as $x^2 + 25y^2 = 225$ we note a sum of second-degree terms with unequal coefficients. The equation is that of an ellipse ($A \neq B$), with the center at (0, 0).

d. Rewriting the equation as $25x^2 - 4y^2 = 100$ we note the equation contains a difference of second-degree terms. The equation represents a central (horizontal) hyperbola (A and B have opposite signs), whose center is at (0, 0).

e. The equation is in factored form and contains a sum of second-degree terms with unequal coefficients. This is the equation of an ellipse ($A \neq B$) with the center at $(2, -3)$.

f. Rewriting the equation as $4(x + 5)^2 - 9(y - 4)^2 = 36$ we note a difference of second-degree terms. The equation represents a horizontal hyperbola (A and B have opposite signs) with center $(-5, 4)$.

B. You've just seen how we can distinguish between the equations of circles, ellipses, and hyperbolas

Now try Exercises 49 through 60 ▶

C. The Foci of a Hyperbola

Like the ellipse, the foci of a hyperbola play an important part in their application. A long distance radio navigation system (called LORAN for short), can be used to determine the location of ships and airplanes and is based on the characteristics of a hyperbola (**see Exercises 85 and 86**). Hyperbolic mirrors are also used in some telescopes, and have the property that a beam of light directed at one focus will be reflected to the second focus. To understand and appreciate these applications, we use the analytic definition of a hyperbola:

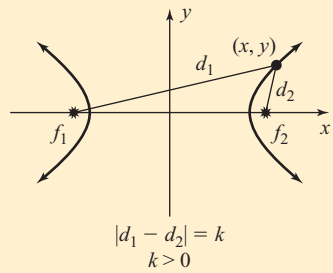
Definition of a Hyperbola

Given two fixed points f_1 and f_2 in a plane, a hyperbola is the set of all points (x, y) such that the distance d_1 from f_1 to (x, y) and the distance d_2 from f_2 to (x, y), satisfy the equation

$$|d_1 - d_2| = k.$$

In other words, the difference of these two distances is a positive constant.

The fixed points f_1 and f_2 are called the foci of the hyperbola, and all such points (x, y) are on the graph of the hyperbola.



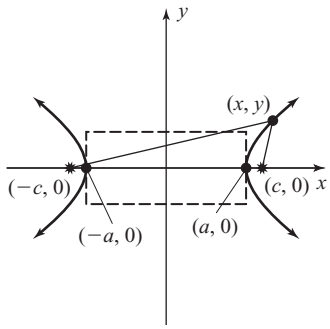


Figure 10.34

As with the analytic definition of the ellipse, it can be shown that the constant k is again equal to $2a$ (for horizontal hyperbolas). To find the equation of a hyperbola in terms of a and b, we use an approach similar to that of the ellipse (see Appendix E), and the result is identical to that seen earlier: $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$ where $b^2 = c^2 - a^2$ (see Figure 10.34).

We now have the ability to *find the foci of any hyperbola*—and can use this information in many significant applications. Since the location of the foci play such an important role, it is best to remember the relationship as $c^2 = a^2 + b^2$ (called the **foci formula** for hyperbolas), noting that for a hyperbola, $c > a$ and $c^2 > a^2$ (also $c > b$ and $c^2 > b^2$). Be sure to note that for ellipses, the foci formula is $c^2 = |a^2 - b^2|$ since $a > c$ (horizontal ellipses) or $b > c$ (vertical ellipses).

EXAMPLE 6 ▶ **Graphing a Hyperbola and Identifying Its Foci by Completing the Square**

For the hyperbola defined by $7x^2 - 9y^2 - 14x + 72y - 200 = 0$, find the coordinates of the center, vertices, foci, and the dimensions of the central rectangle. Then sketch the graph, including the asymptotes.

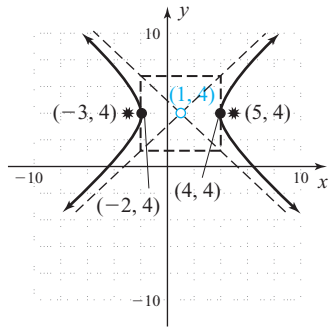
Solution ▶

$$7x^2 - 9y^2 - 14x + 72y - 200 = 0 \qquad \text{given}$$

$$7x^2 - 14x - 9y^2 + 72y = 200 \qquad \text{group terms; add 200}$$

$$7(x^2 - 2x + ____) - 9(y^2 - 8y + ____) = 200 \qquad \text{factor out leading coefficients}$$

$$7(x^2 - 2x + 1) - 9(y^2 - 8y + 16) = 200 + 7 + (-144) \qquad \text{complete the square}$$



adds $7(1) = 7$; adds $-9(16) = -144$; $\rightarrow$ add $7 + (-144)$ to right-hand side

$$7(x - 1)^2 - 9(y - 4)^2 = 63 \qquad \text{factored form}$$

$$\frac{(x - 1)^2}{9} - \frac{(y - 4)^2}{7} = 1 \qquad \text{divide by 63 and simplify}$$

$$\frac{(x - 1)^2}{3^2} - \frac{(y - 4)^2}{(\sqrt{7})^2} = 1 \qquad \text{write denominators in squared form}$$

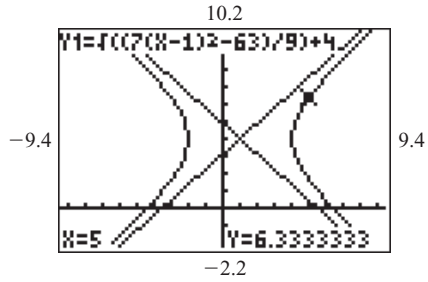
This is a horizontal hyperbola with $a = 3$ ($a^2 = 9$) and $b = \sqrt{7}$ ($b^2 = 7$). The center is at $(1, 4)$, with vertices $(-2, 4)$ and $(4, 4)$. Using the foci formula $c^2 = a^2 + b^2$ yields $c^2 = 9 + 7 = 16$, showing the foci are $(-3, 4)$ and $(5, 4)$ (4 units from center). The central rectangle is $2(3) = 6$ by $2\sqrt{7} \approx 5.29$. Drawing the rectangle and sketching the asymptotes results in the graph shown.

Horizontal hyperbola

Center at $(1, 4)$
Vertices at $(-2, 4)$ and $(4, 4)$

Transverse axis: $y = 4$
Conjugate axis: $x = 1$
Location of foci: $(-3, 4)$ and $(5, 4)$

Width of rectangle
(horizontal dimension and distance between vertices)
$2a = 2(3) = 6$



Length of rectangle
(vertical dimension)
$2b = 2(\sqrt{7}) \approx 5.29$

Now try Exercises 61 through 70 ▶

A focal chord for a horizontal hyperbola is a vertical line segment through a focus with endpoints on the hyperbola. Similar to a focal chord of an ellipse, we can use its length to find additional points on the graph of the hyperbola. The total length is once again $L = \frac{2b^2}{a}$ (for a horizontal hyperbola), meaning the distance from the foci

to the graph (along the focal chord) is $\frac{b^2}{a}$. For Example 6, $a = 3$ and $b^2 = 7$, so the vertical distance from focus to graph (in either direction) is $\frac{7}{3} = 2.\overline{3}$. From the left focus $(-3, 4)$, we can now graph the additional points $(-3, 4 + 2.\overline{3}) = (-3, 6.\overline{3})$, and $(-3, 4 - 2.\overline{3}) = (-3, 1.\overline{6})$. From the right focus $(5, 4)$, we obtain $(5, 6.\overline{3})$ and $(5, 1.\overline{6})$. Graphical verification is provided in Figure 10.35. Also **see Exercise 80.**

Figure 10.35

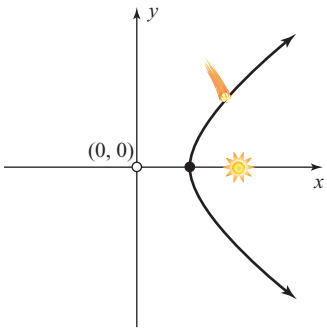
C. You've just seen how we can locate the foci of a hyperbola and use the foci and other features to write its equation

As with the ellipse, if any two of the values for a, b, and c are known, the relationship between them can be used to construct the equation of the hyperbola. **See Exercises 71 through 78.**

D. Applications Involving Foci

Applications involving the foci of a conic section can take many forms. As before, only partial information about the hyperbola may be available, and we'll determine a solution by manipulating a given equation or constructing an equation from given facts.

EXAMPLE 7 ▶ **Applying the Properties of a Hyperbola—The Path of a Comet**



Comets with a high velocity cannot be captured by the Sun's gravity, and are slung around the Sun in a hyperbolic path with the Sun at one focus. If the path illustrated by the graph shown is modeled by the equation $2116x^2 - 400y^2 = 846{,}400$, how close did the comet get to the Sun? Assume units are in millions of miles and round to the nearest million.

Solution ▶ We are essentially asked to find the distance between a vertex and focus. Begin by writing the equation in standard form:

$$2116x^2 - 400y^2 = 846{,}400 \quad \text{given}$$

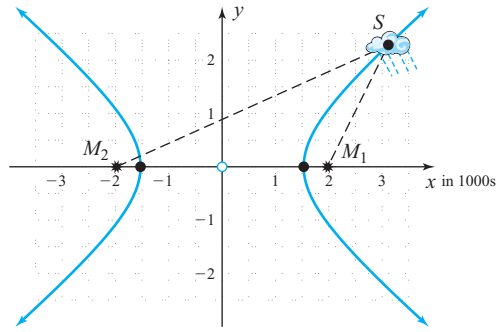
$$\frac{x^2}{400} - \frac{y^2}{2116} = 1 \quad \text{divide by } 846{,}400$$

$$\frac{x^2}{20^2} - \frac{y^2}{46^2} = 1 \quad \text{write denominators in squared form}$$

This is a horizontal hyperbola with $a = 20$ $(a^2 = 400)$ and $b = 46$ $(b^2 = 2116)$. Use the foci formula to find c^2 and c.

$$c^2 = a^2 + b^2$$
$$c^2 = 400 + 2116$$
$$c^2 = 2516$$
$$c \approx -50 \text{ and } c \approx 50$$

Since $a = 20$ and $|c| \approx 50$, the comet came within about $50 - 20 = 30$ million miles of the Sun.



Now try Exercises 81 through 84 ▶

EXAMPLE 8 ▶ **Applying the Properties of a Hyperbola—The Location of a Storm**

Two amateur meteorologists, living 4 km apart (4000 m), see a storm approaching. The one farthest from the storm hears a loud clap of thunder 9 sec after the one nearest. Assuming the speed of sound is 340 m/sec, determine an equation that models possible locations for the storm at this time.

Solution ▶ Let M_1 represent the meteorologist nearest the storm and M_2 the farthest. Since M_2 heard the thunder 9 sec after M_1, M_2 must be $9 \cdot 340 = 3060$ m farther away from the storm S. In other words, from our definition of a hyperbola, we have $|d_1 - d_2| = 3060$. The set of all points that satisfy this equation will be on the graph of a hyperbola, and we'll use this fact to develop an equation model for possible locations of the storm. Let's place the information on a coordinate grid. For convenience, we'll use the straight line distance between M_1 and M_2 as the x-axis, with the origin an equal distance from each. With the constant difference equal to 3060, we have $2a = 3060$, $a = 1530$ from the definition of a hyperbola, giving $\frac{x^2}{1530^2} - \frac{y^2}{b^2} = 1$. With $c = 2000$ m (the distance from the origin to M_1 or M_2), we find the value of b using

the equation $c^2 = a^2 + b^2$: $2000^2 = 1530^2 + b^2$ or $b^2 = (2000)^2 - (1530)^2 = 1{,}659{,}100 \approx 1288^2$. The equation that models possible locations of the storm is $\frac{x^2}{1530^2} - \frac{y^2}{1288^2} \approx 1$.

10.3 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. The line that passes through the vertices of a hyperbola is called the _____ axis.
2. The center of a hyperbola is located _____ between the vertices.
3. The conjugate axis is _____ to the _____ axis and contains the _____ of the hyperbola.
4. The center of the hyperbola defined by $\frac{(x-2)^2}{4^2} - \frac{(y-3)^2}{5^2} = 1$ is at _____.

5. Compare/Contrast the two methods used to find the asymptotes of a hyperbola. Include an example illustrating both methods.

6. Explore/Explain why $A(x-h)^2 - B(y-k)^2 = F$, $(A, B > 0)$ results in a hyperbola regardless of whether $A = B$ or $A \neq B$. Illustrate with an example.

▶ DEVELOPING YOUR SKILLS

Graph each hyperbola. Label the center, vertices, and any additional points used.

7. $\frac{x^2}{9} - \frac{y^2}{4} = 1$

8. $\frac{x^2}{16} - \frac{y^2}{9} = 1$

9. $\frac{x^2}{4} - \frac{y^2}{9} = 1$

10. $\frac{x^2}{25} - \frac{y^2}{16} = 1$

11. $\frac{x^2}{49} - \frac{y^2}{16} = 1$

12. $\frac{x^2}{25} - \frac{y^2}{9} = 1$

13. $\frac{x^2}{36} - \frac{y^2}{16} = 1$

14. $\frac{x^2}{81} - \frac{y^2}{16} = 1$

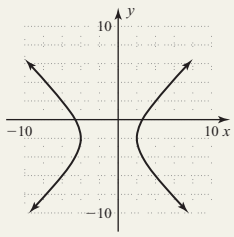
15. $\frac{y^2}{9} - \frac{x^2}{1} = 1$

16. $\frac{y^2}{1} - \frac{x^2}{4} = 1$

17. $\frac{y^2}{12} - \frac{x^2}{4} = 1$

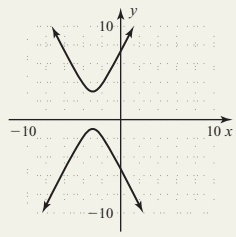
18. $\frac{y^2}{9} - \frac{x^2}{18} = 1$

19. $\frac{y^2}{9} - \frac{x^2}{9} = 1$



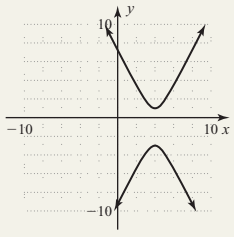
20. $\frac{y^2}{4} - \frac{x^2}{4} = 1$

21. $\frac{y^2}{36} - \frac{x^2}{25} = 1$

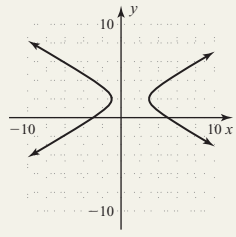


22. $\frac{y^2}{16} - \frac{x^2}{4} = 1$

For the graphs given, state the location of the vertices and the equation of the transverse axis. Then identify the location of the center and the equation of the conjugate axis. Note the scale used on each axis.



23.



24.

25.

26.

Sketch a complete graph of each equation, including the asymptotes. Be sure to identify the center and vertices.

27. $\frac{(y+1)^2}{4} - \frac{x^2}{25} = 1$

28. $\frac{y^2}{4} - \frac{(x-2)^2}{9} = 1$

29. $\frac{(x-3)^2}{36} - \frac{(y+2)^2}{49} = 1$

30. $\frac{(x-2)^2}{9} - \frac{(y-1)^2}{4} = 1$

31. $\frac{(y+1)^2}{7} - \frac{(x+5)^2}{9} = 1$

32. $\frac{(y-3)^2}{16} - \frac{(x+2)^2}{5} = 1$

33. $(x-2)^2 - 4(y+1)^2 = 16$

34. $9(x+1)^2 - (y-3)^2 = 81$

35. $2(y+3)^2 - 5(x-1)^2 = 50$

36. $9(y-4)^2 - 5(x-3)^2 = 45$

37. $12(x-4)^2 - 5(y-3)^2 = 60$

38. $8(x-4)^2 - 3(y-3)^2 = 24$

39. $16x^2 - 9y^2 = 144$

40. $16x^2 - 25y^2 = 400$

41. $9y^2 - 4x^2 = 36$

42. $25y^2 - 4x^2 = 100$

43. $12x^2 - 9y^2 = 72$

44. $36x^2 - 20y^2 = 180$

Graph each hyperbola by writing the equation in standard form. Label the center and vertices, and sketch the asymptotes. Then use a graphing calculator to graph each relation and locate four additional points whose coordinates are rational.

45. $4x^2 - y^2 + 40x - 4y + 60 = 0$

46. $x^2 - 4y^2 - 12x - 16y + 16 = 0$

47. $4y^2 - x^2 - 24y - 4x + 28 = 0$

48. $-9x^2 + 4y^2 - 18x - 24y - 9 = 0$

Classify each equation as that of a circle, ellipse, or hyperbola. Justify your response (assume all are nondegenerate).

49. $-4x^2 - 4y^2 = -24$

50. $9y^2 = -4x^2 + 36$

51. $x^2 + y^2 = 2x + 4y + 4$

52. $x^2 = y^2 + 6y - 7$

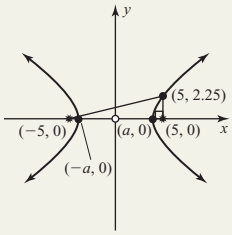
53. $2x^2 - 4y^2 = 8$

54. $36x^2 + 25y^2 = 900$

55. $x^2 + 5 = 2y^2$

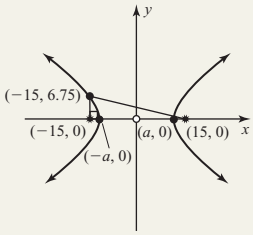
56. $x + y^2 = 3x^2 + 9$

57. $2x^2 = -2y^2 + x + 20$



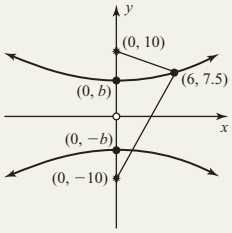
58. $2y^2 + 3 = 6x^2 + 8$

59. $16x^2 + 5y^2 - 3x + 4y = 538$

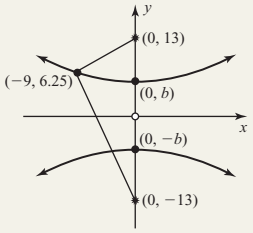


60. $9x^2 + 9y^2 - 9x + 12y + 4 = 0$

Use the definition of a hyperbola to find the distance between the vertices and the dimensions of the rectangle centered at (h, k). Figures are not drawn to scale. Note that Exercises 63 and 64 are *vertical hyperbolas*.



61.



62.

63.

64.

Write each equation in standard form to find and list the coordinates of the (a) center, (b) vertices, (c) foci, and (d) dimensions of the central rectangle. Then (e) sketch the graph, including the asymptotes.

65. $4x^2 - 9y^2 - 24x + 72y - 144 = 0$

66. $4x^2 - 36y^2 - 40x + 144y - 188 = 0$

67. $4y^2 - 16x^2 - 24y - 28 = 0$

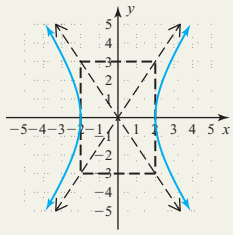
68. $4y^2 - 81x^2 - 162x - 405 = 0$

69. $9x^2 - 3y^2 - 54x - 12y + 33 = 0$

70. $10x^2 + 60x - 5y^2 + 20y - 20 = 0$

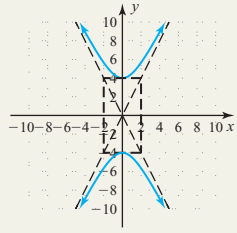
Find the equation of the hyperbola (in standard form) that satisfies the following conditions:

71. vertices at $(-6, 0)$ and $(6, 0)$; foci at $(-8, 0)$ and $(8, 0)$



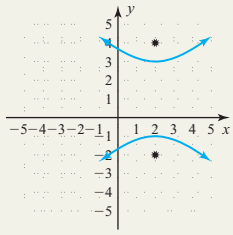
72. vertices at $(-4, 0)$ and $(4, 0)$; foci at $(-6, 0)$ and $(6, 0)$

73. foci at $(-2, -3\sqrt{2})$ and $(-2, 3\sqrt{2})$; length of conjugate axis: 6 units

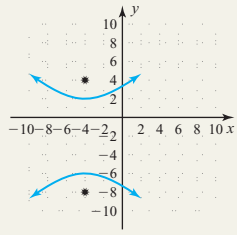


74. foci at $(-5, 2)$ and $(7, 2)$; length of conjugate axis: 8 units

Use the characteristics of a hyperbola and the graph given to write the related equation and state the location of the foci (75 and 76) or the dimensions of the central rectangle (77 and 78).



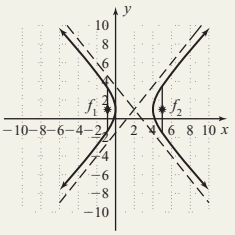
75.



76.

77.

78.



▶ WORKING WITH FORMULAS

79. Equation of a semi-hyperbola: $y = \sqrt{\dfrac{36 - 4x^2}{-9}}$

The "upper half" of a certain hyperbola is given by the equation shown. (a) Simplify the radicand, (b) state the domain of the expression, and (c) enter the expression as Y_1 on a graphing calculator and graph. What is the equation for the "lower half" of this hyperbola?

80. Focal chord of a hyperbola: $L = \dfrac{2m^2}{n}$

The focal chords of a hyperbola are line segments parallel to the conjugate axis with endpoints on the hyperbola, and containing points f_1 and f_2 (see grid). The length of the chord is given by the formula shown, where n is the distance from center to vertex and m is the distance from center to one side of the central rectangle. Use the formula to find the length of the focal chord for the hyperbola indicated, then compare the calculated value with the length estimated from the given graph:

$$\frac{(x-2)^2}{4} - \frac{(y-1)^2}{5} = 1.$$

▶ APPLICATIONS

81. Stunt pilots: At an air show, a stunt plane dives along a hyperbolic path whose vertex is directly over the grandstands. If the plane's flight path can be modeled by the hyperbola $25y^2 - 1600x^2 = 40{,}000$, what is the minimum altitude of the plane as it passes over the stands? Assume x and y are in yards.

82. Flying clubs: To test their skill as pilots, the members of a flight club attempt to drop sandbags on a target placed in an open field, by diving along a hyperbolic path whose vertex is directly over the target area. If the flight path of the plane flown by the club's president is modeled by $9y^2 - 16x^2 = 14{,}400$, what is the minimum altitude of her plane as it passes over the target? Assume x and y are in feet.

83. Charged particles: It has been shown that when like particles with a common charge are hurled at each other, they deflect and travel along paths that are hyperbolic. Suppose the paths of two such particles is modeled by the hyperbola $x^2 - 9y^2 = 36$. What is the minimum distance between the particles as they approach each other? Assume x and y are in microns.

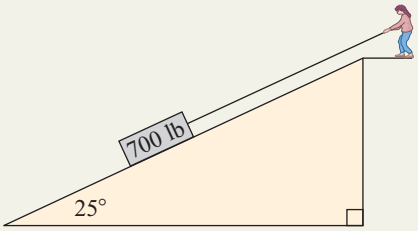
84. Nuclear cooling towers: The natural draft cooling towers for nuclear power stations are called *hyperboloids of one sheet.* The perpendicular cross sections of these hyperboloids form two branches of a hyperbola. Suppose the central cross section of one such tower is modeled by the hyperbola $1600x^2 - 400(y - 50)^2 = 640{,}000$. What is the minimum distance between the sides of the tower? Assume x and y are in feet.

85. Locating a ship using radar: Under certain conditions, the properties of a hyperbola can be used to help locate the position of a ship. Suppose two radio stations are located 100 km apart along a straight shoreline. A ship is sailing parallel to the shore and is 60 km out to sea. The ship sends out a distress call that is picked up by the closer station in 0.4 milliseconds (msec—one-thousandth of a second), while it takes 0.5 msec to reach the station that is farther away. Radio waves travel at a speed of approximately 300 km/msec. Use this information to find the equation of a hyperbola that will help you find the location of the ship, then find the coordinates of the ship. (*Hint:* Draw the hyperbola on a coordinate system with the radio stations on the x-axis at the foci, then use the definition of a hyperbola.)

86. Locating a plane using radar: Two radio stations are located 80 km apart along a straight shoreline, when a "Mayday" call (a plea for immediate help) is received from a plane that is about to ditch in the ocean (attempt a water landing). The plane was flying at low altitude, parallel to the shoreline, and 20 km out when it ran into trouble. The plane's distress call is picked up by the closer station in 0.1 msec, while it takes 0.3 msec to reach the other. Use this information to construct the equation of a hyperbola that will help you find the location of the ditched plane, then find the coordinates of the plane. Also see Exercise 85.

▶ EXTENDING THE CONCEPT

87. For a greater understanding as to *why* the branches of a hyperbola are asymptotic, solve $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$ for y, then consider what happens as $x \to \infty$ (note that $x^2 - k \approx x^2$ for large x).



88. Which has a greater area: (a) The central rectangle of the hyperbola given by $(x - 5)^2 - (y + 4)^2 = 57$, (b) the circle given by $(x - 5)^2 + (y + 4)^2 = 57$, or (c) the ellipse given by $9(x - 5)^2 + 10(y + 4)^2 = 570$?

89. It is possible for the plane to intersect only the vertex of the cone or to be tangent to the sides. These are called **degenerate cases** of a conic section. Many times we're unable to tell if the equation represents a degenerate case until it's written in standard form. Write the following equations in standard form and comment.

a. $4x^2 - 32x - y^2 + 4y + 60 = 0$ **b.** $x^2 - 4x + 5y^2 - 40y + 84 = 0$

▶ MAINTAINING YOUR SKILLS

90. (8.3) In weight-lifting competitions, Ursula Unger has shown she can lift up to 350 lb. Use a vector analysis to determine whether she will be able to pull the crate up the frictionless ramp shown.

91. (6.1) The wheels on a motorized scooter are rotating at 403 rpm. If the wheels have a 2.5 in. radius, how fast is the scooter traveling in miles per hour?

92. (4.2) The number $z = 1 + i\sqrt{2}$ is a solution to two out of the three equations given. Which two?

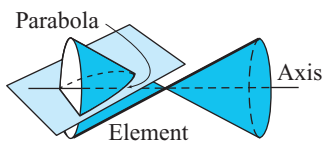
a. $x^4 + 4 = 0$

b. $x^3 - 6x^2 + 11x - 12 = 0$

c. $x^2 - 2x + 3 = 0$

93. (9.3) A government-approved company is licensed to haul toxic waste. Each container of solid waste weighs 800 lb and has a volume of 100 ft^3. Each container of liquid waste weighs 1000 lb and is 60 ft^3 in volume. The revenue from hauling solid waste is \$300 per container, while the revenue from liquid waste is \$350 per container. The truck used by this company has a weight capacity of 39.8 tons and a volume capacity of 6960 ft^3. What combination of solid and liquid waste containers will produce the maximum revenue?

10.4 The Analytic Parabola



LEARNING OBJECTIVES

In Section 10.4 you will see how we can:

- ❑ **A.** Graph parabolas with a horizontal axis of symmetry
- ❑ **B.** Identify and use the focus-directrix form of the equation of a parabola
- ❑ **C.** Solve applications of the analytic parabola

In previous coursework, you likely learned that the graph of a quadratic function was a parabola. Parabolas are actually the fourth and final member of the family of conic sections, and as we saw in Section 10.1, the graph can be obtained by observing the intersection of a plane and a cone. If the plane is parallel to the generator of the cone (shown as a dark line in Figure 10.36), the intersection of the plane with one nappe forms a parabola. In this section we develop the general equation of a parabola from its analytic definition, opening a new realm of applications that extends far beyond those involving only zeroes and extreme values.

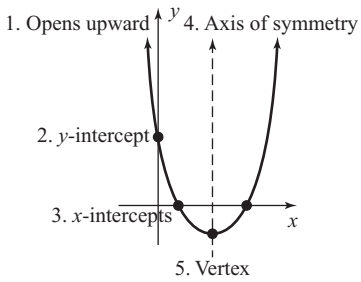


Figure 10.36

A. Parabolas with a Horizontal Axis

An introductory study of parabolas generally involves those with a vertical axis, defined by the equation $y = ax^2 + bx + c$. Unlike the previous conic sections, this equation has *only one second-degree (squared) term in x* and defines a function. As a

Figure 10.37

review, the primary characteristics are listed here and illustrated in Figure 10.37. **See Exercises 7 through 12.**

Vertical Parabolas

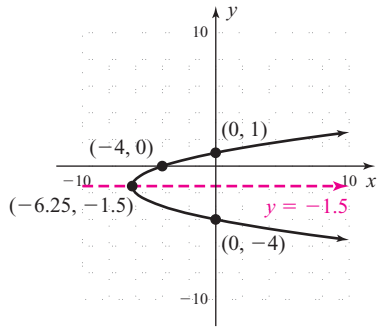
For a second-degree equation of the form $y = ax^2 + bx + c$, the graph is a vertical parabola with these characteristics:

1. opens upward if $a > 0$, downward if $a < 0$.
2. y-intercept: $(0, c)$ (substitute 0 for x)
3. x-intercept(s): substitute 0 for y and solve.
4. axis of symmetry: $x = \dfrac{-b}{2a}$
5. vertex: $(h, k) = \left(\dfrac{-b}{2a}, \dfrac{4ac - b^2}{4a}\right)$

Horizontal Parabolas

Similar to our study of horizontal and vertical hyperbolas, the graph of a parabola can open *to the right or left,* as well as up or down. After interchanging the variables x and y in the standard equation, we obtain the parabola $x = ay^2 + by + c$, noting the resulting graph will be a reflection about the line $y = x$. Here, the axis of symmetry is a horizontal line and factoring or the quadratic formula is used to find the *y-intercepts* (if they exist). Note that although the graph is still a parabola—*it is not the graph of a function.*

Horizontal Parabolas



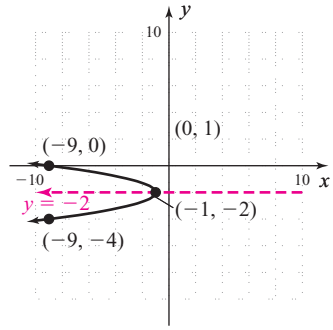
For a second-degree equation of the form $x = ay^2 + by + c$, the graph is a horizontal parabola with these characteristics:

1. opens right if $a > 0$, left if $a < 0$.
2. x-intercept: $(c, 0)$ (substitute 0 for y)
3. y-intercept(s): substitute 0 for x and solve.
4. axis of symmetry: $y = \dfrac{-b}{2a}$
5. vertex: $(h, k) = \left(\dfrac{4ac - b^2}{4a}, \dfrac{-b}{2a}\right)$

EXAMPLE 1 ▶ **Graphing a Horizontal Parabola**

Graph the relation whose equation is $x = y^2 + 3y - 4$, then state the domain and range of the relation.

Solution ▶ Since the equation has a single squared term in y, the graph will be a horizontal parabola. With $a > 0$ ($a = 1$), the parabola opens to the right. The x-intercept is $(-4, 0)$. Factoring shows the y-intercepts are $y = -4$ and $y = 1$. The axis of symmetry is $y = \frac{-3}{2} = -1.5$, and substituting this value into the original equation gives $x = -6.25$. The coordinates of the vertex are $(-6.25, -1.5)$. Using horizontal and vertical boundary lines we find the domain for this relation is $x \in [-6.25, \infty)$ and the range is $y \in (-\infty, \infty)$. The graph is shown.



Now try Exercises 13 through 18 ▶

As with the vertical parabola, the equation of a horizontal parabola can be written as a transformation: $x = a(y \pm k)^2 \pm h$ by completing the square. Note that in this case, the vertical shift is k units *opposite the sign,* with a horizontal shift of h units in the same direction as the sign.

EXAMPLE 2 ▶ Graphing a Horizontal Parabola by Completing the Square

Graph by completing the square: $x = -2y^2 - 8y - 9$, then state the domain and range.

Solution ▶ Using the original equation, we note the graph will be a horizontal parabola opening to the left ($a = -2$) and have an x-intercept of $(-9, 0)$. Completing the square gives $x = -2(y^2 + 4y + 4) - 9 + 8$, so the equation of this parabola in shifted form is

$$x = -2(y + 2)^2 - 1$$

The vertex is at $(-1, -2)$ and $y = -2$ is the axis of symmetry. This means there are no y-intercepts, a fact that comes to light when we attempt to solve the equation after substituting 0 for x:

$$-2(y + 2)^2 - 1 = 0 \quad \text{substitute 0 for } x$$

$$(y + 2)^2 = -\frac{1}{2} \quad \text{no real roots}$$

Using symmetry, the point $(-9, -4)$ is also on the graph. After plotting these points we obtain the graph shown. From the graph, the domain is $x \in (-\infty, -1]$ and the range is $y \in \mathbb{R}$.

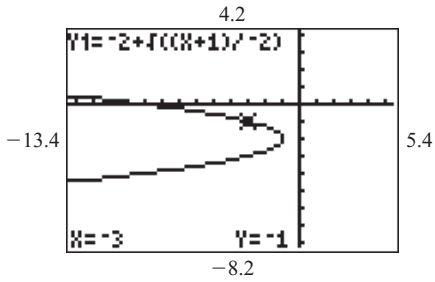
Now try Exercises 19 through 36 ▶

As with the other relations graphed in this chapter, a horizontal parabola also fails the vertical line test and we must graph the relation in two pieces. Using the equation from Example 2 we have

$$x = -2(y + 2)^2 - 1 \quad \text{shifted form}$$

$$x + 1 = -2(y + 2)^2 \quad \text{isolate } y\text{-term}$$

$$\frac{x + 1}{-2} = (y + 2)^2 \quad \text{divide by } -2$$



$$\pm\sqrt{\frac{x + 1}{-2}} = y + 2 \quad \text{take square roots}$$

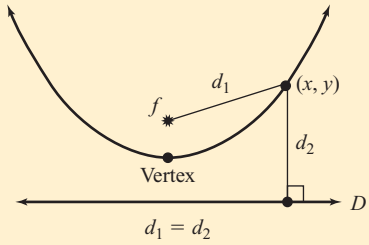
$$-2 \pm \sqrt{\frac{x + 1}{-2}} = y \quad \text{solve for } y$$

$$Y_1 = -2 + \sqrt{\frac{X + 1}{-2}}, Y_2 = -2 - \sqrt{\frac{X + 1}{-2}}$$

The graph is given in Figure 10.38, and shows that $(-3, -1)$ is also a point on the graph.

Figure 10.38

A. You've just seen how we can graph parabolas with a horizontal axis of symmetry



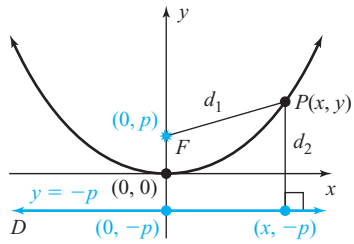
B. The Focus-Directrix Form of the Equation of a Parabola

As with the ellipse and hyperbola, many significant applications of the parabola rely on its analytical definition rather than its algebraic form. From the construction of radio telescopes to the manufacture of flashlights, the location of the focus of a parabola is

critical. To understand these and other applications, we use the analytic definition of a parabola first introduced in Section 10.1.

Definition of a Parabola

Given a fixed point f and fixed line D in the plane, a parabola is the set of all points (x, y) such that the distance from f to (x, y) is equal to the distance from line D to (x, y). The fixed point f is the **focus** of the parabola, and the fixed line is the **directrix.**



WORTHY OF NOTE

For the analytic parabola, we use p to designate the focus since c is so commonly used as the constant term in $y = ax^2 + bx + c$.

The general equation of a parabola can be obtained by combining this definition with the distance formula. With no loss of generality, we can assume the parabola shown in the definition box is oriented in the plane with the vertex at $(0, 0)$ and the focus at $(0, p)$. As the diagram in Figure 10.39 indicates, this gives the directrix an equation of $y = -p$ with all points on D having coordinates of $(x, -p)$. Using $d_1 = d_2$ the distance formula yields

Figure 10.39

$$\sqrt{(x-0)^2 + (y-p)^2} = \sqrt{(x-x)^2 + (y+p)^2} \quad \text{from the definition}$$
$$(x-0)^2 + (y-p)^2 = (x-x)^2 + (y+p)^2 \quad \text{square both sides}$$
$$x^2 + y^2 - 2py + p^2 = 0 + y^2 + 2py + p^2 \quad \text{simplify; expand binomials}$$
$$x^2 - 2py = 2py \quad \text{subtract } p^2 \text{ and } y^2$$
$$x^2 = 4py \quad \text{isolate } x^2$$

The resulting equation is called the **focus-directrix form** of a *vertical parabola* with center at $(0, 0)$. If we had begun by orienting the parabola so it opened to the right, we would have obtained the equation of a *horizontal parabola* with center $(0, 0)$: $y^2 = 4px$.

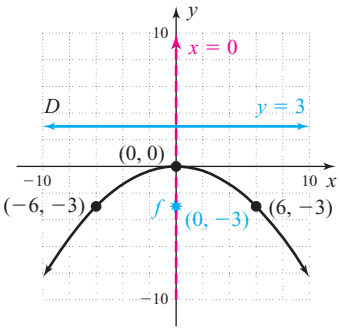
The Equation of a Parabola in Focus-Directrix Form

Vertical Parabola	**Horizontal Parabola**
$x^2 = 4py$	$y^2 = 4px$
focus $(0, p)$, directrix: $y = -p$	focus at $(p, 0)$, directrix: $x = -p$
If $p > 0$, opens upward.	If $p > 0$, opens to the right.
If $p < 0$, opens downward.	If $p < 0$, opens to the left.

For a parabola, note there is only one second-degree term.

EXAMPLE 3 ▶ **Locating the Focus and Directrix of a Parabola**

Find the vertex, focus, and directrix for the parabola defined by $x^2 = -12y$. Then sketch the graph, including the focus and directrix.

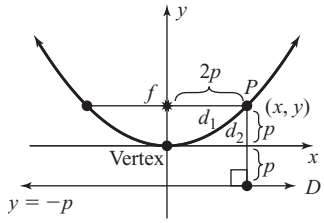


Solution ▶ Since the x-term is squared and no shifts have been applied, the graph will be a vertical parabola with a vertex of $(0, 0)$. Use a direct comparison between the given

equation and the focus-directrix form to determine the value of p:

$$\begin{aligned} x^2 &= -12y && \text{given equation} \\ &\downarrow \\ x^2 &= 4py && \text{focus-directrix form} \end{aligned}$$

This shows:



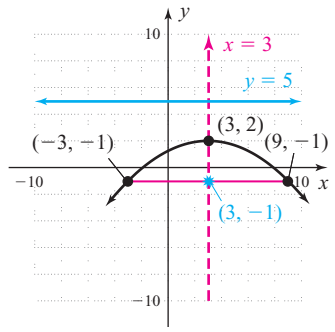
$$\begin{aligned} 4p &= -12 \\ p &= -3 \end{aligned}$$

Since $p = -3$ ($p < 0$), the parabola opens downward, with the focus at $(0, -3)$ and directrix $y = 3$. To complete the graph we need a few additional points. Since 36 is divisible by 12, we can use inputs of $x = 6$ and $x = -6$ $[(-6)^2 = 6^2 = 36]$, giving the points $(6, -3)$ and $(-6, -3)$. Note the axis of symmetry is $x = 0$. The graph is shown.

Now try Exercises 37 through 48 ▶

Figure 10.40

As an alternative to calculating additional points to sketch the graph, we can use what is called the **focal chord** of the parabola. Similar to the ellipse and hyperbola, the focal chord is the line segment that contains the focus, is parallel to the directrix, and has its endpoints on the graph. Using the definition of a parabola and the diagram in Figure 10.40, we note the vertical distance from (x, y) to the directrix $y = -p$ is $2p$. Since $d_1 = d_2$ a line segment parallel to the directrix from the focus to the graph will also have a length of $|2p|$, and the focal chord of any parabola has a total length of $|4p|$. Note that in Example 3, the points we happened to choose were actually the endpoints of the focal chord.



Finally, if the vertex of a vertical parabola is shifted to (h, k), the equation will have the form $(x \pm h)^2 = 4p(y \pm k)$. As with the other conic sections, both the horizontal and vertical shifts are "opposite the sign."

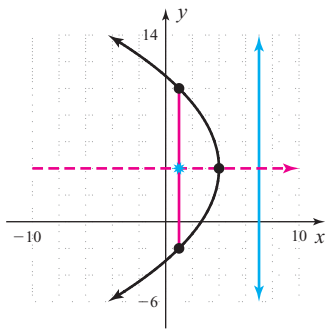
EXAMPLE 4 ▶ **Locating the Focus and Directrix of a Parabola**

Find the vertex, focus, and directrix for the parabola whose equation is given, then sketch the graph, including the focus, focal chord, and directrix:
$x^2 - 6x + 12y - 15 = 0$.

Solution ▶ Since only the x-term is squared, the graph will be a vertical parabola. To find the end-behavior, vertex, focus, and directrix, we complete the square in x and use a direct comparison between the shifted form and the focus-directrix form:

$$\begin{aligned} x^2 - 6x + 12y - 15 &= 0 && \text{given equation} \\ x^2 - 6x + ___ &= -12y + 15 && \text{complete the square in } x \\ x^2 - 6x + 9 &= -12y + 24 && \text{add 9} \\ (x - 3)^2 &= -12(y - 2) && \text{factor} \end{aligned}$$

Notice the parabola has been shifted 3 units right and 2 up, so *all features of the parabola will likewise be shifted.* Since we have $4p = -12$ (the coefficient of the linear term), we know $p = -3$ ($p < 0$) and the parabola opens downward. If the parabola were in standard position, the vertex would be at $(0, 0)$, the focus at $(0, -3)$ and the directrix a horizontal line at $y = 3$. But since the parabola is shifted 3 right and 2 up, we add 3 to all x-values and 2 to all y-values to locate the features of the shifted parabola. The vertex is at $(0 + 3, 0 + 2) = (3, 2)$. The focus is $(0 + 3, -3 + 2) = (3, -1)$ and the directrix is $y = 3 + 2 = 5$. Finally, the horizontal distance from the focus to the graph is $|2p| = 6$ units (since $|4p| = 12$), giving us the additional points $(-3, -1)$ and $(9, -1)$ as endpoints of the focal chord. The graph is shown.



Now try Exercises 49 through 60 ▶

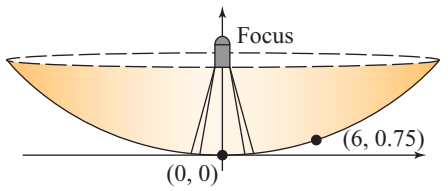
In many cases, we need to construct the equation of the parabola when only partial information in known, as illustrated in Example 5.

EXAMPLE 5 ▶ **Constructing the Equation of a Parabola**

Find the equation of the parabola with vertex (4, 4) and focus (1, 4). Then graph the parabola using the equation and focal chord.

Solution ▶ As the vertex and focus are on a horizontal line, we have a horizontal parabola with general equation $(y \pm k)^2 = 4p(x \pm h)$. The distance p from vertex to focus is 3 units, and with the focus to the left of the vertex, the parabola opens left so $p = -3$. Using the focal chord, the vertical distance from (1, 4) to the graph is $|2p| = |2(-3)| = 6$, giving points (1, 10) and (1, −2). The vertex is shifted 4 units right and 4 units up from (0, 0), showing $h = 4$ and $k = 4$, and the equation of the parabola must be $(y - 4)^2 = -12(x - 4)$, with directrix $x = 7$. The graph is shown.

Now try Exercises 61 through 76 ▶



B. You've just seen how we can identify and use the focus-directrix form of the equation of a parabola

C. Application of the Analytic Parabola

Here is just one of the many ways the analytic definition of a parabola can be applied. There are several others in the Exercise Set. Many applications use the parabolic property that light or sound coming in parallel to the axis of a parabola will be reflected to the focus.

EXAMPLE 6 ▶ **Locating the Focus of a Parabolic Receiver**

The diagram shows the cross section of a radio antenna dish. Engineers have located a point on the cross section that is 0.75 m above and 6 m to the right of the vertex. At what coordinates should the engineers build the focus of the antenna?

Solution ▶ By inspection we see this is a vertical parabola with center at (0, 0). This means its equation must be of the form $x^2 = 4py$. Because we know (6, 0.75) is a point on this graph, we can substitute (6, 0.75) in this equation and solve for p:

$x^2 = 4py$		equation for vertical parabola, vertex at (0, 0)
$(6)^2 = 4p(0.75)$		substitute 6 for x and 0.75 for y
$36 = 3p$		simplify
$p = 12$		result

With $p = 12$, we see that the focus must be located at (0, 12), or 12 m directly above the vertex.

Now try Exercises 79 through 86 ▶

C. You've just seen how we can solve applications of the analytic parabola

Note that in many cases, the focus of a parabolic dish may be above the rim of the dish.

10.4 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. The equation $x = ay^2 + by + c$ is that of a(n) _____ parabola, opening to the _____ if $a > 0$ and to the left if _____.
2. If point P is on the graph of a parabola with directrix D, the distance from P to line D is equal to the distance between P and the _____.
3. Given $y^2 = 4px$, the focus is at _____ and the equation of the directrix is _____.
4. Given $x^2 = -16y$, the value of p is _____ and the coordinates of the focus are _____.
5. Discuss/Explain how to find the vertex, directrix, and focus from the equation $(x - h)^2 = 4p(y - k)$.
6. If a horizontal parabola has a vertex of $(2, -3)$ with $a > 0$, what can you say about the y-intercepts? Will the graph always have an x-intercept? Explain.

▶ DEVELOPING YOUR SKILLS

Find the x- and y-intercepts (if they exist) and the vertex of the parabola. Then sketch the graph by using symmetry and a few additional points or completing the square and shifting a parent function. Scale the axes as needed to comfortably fit the graph and state the domain and range.

7. $y = x^2 - 2x - 3$
8. $y = x^2 + 6x + 5$
9. $y = -2x^2 + 8x + 10$
10. $y = -3x^2 - 12x + 15$
11. $y = 2x^2 + 5x - 7$
12. $y = 2x^2 - 7x + 3$

Find the x- and y-intercepts (if they exist) and the vertex of the graph. Then sketch the graph using symmetry and a few additional points (scale the axes as needed). Finally, state the domain and range of the relation.

13. $x = y^2 - 2y - 3$
14. $x = y^2 - 4y - 12$
15. $x = -y^2 + 6y + 7$
16. $x = -y^2 + 8y - 12$
17. $x = -y^2 + 8y - 16$
18. $x = -y^2 + 6y - 9$

Sketch by completing the square and using symmetry and shifts of a basic function. Be sure to find the x- and y-intercepts (if they exist) and the vertex of the graph, then state the domain and range of the relation.

19. $x = y^2 - 6y$
20. $x = y^2 - 8y$
21. $x = y^2 - 4$
22. $x = y^2 - 9$
23. $x = -y^2 + 2y - 1$
24. $x = -y^2 + 4y - 4$
25. $x = y^2 + y - 6$
26. $x = y^2 + 4y - 5$
27. $x = y^2 - 10y + 4$
28. $x = y^2 + 12y - 5$
29. $x = 3 - 8y - 2y^2$
30. $x = 2 - 12y + 3y^2$
31. $y = (x - 2)^2 + 3$
32. $y = (x + 2)^2 - 4$
33. $x = (y - 3)^2 + 2$
34. $x = (y + 1)^2 - 4$
35. $x = 2(y - 3)^2 + 1$
36. $x = -2(y + 3)^2 - 5$

Find the vertex, focus, and directrix for the parabolas defined by the equations given, then use this information to sketch a complete graph (illustrate and name these features). For Exercises 49 to 60, also include the focal chord.

37. $x^2 = 8y$
38. $x^2 = 16y$
39. $x^2 = -24y$
40. $x^2 = -20y$
41. $x^2 = 6y$
42. $x^2 = 18y$
43. $y^2 = -4x$
44. $y^2 = -12x$
45. $y^2 = 18x$
46. $y^2 = 20x$
47. $y^2 = -10x$
48. $y^2 = -14x$
49. $x^2 - 8x - 8y + 16 = 0$
50. $x^2 - 10x - 12y + 25 = 0$
51. $x^2 - 14x - 24y + 1 = 0$
52. $x^2 - 10x - 12y + 1 = 0$
53. $3x^2 - 24x - 12y + 12 = 0$
54. $2x^2 - 8x - 16y - 24 = 0$
55. $y^2 - 12y - 20x + 36 = 0$

56. $y^2 - 6y - 16x + 9 = 0$

57. $y^2 - 6y + 4x + 1 = 0$

58. $y^2 - 2y + 8x + 9 = 0$

59. $2y^2 - 20y + 8x + 2 = 0$

60. $3y^2 - 18y + 12x + 3 = 0$

For Exercises 61–72, find the equation of the parabola in standard form that satisfies the conditions given.

61. focus: $(0, 2)$
directrix: $y = -2$

62. focus: $(0, -3)$
directrix: $y = 3$

63. focus: $(4, 0)$
directrix: $x = -4$

64. focus: $(-3, 0)$
directrix: $x = 3$

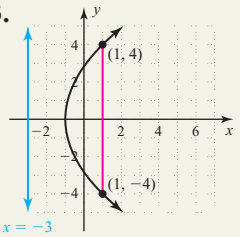
65. focus: $(0, -5)$
directrix: $y = 5$

66. focus: $(5, 0)$
directrix: $x = -5$

67. vertex: $(2, -2)$
focus: $(-1, -2)$

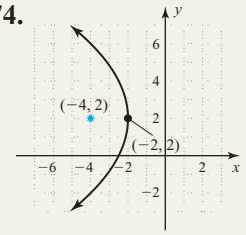
68. vertex: $(4, 1)$
focus: $(1, 1)$

69. vertex: $(4, -7)$
focus: $(4, -4)$



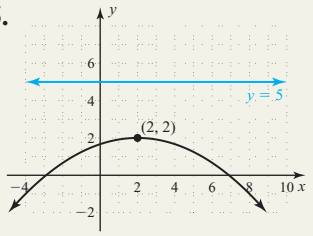
70. vertex: $(-3, -4)$
focus: $(-3, -1)$

71. focus: $(3, 4)$
directrix: $y = 0$

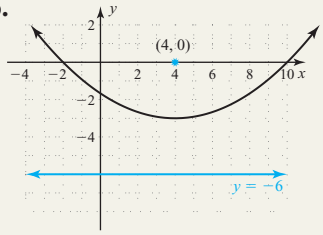


72. focus: $(-1, 2)$
directrix: $x = -5$

For the graphs in Exercises 73–76, only two of the following four features are displayed: vertex, focus, directrix, and endpoints of the focal chord. Find the remaining two features and the equation of the parabola.

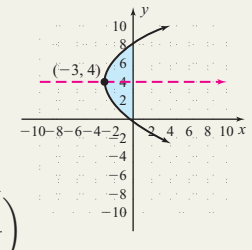


73.



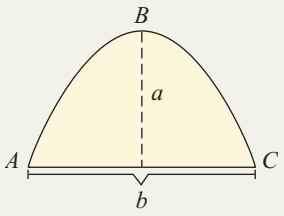
74.

75.



76.

▶ WORKING WITH FORMULAS



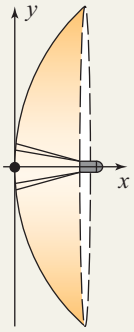
77. The area of a right parabolic segment: $A = \frac{2}{3}ab$

A *right parabolic segment* is that part of a parabola formed by a line perpendicular to its axis, which cuts the parabola. The area of this segment is given by the formula shown, where b is the length of the chord cutting the parabola and a is the perpendicular distance from the vertex to this chord. What is the area of the parabolic segment shown in the figure?

78. The arc length of a right parabolic segment: $\frac{1}{2}\sqrt{b^2 + 16a^2} + \frac{b^2}{8a}\ln\left(\frac{4a + \sqrt{b^2 + 16a^2}}{b}\right)$

Although a fairly simple concept, finding the length of the parabolic arc traversed by a projectile requires a good deal of computation. To find the length of the arc ABC shown, we use the formula given where a is the maximum height attained by the projectile, b is the horizontal distance it traveled, and "ln" represents the natural log function. Suppose a baseball thrown from centerfield reaches a maximum height of 20 ft and traverses an arc length of 340 ft. Will the ball reach the catcher 310 ft away without bouncing?

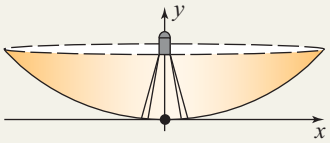
▶ APPLICATIONS



79. Parabolic car headlights: The cross section of a typical car headlight can be modeled by an equation similar to $25x = 16y^2$, where x and y are in inches and $x \in [0, 4]$. Use this information to graph the relation for the indicated domain.

80. Parabolic flashlights: The cross section of a typical flashlight reflector can be modeled by an equation similar to $4x = y^2$, where x and y are in centimeters and $x \in [0, 2.25]$. Use this information to graph the relation for the indicated domain.

81. Parabolic sound receivers: Sound technicians at professional sports events often use parabolic receivers as they move along the sidelines. If a two-dimensional cross section of the receiver is modeled by the equation $y^2 = 54x$, and is 36 in. in *diameter,* how deep is the parabolic receiver? What is the location of the focus? [*Hint:* Graph the parabola on the coordinate grid (scale the axes).]



Exercise 81

82. Parabolic sound receivers: Private investigators will often use a smaller and less expensive parabolic receiver (see Exercise 81) to gather information for their clients. If a two-dimensional cross section of the receiver is modeled by the equation $y^2 = 24x$, and the receiver is 12 in. in *diameter,* how deep is the parabolic dish? What is the location of the focus?

83. Parabolic radio wave receivers: The program known as S.E.T.I. (Search for Extra-Terrestrial Intelligence) involves a group of scientists using radio telescopes to look for radio signals from possible intelligent species in outer space. The radio telescopes are actually parabolic dishes that vary in size from a few feet to hundreds of feet in diameter. If a particular radio telescope is 100 ft in diameter and has a cross section modeled by the equation $x^2 = 167y$, how deep is the parabolic dish? What is the location of the focus? [*Hint:* Graph the parabola on the coordinate grid (scale the axes).]

84. Solar furnace: Another form of technology that uses a parabolic dish is called a solar furnace. In general, the rays of the Sun are reflected by the dish and concentrated at the focus, producing extremely high temperatures. Suppose the dish of one of these parabolic reflectors has a 30-ft diameter and a cross section modeled by the equation $x^2 = 50y$. How deep is the parabolic dish? What is the location of the focus?

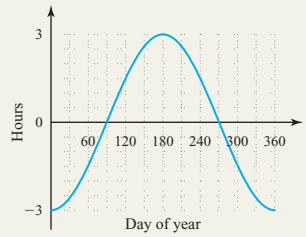
85. Commercial flashlights: The reflector of a large, commercial flashlight has the shape of a parabolic dish, with a diameter of 10 cm and a depth of 5 cm. What equation will the engineers and technicians use for the manufacture of the dish? How far from the vertex (the lowest point of the dish) will the bulb be placed? (*Hint:* Analyze the information using a coordinate system.)

86. Industrial spotlights: The reflector of an industrial spotlight has the shape of a parabolic dish with a diameter of 120 cm. What is the depth of the dish if the correct placement of the bulb is 11.25 cm above the vertex (the lowest point of the dish)? What equation will the engineers and technicians use for the manufacture of the dish? (*Hint:* Analyze the information using a coordinate system.)

▶ EXTENDING THE CONCEPT

87. In a study of quadratic graphs from the equation $y = ax^2 + bx + c$, no mention is made of a parabola's focus and directrix. Generally, when $a \geq 1$, the focus of a parabola is very near its vertex. Complete the square of the function $y = 2x^2 - 8x$ and write the result in the form $(x - h)^2 = 4p(y - k)$. What is the value of p? What are the coordinates of the vertex?

88. Like the ellipse and hyperbola, the focal chord of a parabola (also called the **latus rectum**) can be used to help sketch its graph. From our earlier work, we know the endpoints of the focal chord are $2p$ units from the focus. Write the equation $-12y + 15 = x^2 - 6x$ in the form $4p(y \pm k) = (x \pm h)^2$, and use the endpoints of the focal chord to help graph the parabola.



▶ MAINTAINING YOUR SKILLS

89. **(4.2/4.3)** Use the function $f(x) = x^5 + 2x^4 + 17x^3 + 34x^2 - 18x - 36$ to comment and give illustrations of the tools available for working with polynomials: (a) synthetic division, (b) rational roots theorem, (c) the remainder and factor theorems, (d) the test for $x = -1$ and $x = 1$, (e) the upper/lower bounds property, (f) Descartes' rule of signs, and (g) roots of multiplicity (bounces, cuts, alternating intervals).

90. **(3.1/4.2)** Find all roots (real and complex) to the equation $x^6 - 64 = 0$. (*Hint:* Begin by factoring the expression as the difference of two perfect squares.)

91. **(7.6)** Find all real solutions to $\sec\theta = 1.1547$ (round to the nearest degree).

92. **(6.3)** The graph shown displays the variation in daylight from an average of 12 hours per day (i.e., the maximum is 15 hours and the minimum is 9). Use the graph to *approximate* the number of days in a year there are 10.5 or less hours of daylight. Answers may vary.

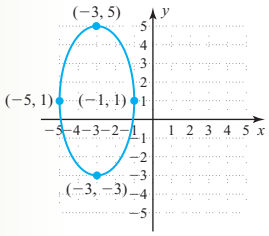
MID-CHAPTER CHECK

Sketch the graph of each conic section.

1. $(x - 4)^2 + (y + 3)^2 = 9$

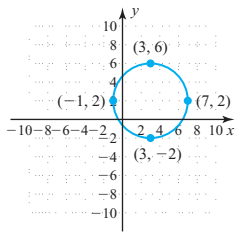
2. $x^2 + y^2 - 10x + 4y + 4 = 0$

3. $\dfrac{(x-2)^2}{16} + \dfrac{(y+3)^2}{1} = 1$



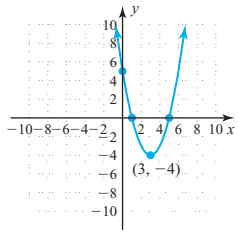
4. $9x^2 + 4y^2 + 18x - 24y + 9 = 0$

5. $\dfrac{(x+3)^2}{9} - \dfrac{(y-4)^2}{4} = 1$



6. $9x^2 - 4y^2 + 18x - 24y - 63 = 0$

7. Find the equation of each relation and state its domain and range.



a.

b.

c.

8. Find the equation of a parabola with focus $(-1, 2)$ and directrix $x = 2$.

9. Find the equation of the ellipse (in standard form) if the vertices are $(-4, 0)$ and $(4, 0)$ and the distance between the foci is $4\sqrt{3}$ units.

10. The radio signal emanating from a tall radio tower spreads evenly in all directions with a range of 50 mi. If the tower is located at coordinates (20, 30) and my home is at coordinates (10, 78), will I be able to pick up this station on my home radio? Assume coordinates are in miles.

REINFORCING BASIC CONCEPTS

More on Completing the Square

From our work so far in Chapter 10, we realize the process of *completing the square* has much greater use than simply as a tool for working with quadratic equations. It is a valuable tool in the application of the conic sections, as well as other areas. The purpose of this *Reinforcing Basic Concepts* is to strengthen the ability and confidence needed to apply the process correctly. This is important because in some cases the values of a and b are rational or irrational numbers. No matter what the context,

1. **The process begins *with a coefficient of 1.*** For $20x^2 + 120x + 27y^2 - 54y + 192 = 0$, we recognize the equation of an ellipse, since the coefficients of the squared terms are positive and unequal. To study or graph this ellipse, we'll use the standard form to identify the values of a, b, and c. Grouping the like-variable terms gives

$$(20x^2 + 120x \quad) + (27y^2 - 54y \quad) + 192 = 0$$

and to complete the square, we factor out the lead coefficient of each group (to get a coefficient of 1):

$$20(x^2 + 6x \quad) + 27(y^2 - 2y \quad) + 192 = 0$$

Subtracting 192 from both sides brings us to the fundamental step for completing the square.

2. **The quantity $\left(\frac{1}{2} \cdot \textit{linear cofficient}\right)^2$ will complete a trinomial square.** For this example we obtain $\left(\frac{1}{2} \cdot 6\right)^2 = 9$ for x, and $\left(\frac{1}{2} \cdot -2\right)^2 = 1$ for y, with these numbers inserted in the appropriate group:

$$20(x^2 + 6x + 9) + 27(y^2 - 2y + 1) = -192 \quad \text{complete the square}$$

Due to the distributive property, we have in effect added $20 \cdot 9 = 180$ and $27 \cdot 1 = 27$ (for a total of 207) to the left side of the equation:

$$\underset{\substack{\text{adds } 20 \cdot 9 = 180 \\ \text{to left side}}}{20(x^2 + 6x + 9)} + \underset{\substack{\text{adds } 27 \cdot 1 = 27 \\ \text{to left side}}}{27(y^2 - 2y + 1)} = -192$$

This brings us to the final step.

3. **Keep the equation in balance.** Since the left side was increased by 207, we also increase the right side by 207.

$$\underset{\substack{\text{adds } 20 \cdot 9 = 180 \\ \text{to left side}}}{20(x^2 + 6x + 9)} + \underset{\substack{\text{adds } 27 \cdot 1 = 27 \\ \text{to left side}}}{27(y^2 - 2y + 1)} = -192 + \underset{\substack{\text{add } 180 + 27 = 207 \\ \text{to right side}}}{207}$$

The quantities in parentheses factor, giving $20(x + 3)^2 + 27(y - 1)^2 = 15$. We then divide by 15 and simplify, obtaining the standard form $\frac{4(x + 3)^2}{3} + \frac{9(y - 1)^2}{5} = 1$. Note the coefficient of each binomial square is not 1, even after setting the equation equal to 1. In the *Strengthening Core Skills* feature of this chapter, we'll look at how to write equations of this type in standard form to obtain the values of a and b. For now, practice completing the square using these exercises.

Exercise 1: $100x^2 - 400x + 18y^2 - 108y + 554 = 0$
Exercise 2: $28x^2 - 56x + 48y^2 + 192y + 195 = 0$

10.5 Nonlinear Systems of Equations and Inequalities

LEARNING OBJECTIVES

In Section 10.5 you will see how we can:

- ❑ **A.** Visualize possible solutions
- ❑ **B.** Solve nonlinear systems using substitution
- ❑ **C.** Solve nonlinear systems using elimination
- ❑ **D.** Solve systems of nonlinear inequalities
- ❑ **E.** Solve applications of nonlinear systems

Equations where the variables have exponents other than 1 or that are transcendental (like logarithmic and exponential equations), are all *nonlinear* equations. A nonlinear system of equations has at least one nonlinear equation, and these systems occur in a great variety.

A. Possible Solutions for a Nonlinear System

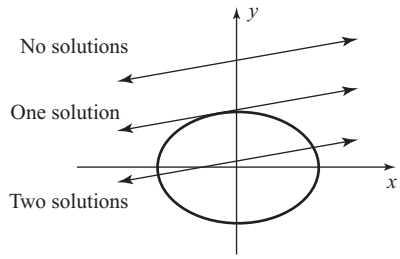
When solving nonlinear systems, it is often helpful to *visualize* the graphs of each equation in the system. This can help determine the number of possible intersections and further assist the solution process.

EXAMPLE 1 ▶ **Visualizing the Number of Possible Intersections for the Graphs in a System**

Identify each equation in the system as that of a line, parabola, circle, ellipse, or hyperbola. Then determine the number of solutions possible by considering the different ways the graphs might intersect: $\begin{cases} 4x^2 + 9y^2 = 36 \\ 2x + 3y = 6 \end{cases}$. Finally, solve the system by graphing.

Solution ▶ The first equation contains a sum of second-degree terms with unequal coefficients, and we recognize this as a central ellipse. The second equation is obviously linear. This means the system may have no solution, one solution, or two solutions, as shown in Figure 10.41. The graph of the system is shown in Figure 10.42 and the two points of intersection appear to be (3, 0) and (0, 2). After checking these in the original equations we find that both are solutions to the system.

Figure 10.41



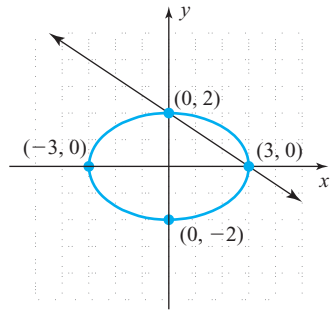


Figure 10.42

☑ **A.** You've just seen how we can visualize possible solutions

Now try Exercises 7 through 12 ▶

B. Solving Nonlinear Systems by Substitution

Since manually graphing nonlinear systems at best offers an *estimate* for the solution (points of intersection may not have rational values), we more often turn to algebraic methods or the use of a graphing calculator. Recall the substitution method involves solving one of the equations for a variable or expression that can be substituted in the other equation, to eliminate one of the variables. As with our study of linear systems, be aware that some nonlinear systems have no solutions.

EXAMPLE 2A ▶ **Solving a Nonlinear System Using Substitution and Graphing Technology**

Solve the system $\begin{cases} y = x^2 - 2x - 3 \\ 2x - y = 7 \end{cases}$ using

a. Substitution.

b. A graphing calculator.

Solution ▶ **a.** Substitution: The first equation is that of a parabola. The second equation is linear. Since the first equation is already written with y in terms of x, we can substitute $x^2 - 2x - 3$ for y in the second equation to solve.

$$\begin{aligned} 2x - y &= 7 && \text{second equation} \\ 2x - (x^2 - 2x - 3) &= 7 && \text{substitute } x^2 - 2x - 3 \text{ for } y \\ 2x - x^2 + 2x + 3 &= 7 && \text{distribute} \\ -x^2 + 4x + 3 &= 7 && \text{combine like terms} \\ x^2 - 4x + 4 &= 0 && \text{set equal to zero} \\ (x - 2)^2 &= 0 && \text{factor} \end{aligned}$$

We find that $x = 2$ is a repeated root.

Since the second equation is simpler than the first, we substitute 2 for x in this equation and find $y = -3$. The ordered pair $(2, -3)$ checks in both equations and the system has only one (repeated) solution at $(2, -3)$.

b. Graphing calculator: The first equation is already in function form (y is written in terms of x), and we can immediately enter $y = x^2 - 2x - 3$ as Y_1 on the Y= screen. After solving $2x - y = 7$ for y, we obtain $y = 2x - 7$, which we enter as Y_2. Using the standard window (ZOOM **6:ZStandard**), we obtain the graphs shown in Figure 10.43. Using the keystrokes 2nd TRACE (**CALC**) **5:intersect**, we obtain the solution shown in Figure 10.44. We suspect that the calculator is trying to display $x = 2$ and $y = -3$ as the point of intersection, and for confirmation we use the **TABLE** feature (Figure 10.45), which shows this is indeed the case.

Figure 10.43

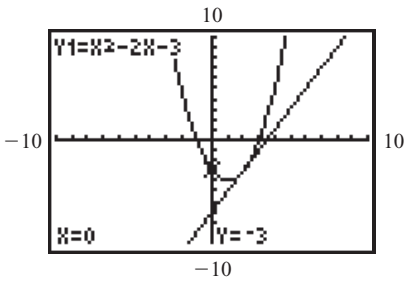

Figure 10.44

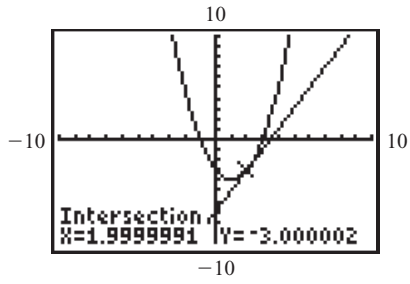

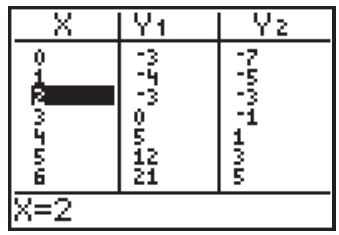

Figure 10.45

EXAMPLE 2B ▶ Solving a System Using Substitution and Graphing Technology

Solve the following system $\begin{cases} y = x^2 + 4x + 4 \\ -(x - 2)^2 = y \end{cases}$ using

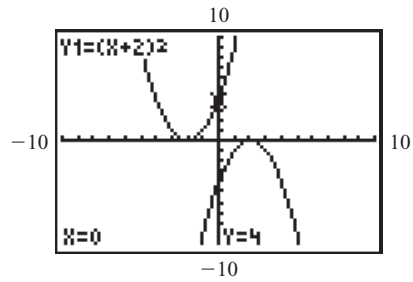
a. Substitution.

b. A graphing calculator.

Solution ▶

a. Substitution: Expanding the binomial square in the second equation gives $y = -(x^2 - 4x + 4)$, then $y = -x^2 + 4x - 4$ after simplification.

The system then becomes: $\begin{cases} y = x^2 + 4x + 4 \\ y = -x^2 + 4x - 4 \end{cases}$. Substituting $-x^2 + 4x - 4$ for y in the first equation gives the following:



$$\begin{aligned} y &= x^2 + 4x + 4 && \text{first equation} \\ -x^2 + 4x - 4 &= x^2 + 4x + 4 && \text{substitute } -x^2 + 4x - 4 \text{ for } y \\ 0 &= 2x^2 + 8 && \text{add } x^2 \text{ and 4; subtract } 4x \\ -8 &= 2x^2 && \text{isolate squared term} \\ -4 &= x^2 && \text{divide by 2} \\ x = \sqrt{-4} \quad &\text{or} \quad x = -\sqrt{-4} && \text{square root property} \\ x = 2i \quad &\text{or} \quad x = -2i && \text{result} \end{aligned}$$

From this result we see that the system has no real solutions, but we continue working to provide the complete complex-number solution. Substituting $2i$ for x in the first equation gives

$$\begin{aligned} y &= x^2 + 4x + 4 && \text{first equation} \\ &= (2i)^2 + 4(2i) + 4 && \text{substitute } 2i \text{ for } x \\ &= 4(-1) + 8i + 4 && \text{simplify} \\ &= 8i && \text{result} \end{aligned}$$

One solution is $(2i, 8i)$. Substituting $-2i$ for x shows the second solution is $(-2i, -8i)$. Both solutions can be verified using back-substitution.

b. Graphing calculator: Both equations can be entered directly on the Y= screen (both have y in terms of x) as Y_1 and Y_2, respectively. Using the standard window, we can easily see that the graphs do not intersect (see figure), indicating there are no real-number solutions.

☑ **B.** You've just seen how we can solve nonlinear systems using substitution

Now try Exercises 13 through 20 ▶

C. Solving Nonlinear Systems by Elimination

When both equations in the system have second-degree terms with like variables, it is generally easier to use the elimination method, rather than substitution.

EXAMPLE 3 ▶ **Solving a Nonlinear System Using Elimination**

Solve the system using elimination: $\begin{cases} 2y^2 - 5x^2 = 13 \\ 3x^2 + 4y^2 = 39 \end{cases}$.

Solution ▶ The first equation contains a *difference of second-degree terms* and is the equation of a central hyperbola. The second has a *sum of second-degree terms* with unequal coefficients, and represents a central ellipse. By mentally visualizing the possibilities, there could be zero, one, two, three, or four points of intersection (see Example 1). However, with both centered at (0, 0), we find there can only be zero, two, or four solutions. After writing the system with the x- and y-terms in the same order, we find that multiplying the first equation by -2 will help eliminate the y-term.

$$\begin{cases} 10x^2 - 4y^2 = -26 \\ 3x^2 + 4y^2 = 39 \end{cases}$$ rewrite first equation and multiply by -2; original second equation

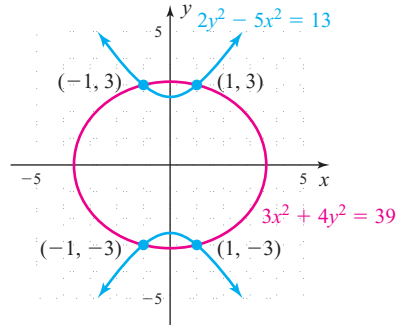
$13x^2 + 0 = 13$ add

$x^2 = 1$ divide by 13

$x = -1$ or $x = 1$ square root property

Substituting $x = 1$ and $x = -1$ into the second equation we obtain:

$3(1)^2 + 4y^2 = 39$ $\quad$ $3(-1)^2 + 4y^2 = 39$



$3 + 4y^2 = 39$ $\quad$ $3 + 4y^2 = 39$

$4y^2 = 36$ $\quad$ $4y^2 = 36$

$y^2 = 9$ $\quad$ $y^2 = 9$

$y = \pm 3$ $\quad$ $y = \pm 3$

Since -1 and 1 each generated *two outputs,* there are a total of *four* ordered pair solutions: $(1, -3)$, $(1, 3)$, $(-1, -3)$, and $(-1, 3)$. The graph is shown and supports our results.

Now try Exercises 21 through 26 ▶

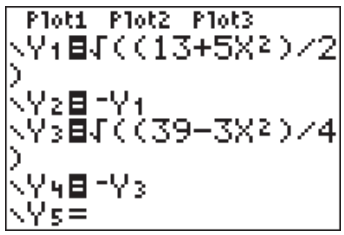
Nonlinear systems like the one in Example 3 can also be solved by graphing the system on a graphing calculator and looking for points of intersection. Solving each equation for y yields the following results.

$2y^2 - 5x^2 = 13$	original equation	$3x^2 + 4y^2 = 39$	
$2y^2 = 13 + 5x^2$	isolate y-term	$4y^2 = 39 - 3x^2$	
$y^2 = \dfrac{13 + 5x^2}{2}$	divide by coefficient	$y^2 = \dfrac{39 - 3x^2}{4}$	
$y = \pm\sqrt{\dfrac{13 + 5x^2}{2}}$	take square roots	$y = \pm\sqrt{\dfrac{39 - 3x^2}{4}}$	

$$Y_1 = \sqrt{\frac{13 + 5X^2}{2}}, Y_2 = -\sqrt{\frac{13 + 5X^2}{2}} \qquad Y_3 = \sqrt{\frac{39 - 3X^2}{4}}, Y_4 = -\sqrt{\frac{39 - 3X^2}{4}}$$

The equations and graphs are shown in Figures 10.46 and 10.47, and verify that the point (1, 3) is a solution to the system. Using symmetry, the other solutions are $(-1, 3)$, $(-1, -3)$, and $(1, -3)$. **See Exercises 27 through 30.**

Figure 10.46



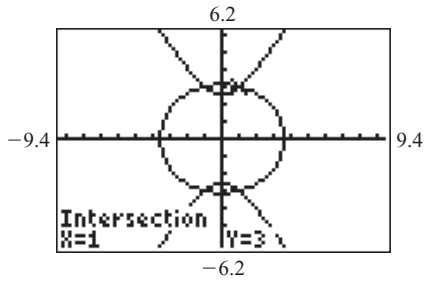


Figure 10.47

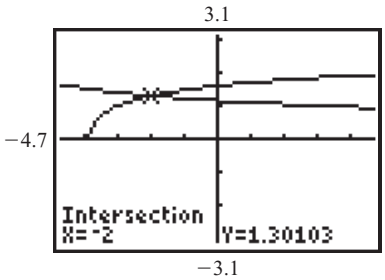
Nonlinear systems may involve other relations as well, including power, polynomial, logarithmic, or exponential functions. These are solved using the same methods.



EXAMPLE 4 ▶ Solving a System of Logarithmic Equations

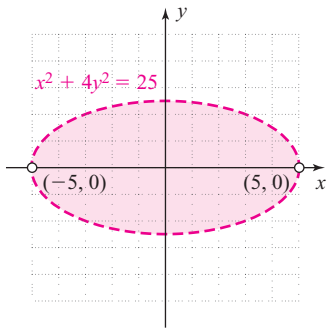
Solve the system using the method of your choice: $\begin{cases} y = -\log(x + 7) + 2 \\ y = \log(x + 4) + 1 \end{cases}$.

Verify your solution using a graphing calculator.

Solution ▶ Since both equations have y written in terms of x, substitution appears to be the most convenient choice. The result is a logarithmic equation, which we can solve using the techniques from Chapter 5.

$\log(x + 4) + 1 = -\log(x + 7) + 2$	substitute $\log(x + 4) + 1$ for y in first equation
$\log(x + 4) + \log(x + 7) = 1$	add $\log(x + 7)$; subtract 1
$\log(x + 4)(x + 7) = 1$	product property of logarithms
$(x + 4)(x + 7) = 10^1$	exponential form
$x^2 + 11x + 18 = 0$	eliminate parentheses and set equal to zero
$(x + 9)(x + 2) = 0$	factor
$x + 9 = 0$ or $x + 2 = 0$	zero factor theorem
$x = -9$ or $x = -2$	possible solutions

By inspection, we see that $x = -9$ is extraneous, since $\log(-9 + 4)$ and $-\log(-9 + 7)$ are not real numbers. Substituting -2 for x in the second equation we find one form of the (exact) solution is $(-2, \log 2 + 1)$. If we substitute -2 for x in the first equation the exact solution is $(-2, -\log 5 + 2)$. Using a calculator we can verify the ordered pairs are equivalent and approximately equal to $(-2, 1.3)$.



Using the ZOOM **4:ZDecimal** feature of graphing calculator produces the screen shown in the figure, which confirms the solution $(-2, \log 2 + 1)$ obtained by substitution.

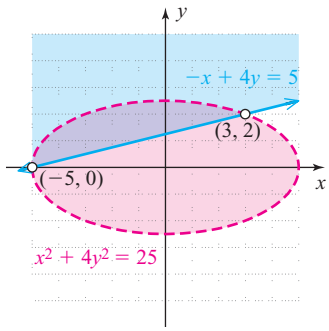
C. You've just seen how we can solve nonlinear systems using elimination

For practice solving more complex systems using a graphing calculator, **see Exercises 43 through 48.**

Figure 10.48



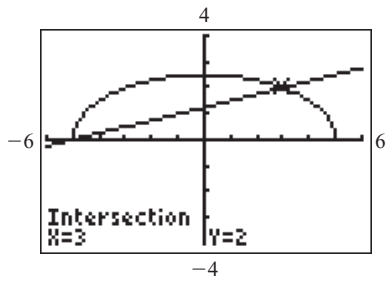
D. Solving Systems of Nonlinear Inequalities

As with our previous work with inequalities in two variables, nonlinear inequalities can be solved by graphing the boundary given by the related equation, and checking the regions that result using a test point. For example, the inequality $x^2 + 4y^2 < 25$ is solved by first graphing $x^2 + 4y^2 = 25$, which is a central ellipse with vertices at $(-5, 0)$ and $(5, 0)$. We then decide whether the boundary is included or excluded (in this case it is not included), and use a test point from either "outside" or "inside" the region formed. The test point $(0, 0)$ results in a true statement since $(0)^2 + 4(0)^2 < 25$, so the inside of the ellipse is shaded to indicate the solution region (Figure 10.48). For a ***system*** of nonlinear inequalities, we identify regions where the solution sets for each inequality overlap, paying special attention to points of intersection.

EXAMPLE 5 ▶ **Solving a System of Nonlinear Inequalities**

Solve the system $\begin{cases} x^2 + 4y^2 < 25 \\ -x + 4y \geq 5 \end{cases}$ by graphing. Verify results using a graphing calculator.

Solution ▶ We recognize the first inequality from Figure 10.48, an ellipse with vertices at $(-5, 0)$ and $(5, 0)$, and a solution region in the interior. The second inequality is linear and after solving for x in the related equation, we use substitution to find points of intersection (if they exist). From $-x + 4y = 5$, we obtain $x = 4y - 5$ and substitute $4y - 5$ for x in $x^2 + 4y^2 = 25$:



$$\begin{aligned} x^2 + 4y^2 &= 25 && \text{given} \\ (4y - 5)^2 + 4y^2 &= 25 && \text{substitute } 4y - 5 \text{ for } x \\ 16y^2 - 40y + 25 + 4y^2 &= 25 && \text{expand} \\ 20y^2 - 40y + 25 &= 25 && \text{simplify} \\ y^2 - 2y &= 0 && \text{subtract 25; divide by 20} \\ y(y - 2) &= 0 && \text{factor} \\ y = 0 \quad \text{or} \quad y &= 2 && \text{result} \end{aligned}$$

Back-substitution shows the graphs intersect at $(-5, 0)$ and $(3, 2)$. Graphing the line through these points and using $(0, 0)$ as a test point shows the upper half plane is the solution region for the linear inequality $[-(0) + 4(0) \geq 5$ is *false*$]$. The overlapping (solution) region for *both* inequalities is the elliptical sector shown in purple. Note the points of intersection are graphed using "open dots" (see figure) since points on the graph of the ellipse are excluded from the solution set.

Our manual sketch indicates the boundaries of the solution region are formed by the line and the upper half of the ellipse. For $x^2 + 4y^2 = 25$, the equation for the upper half of the ellipse is $y = \sqrt{\dfrac{25 - x^2}{4}}$, which we enter as Y_1. Solving the second equation for y we obtain $y = \dfrac{x + 5}{4}$ and enter this as Y_2. The resulting graph is shown in Figure 10.49 using the window displayed. As the test point indicated, the region below the half-ellipse and above the line forms the solution region. As in Section 9.3, we use the

Figure 10.49

shading capability of the graphing calculator by selecting the "◣" and "◥" symbols as shown in Figure 10.50. The resulting graph is shown in Figure 10.51, and appears to support the graphical solution completed by hand.

Figure 10.50

Now try Exercises 49 through 56 ▶

E. Solving Applications of Nonlinear Systems

In the business world, a fast growing company can often reduce the average price of its products using what are called the **economies of scale.** These would include the ability to buy necessary materials in larger quantities, integrating new technology into the production process, and other means. However, there are also countering forces called the **diseconomies of scale,** which may include the need to hire additional employees, rent more production space, and the like. Companies often use a break-even analysis to determine the production level at which these forces stabilize.

EXAMPLE 6 ▶ **Solving an Application of Nonlinear Systems—Economies of Scale**

Suppose the cost to produce a new and inexpensive shoe made from molded plastic is modeled by the function $C(x) = x^2 - 5x + 18$, where $C(x)$ represents the cost to produce x thousand of these shoes. Similarly, revenue from the sales of these shoes is modeled by $R(x) = -x^2 + 10x - 4$. Use a break-even analysis to find the quantity of sales that will cause the company to break even.

Solution ▶ Essentially we are asked to solve the system formed by the two equations: $\begin{cases} C(x) = x^2 - 5x + 18 \\ R(x) = -x^2 + 10x - 4 \end{cases}$. Since we want to know the point where the company breaks even, we set $C(x) = R(x)$ and solve.

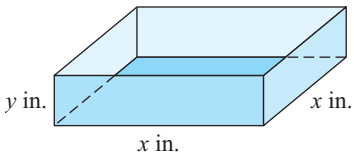
$$\begin{aligned} C(x) &= R(x) && \text{break even: cost = revenue} \\ x^2 - 5x + 18 &= -x^2 + 10x - 4 && \text{substitute for } C(x) \text{ and } R(x) \\ 2x^2 - 15x + 22 &= 0 && \text{set equal to zero} \\ (2x - 11)(x - 2) &= 0 && \text{factored form} \\ x &= \frac{11}{2} \text{ or } x = 2 && \text{result} \end{aligned}$$

With x in thousands, it appears the company will break even if either 2000 shoes or 5500 shoes are made and sold.

Now try Exercises 59 and 60 ▶

There are actually a large number of significant applications that involve nonlinear systems. Solutions to many of these are difficult to solve manually, and it's here that a

skillful use of technology displays its ultimate value. One such application involves the manufacture of cardboard boxes (a billion dollar industry) used to ship goods and commodities all over the globe. Designing a box with the desired volume and needed dimensions often involves the use of a nonlinear system.



EXAMPLE 7 ▶ Manufacturing Cardboard Boxes

In order to transport seedlings from the nursery to the market, a manufacturing engineer designs an open box with a square bottom and four sides of equal height. For the most efficient fit, the volume of the box must be 900 in^3 and use 465 in^2 of cardboard stock. Find the dimensions of the box.

Solution ▶ After carefully drawing a diagram (see Figure 10.52), we let x represent the length and width of the square bottom, and y represent the height. The volume of the box is then represented by $x^2y = 900$ in^3 ($V = LWH$), and the surface area by $x^2 + 4xy = 465$ ($SA = S^2 + 4SH$). The resulting system is $\begin{cases} x^2y = 900 \\ x^2 + 4xy = 645 \end{cases}$. Solving for y in the first equation, we obtain $y = \dfrac{900}{x^2}$ and can now substitute this result into the second equation to obtain an equation in x alone:

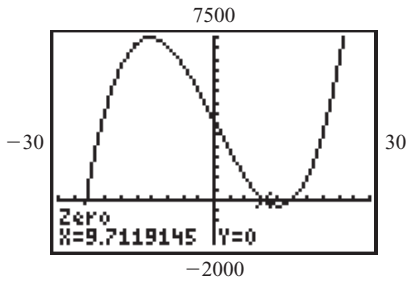


Figure 10.52

$$\begin{aligned}
x^2 + 4xy &= 465 && \text{second equation} \\
x^2 + 4x\left(\frac{900}{x^2}\right) &= 465 && \text{substitute } \frac{900}{x^2} \text{ for } y \\
x^2 + \frac{3600}{x} &= 465 && \text{simplify} \\
x^3 + 3600 &= 465x && \text{multiply by } x \text{ (clear denominator)} \\
x^3 - 465x + 3600 &= 0 && \text{set equal to zero}
\end{aligned}$$

The zeroes of this cubic equation will give the dimensions of the base. A comprehensive graph of this function (using window size $[-30, 30]$ for x and $[-2000, 7500]$ for y) shows there are three zeroes, but one of them is negative and is discounted in this context (Figure 10.53).

Figure 10.53

Using the 2nd TRACE **(CALC) 2:zero** option, we find the positive zeroes are $x \approx 9.7$ (shown) and $x = 15$, and there turns out to be *two* solutions. Substituting 9.7 for x in the first equation,

$$\begin{aligned}
x^2y &= 900 && \text{first equation} \\
(9.7)^2y &= 900 && \text{substitute 9.7 for } x \\
(94.09)y &= 900 && \text{square 9.7} \\
y &\approx 9.6 && \text{divide}
\end{aligned}$$

yields $y \approx 9.6$ in. for the height of the box, which does not seem practical for transporting seedlings. Substituting 15 for x gives $y = 4$ in. as the height, which seems more reasonable. The dimensions of the box will most likely be 15 in. × 15 in. × 4 in.

Now try Exercises 61 and 62 ▶

☑ **E.** You've just seen how we can solve applications of nonlinear systems

For additional applications of nonlinear systems, **see Exercises 63 through 70.**

10.5 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. Draw sketches showing the different ways each pair of relations can intersect and give one, two, three, and/or four points of intersection. If a given number of intersections is not possible, so state.

a. circle and line **b.** parabola and line

c. circle and parabola **d.** circle and hyperbola

e. hyperbola and ellipse **f.** circle and ellipse

2. By inspection only, identify the systems having *no solutions* and justify your choices.

a. $\begin{cases} y^2 - x^2 = 16 \\ x^2 + y^2 = 9 \end{cases}$ **b.** $\begin{cases} y = x^2 + 4 \\ x^2 + 4y^2 = 4 \end{cases}$

c. $\begin{cases} y = x + 1 \\ 3x^2 + 4y^2 = 12 \end{cases}$

3. The solution to a system of nonlinear inequalities is a(n) _____ of the plane where the _____ for each individual inequality overlap.

4. When both equations in the system have at least one _____ -degree term, it is generally easier to use the _____ method to find a solution.

5. Suppose a nonlinear system contained a central hyperbola and an exponential function. Are three solutions possible? Are four solutions possible? Explain/Discuss.

6. Solve the system twice, once using elimination, then again using substitution. Compare/Contrast each process and comment on which is more efficient in this case: $\begin{cases} 4x^2 + y^2 = 25 \\ 2x^2 + y = 5 \end{cases}$.

▶ DEVELOPING YOUR SKILLS

Identify each equation in the system as that of a line, parabola, circle, ellipse, or hyperbola, and solve the system by graphing.

7. $\begin{cases} x^2 + y = 6 \\ x + y = 4 \end{cases}$ **8.** $\begin{cases} -2x + y = 4 \\ 4x^2 + y^2 = 16 \end{cases}$

9. $\begin{cases} y - x^2 = -1 \\ 4x^2 + y^2 = 100 \end{cases}$ **10.** $\begin{cases} x^2 + y^2 = 25 \\ x^2 + y = 13 \end{cases}$

11. $\begin{cases} x^2 - y^2 = 9 \\ x^2 + y^2 = 41 \end{cases}$ **12.** $\begin{cases} 4x^2 - y^2 = 36 \\ y^2 + 9x^2 = 289 \end{cases}$

Solve using substitution. Find both real and complex solutions (if they exist). In Exercises 17 and 18, substitute for x^2 (not y).

13. $\begin{cases} x^2 + y^2 = 25 \\ y - x = 1 \end{cases}$ **14.** $\begin{cases} x + 7y = 50 \\ x^2 + y^2 = 100 \end{cases}$

15. $\begin{cases} x^2 + 4y^2 = 25 \\ x + 2y = 7 \end{cases}$ **16.** $\begin{cases} x^2 - 2y^2 = 8 \\ x + y = 6 \end{cases}$

17. $\begin{cases} x^2 + y = 13 \\ 9x^2 - y^2 = 81 \end{cases}$ **18.** $\begin{cases} y - x^2 = -10 \\ 4x^2 + y^2 = 100 \end{cases}$

19. $\begin{cases} y + x^2 = 6x \\ y - 23 = (x + 3)^2 \end{cases}$ **20.** $\begin{cases} x^2 + y^2 = 16 \\ y - x = -6 \end{cases}$

Solve using elimination. Find both real and complex solutions (if they exists).

21. $\begin{cases} x^2 + y^2 = 25 \\ 2x^2 - 3y^2 = 5 \end{cases}$ **22.** $\begin{cases} y^2 - x^2 = 12 \\ x^2 + y^2 = 20 \end{cases}$

23. $\begin{cases} x^2 + y^2 = 6 \\ y = x - 4 \end{cases}$ **24.** $\begin{cases} y + x^2 = 8x \\ y - 34 = (x + 4)^2 \end{cases}$

25. $\begin{cases} 5x^2 - 2y^2 = 75 \\ 2x^2 + 3y^2 = 125 \end{cases}$ **26.** $\begin{cases} 3x^2 - 7y^2 = 20 \\ 4x^2 + 9y^2 = 45 \end{cases}$

Solve the following systems using a graphing calculator. Round approximate solutions to three decimal places.

27. $\begin{cases} (x - 2)^2 + y^2 = 20 \\ \dfrac{x^2}{4} + y = 8 \end{cases}$

28. $\begin{cases} 4x^2 - (y - 12)^2 = 441 \\ x^2 + (y - 12)^2 = 1764 \end{cases}$

29. $\begin{cases} (x - 10)^2 + (y - 10)^2 = 144 \\ (x + 4)^2 + y^2 = 144 \end{cases}$

30. $\begin{cases} 3(x + 24)^2 + y^2 = 196 \\ 4x + 4y = -31 \end{cases}$

Solve using the method of your choice. Find both real and complex solutions (if they exist). Answer in exact form.

31. $\begin{cases} y - 5 = \log x \\ y = 6 - \log(x - 3) \end{cases}$

32. $\begin{cases} y = \log(x + 4) + 1 \\ y - 2 = -\log(x + 7) \end{cases}$

33. $\begin{cases} y = \ln(x^2) + 1 \\ y - 1 = \ln(x + 12) \end{cases}$

34. $\begin{cases} \log(x + 1.1) = y + 3 \\ y + 4 = \log(x^2) \end{cases}$

35. $\begin{cases} y - 9 = e^{2x} \\ 3 = y - 7e^x \end{cases}$

36. $\begin{cases} y - 2e^{2x} = 5 \\ y - 1 = 6e^x \end{cases}$

37. $\begin{cases} y = 4^{x+3} \\ y - 2^{x^2+3x} = 0 \end{cases}$

38. $\begin{cases} y - 3^{x^2+2x} = 0 \\ y = 9^{x+2} \end{cases}$

39. $\begin{cases} x^3 - y = 2x \\ y - 5x = -6 \end{cases}$

40. $\begin{cases} y - x^3 = -2 \\ y + 4 = 3x \end{cases}$

41. $\begin{cases} x^2 - 6x = y - 4 \\ y - 2x = -8 \end{cases}$

42. $\begin{cases} y + x = -2 \\ y + 4x = x^2 \end{cases}$

Solve each system using a graphing calculator. Round solutions to hundredths (as needed).

43. $\begin{cases} x^2 + y^2 = 34 \\ y^2 + (x - 3)^2 = 25 \end{cases}$

44. $\begin{cases} 5x^2 + 5y^2 = 40 \\ y + 2x = x^2 - 6 \end{cases}$

45. $\begin{cases} y = 2^x - 3 \\ y + 2x^2 = 9 \end{cases}$

46. $\begin{cases} y = -2\log(x + 8) \\ y + x^3 = 4x - 2 \end{cases}$

47. $\begin{cases} y = \dfrac{1}{(x - 3)^2} + 2 \\ (x - 3)^2 + y^2 = 10 \end{cases}$

48. $\begin{cases} y^2 + x^2 = 5 \\ y = \dfrac{1}{x - 1} - 2 \end{cases}$

Solve each system of inequalities. Verify results using a graphing calculator.

49. $\begin{cases} y - x^2 \geq 1 \\ x + y \leq 3 \end{cases}$

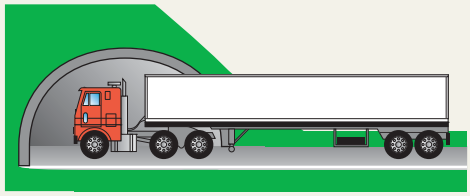
50. $\begin{cases} x^2 + y^2 \leq 25 \\ x + 2y \leq 5 \end{cases}$

51. $\begin{cases} x^2 + y^2 > 16 \\ x^2 + y^2 \leq 64 \end{cases}$

52. $\begin{cases} y + 4 \geq x^2 \\ x^2 + y^2 \leq 34 \end{cases}$

53. $\begin{cases} y - x^2 \leq -16 \\ y^2 + x^2 < 9 \end{cases}$

54. $\begin{cases} x^2 + y^2 \leq 16 \\ x + 2y > 10 \end{cases}$



55. $\begin{cases} y^2 + x^2 \leq 25 \\ |x| - 1 > -y \end{cases}$

56. $\begin{cases} y^2 + x^2 \leq 4 \\ x + y < 4 \end{cases}$

▶ WORKING WITH FORMULAS

57. Tunnel clearance: $h = b\sqrt{1 - \left(\dfrac{d}{a}\right)^2}$

The maximum rectangular clearance allowed by an elliptical tunnel can be found using the formula shown, where $\begin{cases} \dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1 \end{cases}$ models the tunnel's elliptical cross section and h is the height of the tunnel at a distance d from the center. If $a = 50$ and $b = 30$, find the maximum clearance at distances of $d = 20$, 30, and 40 ft from center.

58. Manufacturing cylindrical vents: $\begin{cases} A = 2\pi rh \\ V = \pi r^2 h \end{cases}$

In the manufacture of cylindrical vents, a rectangular piece of sheet metal is rolled, riveted, and sealed to form the vent. The radius and height required to form a vent with a specified volume, using a piece of sheet metal with a given area, can be found by solving the system shown. Use the system to find the radius and height if the volume required is 4071 cm^3 and the area of the rectangular piece is 2714 cm^2.

▶ APPLICATIONS

Solve the following applications of economies of scale.

59. World's most inexpensive car: Early in 2008, The Tata Company (India) unveiled the Tata Nano, the world's most inexpensive car. With its low price and 54 miles per gallon, the car may prove to be very popular. *Assume* the cost to produce these cars is modeled by the function $C(x) = 2.5x^2 - 120x + 3500$, where $C(x)$ represents the cost to produce x thousand cars. Suppose the revenue from the sales of these cars is modeled by $R(x) = -2x^2 + 180x - 500$. Use a break-even analysis to find the quantity of sales (to the nearest hundred) that will cause the company to break even.

60. Document reproduction: In a world of technology, document reproduction has become a billion dollar business. With very stiff competition, the price of a single black and white copy has varied greatly is recent years. Suppose the cost to produce these copies is modeled by the function $C(x) = 0.1x^2 - 1.2x + 7$, where $C(x)$ represents the cost to produce x hundred thousand copies. If the revenue from the sales of these copies is modeled by $R(x) = -0.1x^2 + 1.8x - 2$, use a break-even analysis to find the quantity of copies sold (to the nearest thousand) that will cause the copy company to break even.

Build the system of nonlinear equations needed to solve the following manufacturing applications, then solve.

61. Dimensions of a pool: A homeowner wants to build a new swimming pool in her backyard. Due to size limitations, she decides to build a square pool with a flat bottom. If the volume of the pool must be 2000 ft^3 and the tile surface for the sides and bottom will be 800 ft^2, what will be the final dimensions of the pool?

62. Box manufacturing: A cardboard box manufacturer receives an order for a large number of boxes for wrapping gifts during the Christmas season. The boxes are to have a square top and bottom, with a volume of 6750 cm^3 and a surface area of 2700 cm^2. Find the dimensions of the box fitting these requirements.

Solve by setting up and solving a system of nonlinear equations.

63. Dimensions of a flag: A large American flag has an area of 85 m^2 and a perimeter of 37 m. Find the dimensions of the flag.

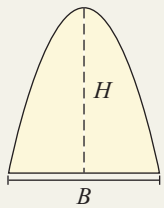
64. Dimensions of a sail: The sail on a boat is a right triangle with a perimeter of 36 ft and a hypotenuse of 15 ft. Find the height and width of the sail.

Exercise 64

65. Dimensions of a tract: The area of a rectangular tract of land is 45 km^2. The length of a diagonal is $\sqrt{106}$ km. Find the dimensions of the tract.

66. Dimensions of a deck: A rectangular deck has an area of 192 ft^2 and the length of the diagonal is 20 ft. Find the dimensions of the deck.

67. Dimensions of a trailer: The surface area of a closed rectangular trailer with square ends is 928 ft^2. If the sum of all edges of the trailer is 164 ft, find its dimensions.



68. Dimensions of a cylindrical tank: The surface area of a closed cylindrical tank is 192π m^2. Find the dimensions of the tank if the volume is 320π m^3 and the radius is as small as possible.

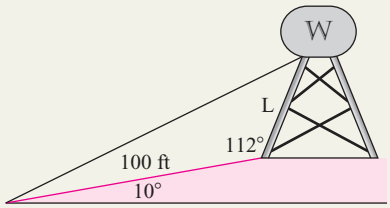
69. Supply and demand: Suppose the monthly market demand D (in ten-thousands of gallons) for a new synthetic oil is related to the price P in dollars by the equation $10P^2 + 6D = 144$. For the market price P, assume the amount D that manufacturers are willing to supply is modeled by $8P^2 - 8P - 4D = 12$. (a) What is the minimum price at which manufacturers are willing to begin supplying the oil? (b) Use this information to create a system of nonlinear equations, then solve the system to find the market equilibrium price (per gallon) and the quantity of oil supplied and sold at this price.

70. Supply and demand: The weekly demand D for organically grown carrots (in thousands of pounds) is related to the price per pound P by the equation $8P^2 + 4D = 84$. At this market price, the amount that growers are willing to supply is modeled by the equation $8P^2 + 6P - 2D = 48$. (a) What is the minimum price at which growers are willing to supply the organically grown carrots? (b) Use this information to create a system of nonlinear equations, then solve the system to find the market equilibrium price (per pound) and the quantity of carrots supplied and sold at this price.

▶ EXTENDING THE CONCEPT

71. The area of a vertical parabolic segment is given by $A = \frac{2}{3}BH$, where B is the length of the horizontal base of the segment and H is the height from the base to the vertex. Investigate how this formula can be used to find the *area* of the solution region for the general system of inequalities shown. $\begin{cases} y \geq x^2 - bx + c \\ y \leq c + bx - x^2 \end{cases}$

(*Hint:* Begin by investigating with $b = 6$ and $c = 8$, then use other values and try to generalize what you find.)



72. For what values of r will the volume of a sphere be numerically equal to its surface area? For what values of r will the volume of a cylinder be numerically equal to its lateral surface area? Can a similar relationship be found for the volume and lateral surface area of a cone? Why or why not?

73. A rectangular fish tank has a bottom and four sides made out of glass. Use a system of equations to help find the dimensions of the tank if the height is 18 in., surface area is 4806 in^2, the tank must hold 108 gal (1 gal $=$ 231 in^3), and all three dimensions are integers.

▶ MAINTAINING YOUR SKILLS

74. **(8.4)** Determine the angle θ between the vectors $\mathbf{u} = 12\mathbf{i} - 35\mathbf{j}$ and $\mathbf{v} = -20\mathbf{i} + 21\mathbf{j}$.

75. **(8.1)** Estimate the length L to the base of the water tank, if the angle of elevation to the base of the tower is 10°, the angle of elevation to the base of the tank is 35°, and the tower makes a 112° angle with the hillside.

76. **(2.2/5.2)** Sketch each transformation:

a. $y = 2|x + 3| - 1$ **b.** $y = \sqrt[3]{x - 2} + 3$

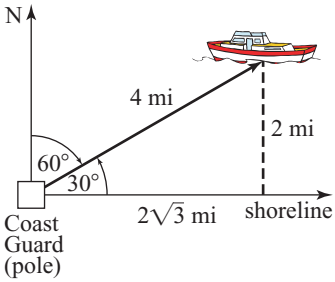
c. $y = -(x + 4)^2 + 3$ **d.** $y = 2^{x+1} - 3$

77. **(1.4)** In 2008, a small business purchased a copier for \$4500. In 2011, the value of the copier had decreased to \$3300. Assuming the depreciation is linear: (a) find the rate-of-change $m = \dfrac{\Delta\text{value}}{\Delta\text{time}}$ and discuss its meaning in this context; (b) find the depreciation equation; and (c) use the equation to predict the copier's value in 2015. (d) If the copier is traded in for a new model when its value is less than \$700, how long will the company use this copier?

10.6 Polar Coordinates, Equations, and Graphs

LEARNING OBJECTIVES

In Section 10.6 you will see how we can:



- ❑ **A.** Plot points given in polar form
- ❑ **B.** Express a point in polar form
- ❑ **C.** Convert between polar form and rectangular form
- ❑ **D.** Sketch basic polar graphs using an r-value analysis
- ❑ **E.** Use symmetry and families of curves to write a polar equation given a polar graph or information about the graph

One of the most enduring goals of mathematics is to express relations with the greatest possible simplicity and ease of use. For $\dfrac{\tan\theta - \cot\theta}{\tan^2\theta - \cot^2\theta} = \sin\theta\cos\theta$, we would definitely prefer working with $\sin\theta\cos\theta$, although the expressions are equivalent. Similarly, we would prefer computing $(3 + i\sqrt{3})^6$ in trigonometric form rather than algebraic form—and would quickly find the result is -1728. In just this way, many equations and graphs are easier to work with in **polar form** rather than rectangular form. In rectangular form, a circle of radius 2 centered at (0, 2) has the equation $x^2 + (y - 2)^2 = 4$. In polar form, the equation of the same circle is simply $r = 4\sin\theta$. As you'll see, polar coordinates offer an alternative method for plotting points and graphing relations.

A. Plotting Points Using Polar Coordinates

Suppose a Coast Guard station receives a distress call from a stranded boat. The boater could attempt to give the location in rectangular form, but this might require imposing an arbitrary coordinate grid on an uneven shoreline, using uncertain points of reference. However, if the radio message said, "We're stranded 4 miles out, at heading 60°," the Coast Guard could immediately locate the boat and send help. In **polar coordinates,** the location "4 miles out, at heading 60°" would be written $(r, \theta) = (4, 30°)$, with r representing the distance from the station and $\theta > 0$ measured from a horizontal axis in the counterclockwise direction (see Figure 10.54). If we placed the scenario on a rectangular grid (assuming a straight shoreline), the coordinates of the boat would be

Figure 10.54

$(2\sqrt{3}, 2)$ using basic trigonometry. As you see, the **polar coordinate system** uses angles and distances to locate a point in the plane. In this example, the Coast Guard station would be considered the **pole** or origin, with the x-axis as the **polar axis** or axis of reference (Figure 10.55). A distinctive feature of polar coordinates is that *we allow r to be negative,* in which case $P(r, \theta)$ is the point $|r|$ units from the pole in a direction opposite $(180°)$ to that of θ (Figure 10.56). For convenience, polar graph paper is often used when working with polar coordinates. It consists of a series of concentric circles that share the same center and have integer radii. The standard angles are marked off in multiples of $\frac{\pi}{12} = 15°$ depending on whether you're working in radians or degrees (Figure 10.57). To plot the point $P(r, \theta)$, go a distance of $|r|$ at $0°$ then move $\theta°$ counterclockwise along a circle of radius r. If $r > 0$, plot a point at that location (you're finished). If $r < 0$, the point is plotted on a circle of the same radius, but $180°$ in the opposite direction.

Figure 10.55

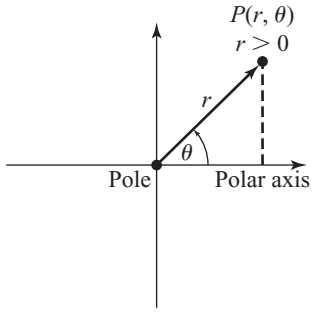


Figure 10.56

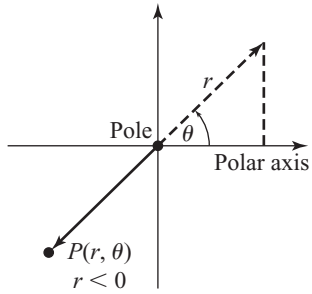

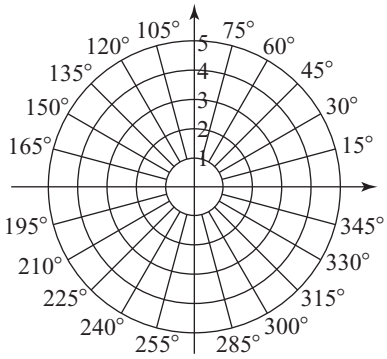

Figure 10.57

Polar graph paper

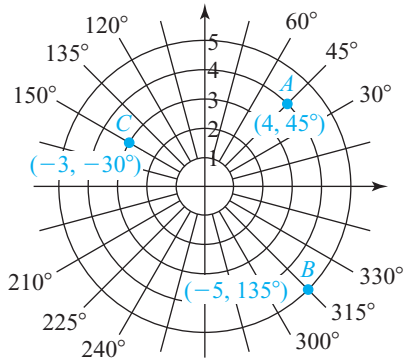
EXAMPLE 1 ▶ **Plotting Points in Polar Coordinates**

Plot each point $P(r, \theta)$ given:

$$A(4, 45°);\ B(-5, 135°);\ C(-3, -30°);\ D\left(2, \frac{2\pi}{3}\right);\ E\left(-5, \frac{\pi}{3}\right);\ \text{and } F\left(3, -\frac{\pi}{6}\right).$$

Solution ▶ For $A(4, 45°)$ go 4 units at $0°$, then rotate $45°$ counterclockwise and plot point A. For $B(-5, 135°)$, move $|-5| = 5$ units at $0°$, rotate $135°$, then actually plot point B $180°$ in the opposite direction, as shown. Point $C(-3, -30°)$ is plotted by moving $|-3| = 3$ units at $0°$, rotating $-30°$, then plotting point C $180°$ in the opposite direction (since $r > 0$). See Figure 10.58. The points $D\left(2, \frac{2\pi}{3}\right)$, $E\left(-5, \frac{\pi}{3}\right)$, and $F\left(3, -\frac{\pi}{6}\right)$ are plotted on the gird in Figure 10.59.

Figure 10.58



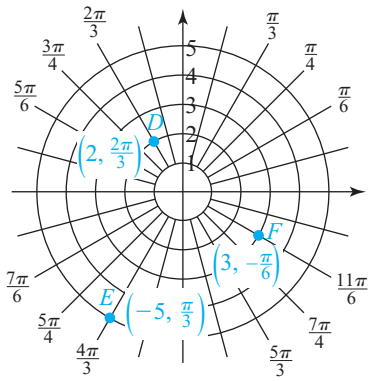


Figure 10.59

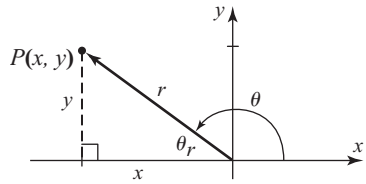
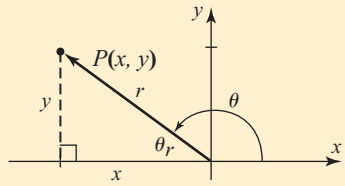
Now try Exercises 7 through 22 ▶



While plotting the points $B(-5, 135°)$ and $F\left(3, -\frac{\pi}{6}\right)$, you likely noticed that the coordinates of a point in polar coordinates are not unique. For $B(-5, 135°)$ it appears more natural to name the location $(5, 315°)$, while for $F\left(3, -\frac{\pi}{6}\right)$, the expression $\left(3, \frac{11\pi}{6}\right)$ is just as reasonable. In fact, for any point $P(r, \theta)$ in polar coordinates, $P(r, \theta \pm 2\pi)$ and $P(-r, \theta \pm \pi)$ name the same location. **See Exercises 23 through 36.**

A. You've just seen how we can plot points given in polar form

B. Expressing a Point in Polar Coordinates



Conversions between rectangular and polar coordinates is a simple application of skills from previous sections, and closely resembles the conversion from the rectangular form to the trigonometric form of a complex number. To make the connection, we first assume $r > 0$ with θ in Quadrant II (see Figure 10.60). In rectangular form, the coordinates of the point are simply (x, y), with the lengths of x and y forming the sides of a right triangle. The distance r from the origin to point P resembles the modulus of a complex number and is computed in the same way: $r = \sqrt{x^2 + y^2}$. As long as $x \neq 0$, we have $\theta_r = \tan^{-1}\left|\frac{y}{x}\right|$, noting θ_r is a reference angle if the terminal side is not in Quadrant I. If needed, refer to Section 6.2 for a review of reference arcs and reference angles.

Figure 10.60

Converting from Rectangular to Polar Coordinates

Any point $P(x, y)$ in rectangular coordinates can be represented as $P(r, \theta)$ in polar coordinates, where $r = \sqrt{x^2 + y^2}$ and $\theta_r = \tan^{-1}\left|\frac{y}{x}\right|$, $x \neq 0$.

EXAMPLE 2 ▶ **Converting a Point from Rectangular Form to Polar Form**

Convert from rectangular to polar form, with $r > 0$ and $0° \leq \theta < 360°$ (round values to one decimal place as needed).

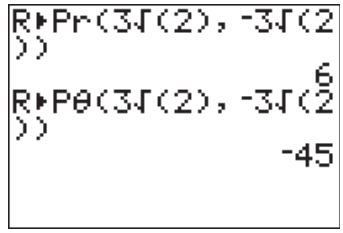
a. $P(-5, 12)$

b. $P(3\sqrt{2}, -3\sqrt{2})$

Solution ▶ **a.** Point $P(-5, 12)$ is in Quadrant II.

$$r = \sqrt{(-5)^2 + 12^2} \qquad \theta_r = \tan^{-1}\left(\frac{12}{5}\right)$$
$$= \sqrt{169} \qquad \theta_r \approx 67.4°$$
$$= 13 \qquad \theta \approx 112.6°$$

$P(-5, 12) \rightarrow P(13, 112.6°)$



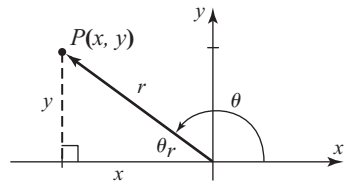
b. Point $P(3\sqrt{2}, -3\sqrt{2})$ is in Quadrant IV.

$$r = \sqrt{(3\sqrt{2})^2 + (-3\sqrt{2})^2} \qquad \theta_r = \tan^{-1}\left(\frac{3\sqrt{2}}{3\sqrt{2}}\right)$$
$$= \sqrt{36} \qquad \theta_r = 45°$$
$$= 6 \qquad \theta = 315°$$
$$P(3\sqrt{2}, -3\sqrt{2}) \rightarrow P(6, 315°)$$

Now try Exercises 37 through 44 ▶

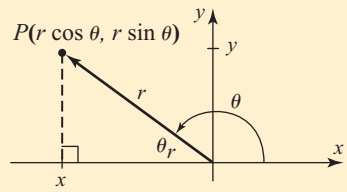
In Sections 6.7 and 8.3, we used the calculator features 2nd APPS **(ANGLE) 5:R→Pr(** and **6:R→Pθ(** without identifying what the notation actually means. Now we recognize that **R→Pr(** takes a point expressed in **R**ectangular form and returns its **P**olar coordinate **r**, while **R→Pθ(** returns its coordinate **θ.** In Figure 10.61, we use these commands to confirm the results of Example 2(b), noting that $-45°$ is coterminal with 315°.

Figure 10.61



☑ **B.** You've just seen how we can express a point in polar form

C. Converting Between Polar Coordinates and Rectangular Coordinates



The conversion from polar form to rectangular form is likewise straightforward. From Figure 10.62 we again note $\cos\theta = \frac{x}{r}$ and $\sin\theta = \frac{y}{r}$, giving $x = r\cos\theta$ and $y = r\sin\theta$. The conversion simply consists of making these substitutions and simplifying.

Figure 10.62

Converting from Polar to Rectangular Coordinates

Any point $P(r, \theta)$ in polar coordinates can be represented as $P(x, y)$ in rectangular coordinates, where $x = r\cos\theta$ and $y = r\sin\theta$.

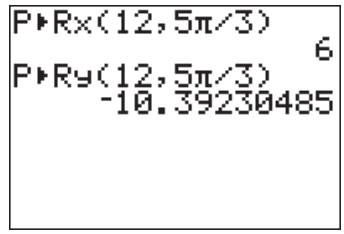
Once again, these conversion formulas have been built in to many calculators. To calculate the **R**ectangular **x** coordinate of a point in **P**olar form, we select option **7:P→Rx(** from the 2nd APPS **(ANGLE)** menu, input the **P**olar coordinates of the point, and press ENTER. Similarly, option **8:P→Ry(** calculates and returns the **y** coordinate.

EXAMPLE 3 ▶ **Converting a Point from Polar Form to Rectangular Form**

Convert from polar to rectangular form (round values to one decimal place as needed).

a. $P\left(12, \frac{5\pi}{3}\right)$ **b.** $P(6, 240°)$

Solution ▶ **a.** Point $P\left(12, \frac{5\pi}{3}\right)$ is in Quadrant IV.



Algebraic Solution

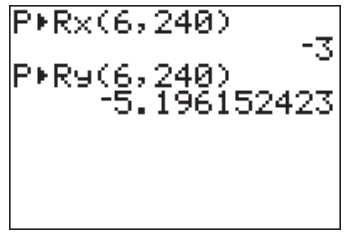
$$x = r\cos\theta \qquad y = r\sin\theta$$
$$= 12\cos\left(\frac{5\pi}{3}\right) \qquad = 12\sin\left(\frac{5\pi}{3}\right)$$
$$= 12\left(\frac{1}{2}\right) \qquad = 12\left(\frac{-\sqrt{3}}{2}\right)$$
$$= 6 \qquad = -6\sqrt{3}$$

$$P\left(12, \frac{5\pi}{3}\right) \rightarrow P(6, -6\sqrt{3}) \approx P(6, -10.4)$$

Graphical Solution

The screen shown is from a calculator in *radian* MODE.

b. Point $P(6, 240°)$ is in Quadrant III.



Algebraic Solution

$$x = 6\cos 240° \qquad y = 6\sin 240°$$
$$= 6\left(-\frac{1}{2}\right) \qquad = 6\left(\frac{-\sqrt{3}}{2}\right)$$
$$= -3 \qquad = -3\sqrt{3}$$

$$P(6, 240°) \rightarrow P(-3, -3\sqrt{3}) \approx P(-3, -5.2)$$

Graphical Solution

The screen shown is from a calculator in *degree* MODE.

Now try Exercises 45 through 52 ▶

Using the relationships $x = r\cos\theta$ and $y = r\sin\theta$, we can convert an equation given in rectangular form to an equivalent equation in polar form.

EXAMPLE 4 ▶ **Converting an Equation from Rectangular Form to Polar Form**

Convert the following equations to polar form.

a. $x^2 + y^2 = 16$ **b.** $y = \frac{1}{x}$

Solution ▶ **a.** The graph of this equation is a circle of radius 4 centered at the origin.

$$x^2 + y^2 = 16 \quad \text{given equation}$$
$$(r\cos\theta)^2 + (r\sin\theta)^2 = 16 \quad \text{substitute } r\cos\theta \text{ for } x \text{ and } r\sin\theta \text{ for } y$$
$$r^2\cos^2\theta + r^2\sin^2\theta = 16 \quad \text{expand squares}$$
$$r^2(\cos^2\theta + \sin^2\theta) = 16 \quad \text{factor out } r^2 \text{ on the left}$$
$$r^2(1) = 16 \quad \text{Pythagorean identity, } \cos^2\theta + \sin^2\theta = 1$$
$$r^2 = 16 \quad \text{Simplify}$$
$$r = 4 \quad \text{square root of both sides}$$

In polar form, the equation of this circle is expressed simply as $r = 4$.

b. For this rational function, we proceed as before, simplifying with algebra and trigonometric identities.

$$y = \frac{1}{x} \qquad \text{given equation}$$
$$r\sin\theta = \frac{1}{r\cos\theta} \qquad \text{substitute } r\cos\theta \text{ for } x \text{ and } r\sin\theta \text{ for } y$$
$$(r\sin\theta)(r\cos\theta) = 1 \qquad \text{multiply both sides by } r\cos\theta$$
$$r^2\sin\theta\cos\theta = 1 \qquad \text{reorder terms}$$
$$2r^2\sin\theta\cos\theta = 2 \qquad \text{multiply both sides by 2}$$
$$r^2\sin 2\theta = 2 \qquad \text{double angle identity: } 2\sin\theta\cos\theta = \sin 2\theta$$

WORTHY OF NOTE

Note in part b of Example 4, the equation was actually simpler in rectangular coordinates.

Multiplying both sides by 2 enabled us to use a double-angle identity and express the rational function in polar form as $r^2\sin 2\theta = 2$. Note the similarity to rectangular coordinates, where there are many different forms in which an equation may be written.

Now try Exercises 53 through 60 ▶

Converting an equation given in polar form to rectangular form relies primarily on the relationships $x = r\cos\theta$, $y = r\sin\theta$, $\tan\theta = \frac{y}{x}$, and $x^2 + y^2 = r^2$. With experience, you will become familiar with various "tricks of the trade," which include

1. Multiplying both sides of an equation by r to yield terms of $r\cos\theta$ or $r\sin\theta$.
2. Taking the tangent of both sides.
3. Squaring both sides of an equation to yield r^2.

EXAMPLE 5 ▶ Converting an Equation from Polar Form to Rectangular Form

Convert the following equations to rectangular form.

a. $\theta = \frac{\pi}{4}$ **b.** $r = 4\sin\theta$

Solution ▶

a. With θ isolated on the left side, we must introduce a trig function.

$$\theta = \frac{\pi}{4} \qquad \text{given equation}$$
$$\tan\theta = \tan\frac{\pi}{4} \qquad \text{take tangent of both sides}$$
$$\frac{y}{x} = 1 \qquad \text{substitute } \frac{y}{x} \text{ for } \tan\theta;\ \tan\frac{\pi}{4} = 1$$
$$y = x \qquad \text{multiply both sides by } x$$

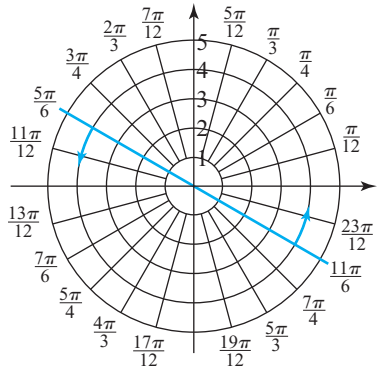
In rectangular form, we recognize the equation $y = x$ as a line with slope 1 passing through the origin.

b. Hoping to use the relationship $y = r\sin\theta$, we proceed as follows:

$$r = 4\sin\theta \qquad \text{given equation}$$
$$r^2 = 4r\sin\theta \qquad \text{multiply both sides by } r$$
$$x^2 + y^2 = 4y \qquad \text{substitute } x^2 + y^2 \text{ for } r^2 \text{ and } y \text{ for } r\sin\theta$$

Using algebra, we can write the equation $x^2 + y^2 = 4y$ as $x^2 + (y - 2)^2 = 4$, which is the standard form of a circle with center $(0, 2)$ and radius 2.

Now try Exercises 61 through 68 ▶



C. You've just seen how we can convert between polar form and rectangular form

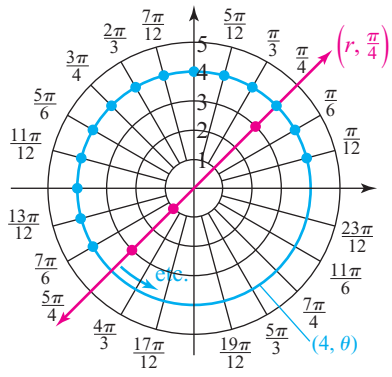
While squaring both sides of the equation in Example 5(b) would also have yielded r^2 on the left, the right would have become $16\sin^2\theta$, which does not easily convert to rectangular form. Often, you will need to try various approaches before finding one that works.

D. Basic Polar Graphs and *r*-Value Analysis

To really understand polar graphs, an intuitive sense of how they're developed is needed. Polar equations are generally stated in terms of r and trigonometric functions of θ, with θ being the input value and r being the output value. First, it helps to view the length r as the long second hand of a clock, but extending an equal distance in both directions from center (Figure 10.63). This "second hand" ticks around the face of the clock in the counterclockwise direction, with the angular measure of each tick being $\frac{\pi}{12}$ radians $= 15°$. As each angle "ticks by," we locate a point somewhere along the radius, depending on whether r is positive or negative, and plot it on the face of the clock before going on to the next tick. For the purposes of this study, we will allow that all polar graphs are continuous and smooth curves, without presenting a formal proof.

Figure 10.63

EXAMPLE 6 ▶ **Graphing Basic Polar Equations**



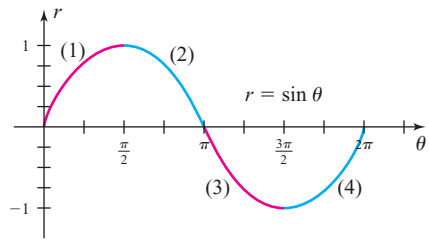
Graph the polar equations.

a. $r = 4$ **b.** $\theta = \frac{\pi}{4}$

Solution ▶

a. For $r = 4$, we're plotting all points of the form $(4, \theta)$ where r has a constant value and θ varies. As the second hand "ticks around the polar grid," we plot all points a distance of 4 units from the pole. As you might imagine, the graph is a circle with radius 4. See Example 4(a).

b. For $\theta = \frac{\pi}{4}$, all points have the form $\left(r, \frac{\pi}{4}\right)$ with $\frac{\pi}{4}$ constant and r varying. In this case, the "second hand" is frozen at $\frac{\pi}{4}$, and we plot any selection of r-values, producing the straight line shown in the figure. See Example 5(a).



Now try Exercises 69 through 72 ▶

To develop an "intuitive sense" that allows for the efficient graphing of more sophisticated equations, we use a technique called ***r*-value analysis.** This technique basically takes advantage of the predictable patterns in $r = \sin\theta$ and $r = \cos\theta$ taken from their graphs, including the zeros and maximum/minimum values.

We begin with the r-value analysis for $r = \sin\theta$, using the graph shown in Figure 10.64. Note the analysis occurs in the four colored parts corresponding to Quadrants I, II, III, and IV, and that the maximum value of $|\sin\theta| = 1$.

Figure 10.64

1. As θ moves from 0 to $\frac{\pi}{2}$, sin θ is positive and $|\sin\theta|$ increases from 0 to 1.
   $\Rightarrow$ for $r = \sin\theta$, r is increasing
2. As θ moves from $\frac{\pi}{2}$ to π, sin θ is positive and $|\sin\theta|$ decreases from 1 to 0.
   $\Rightarrow$ for $r = \sin\theta$, r is decreasing
3. As θ moves from π to $\frac{3\pi}{2}$, sin θ is negative and $|\sin\theta|$ increases from 0 to 1.
   $\Rightarrow$ for $r = \sin\theta$, $|r|$ is increasing
4. As θ moves from $\frac{3\pi}{2}$ to 2π, sin θ is negative and $|\sin\theta|$ decreases from 1 to 0.
   $\Rightarrow$ for $r = \sin\theta$, $|r|$ is decreasing

In summary, note that the value of $|r|$ goes through four cycles, two where it is increasing from 0 to 1 (in red), and two where it is decreasing from 1 to 0 (in blue).

WORTHY OF NOTE

It is important to remember that if $r < 0$, the related point on the graph is $|r|$ units from center, *180° in the opposite direction:* $(-r, \theta) \rightarrow (r, \theta + 180°)$.

EXAMPLE 7 ▶ Graphing Polar Equations Using an *r*-Value Analysis

Sketch the graph of $r = 4 \sin\theta$ using an r-value analysis.

Solution ▶

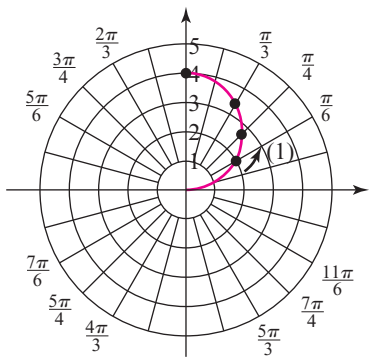
Begin by noting that $r = 0$ at $\theta = 0$, and will increase from 0 to 4 as the clock "ticks" from 0 to $\frac{\pi}{2}$, since sin θ is increasing from 0 to 1. (1) For $\theta = \frac{\pi}{6}, \frac{\pi}{4}$, and $\frac{\pi}{3}$, $r = 2$, $r \approx 2.8$, and $r \approx 3.5$, respectively (at $\theta = \frac{\pi}{2}$, $r = 4$). See Figure 10.65. (2) As θ continues "ticking" from $\frac{\pi}{2}$ to π, $|r|$ decreases from 4 to 0, since sin θ is decreasing from 1 to 0. For $\theta = \frac{2\pi}{3}, \frac{3\pi}{4}$, and $\frac{5\pi}{6}$, $r \approx 3.5$, $r \approx 2.8$, and $r = 2$, respectively (at $\theta = \pi$, $r = 0$). See Figure 10.66. (3) From π to $\frac{3\pi}{2}$, $|r|$ increases from 0 to 4, but since $r < 0$, this portion of the graph is reflected back into

WORTHY OF NOTE

While the same graph is obtained by simply plotting points, using an r-value analysis is often more efficient, particularly with more complex equations.

θ	$r = 4 \sin\theta$
0	0
$\frac{\pi}{6}$	2
$\frac{\pi}{4}$	$2\sqrt{2} \approx 2.8$
$\frac{\pi}{3}$	$2\sqrt{3} \approx 3.5$
$\frac{\pi}{2}$	4
$\frac{2\pi}{3}$	$2\sqrt{3} \approx 3.5$
$\frac{3\pi}{4}$	$2\sqrt{2} \approx 2.8$
$\frac{5\pi}{6}$	2
π	0

Figure 10.65



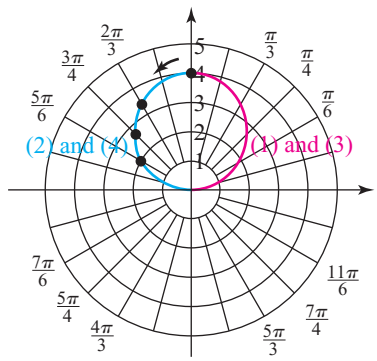


Figure 10.66

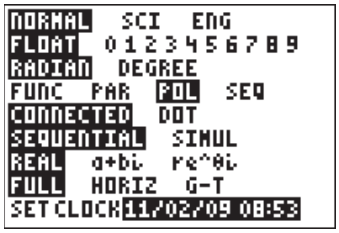

Quadrant I, overlapping the portion already drawn from 0 to $\frac{\pi}{2}$. (4) From $\frac{3\pi}{2}$ to 2π, $|r|$ decreases from 4 to 0, overlapping the portion drawn from $\frac{\pi}{2}$ to π. We conclude the graph is a closed figure limited to Quadrants I and II as shown in Figure 10.66. This is a circle with radius 2, centered at (0, 2) [see Example 5(b)]. In summary:

$r = 4 \sin \theta$

θ	0 to $\frac{\pi}{2}$	$\frac{\pi}{2}$ to π	π to $\frac{3\pi}{2}$	$\frac{3\pi}{2}$ to 2π
$\lvert r \rvert$	0 to 4	4 to 0	0 to 4	4 to 0

Now try Exercises 73 and 74 ▶

Figure 10.67

Most graphing calculators are programmed to evaluate and graph four kinds of relations—functions, sequences, polar equations, and parametric equations. This is the reason the "default" variable key (X,T,θ,n) is embossed with four different input variables. The X is used for functions, T for parametric equations (Section 10.8), θ for polar equations, and n for relations defined by a sequence (Section 11.1). To change the operating mode of the calculator, press the MODE key, highlight the desired operating mode, and press ENTER (Figure 10.67). In this case, our main interest is polar equations. Note the Y= screen obtained while in **Pol** (polar mode) is similar to that obtained in **Func** (function mode), except the dependent variable is now r_i instead of Y_i (Figure 10.68). In addition, a θ now appears when the variable key (X,T,θ,n) is pressed, rather than an X as when in function mode. Verify by entering the equation from Example 7, $r_1 = 4 \sin \theta$, as shown. Since polar graphs are by nature different from polynomial graphs, the WINDOW screen also takes on a different appearance (Figure 10.69). We can still set a desired window size or use the ZOOM options as before, and we can also state the desired interval for θ, and indicate the interval between plotted points using θstep. The standard settings (ZOOM 6) are shown in Figure 10.69, where we note that $\theta\text{step} = \frac{\pi}{24} \approx 0.13$. Knowing that the graph of r_1 is a circle of radius 4 centered at (0, 2), we set the window appropriately to obtain the GRAPH shown in Figure 10.70.

Figure 10.68

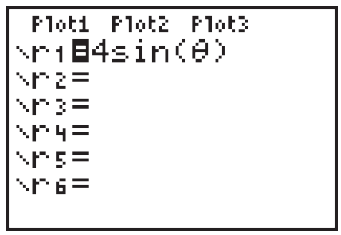

Figure 10.69

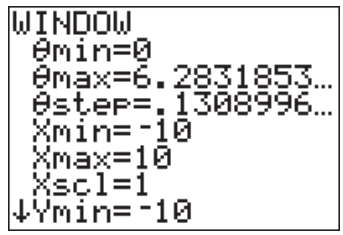

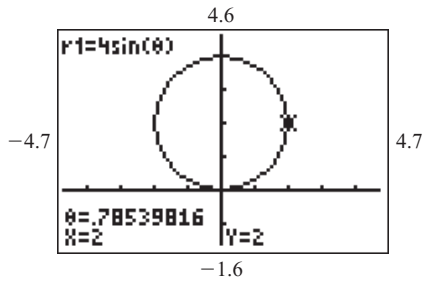

Figure 10.70

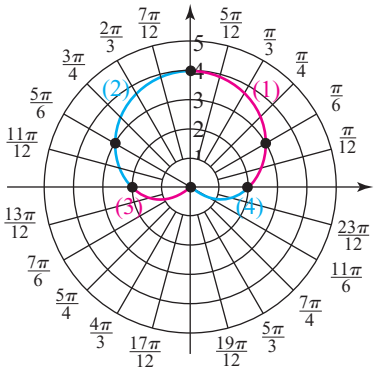
Although it takes some effort, r-value analysis offers an efficient way to graph polar equations, and gives a better understanding of graphing in polar coordinates. In addition, it often enables you to sketch the graph with a minimum number of calculations and plotted points. As you continue using the technique, it will help to have Figure 10.64 in plain view for quick reference, as well as the corresponding analysis of $y = \cos \theta$ for polar graphs involving cosine **(see Exercise 114).**

EXAMPLE 8 ▶ **Graphing Polar Equations Using an *r*-Value Analysis**

Sketch the graph of $r = 2 + 2 \sin \theta$ using an *r*-value analysis. Use a calculator to verify your graph.

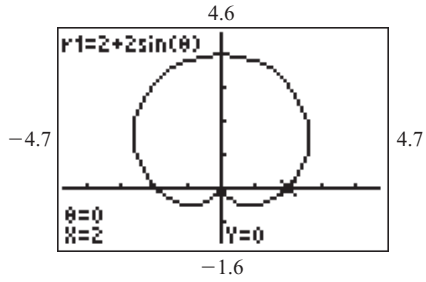
Solution ▶ Since the minimum value of $\sin \theta$ is -1, we note that r will always be greater than or equal to zero. At $\theta = 0$, r has a value of 2 ($\sin 0 = 0$), and will increase from 2 to 4 as the clock "ticks" from 0 to $\frac{\pi}{2}$ ($\sin \theta$ is positive and $|\sin \theta|$ is increasing).



From $\frac{\pi}{2}$ to π, r decreases from 4 to 2 ($\sin \theta$ is positive and $|\sin \theta|$ is decreasing).

From π to $\frac{3\pi}{2}$, r decreases from 2 to 0 ($\sin \theta$ is negative and $|\sin \theta|$ is increasing);

and from $\frac{3\pi}{2}$ to 2π, r increases from 0 to 2 ($\sin \theta$ is negative and $|\sin \theta|$ is decreasing).



We conclude the graph is a closed figure containing the points $(2, 0)$, $\left(4, \frac{\pi}{2}\right)$, $(2, \pi)$, and $\left(0, \frac{3\pi}{2}\right)$. Noting that $\theta = \frac{\pi}{6}$ and $\theta = \frac{5\pi}{6}$ will produce integer values, we evaluate $r = 2 + 2 \sin \theta$ and obtain the additional points $\left(3, \frac{\pi}{6}\right)$ and $\left(3, \frac{5\pi}{6}\right)$. Using these points and the *r*-value analysis produces the graph shown in Figure 10.71, called a **cardioid** (from the limaçon family of curves). In Figure 10.72, a calculator verifies our graph. In summary we have:

Figure 10.71

θ	$r = 2 + 2 \sin \theta$
(1) 0 to $\frac{\pi}{2}$	2 to 4
(2) $\frac{\pi}{2}$ to π	4 to 2
(3) π to $\frac{3\pi}{2}$	2 to 0
(4) $\frac{3\pi}{2}$ to 2π	0 to 2

Figure 10.72

Now try Exercises 75 through 78 ▶

☑ **D.** You've just seen how we can sketch basic polar graphs using an *r*-value analysis

WORTHY OF NOTE

In mathematics we refer to the tests for polar symmetry as *sufficient but not necessary conditions*. The tests are *sufficient* to show symmetry (if the test is satisfied, the graph must be symmetric), but the tests are *not necessary* to show symmetry (the graph may be symmetric even if the test is not satisfied).

E. Symmetry and Families of Polar Graphs

Even with a careful *r*-value analysis, some polar graphs require a good deal of effort to produce. In many cases, symmetry can be a big help, as can recognizing certain families of equations and their related graphs. As with other forms of graphing, gathering this information beforehand will enable you to graph relations with a smaller number of plotted points. Figures 10.73 to 10.76 offer some examples of symmetry for polar graphs.

The tests for symmetry in polar coordinates bear a strong resemblance to those for rectangular coordinates, but there is a major difference. Since there are many different ways to name a point in polar coordinates, a polar graph may actually exhibit a form of symmetry without satisfying the related test. In other words, the tests are *sufficient* to establish symmetry, but not *necessary*.

Figure 10.73
Vertical-axis symmetry:
$r = -2 - 2\sin\theta$

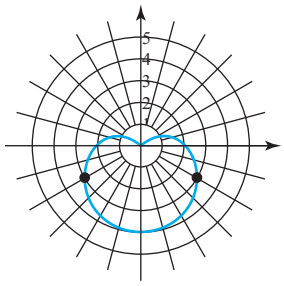


Figure 10.74
Polar-axis symmetry:
$r = 5\cos\theta$

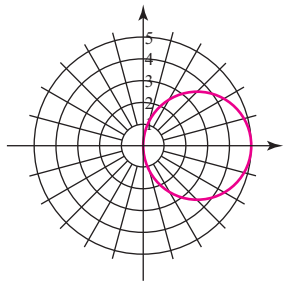

Figure 10.75
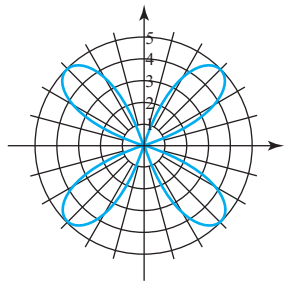
Polar symmetry:
$r = 5\sin(2\theta)$



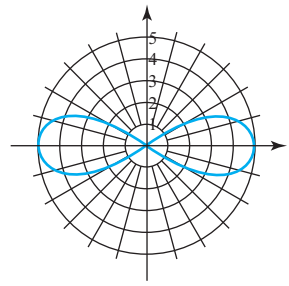


Figure 10.76
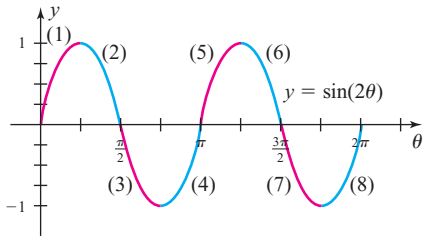
Polar symmetry:
$r^2 = 25\cos(2\theta)$

The formal tests for symmetry are explored in **Exercises 116 to 118.** For our purposes, we'll rely on a somewhat narrower view, one that is actually a synthesis of our observations here and our previous experience with the sine and cosine.



Symmetry for Graphs of Certain Polar Equations

Given the polar equation $r = f(\theta)$,

1. If $f(\theta)$ represents an expression in terms of sine(s), the graph will be symmetric to $\theta = \dfrac{\pi}{2}$: (r, θ) and $(r, \pi - \theta)$ are on the graph.
2. If $f(\theta)$ represents an expression in terms of cosine(s), the graph will be symmetric to $\theta = 0$: (r, θ) and $(r, -\theta)$ are on the graph.

While the fundamental ideas from Examples 7 and 8 go a long way toward graphing other polar equations, our discussion would not be complete without a review of the *period* of sine and cosine. Many polar equations have factors of $\sin(n\theta)$ or $\cos(n\theta)$ in them, and it helps to recall the period formula $P = \dfrac{2\pi}{n}$. Comparing $r = 4\sin\theta$ from Example 7 with $r = 4\sin(2\theta)$, we note the period of sine changes from $P = 2\pi$ to $P = \dfrac{2\pi}{2} = \pi$, *meaning there will be twice as many cycles* and $|r|$ will now go through *eight* cycles—four where $|\sin(2\theta)|$ is increasing from 0 to 1 (in red), and four where it is decreasing from 1 to 0 (in blue). See Figure 10.77.

Figure 10.77

EXAMPLE 9 ▶ **Sketching Polar Graphs Using Symmetry and *r*-Values**

Sketch the graph of $r = 4\sin(2\theta)$ using symmetry and an r-value analysis. Use a calculator to verify your graph.

Solution ▶ Since r is expressed in terms of sine, the graph will be symmetric to $\theta = \dfrac{\pi}{2}$. We note that $r = 0$ at $\theta = \dfrac{n\pi}{2}$, where n is any integer, and the graph will go through the pole at these points. This also tells us the graph will be a closed figure. From

the graph of $\sin(2\theta)$ in Figure 10.80, we see $|\sin(2\theta)| = 1$ at $\theta = \frac{\pi}{4}, \frac{3\pi}{4}, \frac{5\pi}{4}$, and $\frac{7\pi}{4}$, so the graph will include the points $\left(4, \frac{\pi}{4}\right), \left(-4, \frac{3\pi}{4}\right), \left(4, \frac{5\pi}{4}\right)$, and $\left(-4, \frac{7\pi}{4}\right)$. Only the analysis of the first four cycles is given next, since the remainder of the graph can be drawn using symmetry.

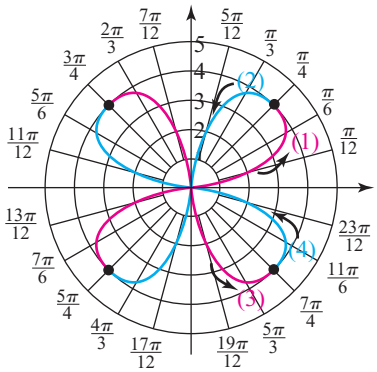


Table 10.1

θ	$r = 4\sin(2\theta)$
0	0
$\frac{\pi}{6}$	$2\sqrt{3} \approx 3.5$
$\frac{\pi}{4}$	4
$\frac{\pi}{3}$	$2\sqrt{3} \approx 3.5$
$\frac{\pi}{2}$	0
$\frac{2\pi}{3}$	$-2\sqrt{3} \approx -3.5$
$\frac{3\pi}{4}$	-4
$\frac{5\pi}{6}$	$-2\sqrt{3} \approx -3.5$
π	0

	Cycle	r-Value Analysis	Location of Graph
(1)	0 to $\frac{\pi}{4}$	$\lvert r\rvert$ increases from 0 to 4	QI ($r > 0$)
(2)	$\frac{\pi}{4}$ to $\frac{\pi}{2}$	$\lvert r\rvert$ decreases from 4 to 0	QI ($r > 0$)
(3)	$\frac{\pi}{2}$ to $\frac{3\pi}{4}$	$\lvert r\rvert$ increases from 0 to 4	QIV ($r < 0$)
(4)	$\frac{3\pi}{4}$ to π	$\lvert r\rvert$ decreases from 4 to 0	QIV ($r < 0$)

Plotting the points and applying the r-value analysis with the symmetry involved produces the graph in the figure, called a **four-leaf rose.** At any time during this process, additional points such as those shown in Table 10.1 can be calculated to "round-out" the graph shown in Figure 10.78.

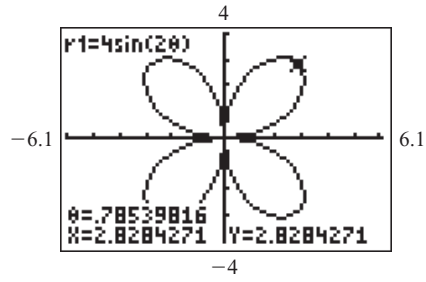

Figure 10.78

$r = 4\sin(2\theta)$

θ	$\lvert r\rvert$
0 to $\frac{\pi}{4}$	0 to 4
$\frac{\pi}{4}$ to $\frac{\pi}{2}$	4 to 0
$\frac{\pi}{2}$ to $\frac{3\pi}{4}$	0 to 4
$\frac{3\pi}{4}$ to π	4 to 0

Figure 10.79

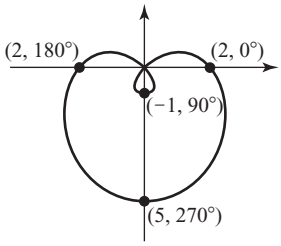
The calculator GRAPH of $r_1 = 4\sin(2\theta)$ with $\theta\text{min} = 0$, $\theta\text{max} = 2\pi$, and $\theta\text{step} = \frac{\pi}{24}$ is shown in Figure 10.79.

Now try Exercises 79 through 86 ▶

Graphing Polar Equations

To assist the process of graphing polar equations:

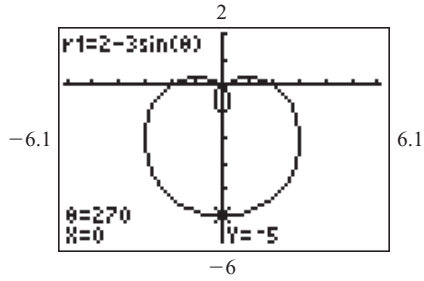
1. Carefully note any symmetries you can use.
2. Have graphs of $y = \sin(n\theta)$ and $y = \cos(n\theta)$ in view for quick reference.
3. Use these graphs to analyze the value of r as the "clock ticks" around the polar grid: (a) determine the max/min r-values and write them in polar form, and (b) determine the polar-axis intercepts and write them in polar form.
4. Plot the points, then use the r-value analysis and any symmetries to complete the graph.



Similar to polynomial graphs, polar graphs come in numerous shapes and varieties, yet many of them share common characteristics and can be organized into certain families. Some of the more common families are illustrated in Appendix F, and give the general equation and related graph for common family members. Also included are characteristics of certain graphs that will enable you to develop the polar equation given its graph or information about its graph. For further investigations using a graphing calculator, **see Exercises 87 through 92.**

EXAMPLE 10 ▶ Graphing a Limaçon Using Stated Conditions

Find the equation of the polar curve satisfying the given conditions, then sketch the graph: limaçon, symmetric to $\theta = 90°$, with $a = 2$ and $b = -3$.



Solution ▶ The general equation of a limaçon symmetric to $\theta = 90°$ is $r = a + b \sin\theta$, so our desired equation is $r = 2 - 3\sin\theta$. Since $|a| < |b|$, the limaçon has an inner loop of length $3 - 2 = 1$ and a maximum distance from the origin of $2 + 3 = 5$. The polar-axis intercepts are $(2, 0°)$ and $(2, 180°)$. With $b < 0$, the graph is reflected across the polar axis (facing "downward"). The complete graph is shown in Figure 10.80.

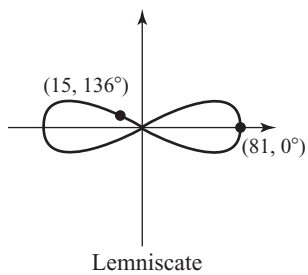
Figure 10.80

θ	$r = 2 - 3\sin\theta$
0°	2
45°	≈ −0.1
90°	−1
135°	≈ −0.1
180°	2
225°	≈ 4.1
270°	5
315°	≈ 4.1
360°	2

Figure 10.81

A calculator in degree MODE with $\theta\text{min} = 0°$, $\theta\text{max} = 360°$, $\theta\text{step} = 7.5°$, and window settings shown verifies our graph (Figure 10.81).

Now try Exercises 95 through 110 ▶



EXAMPLE 11 ▶ Modeling the Flight Path of a Scavenger Bird

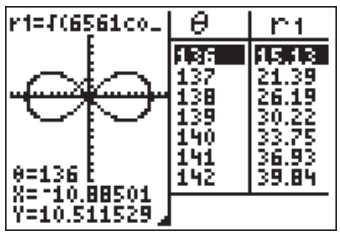
Scavenger birds sometimes fly over dead or dying animals (called carrion) in a "figure-eight" formation, closely resembling the graph of a lemniscate. Suppose the flight path of one of these birds was plotted and found to contain the polar coordinates $(81, 0°)$ and $(0, 45°)$. Find the equation of the lemniscate. If the bird lands at the point $(r, 136°)$, how far is it from the carrion? Assume r is in yards. Use a calculator to check your result.

Solution ▶ Since $(81, 0°)$ is a point on the graph (Figure 10.82), the lemniscate is symmetric to the polar axis and the general equation is $r^2 = a^2\cos(2\theta)$. The point $(81, 0°)$ indicates $81^2 = a^2$, hence the equation is $r^2 = 6561\cos(2\theta)$. At $\theta = 136°$ we have $r^2 = 6561\cos 272°$, and the bird has landed $r \approx 15$ yd away.

θ	$r = \sqrt{6561\cos(2\theta)}$
0°	81
30°	≈ 57.3
60°	error
90°	error
120°	error
150°	≈ 57.3
180°	81

Figure 10.82

Lemniscate



Check ▶ To begin, we take the square root of each side of the general equation $r^2 = 6561\cos(2\theta)$ and enter $r_1 = \sqrt{6561\cos(2\theta)}$ in our calculator. Next, set the calculator to **G-T** (MODE) to simultaneously display the graph and table (Figure 10.83). With (WINDOW) settings of $\theta\text{min} = 0°$, $\theta\text{max} = 360°$, $\theta\text{step} = 1°$, $\text{Xmin} = -100$, $\text{Xmax} = 100$, $\text{Ymin} = -100$, and $\text{Ymax} = 100$, our calculator produces the graph of the lemniscate shown in Figure 10.84. The keystrokes (2nd) (TRACE) **(CALC) 1:value** enables us to enter 136°, see the rectangular coordinates of the bird, and verify the distance $r \approx 15$ yd using the table (Figure 10.84).

WORTHY OF NOTE
Because of the polar symmetry of lemniscates, the points described by $r = -\sqrt{6561\cos(2\theta)}$ will be plotted by r_1 as the "second hand ticks around the graph."

Figure 10.83

Figure 10.84

Now try Exercises 111 through 113 ▶

E. You've just seen how we can use symmetry and families of curves to write a polar equation given a polar graph or information about the graph

You've likely been wondering how the different families of polar graphs were named. The roses are easy to figure as each graph has a flower-like appearance. The limaçon (pronounced li-ma-sawn) family takes its name from the Latin words *limax* or *lamacis,* meaning "snail." With some imagination, these graphs do have the appearance of a snail shell. The cardioids are a subset of the limaçon family and are so named due to their obvious resemblance to the human heart. In fact, the name stems from the Greek *kardia* meaning heart, and many derivative words are still in common use (a cardiologist is one who specializes in a study of the heart). Finally, there is the lemniscate family, a name derived from the Latin *lemniscus,* which describes a certain kind of ribbon. Once again, a little creativity enables us to make the connection between ribbons, bows, and the shape of this graph.

10.6 EXERCISES

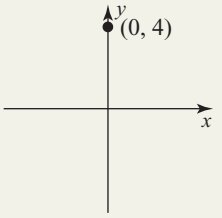
▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. The point (r, θ) is said to be written in _____ coordinates.
2. In polar coordinates, the origin is called the _____ and the horizontal axis is called the _____ axis.
3. The point $(4, 135°)$ is located in Q _____, while $(-4, 135°)$ is located in Q _____.
4. If a polar equation is given in terms of cosine, the graph will be symmetric to _____.
5. Write out the procedure for plotting points in polar coordinates, as though you were explaining the process to a friend.
6. Discuss the graph of $r = 6\cos\theta$ in terms of an r-value analysis, using $y = \cos\theta$ and a color-coded graph.

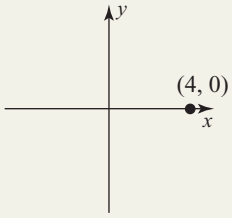
▶ DEVELOPING YOUR SKILLS

Plot the following points using polar graph paper.



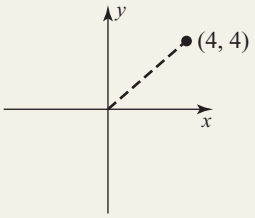
7. $\left(4, \frac{\pi}{2}\right)$ **8.** $\left(3, \frac{3\pi}{2}\right)$ **9.** $\left(2, \frac{5\pi}{4}\right)$

10. $\left(4.5, -\frac{\pi}{3}\right)$ **11.** $\left(-5, \frac{5\pi}{6}\right)$ **12.** $\left(-4, \frac{7\pi}{4}\right)$

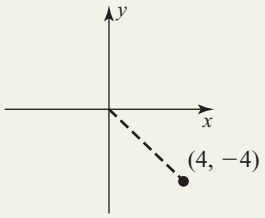


13. $\left(-3, -\frac{2\pi}{3}\right)$ **14.** $\left(-4, -\frac{\pi}{4}\right)$

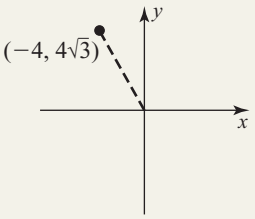
Express the points shown using polar coordinates with θ in radians, $0 \le \theta < 2\pi$ and $r > 0$.



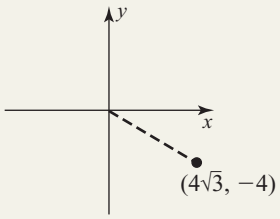
15.



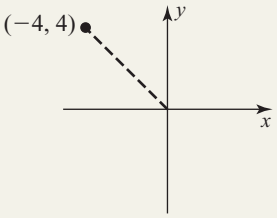
16.



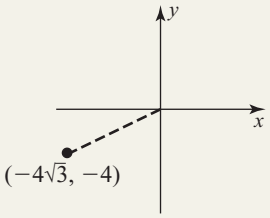
17.



18.



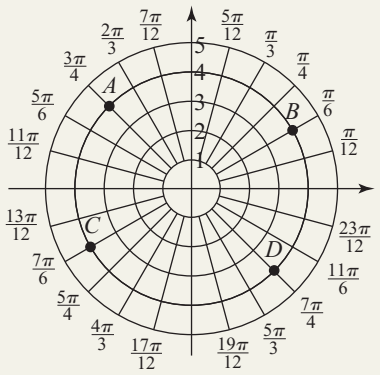
19.



20.

21.

22.



List three alternative ways the given points can be expressed in polar coordinates using $r > 0$, $r < 0$, and $\theta \in [-2\pi, 2\pi)$.

23. $\left(3\sqrt{2}, \frac{3\pi}{4}\right)$ **24.** $\left(4\sqrt{3}, -\frac{5\pi}{3}\right)$

25. $\left(-2, \frac{11\pi}{6}\right)$ **26.** $\left(-3, -\frac{7\pi}{6}\right)$

Match each (r, θ) given to one of the points A, B, C, or D shown.

Exercise 27–36

27. $\left(4, -\frac{5\pi}{6}\right)$ **28.** $\left(4, -\frac{5\pi}{4}\right)$

29. $\left(-4, \frac{\pi}{6}\right)$ **30.** $\left(-4, \frac{3\pi}{4}\right)$

31. $\left(-4, -\frac{5\pi}{4}\right)$ **32.** $\left(-4, -\frac{\pi}{4}\right)$

33. $\left(4, \frac{13\pi}{6}\right)$ **34.** $\left(4, \frac{19\pi}{6}\right)$

35. $\left(-4, -\frac{21\pi}{4}\right)$ **36.** $\left(4, -\frac{35\pi}{6}\right)$

Convert from rectangular coordinates to polar coordinates. A diagram may help. Use a calculator to verify your results.

37. $(-8, 0)$ **38.** $(0, -7)$

39. $(4, 4)$ **40.** $(4\sqrt{3}, 4)$

41. $(5\sqrt{2}, 5\sqrt{2})$ **42.** $(6, -6\sqrt{3})$

43. $(-5, -12)$ **44.** $(-3.5, 12)$

Convert from polar coordinates to rectangular coordinates. A diagram may help. Use a calculator to verify your results.

45. $(8, 45°)$ **46.** $(6, 60°)$

47. $\left(4, \frac{3\pi}{4}\right)$ **48.** $\left(5, \frac{5\pi}{6}\right)$

49. $\left(-2, \frac{7\pi}{6}\right)$ **50.** $\left(-10, \frac{4\pi}{3}\right)$

51. $(-5, -135°)$ **52.** $(-4, -30°)$

Convert the following equations to polar form.

53. $x^2 = 25 - y^2$

54. $y = \sqrt{3}x$

55. $x = \dfrac{3}{y}$

56. $6xy = 1$

57. $y = 3x^2 + x$

58. $y^2 = 5x$

59. $x^2 - y^2 = x^4 + 2x^2y^2 + y^4$

60. $x^2 - y^2 = 2xy$

Convert the following equations to rectangular form.

61. $r = 6\cos\theta$

62. $r = 2\sin\theta$

63. $r = 2\sec\theta$

64. $r = -3\csc\theta$

65. $r = \sqrt{r\cos\theta - 1}$

66. $r\sin\theta = r\sqrt{\cos 2\theta}$

67. $r = \dfrac{1}{1 + \sin\theta}$

68. $r = \dfrac{6}{2 + 4\sin\theta}$

Sketch each polar graph using an *r*-value analysis (a table may help), symmetry, and any convenient points. Use a calculator to verify your results from Exercises 75 through 86.

69. $r = 5$

70. $r = 6$

71. $\theta = \dfrac{\pi}{6}$

72. $\theta = -\dfrac{3\pi}{4}$

73. $r = 4\cos\theta$

74. $r = 2\sin\theta$

75. $r = 3 + 3\sin\theta$

76. $r = 2 + 2\cos\theta$

77. $r = 2 - 4\sin\theta$

78. $r = 1 - 2\cos\theta$

79. $r = 5\cos(2\theta)$

80. $r = 3\sin(4\theta)$

81. $r = 4\sin 2\theta$

82. $r = 6\cos(5\theta)$

83. $r^2 = 9\sin(2\theta)$

84. $r^2 = 16\cos(2\theta)$

85. $r = 4\sin\left(\dfrac{\theta}{2}\right)$

86. $r = 6\cos\left(\dfrac{\theta}{2}\right)$

Use a graphing calculator in polar mode to produce the following polar graphs.

87. $r = 4\sqrt{1 - \sin^2\theta}$, *a hippopede*

88. $r = 3 + \csc\theta$, *a conchoid*

89. $r = 2\cos\theta\cot\theta$, *a cissoid*

90. $r = \cot\theta$, *a kappa curve*

91. $r = 8\sin\theta\cos^2\theta$, *a bifoliate*

92. $r = 8\cos\theta(4\sin^2\theta - 2)$, *a folium*

▶ WORKING WITH FORMULAS

93. The midpoint formula in polar coordinates:

$$M = \left(\frac{r\cos\alpha + R\cos\beta}{2}, \frac{r\sin\alpha + R\sin\beta}{2}\right)$$

The midpoint of a line segment connecting the points (r, α) and (R, β) in polar coordinates can be found using the formula shown. Find the midpoint of the line segment between $(r, \alpha) = (6, 45°)$ and $(R, \beta) = (8, 30°)$, then convert these points to rectangular coordinates and find the midpoint using the "standard" formula. Do the results match?

94. The distance formula in polar coordinates:

$$d = \sqrt{R^2 + r^2 - 2Rr\cos(\alpha - \beta)}$$

Using the law of cosines, it can be shown that the distance between the points (R, α) and (r, β) in polar coordinates is given by the formula indicated. Use the formula to find the distance between $(R, \alpha) = (6, 45°)$ and $(r, \beta) = (8, 30°)$, then convert these to rectangular coordinates and compute the distance between them using the "standard" formula. Do the results match?

▶ APPLICATIONS

Polar graphs: Find the equation of a polar graph satisfying the given conditions, then sketch the graph.

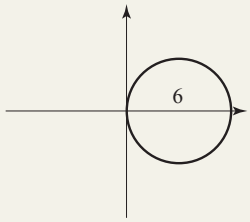
95. limaçon, symmetric to polar axis, $a = 4$ and $b = 4$

96. rose, four petals, two petals symmetric to the polar axis, $a = 6$

97. rose, five petals, one petal symmetric to the polar axis, $a = 4$

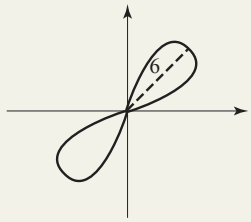
98. limaçon, symmetric to $\theta = \dfrac{\pi}{2}$, $a = 2$ and $b = 4$

99. lemniscate, $a = 4$ through $(\pi, 4)$



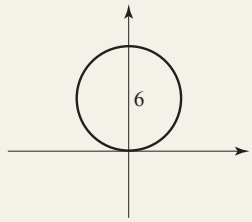
100. lemniscate, $a = 8$ through $\left(8, \frac{\pi}{4}\right)$

101. circle, symmetric to $\theta = \frac{\pi}{2}$, center at $\left(2, \frac{\pi}{2}\right)$, containing $\left(2, \frac{\pi}{6}\right)$

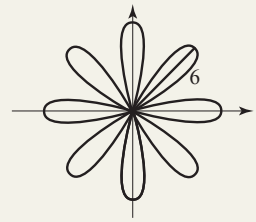


102. circle, symmetric to polar axis, through $(6, \pi)$

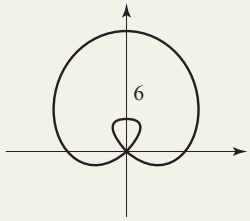
Matching: Match each graph to its equation a through h, which follow. Justify your answers.



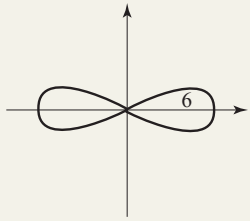
103.



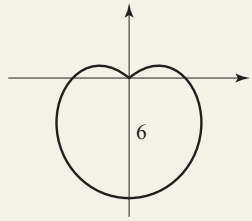
104.



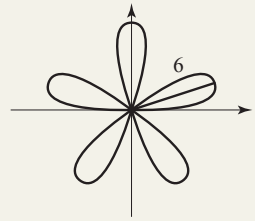
105.



106.

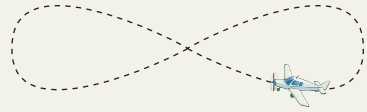


107.



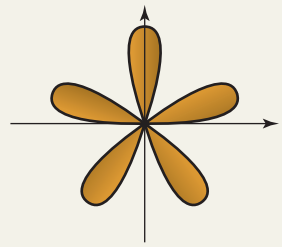
108.

109.



110.

a. $r = 6\cos\theta$ **b.** $r = 3 - 3\sin\theta$ **c.** $r = 6\cos(4\theta)$ **d.** $r^2 = 36\cos(2\theta)$



e. $r^2 = 36\sin(2\theta)$ **f.** $r = 2 + 4\sin\theta$ **g.** $r = 6\sin\theta$ **h.** $r = 6\sin(5\theta)$

111. Figure eights: Waiting for help to arrive on foot, a light plane is circling over some stranded hikers using a "figure eight" formation, closely resembling the graph of a lemniscate. Suppose the flight path of the plane was plotted (using the hikers as the origin) and found to contain the polar coordinates (7200, 45°) and (0, 90°) with r in meters. Find the equation of the lemniscate.

112. Animal territories: Territorial animals often prowl the borders of their territory, marking the boundaries with various bodily excretions. Suppose the territory of one such animal was limaçon shaped, with the pole representing the den of the animal. Find the polar equation defining the animal's territory if markings are left at (750, 0°), (1000, 90°), and (750, 180°). Assume r is in meters.

113. Prop manufacturing: The propellers for a toy boat are manufactured by stamping out a rose with n petals and then bending each blade. If the manufacturer wants propellers with five blades and a radius of 15 mm, what two polar equations will satisfy these specifications?

114. Polar curves and cosine: Do a complete r-value analysis for graphing polar curves involving cosine. Include a color-coded graph showing the relationship between r and θ, similar to the analysis for sines that preceded Example 8.

▶ EXTENDING THE CONCEPT

115. The polar graph $r = a\theta$ is called the *Spiral of Archimedes.* Consider the spiral $r = \frac{1}{2}\theta$. As this graph spirals around the origin, what is the distance between each positive, polar intercept? In QI, what is the distance between consecutive branches of the spiral each time it intersects $\theta = \frac{\pi}{4}$? What is the distance between consecutive branches of the spiral at $\theta = \frac{\pi}{2}$? What can you conclude?

As mentioned in the exposition, tests for symmetry of polar graphs are sufficient to show symmetry (if the test is satisfied, the graph must be symmetric), but the tests are not necessary to show symmetry (the graph may be symmetric even if the test is not satisfied). For $r = f(\theta)$, the formal tests for the symmetry are: (1) the graph will be symmetric to the polar axis if $f(\theta) = f(-\theta)$; (2) the graph will be symmetric to the line $\theta = \frac{\pi}{2}$ if $f(\pi - \theta) = f(\theta)$; and (3) the graph will be symmetric to the pole if $f(\theta) = -f(\theta)$.

116. Sketch the graph of $r = 4\sin(2\theta)$. Show the equation fails the first test, yet the graph is still symmetric to the polar axis.

117. Why is the graph of every lemniscate symmetric to the pole?

118. Verify that the graph of every limaçon of the form $r = a + b\cos\theta$ is symmetric to the polar axis.

119. The graphs of $r = a\sin(n\theta)$ and $r = a\cos(n\theta)$ are from the rose family of polar graphs. If n is odd, there are n petals in the rose, and if n is even, there are $2n$ petals. An interesting extension of this fact is that the n petals enclose exactly 25% of the area of the circumscribed circle, and the $2n$ petals enclose exactly 50%. Find the area within the boundaries of the rose defined by $r = 6\sin(5\theta)$.

▶ MAINTAINING YOUR SKILLS

120. (7.4) Verify the following is an identity: $\cos^2 x - \sin^2 x = 1 - \sin(2x)\tan x$.

121. (7.7) Solve for $t \in [0, 2\pi)$:

$$20 = 5 - 30\sin\left(2t - \frac{\pi}{6}\right).$$

122. (2.3) Solve the absolute value inequality. Answer in interval notation:
$-3|2x + 5| - 7 > -19$

123. (2.5) Graph the piecewise-defined function shown and state its domain and range.

$$f(x) = \begin{cases} x + 2 & -5 \le x < -1 \\ x & -1 \le x < 2 \\ 4 & 2 < x \le 5 \end{cases}$$

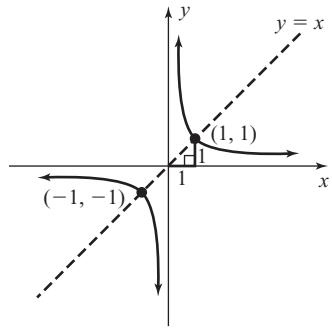
10.7 More on the Conic Sections: Rotation of Axes and Polar Form

LEARNING OBJECTIVES

In Section 10.7 you will see how we can:

- ❑ **A.** Graph conic sections that have nonvertical and nonhorizontal axes (rotated conics)
- ❑ **B.** Identify conics using the discriminant of the polynomial form—the invariant $B^2 - 4AC$
- ❑ **C.** Write the equation of a conic section in polar form
- ❑ **D.** Solve applications involving the conic sections in polar form

Our study of conic sections would not be complete without considering conic sections whose graphs are not symmetric to a vertical or horizontal axis. The axis of symmetry still exists, but is rotated by some angle. We'll first study these **rotated conics** using the equation in its polynomial form, then investigate some interesting applications of the polar form.



A. Rotated Conics and the Rotation of Axes

It's always easier to understand a new idea in terms of a known idea, so we begin our study with a review of the reciprocal function $y = \frac{1}{x}$. From the equation we note:

1. The denominator is zero when $x = 0$, and the y-axis is a vertical asymptote (the vertical line $x = 0$).
2. Since the degree of the numerator is less than the degree of the denominator, the x-axis is a horizontal asymptote (the horizontal line $y = 0$).
3. Since $x < 0$ implies $y < 0$ and $x > 0$ implies $y > 0$, the graph will have two branches—one in the first quadrant and one in the third.

Note the polynomial form of this equation is $xy = 1$. The resulting graph is shown in Figure 10.85, *and is actually the graph of a hyperbola with a transverse axis of* $y = x$. Using the 45°-45°-90° triangle indicated, we find the distance from the origin to each vertex is $\sqrt{2}$. If we rotated the hyperbola 45° clockwise, we would obtain a more "standard" graph with a horizontal transverse axis and vertices at $(\pm a, 0) \rightarrow (\pm\sqrt{2}, 0)$. The asymptotes would be $y = \pm 1x$, and since $y = \pm\frac{b}{a}x$ is the general form we know $b = \pm\sqrt{2}$. This information can be used to find the equation of the rotated hyperbola.

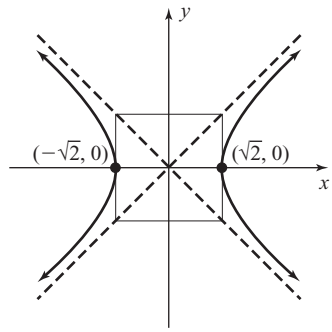


Figure 10.85

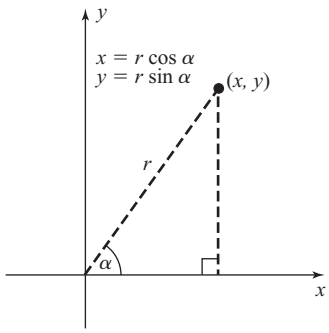
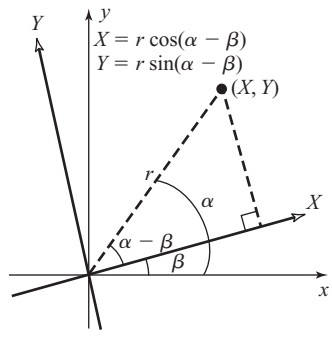
EXAMPLE 1 ▶ **Finding the Equation of a Rotated Conic from Its Graph**



The hyperbola $xy = 1$ is rotated clockwise 45°, with new vertices at $(\pm\sqrt{2}, 0)$, asymptotes at $y = \pm 1x$ and $b = \pm\sqrt{2}$. Find the equation and graph the hyperbola.

Solution ▶ Using the standard form $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$ and substituting $\pm\sqrt{2}$ for a and b, the equation of the rotated hyperbola is $\frac{x^2}{2} - \frac{y^2}{2} = 1$ or $x^2 - y^2 = 2$ in polynomial form. The resulting graph is the central hyperbola shown.



Now try Exercises 7 and 8 ▶

Figure 10.86

It's important to note the equation of the rotated hyperbola *is devoid of the mixed "xy" term.* In nondegenerate cases, the equation $Ax^2 + Cy^2 + Dx + Ey + F = 0$ is the polynomial form of a conic with axes that are vertical/horizontal. However, the most general form of the equation is $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$, and includes this Bxy term. As noted in Example 1, the inclusion of this term will rotate the graph through some angle β. Based on these observations, we reason that one approach to graphing these conics is to find the angle of rotation β with respect to the xy-axes. We can then use β to rewrite the equation so that it corresponds to a new set of XY-axes, *which are parallel to the axes of the conic*. The mixed xy-term will be absent from the new equation and we can graph the conic on the new axes using the same ideas as before (identifying a, b, foci, and so on). To find β, recall that a point (x, y) in the xy-plane can be written $x = r\cos\alpha$, $y = r\sin\alpha$, as in Figure 10.86. The diagram in Figure 10.87 shows the axes of a new XY-plane, rotated counterclockwise by angle β. In this new plane, the coordinates of the point (x, y) become $X = r\cos(\alpha - \beta)$ and $Y = r\sin(\alpha - \beta)$ as shown. Using the difference identities for sine and cosine and substituting $x = r\cos\alpha$ and $y = r\sin\alpha$ leads to:

Figure 10.87

$$\begin{aligned} X &= r\cos(\alpha - \beta) \\ &= r(\cos\alpha\cos\beta + \sin\alpha\sin\beta) \\ &= r\cos\alpha\cos\beta + r\sin\alpha\sin\beta \\ &= x\cos\beta + y\sin\beta \end{aligned} \qquad \begin{aligned} Y &= r\sin(\alpha - \beta) \\ &= r(\sin\alpha\cos\beta - \cos\alpha\sin\beta) \\ &= r\sin\alpha\cos\beta - r\cos\alpha\sin\beta \\ &= y\cos\beta - x\sin\beta \end{aligned}$$

The last two equations can be written as a system, which we will use to solve for x and y in terms of X and Y.

$$\begin{cases} X = x\cos\beta + y\sin\beta \\ Y = y\cos\beta - x\sin\beta \end{cases} \quad \text{original system}$$

$$\begin{cases} X\cos\beta = x\cos^2\beta + y\sin\beta\cos\beta & \text{multiply second equation by } \cos\beta \\ Y\sin\beta = y\sin\beta\cos\beta - x\sin^2\beta & \text{multiply second equation by } \sin\beta \end{cases}$$

$$X\cos\beta - Y\sin\beta = x\cos^2\beta + x\sin^2\beta \quad \text{first equation – second equation}$$

$$X\cos\beta - Y\sin\beta = x \quad \text{factor out } x\,(\cos^2\beta + \sin^2\beta = 1)$$

WORTHY OF NOTE

If you are familiar with matrices, it may be easier to remember the rotation formulas in their matrix form, since the pattern of functions is the same, with only a difference in sign:

$$\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} \cos\beta & -\sin\beta \\ \sin\beta & \cos\beta \end{bmatrix}\begin{bmatrix} X \\ Y \end{bmatrix}$$

$$\begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} \cos\beta & \sin\beta \\ -\sin\beta & \cos\beta \end{bmatrix}\begin{bmatrix} x \\ y \end{bmatrix}$$

See Exercises 86 and 87.

Re-solving the system for y results in $y = X\sin\beta + Y\cos\beta$, yielding what are called the **rotation of axes formulas (see Exercise 79).**

Rotation of Axes Formulas

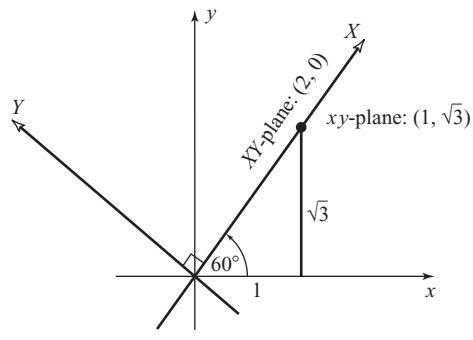
If the x- and y-axes of the xy-plane are rotated counterclockwise by the (acute) angle β to form the X- and Y-axes of an XY-plane, the coordinates of the points (x, y) and (X, Y) are related by the formulas

$$\begin{aligned} x &= X\cos\beta - Y\sin\beta \\ y &= X\sin\beta + Y\cos\beta \end{aligned} \qquad \begin{aligned} X &= x\cos\beta + y\sin\beta \\ Y &= -x\sin\beta + y\cos\beta \end{aligned}$$

EXAMPLE 2 ▶ **Naming the Location of a Point After Rotating the Axes**

Given the point $(1, \sqrt{3})$ in the xy-plane, find the coordinates of this point in the XY-plane given the angle β between the xy-axes and the XY-axes is 60°.

Solution ▶ Using the formulas with $x = 1$, $y = \sqrt{3}$, and $\beta = 60°$, we obtain



$$\begin{aligned} X &= x\cos\beta + y\sin\beta \\ &= 1\cos 60° + \sqrt{3}\sin 60° \\ &= \left(\frac{1}{2}\right) + \sqrt{3}\left(\frac{\sqrt{3}}{2}\right) \\ &= 2 \end{aligned} \qquad \begin{aligned} Y &= -x\sin\beta + y\cos\beta \\ &= -1\sin 60° + \sqrt{3}\cos 60° \\ &= -\frac{\sqrt{3}}{2} + \frac{\sqrt{3}}{2} \\ &= 0 \end{aligned}$$

The coordinates of $P(X, Y)$ would be $(2, 0)$.

Now try Exercises 9 through 16 ▶

The diagram in Figure 10.88 provides a more intuitive look at the rotation from Example 2. As you can see, a 30°-60°-90° triangle is formed with a hypotenuse of 2, giving coordinates $(2, 0)$ in the XY-plane.

Figure 10.88

EXAMPLE 3 ▶ Writing the Equation of a Rotated Conic

The equation $X^2 + 4Y^2 = 16$ describes a central ellipse in the XY-plane. Given the XY-axes are formed by a 45° counterclockwise rotation of the xy-axes, what is the corresponding equation in the xy-plane?

Solution ▶ We proceed as before, using the rotation formulas $X = x\cos\beta + y\sin\beta$ and $Y = y\cos\beta - x\sin\beta$. With $\beta = 45°$ we have $\cos\beta = \sin\beta = \frac{\sqrt{2}}{2}$, yielding

$$X^2 + 4Y^2 = 16$$

$$(x\cos\beta + y\sin\beta)^2 + 4(y\cos\beta - x\sin\beta)^2 = 16 \quad \text{use rotation formulas}$$

$$\left(\frac{\sqrt{2}}{2}x + \frac{\sqrt{2}}{2}y\right)^2 + 4\left(\frac{\sqrt{2}}{2}y - \frac{\sqrt{2}}{2}x\right)^2 = 16 \quad \text{substitute } \frac{\sqrt{2}}{2} \text{ for } \sin\beta \text{ and } \cos\beta$$

$$\left(\frac{1}{2}x^2 + xy + \frac{1}{2}y^2\right) + 4\left(\frac{1}{2}x^2 - xy + \frac{1}{2}y^2\right) = 16 \quad \text{square binomials}$$

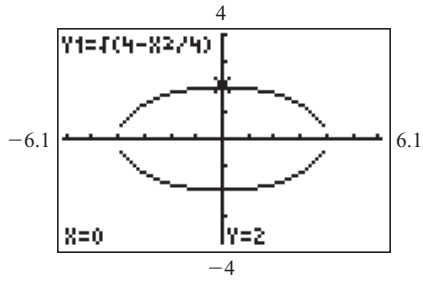
$$\frac{1}{2}x^2 + xy + \frac{1}{2}y^2 + 2x^2 - 4xy + 2y^2 = 16 \quad \text{distribute}$$

$$\frac{5}{2}x^2 - 3xy + \frac{5}{2}y^2 = 16 \quad \text{result}$$

Now try Exercises 17 through 20 ▶

In Section 10.2, we used our calculator to graph central ellipses like $X^2 + 4Y^2 = 16$ from Example 3 by solving for Y and, in this case, entering the two halves as $Y_1 = \sqrt{4 - \frac{X^2}{4}}$ and $Y_2 = -\sqrt{4 - \frac{X^2}{4}}$ (see Figure 10.89). Similarly, a calculator can graph the rotated ellipse described by the equation $\frac{5}{2}x^2 - 3xy + \frac{5}{2}y^2 = 16$. Begin by rewriting the equation as $\frac{5}{2}y^2 - 3xy + \frac{5}{2}x^2 - 16 = 0$ with the goal of solving for y. Since the equation is quadratic (in terms of y), we substitute $a = \frac{5}{2}$, $b = -3x$, and $c = \frac{5}{2}x^2 - 16$ into the quadratic formula and find $y = \frac{3x \pm \sqrt{160 - 16x^2}}{5}$ (verify this). Now we can easily enter $Y_1 = \frac{3X + \sqrt{160 - 16X^2}}{5}$ and $Y_2 = \frac{3X - \sqrt{160 - 16X^2}}{5}$ into our calculator and graph the rotated ellipse (see Figure 10.90). Note the XY-axes have also been graphed as $Y_3 = X$ and $Y_4 = -X$.

Figure 10.89



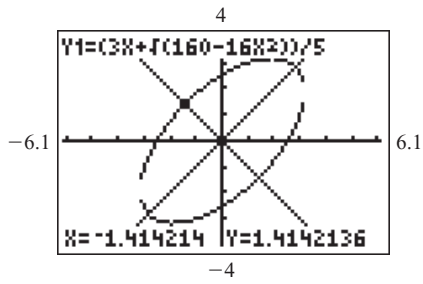


Figure 10.90

Note the equation of the conic in the standard xy-plane contains the "mixed" Bxy-term. In practice, we seek to reverse this procedure by starting in the xy-plane, and finding the angle β needed to *eliminate* the Bxy-term. Using the rotation formulas and the appropriate angle β, the equation $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$ becomes $aX^2 + cY^2 + dX + eY + f = 0$, where the xy-term is absent. To find the angle β, note that without loss of generality, we can assume $D = E = 0$ since only the

second-degree terms are used to identify a conic. Starting with the simplified equation $Ax^2 + Bxy + Cy^2 + F = 0$ and using the rotation formulas we obtain

$$\begin{array}{ccccccc} Ax^2 & + & Bx & \cdot & y & + & Cy^2 & + F = 0 \end{array}$$

$$A(X\cos\beta - Y\sin\beta)^2 + B(X\cos\beta - Y\sin\beta)(X\sin\beta + Y\cos\beta) + C(X\sin\beta + Y\cos\beta)^2 + F = 0$$

Expanding this expression and collecting like terms **(see Exercise 80),** gives the following expressions for coefficients a, b, and c of the corresponding equation $aX^2 + bXY + cY^2 + f = 0$:

$a \to A\cos^2\beta + B\sin\beta\cos\beta + C\sin^2\beta$ — a is the coefficient of X^2

$b \to -2A\sin\beta\cos\beta + B(\cos^2\beta - \sin^2\beta) + 2C\sin\beta\cos\beta$ — b is the coefficient of XY

$c \to A\sin^2\beta - B\sin\beta\cos\beta + C\cos^2\beta$ — c is the coefficient of Y^2

$f \to F$ — $f = F$ (the constant remains unchanged)

To accomplish our purpose, we require the coefficient b to be zero. While this expression looks daunting, the double-angle identities for sine and cosine simplify it very nicely:

$$b \to -A(2\sin\beta\cos\beta) + B(\cos^2\beta - \sin^2\beta) + C(\mathbf{2\sin\beta\cos\beta}) = 0 \quad (1)$$

$$-A\sin(2\beta) + B\cos(2\beta) + C\,\mathbf{\sin(2\beta)} = 0 \quad (2)$$

$$(C - A)\sin(2\beta) = -B\cos(2\beta) \quad (3)$$

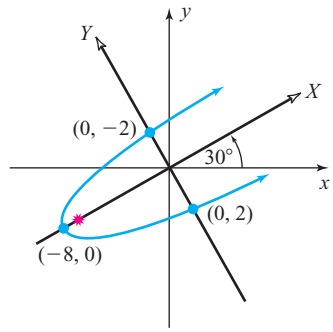
$$\tan(2\beta) = \frac{-B}{C - A} \quad (4)$$

$$\tan(2\beta) = \frac{B}{A - C};\ A \neq C \quad (5)$$

Note from line (3) that $A = C$ would imply $\cos(2\beta) = 0$, giving $2\beta = 90°$ or $-90°$, with $\beta = 45°$ or $-45°$ (for the sake of convenience, we select the angle in QI). This fact can many times be used to great advantage. If $A \neq C$, $\tan(2\beta) = \dfrac{B}{A - C}$ and we choose 2β between 0 and 180° so that β will be in the first quadrant $[0 < \beta < 90°]$.

The Equation of a Conic After Rotating the Axes

For a conic defined by $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$ and its graph in the xy-plane, an angle β can be determined using $\tan(2\beta) = \dfrac{B}{A - C}$ and used in the rotation formulas to find a polynomial $aX^2 + cY^2 + dX + eY + f = 0$ in an XY-plane, where the conic is either vertical or horizontal.



EXAMPLE 4 ▶ **Rotating the Axes to Eliminate the *Bxy*-Term**

For $x^2 - 2\sqrt{3}xy + 3y^2 - \sqrt{3}x - y - 16 = 0$, eliminate the xy-term using a rotation of axes and identify the conic associated with the resulting equation. Then sketch the graph of the rotated conic in the XY-plane.

Solution ▶ Since $A \neq C$, we find β using $\tan(2\beta) = \dfrac{B}{A - C}$, giving $\tan(2\beta) = \dfrac{-2\sqrt{3}}{1 - 3} = \sqrt{3}$. This shows $2\beta = \tan^{-1}\sqrt{3}$, yielding $2\beta = 60°$ so $\beta = 30°$. Using $\cos 30° = \dfrac{\sqrt{3}}{2}$ and $\sin 30° = \dfrac{1}{2}$ along with the rotation formulas we obtain the following XY-equation, with corresponding terms shown side-by-side for clarity:

Given Term in xy-Plane		Corresponding Term in XY-Plane
x^2	$\longrightarrow$	$\left(\frac{\sqrt{3}}{2}X - \frac{1}{2}Y\right)^2 = \frac{3}{4}X^2 - \frac{\sqrt{3}}{2}XY + \frac{1}{4}Y^2$
$-2\sqrt{3}xy$	$\longrightarrow$	$-2\sqrt{3}\left(\frac{\sqrt{3}}{2}X - \frac{1}{2}Y\right)\left(\frac{1}{2}X + \frac{\sqrt{3}}{2}Y\right) = -\frac{3}{2}X^2 - \sqrt{3}XY + \frac{3}{2}Y^2$
$3y^2$	$\longrightarrow$	$3\left(\frac{1}{2}X + \frac{\sqrt{3}}{2}Y\right)^2 = \frac{3}{4}X^2 + 3\frac{\sqrt{3}}{2}XY + \frac{9}{4}Y^2$
$-\sqrt{3}x$	$\longrightarrow$	$-\sqrt{3}\left(\frac{\sqrt{3}}{2}X - \frac{1}{2}Y\right) = -\frac{3}{2}X + \frac{\sqrt{3}}{\mathbf{2}}Y$
$-y$	$\longrightarrow$	$-\left(\frac{1}{2}X + \frac{\sqrt{3}}{2}Y\right) = -\frac{1}{2}X - \frac{\sqrt{3}}{\mathbf{2}}Y$
-16	$\longrightarrow$	-16

Adding the like terms on the far right, the X^2-terms (in red), the Y-terms (**in bold**), and the mixed XY-terms (in blue) sum to zero, leaving the equation $-2X + 4Y^2 - 16 = 0$, which is the parabola defined by $Y^2 = \frac{1}{2}(X + 8)$. This parabola is symmetric to the X-axis and opens to the right, with a vertex at $(-8, 0)$, Y-intercepts at $(0, -2)$ and $(0, 2)$, focus at $(-\frac{63}{8}, 0)$ and directrix through $(-\frac{65}{8}, 0)$. The graph is shown in the figure.

Now try Exercises 21 through 30 ▶

A. You've just seen how we can graph conic sections that have nonvertical and nonhorizontal axes (rotated conics)

In Example 4, the angle β was a **standard angle** and easily found. In general, this is not the case and finding exact values of $\cos\beta$ and $\sin\beta$ for use in the rotation formulas requires using $\tan(2\beta) = \dfrac{\sin(2\beta)}{\cos(2\beta)}$, the corresponding (triangle) diagram, and the identities $\cos\beta = \sqrt{\dfrac{1 + \cos(2\beta)}{2}}$ and $\sin\beta = \sqrt{\dfrac{1 - \cos(2\beta)}{2}}$. **See Exercises 31, 32, 84, and 85** for further study.

B. Identifying Conics Using the Discriminant

In addition to rotating the axes, the inclusion of the "xy-term" makes it impossible to identify the conic section using the tests seen earlier. For example, having $A = C$ no longer guarantees a circle, and $A = 0$ or $C = 0$ does not guarantee a parabola. Rather than continuing to look at what the mixed term and the resulting rotation *changes,* we now look at what the rotation *does not change*, called **invariants** of the transformation. These invariants can be used to double-check the algebra involved and to identify the conic using the **discriminant.** These are given here without proof.

Invariants of a Rotation and Classification Using the Discriminant

By rotating the coordinate axes through a predetermined angle β,

the equation $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$
can be transformed into $aX^2 + cY^2 + dX + eY + f = 0$

in which the xy-term is absent. This rotation has the following invariants:

(1) $F = f$ (2) $A + C = a + c$ (3) $B^2 - 4AC = b^2 - 4ac$.

The discriminant of a conic equation in polynomial form is $B^2 - 4AC$. Except in degenerate cases, the graph of the equation can be classified as follows:

If $B^2 - 4AC = 0$, the graph will be a parabola.
If $B^2 - 4AC < 0$, the graph will be a circle or an ellipse.
If $B^2 - 4AC > 0$, the graph will be a hyperbola.

EXAMPLE 5A ▶ Verifying the Invariants of a Rotation of Axes

Verify the invariants just given using the equations from Example 4. Also verify the discriminant test.

Solution ▶ From the equation $x^2 - 2\sqrt{3}xy + 3y^2 - \sqrt{3}x - y - 16 = 0$, we have $A = 1, B = -2\sqrt{3}, C = 3, D = -\sqrt{3}, E = -1$, and $F = -16$. After applying the rotation the equation became $-2X + 4Y^2 - 16 = 0$, with $a = 0, b = 0, c = 4, d = -2, e = 0$, and $f = -16$. Checking each invariant gives:

(1) $-16 = -16$ ✓
(2) $1 + 3 = 0 + 4$ ✓
(3) $(-2\sqrt{3})^2 - 4(1)(3) = (0)^2 - 4(0)(4)$ ✓

With $B^2 - 4AC = 0$, the discriminant test indicates the conic is a parabola ✓.

EXAMPLE 5B ▶ Identifying the Equation of a Conic Using the Discriminant

Use the discriminant to identify each equation as that of a circle, ellipse, parabola, or hyperbola, but do not graph the equation.

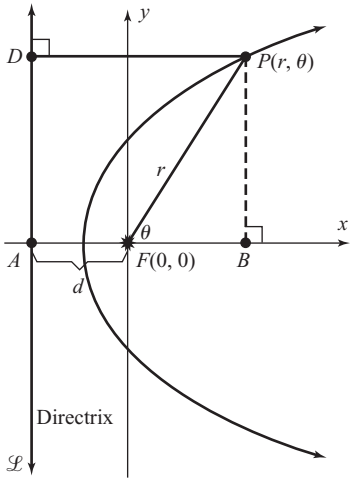
a. $3x^2 - 4xy + 3y^2 + 6x + 12y - 2 = 0$
b. $4x^2 + 9xy + 4y^2 - 8x + 24y + 9 = 0$
c. $6x^2 - 7xy + y^2 - 5 = 0$
d. $x^2 - 6xy + 9y^2 + 6x = 0$

Solution ▶

a. $A = 3; B = -4; C = 3$
$B^2 - 4AC = (-4)^2 - 4(3)(3)$
$= -20$
circle or ellipse

b. $A = 4; B = 9; C = 4$
$B^2 - 4AC = (9)^2 - 4(4)(4)$
$= 17$
hyperbola

c. $A = 6; B = -7; C = 1$
$B^2 - 4AC = (-7)^2 - 4(6)(1)$
$= 25$
hyperbola



d. $A = 1; B = -6; C = 9$
$B^2 - 4AC = (-6)^2 - 4(1)(9)$
$= 0$
parabola

B. You've just seen how we can identify conics using the discriminant of the polynomial form—the invariant $B^2 - 4AC$

Now try Exercises 33 through 36 ▶

C. Conic Equations in Polar Form

Figure 10.91

You might recall that earlier in this chapter we defined ellipses and hyperbolas in terms of a distance between two points, but a parabola in terms of a distance between a point and a line (the focus and directrix). Actually, all conic sections can be defined using a focus/directrix development *and written in polar form.* This serves to unify and greatly simplify their study. We begin by revisiting the focus/directrix development of a parabola, using a directrix $\mathcal{L}$ and placing the focus at the origin. With the polar axis as the axis of symmetry and the point $P(r, \theta)$ in polar coordinates, we obtain the graph shown in Figure 10.91. Given D and A are points on $\mathcal{L}$ (with A on the polar axis), we note the following:

(1) $\overline{DP} = \overline{FP}$ definition of a parabola
(2) $\overline{DP} = \overline{AB}$ equal line segments
(3) $\overline{FB} = r\cos\theta$ $\cos\theta = \dfrac{\overline{FB}}{r}$
(4) $\overline{AB} = \overline{AF} + \overline{FB}$ sum of line segments

Using the preceding equations and representing the distance $\overline{AF}$ by the constant d, we obtain this sequence:

$\overline{AB} = d + r\cos\theta$ substitute d for $\overline{AF}$ and $r\cos\theta$ for $\overline{FB}$
$\overline{FP} = d + r\cos\theta$ substitute $\overline{FP}$ for $\overline{AB}$ since $\overline{FP} = \overline{DP} = \overline{AB}$
$r = d + r\cos\theta$ substitute r for $\overline{FP}$

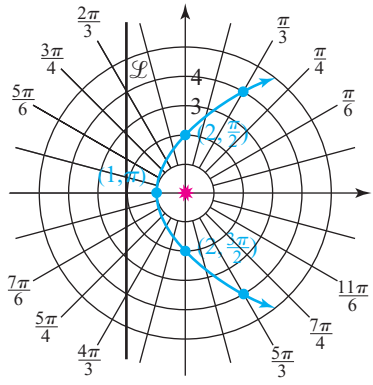
Solving the last equation for r we have $r - r\cos\theta = d$, then $r = \dfrac{d}{1 - \cos\theta}$, which is the equation of a parabola in polar form with its focus at the origin, vertex at $\left(\dfrac{d}{2}, \pi\right)$, and y-intercepts at $\left(d, \dfrac{\pi}{2}\right)$ and $\left(d, \dfrac{3\pi}{2}\right)$. Note the constant "1" in the denominator is a key characteristic of polar equations, and helps define the standard form.

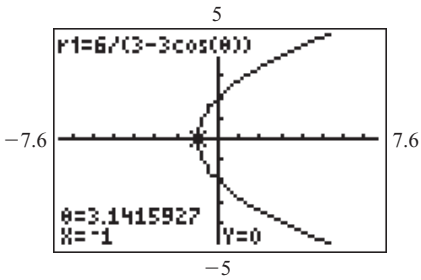
EXAMPLE 6A ▶ Identifying a Conic from Its Polar Equation

Verify the equation $r = \dfrac{6}{3 - 3\cos\theta}$ represents a parabola, then describe and sketch the graph. Use a calculator to verify your sketch.

Solution ▶ Write the equation in standard form by dividing the numerator and denominator by 3, obtaining $r = \dfrac{2}{1 - \cos\theta}$. From this we see $d = 2$ and the equation represents a parabola symmetric to the polar axis, with vertex at $(1, \pi)$ and y-intercepts at $\left(2, \dfrac{\pi}{2}\right)$ and $\left(2, \dfrac{3\pi}{2}\right)$, as shown in Figure 10.92. A calculator in radian and polar MODE with $\theta\text{min} = 0$, $\theta\text{max} = 2\pi$, $\theta\text{step} = \dfrac{\pi}{24}$ and window settings shown produces the graph in Figure 10.93 and verifies our sketch.

Figure 10.92





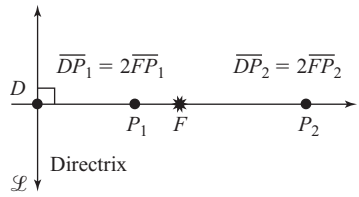


Figure 10.93

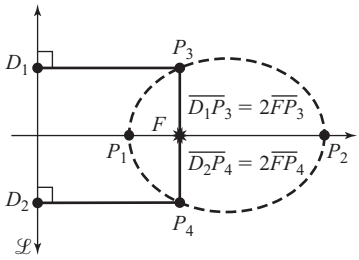


The polar equation for a parabola depended on $\overline{DP}$ and $\overline{FP}$ being equal in length, with ratio $\dfrac{\overline{FP}}{\overline{DP}} = 1$. But what if this ratio is not equal to 1? Similar to our introduction

Figure 10.94

to conics in Section 10.1, we assume $\dfrac{\overline{FP}}{\overline{DP}} = \dfrac{1}{2}$ and investigate the graph that results. Cross-multiplying gives $2\overline{FP} = \overline{DP}$, which states that the distance from D to P is twice the distance from F to P. Note that we are able to locate *two points P_1 and P_2 on the polar axis* that satisfy this relation, rather than only one as in the case of the parabola. Figure 10.94 illustrates the location of these points. Using the focal chord for convenience, two additional points P_3 and P_4 can be located that also satisfy the stated condition (see Figure 10.95). In fact, we can locate an infinite number of these points using $\dfrac{\overline{FP}}{\overline{DP}} = \dfrac{1}{2}$, and the resulting graph appears to be an ellipse (and is definitely *not* a parabola). These illustrations provide the basis for stating a general focus/directrix definition of the conic sections. The ratio $\dfrac{\overline{FP}}{\overline{DP}}$ is often represented by the letter e, and represents the **eccentricity** of the conic. Using $\overline{FP} = r$ and $\overline{DP} = d + r\cos\theta$ from our initial development, $\dfrac{\overline{FP}}{\overline{DP}} = \dfrac{r}{d + r\cos\theta} = e$, which enables us to state the general equation of a conic in polar form. Solving for r leads to the equation $r = \dfrac{de}{1 - e\cos\theta}$, where the type of conic depends solely on e. Depending on the orientation of the conic, the general form may involve sine instead of cosine, and have a sum of terms in the denominator rather than a difference. Note once again that if $e = 1$, the relation simplifies into the parabolic equation seen earlier.

Figure 10.95

The Standard Equation of a Conic in Polar Form

Given a conic section with eccentricity e, one foci at the pole of the $r\theta$-plane, and directrix $\mathcal{L}$ located d units from this focus. Then the polar equations

$$r = \frac{de}{1 \pm e\cos\theta} \quad \text{and} \quad r = \frac{de}{1 \pm e\sin\theta}$$

represent one of the conic sections as determined by the value of e.

- If $e = 1$, the graph is a parabola.
- If $0 < e < 1$, the graph is an ellipse.
- If $e > 1$, the graph is a hyperbola.

For the ellipse and hyperbola, the major axis and transverse axis (respectively) are both perpendicular to the directrix and contain the vertices and foci. From our development of ellipses in Section 10.2, eccentricity can then be expressed in terms of a and c, as the ratio $e = \dfrac{c}{a}$.

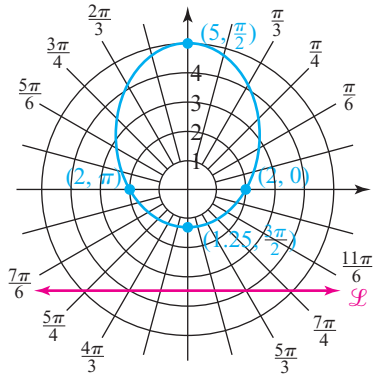
As in our previous study of polar equations, if the equation involves cosine the graph will be symmetric to the polar axis. If the graph involves sine, the line $\theta = \dfrac{\pi}{2}$ is the axis of symmetry. In addition, if the denominator contains a difference of terms (as in Example 6A), the graph will be above or to the right of the directrix (depending on whether the equation involves sine or cosine). If the denominator contains a sum of terms, the graph will be below or to the left of the directrix.

EXAMPLE 6B ▶ **Using the Standard Equation to Graph a Conic in Polar Form**

Determine if the equation $r = \dfrac{10}{5 - 3\sin\theta}$ represents a parabola, ellipse, or hyperbola. Then describe and sketch the graph. Check your results with a calculator.

Solution ▶ To write the equation in standard form, we divide both numerator and denominator by 5, obtaining the equation $r = \dfrac{2}{1 - \frac{3}{5}\sin\theta}$. From the standard form we note $e = \dfrac{3}{5}$ so the equation represents an ellipse. With a difference of terms and the sine function involved, the graph is symmetric to $\theta = \dfrac{\pi}{2}$ and is above the directrix. Given so much information by the equation, we require very few points to sketch the graph and settle for those generated by $\theta = 0, \dfrac{\pi}{2}, \pi$, and $\dfrac{3\pi}{2}$, yielding the points $(2, 0), \left(5, \dfrac{\pi}{2}\right), (2, \pi)$, and $\left(\dfrac{5}{4}, \dfrac{3\pi}{2}\right)$. The graph is shown in Figure 10.96. A calculator in radian MODE with $\theta\text{min} = 0$, $\theta\text{max} = 2\pi$, $\theta\text{step} = \dfrac{\pi}{24}$ and window settings shown verifies our graph (Figure 10.97).

Figure 10.96



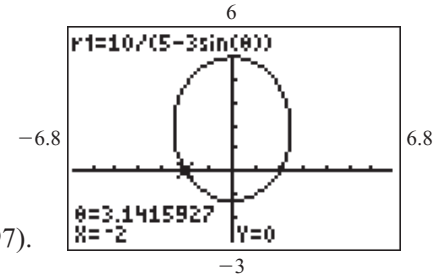


Figure 10.97

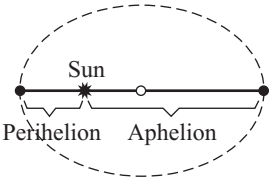
C. You've just seen how we can write the equation of a conic section in polar form

Now try Exercises 37 through 56 ▶

D. Applications of Conics in Polar Form

For centuries it has been known that the orbits of the planets around the Sun are elliptical, with the Sun at one focus. In addition, comets may approach our Sun in elliptical, hyperbolic, or parabolic paths with the Sun again at the foci. This makes planetary studies a very natural application of the conic sections in polar form. To aid this study, it helps to know that in an elliptical orbit, the maximum distance of a planet from the Sun is called its **aphelion,** and the shortest distance is the **perihelion** (Figure 10.98). This means the length of the major axis is "aphelion + perihelion," enabling us to find the value of c if the aphelion and perihelion are known (Figure 10.99). Using $e = \dfrac{c}{a}$, we can then find the eccentricity of the planet's orbit.

Figure 10.98



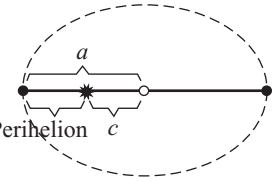


Figure 10.99

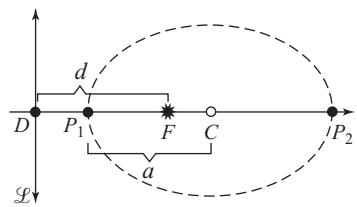
EXAMPLE 7 ▶ **Determining the Eccentricity of a Planet's Orbit**

In its elliptical orbit around the Sun, Mars has an aphelion of 154.9 million miles and a perihelion of 128.4 million miles. What is the eccentricity of its orbit?

Solution ▶ The length of the major axis would be $2a = (154.9 + 128.4)$ million mi, yielding a semimajor axis of $a = 141.65$ million miles. Since $a = c +$ perihelion (Figure 10.99), we have $141.65 = c + 128.4$ so $c = 13.25$. The eccentricity of the orbit is $e = \frac{c}{a} = \frac{13.25}{141.65}$ or about 0.0935.

Now try Exercises 59 and 60 ▶

We can also find the perihelion and aphelion directly in terms of a (semimajor axis) and e (eccentricity) if these quantities are known. Using $a = c +$ perihelion, we obtain: perihelion $= a - c$. For $e = \frac{c}{a}$, we have $ea = c$ and by direct substitution we obtain: perihelion $= a - ea = a(1 - e)$. For Example 8, recall that "AU" designates an *astronomical unit*, and represents the mean distance from the Earth to the Sun, approximately 92.96 million miles.



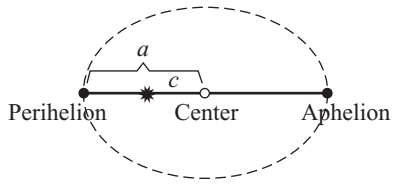
EXAMPLE 8 ▶ **Determining the Perihelion of a Planet's Orbit**

The orbit of the planet Jupiter has a semimajor axis of 5.2 AU (1 AU $\approx$ 92.96 million miles) and an eccentricity of 0.0489. What is the closest distance from Jupiter to the Sun?

Solution ▶ With perihelion $= a(1 - e)$, we have $5.2(1 - 0.0489) \approx 4.946$. At its closest approach, Jupiter is 4.946 AU from the Sun (about 460 million miles).

Now try Exercises 61 and 62 ▶

Figure 10.100



To find the polar equation of a planetary orbit, it's helpful to write the general polar equation in terms of the semimajor axis a, which is often known or easily found, rather than in terms of the distance d from directrix to focus, which is often unknown. Consider the diagram in Figure 10.100, which shows an elliptical orbit with the Sun at one focus, vertices P_1 and P_2 (perihelion and aphelion), and the center C of the ellipse. Assume the point P used to define the conic sections is at position P_1, giving $\frac{\overline{FP_1}}{\overline{DP_1}} = e$. From the discussion preceding Example 8 we have $\overline{FP_1} = a(1 - e)$. Substituting $a(1 - e)$ for $\overline{FP_1}$ and solving for $\overline{DP_1}$ gives $\overline{DP_1} = \frac{a(1 - e)}{e}$. Using $d = \overline{DP_1} + \overline{FP_1}$, we obtain the following sequence:

$$
\begin{aligned}
d &= \overline{DP_1} + \overline{FP_1} \\
&= \frac{a(1 - e)}{e} + a(1 - e) && \text{substitute } \tfrac{a(1 - e)}{e} \text{ for } \overline{DP_1} \text{ and } a(1 - e) \text{ for } \overline{FP_1} \\
&= \frac{a(1 - e)}{e} + \frac{ae(1 - e)}{e} && \text{common denominator} \\
&= \frac{a(1 - e)(1 + e)}{e} && \text{combine terms, factor out } a(1 - e) \\
&= \frac{a(1 - e^2)}{e} && (1 - e)(1 + e) = 1 - e^2 \\
de &= a(1 - e^2) && \text{multiply by } e
\end{aligned}
$$

Substituting $a(1 - e^2)$ for de in the standard equation $r = \dfrac{de}{1 - e\cos\theta}$ gives the equation of the orbit entirely in terms of a and e: $r = \dfrac{a(1 - e^2)}{1 - e\cos\theta}$.

EXAMPLE 9 ▶ Writing the Polar Equation of an Ellipse from Given Information

At its aphelion, the Kuiper object Pluto is the most distant from the Sun at 4538 million miles. It has a perihelion of 2756 million miles. Use this information to find the polar equation that models the orbit of Pluto, then find the length of the focal chord for this ellipse.

Solution ▶ With all figures in millions of miles, the major axis is $2a = 4538 + 2756 = 7294$, so the semimajor axis has length $a = 3647$. With $a = c +$ perihelion, we obtain $3647 = c + 2756$ or $c = 891$. The eccentricity of the orbit is $e = \dfrac{891}{3647} \approx 0.244$. The polar equation for the orbit of Pluto is $r \approx \dfrac{(3647)(1 - [0.244]^2)}{1 - [0.244]\cos\theta}$ or $r \approx \dfrac{3430}{1 - 0.244\cos\theta}$. Substituting $\theta = \dfrac{\pi}{2}$ (since the left-most focus is at the pole), we obtain $r = 3430$, so the length of the focal chord is $2(3430) = 6860$ million miles.

Now try Exercises 65 through 70 ▶

☑ **D.** you've just seen how we can solve applications involving the conic sections in polar form

10.7 EXERCISES

▶ CONCEPTS AND VOCABULARY

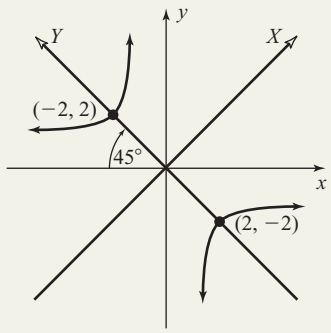
Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. The set of points (x, y) in the xy-plane are related to points (X, Y) in the XY-plane by the _____ _____ _____ formulas. To find the angle β between the original axes and the rotated axes, we use $\tan(2\beta) =$ _____.

2. For a point P on the graph of a conic with focus F and D a point on the directrix, the ratio $\dfrac{\overline{FP}}{\overline{DP}}$ gives the _____ of the graph. For the eccentricity e, if $e = 1$ the graph is a _____, if $e > 1$ the graph is a _____, and if $0 < e < 1$ the graph will be an ellipse.

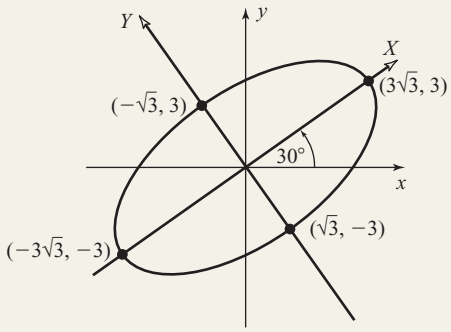
3. Features or relationships that do not change when certain transformations are applied are called _____ of the transformation.

4. The _____ form of the equation of a conic is $r = \dfrac{de}{1 \pm e\cos\theta}$ if the graph is symmetric to the _____ axis, and $r = \dfrac{de}{1 \pm e\sin\theta}$ if symmetric to the line _____.



5. Discuss the advantages of graphing a rotated conic using the rotation of axes over graphing by simply plotting points.

6. Discuss the primary advantages of using $r = \dfrac{a(1 - e^2)}{1 - e\cos\theta}$ rather than $r = \dfrac{de}{1 - e\cos\theta}$ to develop an equation of planetary orbit.



▶ DEVELOPING YOUR SKILLS

The graph of a conic rotated in the *xy*-plane is given. Use the graph (not the rotation of axes formulas) to find the equation of the conic in the *XY*-plane.

7.

8.

Given the point (x, y) in the *xy*-plane, find the coordinates of this point in the *XY*-plane given the angle β between the *xy*-axes and the *XY*-axes is 45°.

9. $(6\sqrt{2}, 6)$ **10.** $(4, 3\sqrt{2})$

11. $(0, 5)$ **12.** $(8, 0)$

Given the point (X, Y) in the *XY*-plane, find the coordinates of this point in the *xy*-plane given the angle β between the *xy*-axes and the *XY*-axes is 30°.

13. $(2, 2\sqrt{3})$ **14.** $(\sqrt{3}, 3)$

15. $(3, 4)$ **16.** $(12, 5)$

The angle β between the *xy*-axes and the *XY*-axes is given. Find the corresponding equation of the given conic sections in the *xy*-plane.

17. $X^2 - Y^2 = 9; 60°$ **18.** $X^2 + Y = 4; 60°$

The conic sections whose equations are given in the *xy*-plane are rotated by the indicated angle. What is the corresponding equation in the *XY*-plane?

19. $3x^2 + 2xy + 3y^2 = 9; 45°$

20. $x^2 + \sqrt{3}xy + 2y^2 = 8; 60°$

For the given conics in the *xy*-plane, (a) use a rotation of axes to find the corresponding equation in the *XY*-plane (clearly state the angle of rotation β), and (b) sketch its graph. Be sure to indicate the characteristic features of each conic in the *XY*-plane.

21. $x^2 + 4xy + y^2 - 2 = 0$

22. $x^2 + 2xy + y^2 - 12 = 0$

23. $5x^2 + 6xy + 5y^2 = 16$

24. $5x^2 - 26xy + 5y^2 = -72$

25. $x^2 + 10\sqrt{3}xy + 11y^2 = -64$

26. $37x^2 + 42\sqrt{3}xy + 79y^2 - 400 = 0$

27. $3x^2 - 2\sqrt{3}xy + y^2 - 8x - 8\sqrt{3}y = 0$

28. $6x^2 - 4\sqrt{3}xy + 2y^2 + 2x + 2\sqrt{3}y = 0$

29. $13x^2 - 6\sqrt{3}xy + 7y^2 - 100 = 0$

30. $x^2 + 4xy + y^2 + 12 = 0$

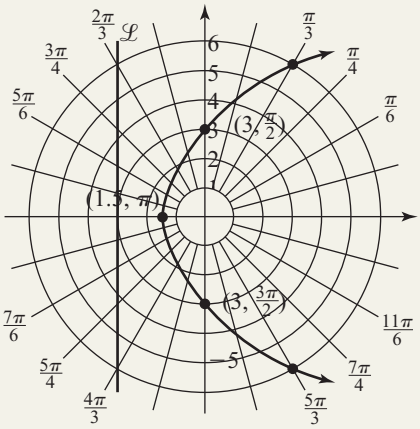
Identify the graph of each equation using the discriminant, then find the value of $\cos(2\beta)$ using $\tan(2\beta) = \dfrac{\sin(2\beta)}{\cos(2\beta)}$ and the related triangle diagram. Finally, find $\sin\beta$ and $\cos\beta$ using the half-angle identities $\cos\beta = \sqrt{\dfrac{1 + \cos(2\beta)}{2}}$ and $\sin\beta = \sqrt{\dfrac{1 - \cos(2\beta)}{2}}$.

31. $12x^2 + 24xy + 5y^2 - 40x - 30y = 25$

32. $25x^2 + 840xy - 16y^2 - 400 = 0$

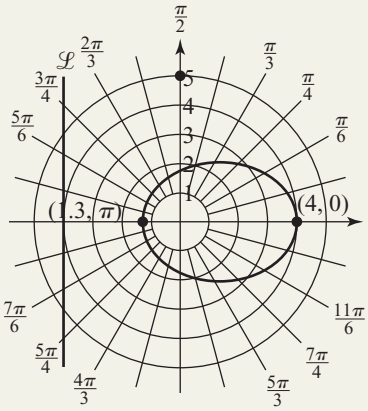
For the following equations, (a) use the discriminant to identify the equation as that of a circle, ellipse, parabola, or hyperbola; (b) find the angle of rotation β and use it to find the corresponding equation in the *XY*-plane; and (c) verify all invariants of the transformation.

33. $x^2 - 2xy + y^2 - 5 = 0$



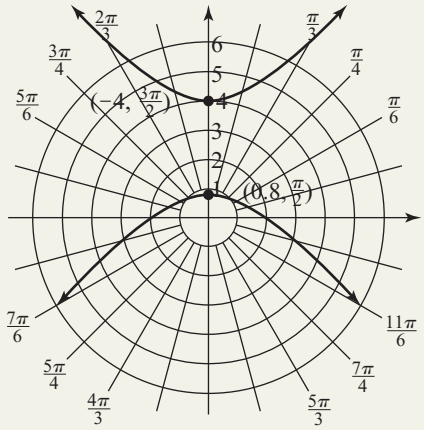
34. $2x^2 - 3xy + 2y^2 = 0$

35. $3x^2 + \sqrt{3}xy + 4y^2 + 4x = 1$

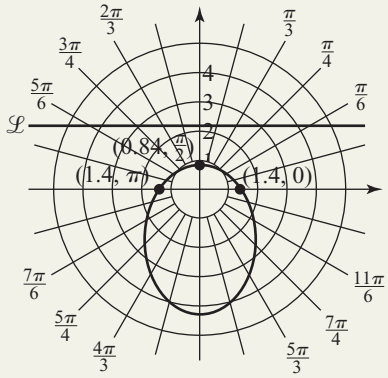


36. $3x^2 + 8\sqrt{3}xy - 5y^2 + 12y = -2$

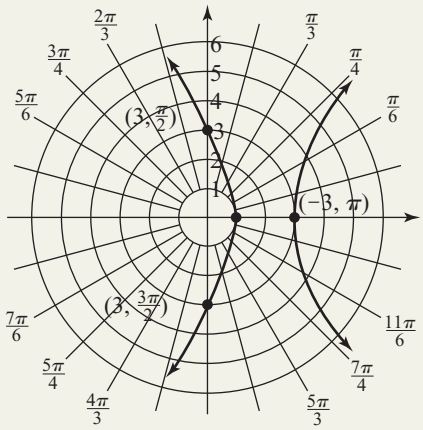
Match each graph to its corresponding equation. Justify your answers (two equations have no match).



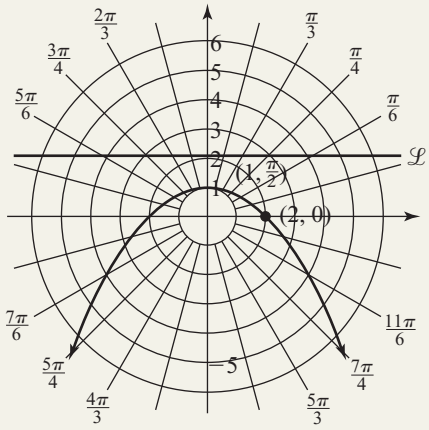
37.



38.



39.



40.

41.

42.

a. $r = \dfrac{10}{5 + 5\sin\theta}$ **b.** $r = \dfrac{8}{4 - 2\cos\theta}$

c. $r = \dfrac{5.4}{3 - 2\sin\theta}$ **d.** $r = \dfrac{4.2}{3 + 2\sin\theta}$

e. $r = \dfrac{12}{4 + 6\sin\theta}$ **f.** $r = \dfrac{6}{2 - 2\cos\theta}$

g. $r = \dfrac{4}{2 + 3\sin\theta}$ **h.** $r = \dfrac{9}{3 + 6\cos\theta}$

For the conic equations given, determine if the equation represents a parabola, ellipse, or hyperbola. Then describe and sketch the graphs using polar graph paper. Verify your sketch with a graphing calculator.

43. $r = \dfrac{4}{2 + 2\sin\theta}$ **44.** $r = \dfrac{10}{5 - 5\sin\theta}$

45. $r = \dfrac{12}{6 - 3\sin\theta}$ **46.** $r = \dfrac{6}{4 + 3\cos\theta}$

47. $r = \dfrac{6}{2 + 4\cos\theta}$ **48.** $r = \dfrac{2}{2 - 3\sin\theta}$

49. $r = \dfrac{5}{5 + 4\cos\theta}$ **50.** $r = \dfrac{2}{4 - 5\sin\theta}$

Write the equation of a conic that satisfies the conditions given. Assume each has one focus at the pole. Note for Exercises 51, 52, and 56, there are four possible equations.

51. ellipse, $e = 0.8$, directrix to focus: $d = 4$

52. hyperbola, $e = 1.25$, directrix to focus: $d = 6$

53. parabola, vertex at $(2, \pi)$

54. ellipse, $e = 0.35$, vertex at $(4, 0)$

55. hyperbola, $e = 1.5$, vertex at $\left(3, \frac{\pi}{2}\right)$

56. parabola, directrix to focus: $d = 5.4$

▶ WORKING WITH FORMULAS

57. Equation of a line in polar form:

$$r = \frac{C}{A\cos\theta + B\sin\theta}$$

For the line $Ax + By = C$ in the xy-plane with slope $m = -\frac{A}{B}$ and y-intercept $\left(0, \frac{C}{B}\right)$, the corresponding equation in the $r\theta$-plane is given by the formula shown. (a) Given the line $2x + 3y = 12$ in the xy-plane, find the corresponding polar equation and (b) verify that $-\frac{A}{B} = -\frac{r(\pi/2)}{r(0)}$.

58. Polar form of an ellipse with center at the pole:

$$r^2 = \frac{a^2b^2}{a^2\sin^2\theta + b^2\cos^2\theta}$$

If an ellipse in the $r\theta$-plane has its center at the pole (with major axis parallel to the x-axis), its equation is given by the formula here, where $2a$ and $2b$ are the lengths of the major and minor axes, respectively. (a) Given an ellipse with center at the pole has a major axis of length 8 and a minor axis of length 4, find the equation of the ellipse in polar form and (b) graph the result on a calculator and verify that $2a = 8$ and $2b = 4$.

▶ APPLICATIONS

Planetary motion: The perihelion, aphelion, and orbital period of the planets Jupiter, Saturn, Uranus, and Neptune are shown in the table. Use the information to answer or complete the following exercises. The formula $L = 2\pi\sqrt{0.5(a^2 + b^2)}$ can be used to estimate the length of the orbital path. Recall for an ellipse, $c^2 = a^2 - b^2$.

Planet	Perihelion (10^6 mi)	Aphelion (10^6 mi)	Period (yr)
Jupiter	460	507	11.9
Saturn	840	941	29.5
Uranus	1703	1866	84
Neptune	2762	2824	164.8

59. Find the eccentricities of the planets Jupiter and Saturn.

60. Find the eccentricities of the planets Uranus and Neptune.

61. The orbit of Pluto (a Kuiper object) has a semimajor axis of 3647 million miles and an eccentricity of $e = 0.2443$. Find the perihelion of Pluto.

62. The orbit of Ceres (a large asteroid) has a semimajor axis 257 million miles and an eccentricity of $e = 0.097$. Find the perihelion of Ceres.

63. Which of the four planets in the table given has the greatest orbital eccentricity?

64. Which of these four planets has the greatest orbital velocity?

65. Find the polar equation modeling the orbit of Jupiter.

66. Find the polar equation modeling the orbit of Saturn.

67. Find the polar equation modeling the orbit of Uranus.

68. Find the polar equation modeling the orbit of Neptune.

69. Suppose all four major planets arrived at the focal chord of their orbit $\left(\theta = \frac{\pi}{2}\right)$ simultaneously. Use the equations in Exercises 65 to 68 to determine the distance between each of the planets at this moment.

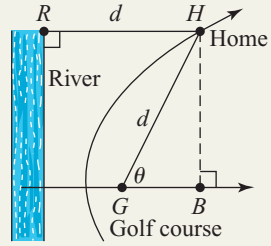
70. The polar equation for the orbit of Pluto (a Kuiper object) was developed in Example 9. From an earlier exercise, the polar equation for the orbit of Neptune is $r \approx \frac{2793}{1 - 0.011\cos\theta}$. Using the **TABLE** of your graphing calculator, determine if Pluto is *always* the farthest planet from the Sun. If not, how much further from the Sun is Neptune than Pluto at their perihelion?

Mirror manufacturing: A modern manufacturer of oval (elliptical) mirrors for consumer use has programmed the equipment to automatically cut the glass for each mirror (major axis horizontal). The most popular mirrors are those that fit within a golden rectangle (ratio of L to W is approximately 1 to 0.618). Find the polar equation the manufacturer should use to program the equipment for mirror orders of the following lengths. Recall that $c^2 = a^2 - b^2$ and $e = \frac{c}{a}$ and assume one focus is at the pole.

71. $L = 4$ ft

72. $L = 3.5$ ft

73. $L = 1.5$ m



74. $L = 0.5$ m

75. Referring to Exercises 71 to 74, find the total cost of each mirror (to the consumer) if they sell for \$75 per square foot (\$807 per square meter). The area of an ellipse is given by $A = \pi ab$.

76. Referring to Exercises 71 to 74, find the total cost of an elliptical frame for each mirror (to the consumer) if the frame sells for \$12.50 per linear foot (\$41.01 per meter). The circumference of an ellipse is approximated by $C = \pi\sqrt{2(a^2 + b^2)}$.

77. Home location: Candice is an enthusiastic golfer and an avid swimmer. After being transferred to a new city, she decides to buy a house that is an equal distance from the local golf course and the river running through the city. If the distance between the river and the golf course at the closest point is 3 mi, find the polar equation of the parabola that will trace through the possible locations for her new home. Assume the golf course is at the focus of the parabola.

Exercise 77

78. Home location: Referring to Exercise 77, assume Candice finds the perfect dream house in a subdivision located at $\left(6, \frac{\pi}{3}\right)$. Does this home fit the criteria (is it an equal distance from the river and golf course)?

79. Solve the system below for y to verify the rotation formula for y given on page 1037.

$$\begin{cases} X = x\cos\beta + y\sin\beta \\ Y = y\cos\beta - x\sin\beta \end{cases}$$

80. Rotation of a conic section: Expand the following, collect like terms, and simplify. Show the result is the equation $aX^2 + bXY + cY^2 + f = 0$, where the coefficients a, b, c, and f are as given on page 1039. $A(X\cos\beta - Y\sin\beta)^2 + B(X\cos\beta - Y\sin\beta)(X\sin\beta + Y\cos\beta) + C(X\sin\beta + Y\cos\beta)^2 + F = 0$

▶ EXTENDING THE CONCEPT

81. Using the rotation of axes formulas in the general equation $Ax^2 + Bxy + Cy^2 + F = 0$ $(D = E = 0)$, we were able to obtain the equation $aX^2 + bXY + cY^2 + f = 0$ (see page 1037), where

$$a \to A\cos^2\beta + B\sin\beta\cos\beta + C\sin^2\beta$$

$$b \to -2A\sin\beta\cos\beta + B(\cos^2\beta - \sin^2\beta) + 2C\sin\beta\cos\beta$$

$$c \to A\sin^2\beta - B\sin\beta\cos\beta + C\cos^2\beta \text{ and } f \to F$$

a. Use these to verify $b^2 - 4ac = B^2 - 4AC$.

b. Use these to verify $a + c = A + C$.

c. Explain why the invariant $f = F$ must always hold.

82. A short-period comet is one that orbits the Sun in 200 yr or less. Two of the best known are Halley's Comet and Encke's Comet. Using any of the resources available to you, find the perihelion and aphelion of each comet and use the information to find the lengths of the semimajor and semiminor axes. Also find the period of each comet. If the length of an elliptical (orbital) path is approximated by $L = 2\pi\sqrt{0.5(a^2 + b^2)}$, find the approximate average speed of each comet in miles per hour. Finally, determine the polar equation of each orbit.

83. In the $r\theta$-plane, the equation of a circle having radius R, center at (R, β), and going through the pole is given by $r = 2R\cos(\theta - \beta)$. Consider the circle defined by $x^2 + y^2 - 6\sqrt{2}x - 6\sqrt{2}y = 0$ in the xy-plane. Verify this circle goes through the origin, then find the equation of the circle in polar form.

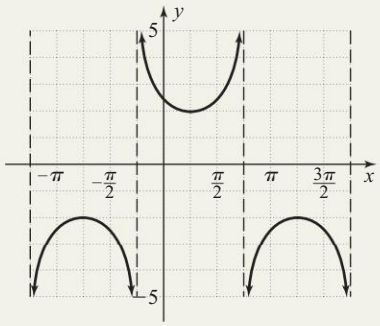
For the given conics in the *xy*-plane, use a rotation of axes to find the corresponding equation in the *XY*-plane. See Exercises 31 and 32.

84. $12x^2 + 24xy + 5y^2 - 40x - 30y = 25$

85. $25x^2 + 840xy - 16y^2 - 400 = 0$

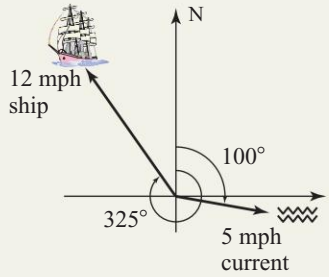
86. A right triangle in the *xy*-plane had vertices at (0, 0), (8, 0), and (8, 6). Use the matrix equation $\begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} \cos\beta & \sin\beta \\ -\sin\beta & \cos\beta \end{bmatrix} \cdot \begin{bmatrix} x \\ y \end{bmatrix}$ to find the vertices in the *XY*-plane after the triangle is rotated 60°.

87. A square in the *XY*-plane has vertices at (0, 0), $(2\sqrt{3}, 2)$, $(2\sqrt{3} - 2, 2 + 2\sqrt{3})$ and $(-2, 2\sqrt{3})$. Use the matrix equation $\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} \cos\beta & -\sin\beta \\ \sin\beta & \cos\beta \end{bmatrix} \cdot \begin{bmatrix} X \\ Y \end{bmatrix}$ to find the vertices in the *xy*-plane after the triangle is rotated −30°.



▶ MAINTAINING YOUR SKILLS

88. **(9.2)** Solve the system using elimination.



$$\begin{cases} x + 2y - z = -3 \\ -2x - 6y + z = 4 \\ 5x + 4y - 2z = -3 \end{cases}$$

89. **(5.5)** Solve for *x* (to the nearest tenth): $21.7 = 77.5e^{-0.0052x} - 44.95$

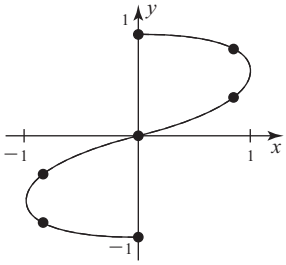
90. **(6.5)** Use the graph shown to write an equation of the form $y = A\sec(Bx + C)$. Clearly state the values of *A*, *B*, and *C*.

91. **(8.3)** A ship is moving at 12 mph on a heading of 325°, with a 5 mph current flowing at a 100° heading. Find the true course and speed of the ship.

10.8 Parametric Equations and Graphs

LEARNING OBJECTIVES

In Section 10.8 you will see how we can:



- ❑ **A.** Sketch the graph of a parametric equation
- ❑ **B.** Write parametric equations in rectangular form
- ❑ **C.** Graph curves from the cycloid family
- ❑ **D.** Solve applications involving parametric equations

A large portion of the mathematics curriculum is devoted to functions, due to their overall importance and widespread applicability. But there are a host of applications for which nonfunctions are a more natural fit. In this section, we show that many *nonfunctions* can be expressed as **parametric equations,** where each is actually a function. These equations can be appreciated for the diversity and versatility they bring to the mathematical spectrum.

A. Sketching a Curve Defined Parametrically

Suppose you were given the set of points in the table on the next page, and asked to come up with an equation model for the data. To begin, you might plot the points to see if any patterns or clues emerge, but in this case the result seems to be a curve we've never seen before (see Figure 10.101).

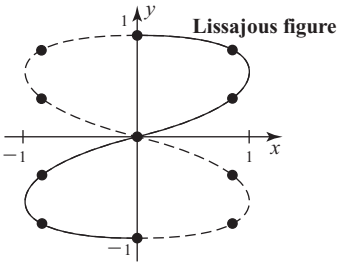


Figure 10.101

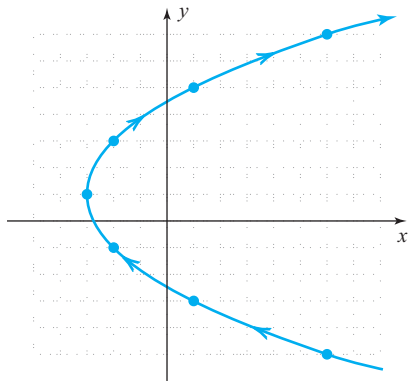
x	0	$\frac{\sqrt{3}}{2}$	$\frac{\sqrt{3}}{2}$	0	$-\frac{\sqrt{3}}{2}$	$-\frac{\sqrt{3}}{2}$	0
y	1	$\frac{\sqrt{3}}{2}$	$\frac{1}{2}$	0	$-\frac{1}{2}$	$-\frac{\sqrt{3}}{2}$	-1

You also might consider running a regression on the data, but it's not possible since the graph is obviously not a function. However, a closer look at the data reveals the y-values could be modeled *independently of the x-values* by a cosine function, $y = \cos t$ for $t \in [0, \pi]$. This observation leads to a closer look at the x-values, which we find could be modeled by a sine function over the same interval, namely, $x = \sin(2t)$ for $t \in [0, \pi]$. These two functions combine to name all points on this curve, and both use the independent variable t called a **parameter.** The functions $x = \sin(2t)$ and $y = \cos t$ are called the parametric equations for this curve. The complete curve, shown in Figure 10.102, is called a **Lissajous figure,** or a closed graph (coincident beginning and ending points) that crosses itself to form two or more loops. Note that since the maximum value of x and y is 1 (the amplitude of each function), the entire figure will fit within a 2×2 rectangle centered at the origin. This observation can often be used to help sketch parametric graphs with trigonometric parameters. In general, parametric equations can take many forms, including polynomial, exponential, trigonometric, and other forms.

Figure 10.102



Parametric Equations

Given the set of points $P(x, y)$ such that $x = f(t)$ and $y = g(t)$, where f and g are both defined on an interval of the domain, the equations $x = f(t)$ and $y = g(t)$ are called parametric equations, with parameter t.

EXAMPLE 1 ▶ **Graphing a Parametric Curve Where *f* and *g* Are Algebraic**

Graph the curve defined by the parametric equations $x = t^2 - 3$ and $y = 2t + 1$.

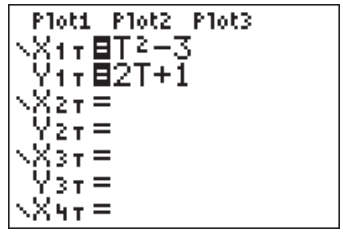
Solution ▶ Begin by creating a table of values using $t \in [-3, 3]$. After plotting ordered pairs (x, y), the result appears to be a parabola, opening to the right.

t	$x = t^2 - 3$	$y = 2t + 1$
−3	6	−5
−2	1	−3
−1	−2	−1
0	−3	1
1	−2	3
2	1	5
3	6	7

Now try Exercises 7 through 12, part a ▶

Most graphers have a parametric MODE that enables you to enter the equations for x and y separately, and graph the resulting points as a single curve. In this mode, the variable key X,T,θ,n produces a **T** when pressed, and the Y= screen prompts you for both X_{iT} *and* Y_{iT}. Verify this by entering $X_{1T} = T^2 - 3$ and $Y_{1T} = 2T + 1$ from Example 1 (Figure 10.103). The WINDOW screen for parametric equations is similar to the screen for polar equations, and as before, we can use the preset ZOOM options or manually set our desired window size along with Tmin, Tmax, and Tstep. To verify the Example 1 result and produce the graph shown in Figure 10.104, size the window as shown and set Tmin $= -3$, Tmax $= 3$, and Tstep $= 0.1$. To see more of the parabola, we must change the window *and* increase the range of T-values the calculator uses.

Figure 10.103



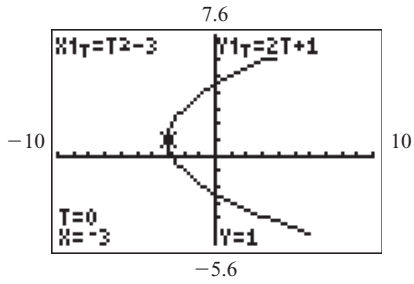


Figure 10.104

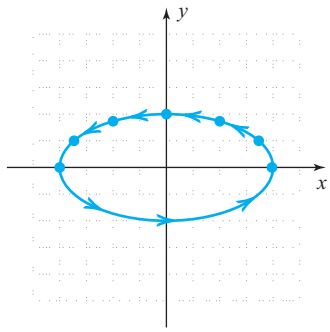
If the parametric equations contain trig functions, we'll often use standard angles as inputs to simplify calculations and the period of the function(s) to help sketch the resulting graph. Also note that successive values of t give rise to a directional evolution of the graph, meaning the curve is traced out in a direction dictated by the points that correspond to the next value of t. The arrows drawn along the graph illustrate this direction, also known as the **orientation** of the graph.

EXAMPLE 2 ▶ Graphing a Parametric Curve Where *f* and *g* Are Trig Functions

Graph the curve defined by the parametric equations $x = 4\cos t$ and $y = 2\sin t$. Use a calculator to verify your graph.



Solution ▶

Using standard angle inputs and knowing the maximum value of any x- and y-coordinate will be 4 and 2, respectively, we begin computing and graphing a few points. After going from 0 to π, we note the graph appears to be a horizontal ellipse. This is verified using standard values from π to 2π. Plotting the points and connecting them with a smooth curve produces the ellipse shown in Figure 10.105. Note the ellipse has a counterclockwise orientation.

WORTHY OF NOTE

Since trig functions are used so frequently in parametric curves, the ZOOM **6:Zstandard** feature automatically sets $[0, 2\pi]$ as the range of T-values.

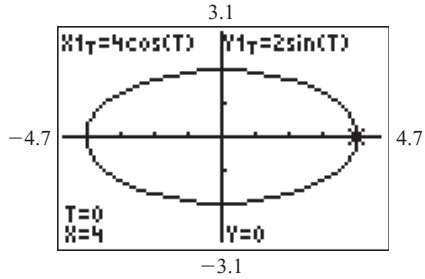


Figure 10.105

t	$x = 4\cos t$	$y = 2\sin t$
0	4	0
$\frac{\pi}{6}$	$2\sqrt{3}$	1
$\frac{\pi}{3}$	2	$\sqrt{3}$
$\frac{\pi}{2}$	0	2
$\frac{2\pi}{3}$	-2	$\sqrt{3}$
$\frac{5\pi}{6}$	$-2\sqrt{3}$	1
π	-4	0

With your calculator in radian MODE, enter $X_{1T} = 4\cos T$ and $Y_{1T} = 2\sin T$ in the Y= screen. With Tmin $= 0$, Tmax $= 2\pi$, and Tstep $= \dfrac{\pi}{24}$, the ZOOM **4:ZDecimal** feature will produce the graph shown in Figure 10.106, verifying our sketch.

Figure 10.106

☑ **A.** You've just seen how we can sketch the graph of a parametric equation

Now try Exercises 13 through 18, part a ▶

B. Writing Parametric Equations in Rectangular Form

When graphing parametric equations, there are sometimes alternatives to simply plotting points. One alternative is to try and *eliminate the parameter*, writing the parametric equations in standard, rectangular form. To accomplish this we use some connection that enables us to "rejoin" the parameterized equations, such as variable t itself, a trigonometric identity, or some other connection.

EXAMPLE 3 ▶ **Eliminating the Parameter to Obtain the Rectangular Form**

Eliminate the parameter from the equations in Example 1: $x = t^2 - 3$ and $y = 2t + 1$.

Solution ▶ Solving for t in the second equation gives $t = \dfrac{y - 1}{2}$, which we then substitute into the first. The result is $x = \left(\dfrac{y - 1}{2}\right)^2 - 3 = \dfrac{1}{4}(y - 1)^2 - 3$. Notice this is indeed a horizontal parabola, opening to the right, with vertex at $(-3, 1)$.

Now try Exercises 7 through 12, part b ▶

EXAMPLE 4 ▶ **Eliminating the Parameter to Obtain the Rectangular Form**

Eliminate the parameter from the equations in Example 2: $x = 4\cos t$ and $y = 2\sin t$.

Solution ▶ Instead of trying to solve for t, we note the parametrized equations involve sine and cosine functions with the same argument (t), and opt to use the identity $\cos^2 t + \sin^2 t = 1$. Squaring both equations and solving for $\cos^2 t$ and $\sin^2 t$ yields $\dfrac{x^2}{16} = \cos^2 t$ and $\dfrac{y^2}{4} = \sin^2 t$. This shows $\cos^2 t + \sin^2 t = \dfrac{x^2}{16} + \dfrac{y^2}{4} = 1$, and as we suspected—the result is a horizontal ellipse with vertices at $(\pm 4, 0)$ and endpoints of the minor axis at $(0, \pm 2)$.

Now try Exercises 13 through 16, part b ▶

It's important to realize that a given curve can be represented parametrically in infinitely many ways. This flexibility sometimes enables us to simplify the given form, or to write a given polynomial form in an equivalent nonpolynomial form. The easiest way to write the function $y = f(x)$ in parametric form is $x = t$; $y = f(t)$, which is valid *as long as t is in the domain of* $f(t)$.

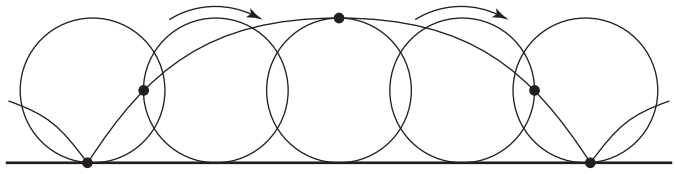
EXAMPLE 5 ▶ **Writing an Equation in Terms of Various Parameters**

Write the equation $y = 4(x - 3)^2 + 1$ in three different parametric forms.

Solution ▶

1. If we let $x = t$, we have $y = 4(t - 3)^2 + 1$.
2. Letting $x = t + 3$ simplifies the related equation for y, and we begin to see some of the advantages of using a parameter: $x = t + 3$; $y = 4t^2 + 1$.
3. As a third alternative, we can let $x = \frac{1}{2}\tan t + 3$, which gives

$$x = \frac{1}{2}\tan t + 3;\ y = 4\left(\frac{1}{2}\tan t\right)^2 + 1 = \tan^2 t + 1 \text{ or } y = \sec^2 t \text{ for } t \in \left(-\frac{\pi}{2}, \frac{\pi}{2}\right).$$



☑ **B.** You've just seen how we can write parametric equations in rectangular form

Now try Exercises 19 through 26 ▶

C. Graphing Curves from the Cycloid Family

The **cycloids** are an important family of curves, and are used extensively to solve what are called **brachistochrone** applications. The name comes from the Greek *brakhus,* meaning short, and *khronos,* meaning time, and deal with finding the path along which a weight will fall in the shortest time possible. Cycloids are an excellent example of why parametric equations are important, as it's very difficult to write them in rectangular form. Consider a point fixed to the circumference of a wheel as it rolls from left to right. If we trace the path of the point as the wheel rolls, the resulting curve is a cycloid. Figure 10.107 shows the location of the point every one-quarter turn.

Figure 10.107

By superimposing a coordinate grid on the diagram in Figure 10.107, we can construct parametric equations that will produce the graph. This is done by developing equations for the location of a point $P(x, y)$ on the circumference of a circle with center (h, k), as the circle rotates through angle t. After a rotation of t rad, the x-coordinate of $P(x, y)$ is $x = h - a$ (Figure 10.108), and the y-coordinate is $y = k - b$. Using a right triangle with the radius as the hypotenuse, we find $\sin t = \frac{a}{r}$ and $\cos t = \frac{b}{r}$, giving

Figure 10.108

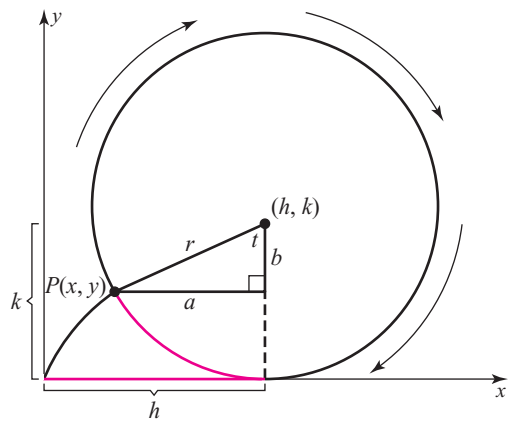


Figure 10.109

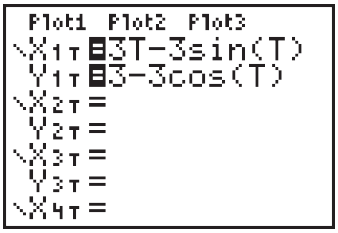

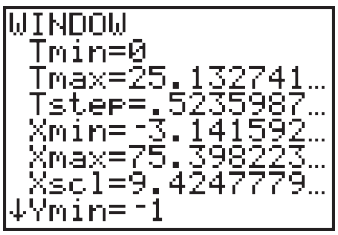

Figure 10.110

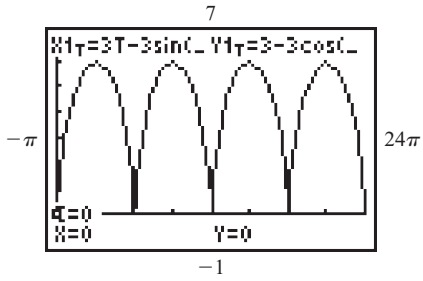
$a = r \sin t$ and $b = r \cos t$. Substituting into $x = h - a$ and $y = k - b$ yields $x = h - r \sin t$ and $y = k - r \cos t$. Since the circle has radius r, we know $k = r$ (the "height" of the center is constantly $k = r$). The arc length subtended by t is the same as the distance h (see Figure 10.108), meaning $h = rt$ (t in radians) Substituting rt for h and r for k in the equations $x = h - r \sin t$ and $y = k - r \cos t$, gives the equation of the cycloid in parametric form: $x = rt - r \sin t$ and $y = r - r \cos t$, sometimes written $x = r(t - \sin t)$ and $y = r(1 - \cos t)$.

After entering the equation of the cycloid formed by a circle of radius $r = 3$ (Figure 10.109), set the viewing window with Ymin $= -1$ and Ymax at slightly more than 6 (since $r = 3$). Since the cycloid completes one cycle every $2\pi r$, we set Xmax at $2\pi rn$, where n is the number of cycles we'd like to see. In this case, we set it for four cycles $(2\pi)(3)(4) = 24\pi$ (Figure 10.110). With $r = 3$ we can set Xscl at $3(2\pi) = 6\pi \approx 18.8$ to tick each cycle, or Xscl $= 3\pi \approx 9.4$ to tick each half cycle (Figure 10.110). We also set Tmin $= 0$, Tmax $= 8\pi \approx 25.1$ for the four cycles, and Tstep $= \dfrac{\pi}{6} \approx 0.52$. The resulting graph is shown in Figure 10.111, which doesn't look much like a cycloid because the current settings do not produce a square viewing window. Using ZOOM **5:ZSquare** (and changing Yscl) produces the graph shown in Figure 10.112, which looks much more like the cycloid we expected.

Figure 10.111



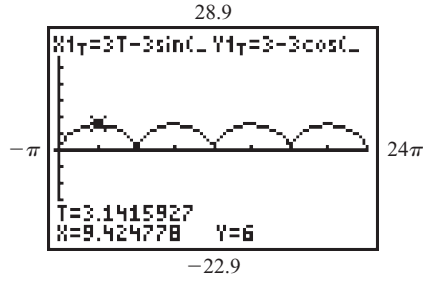


Figure 10.112

EXAMPLE 6 ▶ Using Technology to Graph a Cycloid

Use a graphing calculator to graph the curve defined by the equations $x = 3 \cos^3 t$ and $y = 3 \sin^3 t$, called a **hypocycloid with four cusps.**

Solution ▶ A hypocycloid is a curve traced out by the path of a point on the circumference of a circle as it rolls *inside a larger circle* of radius r (see Figure 10.113). Here $r = 3$ and we set Xmax and Ymax accordingly. Knowing ahead of time the hypocycloid will have four cusps, we set Tmax $= 4(2\pi) \approx 25.13$ to show all four. The window settings used and the resulting graph are shown in Figures 10.114 and 10.115.

Figure 10.113

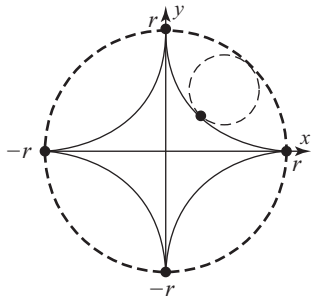

Figure 10.114

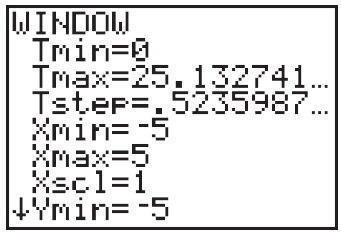

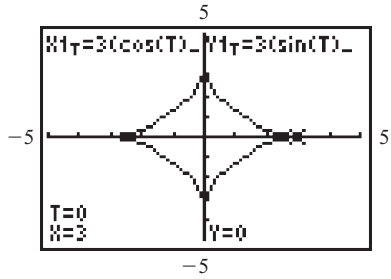

Figure 10.115

C. You've just seen how we can graph curves from the cycloid family

Now try Exercises 27 through 35 ▶

D. Common Applications of Parametric Equations

In Example 1 the parameter was simply the *real number t*, which enabled us to model the x- and y-values of an ordered pair (x, y) independently. In Examples 2 and 6, the parameter t represented an *angle*. Here we introduce yet another kind of parameter, that of *time t*.

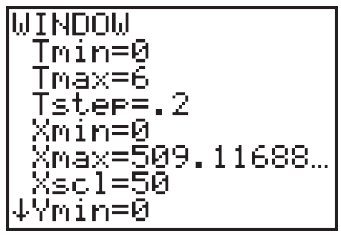
A **projectile** is any object thrown, dropped, or projected in some way with no continuing source of propulsion. The parabolic path traced out by the projectile (assuming negligible air resistance) was fully developed in Section 8.4. It is stated again here in parametric terms. For the projectile's location $P(x, y)$ and any time t in seconds, the x-coordinate (horizontal distance from point of projection) is given by $x = v_0 t \cos\theta$, where v_0 is the initial velocity in feet per second and t is the time in seconds. The y-coordinate (vertical height) is $y = v_0 t \sin\theta - 16t^2$.

EXAMPLE 7 ▶ **Using Parametric Equations in Projectile Applications**

As part of a circus act, Karl the Human Cannonball is shot out of a specially designed cannon at an angle of 40° with an initial velocity of 120 ft/sec. Use a graphing calculator to graph the resulting parametric curve. Then use the graph to determine how high the ringmaster must place a circular ring for Karl to be shot through at the maximum height of his trajectory, and how far away the net must be placed to catch Karl.

Solution ▶ The information given leads to the equations $x = 120t \cos 40°$ and $y = 120t \sin 40° - 16t^2$. Enter these equations on the Y= screen of your calculator, remembering to reset the MODE to degrees (circus clowns may not know or understand radians). To set the window size, we can use trial and error, or estimate using $\theta = 45°$ (instead of 40°) and an estimate for t (the time that Karl will stay aloft). With $t = 6$ we get estimates of $x = 120(6)\left(\frac{\sqrt{2}}{2}\right) = 360\sqrt{2}$ for the horizontal distance. To find a range for y, use $t = 3$ since the maximum height of the parabolic path will occur halfway through the flight. This gives an estimate of $120(3)\left(\frac{\sqrt{2}}{2}\right) - 16(9) = 180\sqrt{2} - 144$ for y. The results are shown in Figures 10.116 and 10.117. Using the TRACE feature or 2nd GRAPH (**TABLE**) feature, we find the center of the net used to catch Karl should be set at a distance of about 440 ft from the cannon, and the ring should be located 220 ft from the cannon at a height of about 93 ft.

Figure 10.116



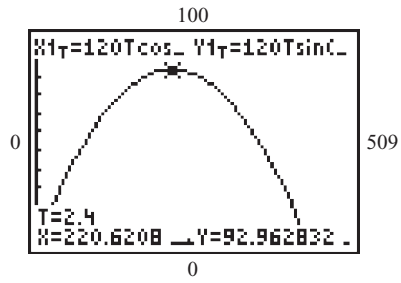


Figure 10.117

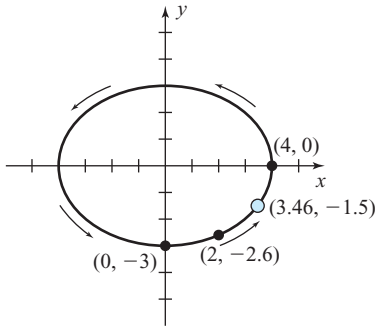

Now try Exercises 46 through 49 ▶

It is well known that planets orbit the Sun in elliptical paths. While we're able to model their orbits in both rectangular and polar form, neither of these forms can give a true picture of the *direction they travel.* This gives parametric forms a great advantage, in that they can model the shape of the orbit, *while also indicating the direction of travel*. We illustrate in Example 8 using a "planet" with a very simple orbit.

EXAMPLE 8 ▶ Modeling Elliptical Orbits Parametrically

The elliptical orbit of a certain planet is defined parametrically as $x = 4 \sin t$ and $y = -3 \cos t$. Graph the orbit and verify that for increasing values of t, the planet orbits in a counterclockwise direction.

Solution ▶ Eliminating the parameter as in Example 4, we obtain the equation $\frac{x^2}{16} + \frac{y^2}{9} = 1$, or the equation of an ellipse with center at (0, 0), major axis of length 8, and minor axis of length 6. The path of the planet is traced out by the ordered pairs (x, y) generated by the parametric equations, shown in the table for $t \in [0, \pi]$. Starting at $t = 0$, $P(x, y)$ begins at $(0, -3)$ with x and y both increasing until $t = \frac{\pi}{2}$. Then from $t = \frac{\pi}{2}$ to $t = \pi$, y continues to increase as x decreases, indicating a counterclockwise orbit in this case. The orbit is illustrated in the figure.

t	$x = 4 \sin t$	$y = -3 \cos t$
0	0	−3
$\frac{\pi}{6}$	2	−2.6
$\frac{\pi}{3}$	3.46	−1.5
$\frac{\pi}{2}$	4	0
$\frac{2\pi}{3}$	3.46	1.5
$\frac{5\pi}{6}$	2	2.6
π	0	3

Now try Exercises 50 and 51 ▶

Most graphing calculators have features that make it easy (and fun) to explore parametric equations by using a circular cursor to trace the path of the plotted points, as they are generated by the equations. This can be used to illustrate the path of a projectile, the distance of a runner, or the orbit of a planet. Operations can also be applied to the parameter T to give the effect of "speed" (the points from one set of equations are plotted faster than the points of a second set). To help illustrate their use, consider the simple, elliptical orbit of a planet in Example 8. Physics tells us the closer a planet is to the Sun, the faster its orbit. In fact, the orbital speed of Mercury is about twice that of Mars and about 10 times as fast as the Kuiper object Pluto (29.8, 15, and 2.9 mi/sec, respectively). With this information, we can explore a number of interesting questions **(see Exercises 52 and 53)**. On the Y= screen of a calculator in radian MODE, let the orbits of Planet 1 and Planet 2 be modeled parametrically by the equations shown in Figure 10.118. Since the orbit of Planet 1 is "smaller" (closer to the Sun), we have T-values growing at a rate that is *four times as fast* as for Planet 2. Notice to the far left of X_{1T}, there is a symbol that looks like an old key "−0." By moving the cursor to the far left of the equation, you can change how the graph will look by repeatedly pressing ENTER. With this symbol in view, the calculator will trace

Figure 10.118

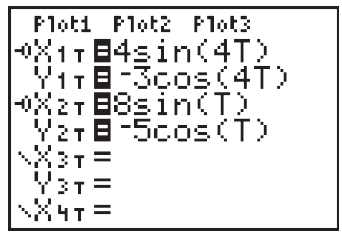

Figure 10.119

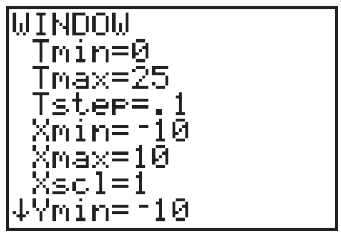

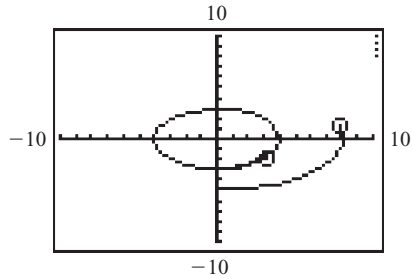

Figure 10.120

out the curve with a circular cursor, which in this case represents the planets as they orbit (be sure you are in simultaneous MODE). Setting the window as in Figure 10.119 and pressing GRAPH produces Figure 10.120, which displays their elliptical paths as they race around the Sun. Notice the inner planet has already completed one orbit while the outer planet has just completed one-fourth of an orbit.

Finally, you may recall from your previous work with linear 3×3 systems, that a dependent system occurs when one of the three equations is a linear combination of the other two. The result is a system with more variables than equations, with solutions expressed in terms of a parameter, or in *parametric form.* These solutions can be explored on a graphing calculator using ordered triples of the form $(t, f(t), g(t))$, where $X_{1T} = f(t)$ and $Y_{1T} = g(t)$ **(see Exercises 54 through 57).**

☑ **D.** You've just seen how we can solve applications involving parametric equations

10.8 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section if needed.

1. When the coordinates of a point (x, y) are generated independently using $x = f(t)$ and $y = g(t)$, t is called a(n) _____.
2. The equations $x = f(t)$ and $y = g(t)$ used to generate the ordered pairs (x, y) are called _____ equations.
3. Parametric equations can both graph a curve *and* indicate the _____ traveled by a point on the curve.
4. To write parametric equations in rectangular form, we must _____ the parameter to write a single equation.
5. Discuss the connection between solutions to dependent systems and the parametric equations studied in this section.
6. In your own words, explain and illustrate the process used to develop the equation of a cycloid. Illustrate with a specific example.

▶ DEVELOPING YOUR SKILLS

For Exercises 7 through 18, (a) graph the curves defined by the parametric equations using the specified interval and identify the graph (if possible) and (b) eliminate the parameter (Exercises 7 to 16 only) and write the corresponding rectangular form.

7. $x = t + 2; t \in [-3, 3]$
   $y = t^2 - 1$
8. $x = t - 3; t \in [-5, 5]$
   $y = 2 - 0.5t^2$
9. $x = (2 - t)^2; t \in [0, 5]$
   $y = (t - 3)^2$
10. $x = t^3 - 3; t \in [-2, 2.5]$
    $y = t^2 + 1$

11. $x = \dfrac{5}{t},\ t \neq 0;\ t \in [-3.5, 3.5]$
$y = t^2$

12. $x = \dfrac{t^3}{10};\ t \in [-5, 5]$
$y = |t|$

13. $x = 4\cos t;\ t \in [0, 2\pi)$
$y = 3\sin t$

14. $x = 2\sin t;\ t \in [0, 2\pi)$
$y = -3\cos t$

15. $x = 4\sin(2t);\ t \in [0, 2\pi)$
$y = 6\cos t$

16. $x = 4\cos(2t);\ t \in \left[\dfrac{\pi}{2}, \dfrac{3\pi}{2}\right]$
$y = 6\sin t$

17. $x = \dfrac{-3}{\tan t};\ t \in (0, \pi)$
$y = 5\sin(2t)$

18. $x = \tan^2 t;\ t \neq \dfrac{\pi}{2},\ t \in [0, \pi]$
$y = 3\cos t$

Write each function in three different parametric forms by altering the parameter. For Exercises 19–22 use at least one trigonometric form, restricting the domain as needed.

19. $y = 3x - 2$

20. $y = 0.5x + 6$

21. $y = (x + 3)^2 + 1$

22. $y = 2(x - 5)^2 - 1$

23. $y = \tan^2(x - 2) + 1$

24. $y = \sin(2x - 1)$

25. Use a graphing calculator or computer to verify that the parametric equations from Example 5 all produce the same graph.

26. Use a graphing calculator or computer to verify that your parametric equations from Exercise 21 all produce the same graph.

The curves defined by the following parametric equations are from the cycloid family. (a) Use a graphing calculator or computer to draw the graph and (b) use the graph to approximate all *x*- and *y*-intercepts, and maximum and minimum values to one decimal place.

27. $x = 8\cos t + 2\cos(4t),\ y = 8\sin t - 2\sin(4t)$, hypocycloid (5-cusp)

28. $x = 8\cos t + 4\cos(2t),\ y = 8\sin t - 4\sin(2t)$, hypocycloid (3-cusp)

29. $x = \dfrac{2}{\tan t},\ y = 8\sin t\cos t$, serpentine curve

30. $x = 8\sin^2 t,\ y = \dfrac{8\sin^3 t}{\cos t}$, cissoid of Diocles

31. $x = 2(\cos t + t\sin t),\ y = 2(\sin t - t\cos t)$, involute of a circle

32. $x = -5\cos^3 t,\ y = -\dfrac{10}{3}\sin^3 t$, evolute of an ellipse

33. $x = 3t - \sin t,\ y = 3 - \cos t$, curtate cycloid

34. $x = t - 3\sin t,\ y = 1 - 3\cos t$, prolate cycloid

35. $x = 2[3\cos t - \cos(3t)],\ y = 2[3\sin t - \sin(3t)]$, nephroid

Use a graphing calculator or computer to draw the following parametrically defined graphs, called Lissajous figures (Exercise 37 is a scaled version of Figure 10.102). Then find the dimensions of the rectangle necessary to frame the figure and state the number of times the graph crosses itself.

36. $x = 6\sin(3t)$
$y = 8\cos t$

37. $x = 6\sin(2t)$
$y = 8\cos t$

38. $x = 8\sin(4t)$
$y = 10\cos t$

39. $x = 5\sin(7t)$
$y = 7\cos(4t)$

40. $x = 8\sin(4t)$
$y = 10\cos(3t)$

41. $x = 10\sin(1.5t)$
$y = 10\cos(2.5t)$

42. Use a graphing calculator to experiment with parametric equations of the form $x = A\sin(mt)$ and $y = B\cos(nt)$. Try different values of A, B, m, and n, then discuss their effect on the Lissajous figures.

43. Use a graphing calculator to experiment with parametric equations of the form $x = \dfrac{a}{\tan t}$ and $y = b\sin t\cos t$. Try different values of a and b, then discuss their effect on the resulting graph, called a serpentine curve. Also see Exercise 29.

▶ WORKING WITH FORMULAS

44. The Folium of Descartes: $x(t) = \dfrac{3kt}{1+t^3}; y(t) = \dfrac{3kt^2}{1+t^3}$

The Folium of Descartes is a parametric curve developed by Descartes in order to test the ability of Fermat to find its maximum and minimum values.

a. Graph the curve on a graphing calculator with $k = 1$ using a decimal window (ZOOM 4), with Tmin $= -6$, Tmax $= 6$, and Tstep $= 0.1$. Locate the coordinates of the tip of the folium (the loop).

b. This graph actually has a discontinuity (a break in the graph). At what value of t does this occur?

c. Experiment with different values of k and generalize its effect on the basic graph.

45. The Witch of Agnesi: $x(t) = 2kt; y(t) = \dfrac{2k}{1+t^2}$

The Witch of Agnesi is a parametric curve named by Maria Agnesi in 1748. Some believe various translations confused the Italian word for *witch* with a similar word that means curve, or turning. In any case, the name stuck. The curve can also be stated in trigonometric form: $x(t) = 2k \cot t$ and $y = 2k \sin^2 t$.

a. Graph the curve with $k = 1$ on a calculator or computer on a decimal window (ZOOM 4) using both of the forms shown with Tmin $= -6$, Tmax $= 6$, and Tstep $= 0.1$. Try to determine the maximum value.

b. Explain why the x-axis is a horizontal asymptote.

c. Experiment with different values of k and generalize its effect on the basic graph.

▶ APPLICATIONS

Model each application using parametric equations, then solve using the GRAPH and TRACE features of a graphing calculator.

46. Archery competition: At an archery contest, a large circular target 5 ft in diameter is laid flat on the ground with the bull's-eye exactly 180 yd (540 ft) away from the archers. Marion draws her bow and shoots an arrow at an angle of 25° above horizontal with an initial velocity of 150 ft/sec (assume the archers are standing in a depression and the arrow is shot from ground level). (a) What was the maximum height of the arrow? (b) Does the arrow hit the target? (c) What is the distance between Marion's arrow and the bull's-eye after the arrow hits?

47. Football competition: As part of their contribution to charity, a group of college quarterbacks participate in a contest. The object is to throw a football through a hoop whose center is 30 ft high and 25 yd (75 ft) away, trying to hit a stationary (circular) target laid on the ground with the center 56 yd (168 ft) away. The hoop and target both have a diameter of 4 ft. On his turn, Lance throws the football at an angle of 36° with an initial velocity of 75 ft/sec. (a) Does the football make it through the hoop? (b) Does the ball hit the target? (c) What is the approximate distance between the football and the center of the target when the ball hits the ground?

48. Walk-off home run: It's the bottom of the ninth, two outs, the count is full, and the bases are loaded with the opposing team ahead 5 to 2. The home team has Heavy Harley, their best hitter at the plate; the opposition has Raymond the Rocket on the mound. Here's the pitch . . . it's a hit . . . a long fly ball to left-center field! If the ball left the bat at an angle of 30° with an initial velocity of 112 ft/sec, will it clear the home run fence, 9 ft high and 320 ft away?

49. Last-second win: It's fourth-and-long, late in the fourth quarter of the homecoming football game, with the home team trailing 29 to 27. The coach elects to kick a field goal, even though the goal posts are 50 yd (150 ft) away from the spot of the kick. If the ball leaves the kicker's foot at an angle of 29° with an initial velocity of 80 ft/sec, and the kick is "true," will the home team win (does the ball clear the 10-ft high cross bar)?

50. Particle motion: The motion of a particle is modeled by the parametric equations $\begin{cases} x = 5t - 2t^2 \\ y = 3t - 2 \end{cases}$. Between $t = 0$ and $t = 1$, is the particle moving to the right or to the left? Is the particle moving upward or downward?

51. Electron motion: The motion of an electron as it orbits the nucleus is modeled by the parametric equations $\begin{cases} x = 6\cos t \\ y = 2\sin t \end{cases}$ with t in radians. Between $t = 2$ and $t = 3$, is the electron moving to the right or to the left? Is the electron moving upward or downward?

52. Verify that the inner planet shown in Figure 10.120 completes four orbits for every single orbit of the outer planet.

53. Suppose that due to some cosmic interference, the orbit of the faster planet from Figure 10.120 begins to decay at a rate of $T^{0.84}$ (replace T with $T^{0.84}$ in both equations for the inner planet). By observation, about how many orbits did the inner planet make for the first revolution of the outer planet? What is the ratio of orbits for the next complete orbit of the outer planet?

Systems applications: Solve the following systems using elimination. If the system is dependent, write the general solution in parametric form and use a calculator to generate several solutions.

54. $\begin{cases} 2x - y + 3z = -3 \\ 3x + 2y - z = 4 \\ 8x + 3y + z = 5 \end{cases}$

55. $\begin{cases} x - 5y + z = 3 \\ 5x + y - 7z = -9 \\ 2x + 3y - 4z = -6 \end{cases}$

56. $\begin{cases} -5x - 3z = -1 \\ x + 2y - 2z = -3 \\ -2x + 6y - 9z = -10 \end{cases}$

57. $\begin{cases} x + y - 5z = -4 \\ 2y - 3z = -1 \\ x - 3y + z = -3 \end{cases}$

58. Regressions and parameters: Draw a scatterplot of the data given in the table. Note that connecting the points with a smooth curve will not result in a function, so a standard regression cannot be run on the data. Now consider the x-values alone—what do you notice? Find a sinusoidal model for the x-values, using $T = 0, 1, 2, 3, \ldots, 8$. Use the same inputs to run some form of regression on the y-values, then use the results to form the "best-fit" parametric equations for this data (use L1 for T, L2 for the x-values, and L3 for the y-values). With your calculator in parametric MODE, enter the equations as X_{1T} and Y_{1T}, then graph these along with the scatterplot (L2, L3) to see the finished result. Use the TABLE feature of your calculator to comment on the accuracy of the model.

x	y
0	0
$\sqrt{2}$	0.25
2	2
$\sqrt{2}$	6.75
0	16
$-\sqrt{2}$	31.25
-2	54
$-\sqrt{2}$	85.75
0	128

59. Regressions and parameters: Draw a scatterplot of the data given in the table, and connect the points with a smooth curve. The result is a function, but no standard regression seems to give an accurate model. The x-values alone are actually generated by an exponential function. Run a regression on these values using $T = 0, 1, 2, 3, \ldots, 8$ as inputs to find the exponential model. Then use the same inputs to run some form of regression on the y-values and use the results to form the "best-fit" parametric equations for this data (use L1 for T, L2 for the x-values, and L3 for the y-values). With your calculator in parametric MODE, enter the equations as X_{1T} and Y_{1T}, then graph these along with the scatterplot (L2, L3) to see the finished result. Use the TABLE feature of your calculator to comment on the accuracy of the model.

x	y
1	0
1.2247	−1.75
1.5	−3
1.8371	−3.75
2.25	−4
2.7557	−3.75
3.375	−3
4.1335	−1.75
5.0625	0

▶ EXTENDING THE CONCEPT

60. The motion of a particle in a certain medium is modeled by the parametric equations $\begin{cases} x = 6\sin(4t) \\ y = 8\cos t \end{cases}$. Initially, use only the 2nd GRAPH **(TABLE)** feature of your calculator (not the graph) to name the intervals for which the particle is moving (a) to the left and upward and (b) to the left and downward. Answer to the nearest tenth (set $\Delta\text{Tbl} = 0.1$). Is it *possible* for this particle to collide with another particle in this medium whose movement is modeled by $\begin{cases} x = 3\cos t + 7 \\ y = 2\sin t + 2 \end{cases}$? Discuss why or why not.

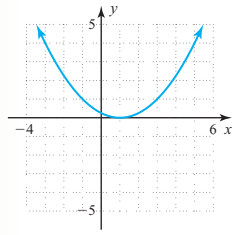
61. Write the function $y = \frac{1}{2}(x + 3)^2 - 1$ in parametric form using the substitution $x = 2\cos t - 3$ and the appropriate double-angle identity. Is the result equivalent to the original function? Why or why not?

▶ MAINTAINING YOUR SKILLS

62. **(1.5)** The price of a popular video game is reduced by 20% and is selling for $39.96. By what percentage must the sale price be increased to return the item to its original price?

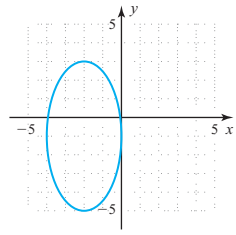
63. **(6.6)** When the tip of the antenna atop the Eiffel Tower is viewed at a distance of 265 ft from its base, the angle of elevation is 76°. Is the Eiffel Tower taller or shorter than the Chrysler Building (New York City) at 1046 ft?

64. **(4.3)** Graph $f(x) = x^3 + 2x^2 - 5x - 6$ using information about end-behavior, y-intercept, x-intercept(s), and midinterval points.



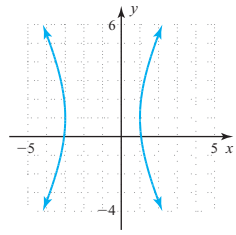
65. **(7.6)** The maximum height a projectile will attain depends on the angle it is projected and its initial velocity. This phenomena is modeled by the function $H = \frac{v^2 \sin^2\theta}{64}$, where v is the initial velocity (in feet/sec) of the projectile and θ is the angle of projection. Find the angle of projection if the projectile attained a maximum height of 151 ft, and the initial velocity was 120 ft/sec.

MAKING CONNECTIONS

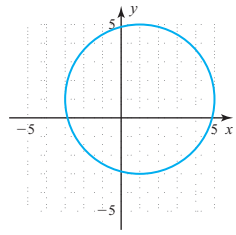


Making Connections: Graphically, Symbolically, Numerically, and Verbally

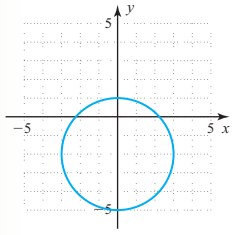
Eight graphs (a) through (h) are given. Match the characteristics shown in 1 through 16 to one of the eight graphs



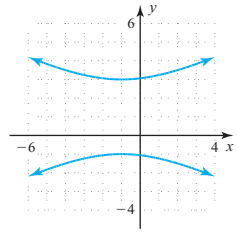
(a)



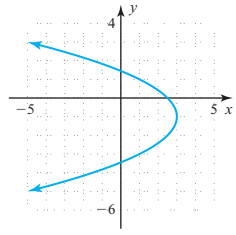
(b)



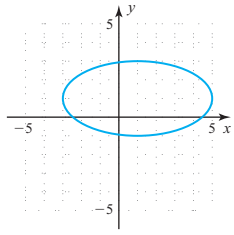
(c)



(d)



(e)



(f)

(g)

(h)

1. ____ $(x - 1)^2 + (y - 1)^2 = 16$

2. ____ $y = \frac{1}{4}(x - 1)^2$

3. ____ foci at $(-1, 1 \pm \sqrt{5})$

4. ____ transverse axis $y = 1$

5. ____ $x = -\frac{1}{2}(y + 1)^2 + 3$

6. ____ domain: $x \in [-3, 5]$, range: $y \in [-3, 5]$

7. ____ $4(x + 1)^2 - (y - 1)^2 = 16$

8. ____ $x^2 + (y - 2)^2 = 9$

9. ____ vertices at $(-3, 1)$ and $(5, 1)$

10. ____ $4(y - 1)^2 - (x + 1)^2 = 16$

11. ____ center at $(0, -2)$

12. ____ focus at $(1, 1)$

13. ____ $4(x + 2)^2 + (y + 1)^2 = 16$

14. ____ $(x - 1)^2 + 4(y - 1)^2 = 16$

15. ____ axis of symmetry: $y = -1$

16. ____ domain: $x \in [-4, 0]$, range: $y \in [-5, 3]$

SUMMARY AND CONCEPT REVIEW

SECTION 10.1 A Brief Introduction to Analytical Geometry

KEY CONCEPTS

- The midpoint and distance formulas play important roles in the study of analytical geometry:

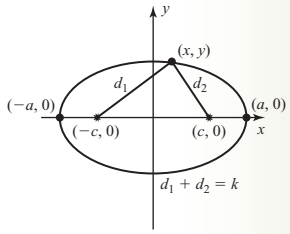
$$\text{midpoint: } (x, y) = \left(\frac{x_2 + x_1}{2}, \frac{y_2 + y_1}{2}\right) \quad \text{distance: } d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

- The perpendicular distance from a point to the line is the length of the line segment perpendicular to the given line with the given point and the point of intersection as endpoints.
- Using these tools, we can verify or construct relationships between points, lines, and curves in the plane; verify properties of geometric figures; prove theorems from Euclidean geometry; and construct relationships that define the conic sections.

EXERCISES

1. Verify the closed figure with vertices $(-3, -4)$, $(-5, 4)$, $(3, 6)$, and $(5, -2)$ is a square.

2. Find the equation of the circle that circumscribes the square in Exercise 1.



3. A theorem from Euclidean geometry states: *If any two points are equidistant from the endpoints of a line segment, they are on the perpendicular bisector of the segment*. Determine if the line through $(-3, 6)$ and $(6, -9)$ is the perpendicular bisector of the segment through $(-5, -2)$ and $(5, 4)$.

4. Four points are given. Verify that the distance from each point to the line $y = -1$ is the same as the distance from the given point to the fixed point $(0, 1)$: $(-6, 9)$, $(-2, 1)$, $(4, 4)$, and $(8, 16)$.

SECTION 10.2 The Circle and the Ellipse

KEY CONCEPTS

- The equation of a circle centered at (h, k) with radius r is $(x - h)^2 + (y - k)^2 = r^2$.
- Dividing both sides by r^2, we obtain the standard form $\dfrac{(x - h)^2}{r^2} + \dfrac{(y - k)^2}{r^2} = 1$, showing the horizontal and vertical distance from center to graph is r.
- The equation of an ellipse in standard form is $\dfrac{(x - h)^2}{a^2} + \dfrac{(y - k)^2}{b^2} = 1$. The center of the ellipse is (h, k), with horizontal distance a and vertical distance b from center to graph.

- Given two fixed points f_1 and f_2 in a plane (called the foci), an ellipse is the set of all points (x, y) such that the distance from the first focus to (x, y), plus the distance from the second focus to (x, y), remains constant.
- For an ellipse, the distance from center to vertex is *greater than* the distance c from center to one focus.
- To find the foci of a horizontal ellipse, use: $a^2 = b^2 + c^2$ (since $a > c$), or $c^2 = |a^2 - b^2|$.

EXERCISES

Sketch the graph of each equation in Exercises 5 through 9.

5. $x^2 + y^2 = 16$

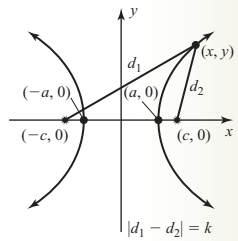
6. $x^2 + 4y^2 = 36$

7. $9x^2 + y^2 - 18x - 27 = 0$

8. $x^2 + y^2 + 6x + 4y + 12 = 0$

9. $\dfrac{(x + 3)^2}{16} + \dfrac{(y - 2)^2}{9} = 1$

10. Find the equation of the ellipse with minor axis of length 6 and foci at $(-4, 0)$ and $(4, 0)$. Then graph the equation on a graphing calculator using a "friendly" window and use the TRACE feature to locate four additional points on the graph with coordinates that are rational.



11. Find the equation of the ellipse with vertices at (a) $(-13, 0)$ and $(13, 0)$, foci at $(-12, 0)$ and $(12, 0)$; (b) foci at $(0, -16)$ and $(0, 16)$, major axis: 40 units.

12. Write the equation in standard form and sketch the graph, noting all of the characteristic features of the ellipse. $4x^2 + 25y^2 - 16x - 50y - 59 = 0$

SECTION 10.3 The Hyperbola

KEY CONCEPTS

- The equation of a *horizontal* hyperbola in standard form is $\dfrac{(x - h)^2}{a^2} - \dfrac{(y - k)^2}{b^2} = 1$. The center of the hyperbola is (h, k) with horizontal distance a from center to vertices, and vertical distance b from center to the midpoint of the sides of the central rectangle.
- Given two fixed points f_1 and f_2 in a plane (called the foci), a hyperbola is the set of all points (x, y) such that the distance from one focus to point (x, y), less the distance from the other focus to (x, y), remains a positive constant: $|d_1 - d_2| = k$.
- For a hyperbola, the distance from center to one vertex is *less than* the distance from center to the focus c.
- To find the foci of a hyperbola: $c^2 = a^2 + b^2$ (since $c > a$).

EXERCISES

Sketch the graph of each equation in Exercises 13 through 17, indicating the center, vertices, and asymptotes.

13. $4y^2 - 25x^2 = 100$

14. $\dfrac{(y-3)^2}{16} - \dfrac{(x+2)^2}{9} = 1$

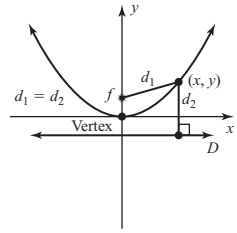
15. $\dfrac{(x+2)^2}{9} - \dfrac{(y-1)^2}{4} = 1$

16. $9y^2 - x^2 - 18y - 72 = 0$

17. $x^2 - 4y^2 - 12x - 8y + 16 = 0$

18. Find the equation of the hyperbola with vertices at $(-3, 0)$ and $(3, 0)$, and asymptotes of $y = \pm\frac{4}{3}x$. Then graph the equation on a graphing calculator using a "friendly" window and use the TRACE feature to locate two additional points with rational coordinates.

19. Find the equation of the hyperbola with (a) vertices at $(\pm 15, 0)$, foci at $(\pm 17, 0)$, and (b) foci at $(0, \pm 5)$ with vertical dimension of central rectangle 8 units.



20. Write the equation in standard form and sketch the graph, noting all of the characteristic features of the hyperbola.

$4x^2 - 9y^2 - 40x + 36y + 28 = 0$

SECTION 10.4 The Analytic Parabola

KEY CONCEPTS

- Horizontal parabolas have equations of the form $x = ay^2 + by + c;\ a \neq 0$.
- A horizontal parabola will open to the right if $a > 0$, and to the left if $a < 0$. The axis of symmetry is $y = \dfrac{-b}{2a}$, with the vertex (h, k) found by evaluating at $y = \dfrac{-b}{2a}$ or by completing the square and writing the equation in shifted form: $(x - h) = a(y - k)^2$.
- Given a fixed point f (called the focus) and fixed line D (called the directrix) in the plane, a parabola is the set of all points (x, y) such that the distance from f to (x, y) is equal to the distance from (x, y) to line D.

- The equation $x^2 = 4py$ describes a vertical parabola, opening upward if $p > 0$, and opening downward if $p < 0$.
- The equation $y^2 = 4px$ describes a horizontal parabola, opening to the right if $p > 0$, and opening to the left if $p < 0$.
- p is the distance from the vertex to the focus (or from the vertex to the directrix).
- The focal chord of a parabola is a line segment that contains the focus and is parallel the directrix, with its endpoints on the graph. It has a total length of $|4p|$, meaning the distance from the focus to a point on the graph (as described) is $|2p|$. It is commonly used to assist in drawing a graph of the parabola.

EXERCISES

For Exercises 21 and 22, find the vertex and x- and y-intercepts if they exist. Then sketch the graph using symmetry and a few points or by completing the square and shifting a parent function.

21. $x = y^2 - 4$

22. $x = y^2 + y - 6$

For Exercises 23 and 24, find the vertex, focus, and directrix for each parabola. Then sketch the graph using this information and the focal chord. Also graph the directrix.

23. $x^2 = -20y$

24. $x^2 - 8x - 8y + 16 = 0$

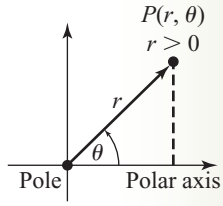
SECTION 10.5 Nonlinear Systems of Equations and Inequalities

KEY CONCEPTS

- Nonlinear systems of equations can be solved using substitution or elimination.
- First identify the graphs of the equations in the system to help determine the possible number of real solutions.
- For systems of nonlinear inequalities, graph the related equation for each inequality given, then use a test point to decide what region to shade as the solution.

- The solution for a system of inequalities is the overlapping region (if it exists) created by the areas shaded for the individual inequalities.
- If the boundary is included, graph it using a solid line; if the boundary is not included (for strict inequalities) use a dashed line.

EXERCISES



Solve Exercises 25–28 using substitution or elimination. For Exercises 29 and 30, graph the solution set. Identify the graph of each relation before you begin. Verify your answers using a graphing calculator if possible.

25. $\begin{cases} x^2 + y^2 = 25 \\ y - x = -1 \end{cases}$ **26.** $\begin{cases} x = y^2 - 1 \\ x + 4y = -5 \end{cases}$ **27.** $\begin{cases} -x^2 + y = -1 \\ x^2 + y^2 = 7 \end{cases}$

28. $\begin{cases} x^2 + y^2 = 10 \\ y - 3x^2 = 0 \end{cases}$ **29.** $\begin{cases} y \le x^2 - 2 \\ x^2 + y^2 \le 16 \end{cases}$ **30.** $\begin{cases} x^2 + y^2 > 9 \\ x^2 + y \le -3 \end{cases}$

SECTION 10.6 Polar Coordinates, Equations, and Graphs

KEY CONCEPTS

- In polar coordinates, the location of a point in the plane is denoted (r, θ), where r is the distance to the point from the origin or *pole*, and θ is the angle between a stipulated polar axis and a ray containing P.
- In the polar coordinate system, the location (r, θ) of a point is not unique for two reasons: (1) the angles θ and $\theta + 2\pi n$ are coterminal (n an integer), and (2) r may be negative.
- The point $P(r, \theta)$ can be converted to $P(x, y)$ in rectangular coordinates where $x = r\cos\theta$ and $y = r\sin\theta$
- The point $P(x, y)$ in rectangular coordinates can be converted to $P(r, \theta)$ in polar coordinates, where $r = \sqrt{x^2 + y^2}$ and $\theta_r = \tan^{-1}\left|\frac{y}{x}\right|$.
- To sketch a polar graph, we view the length r as being along the second hand of a clock, ticking in a counterclockwise direction. Each "tick" is $\frac{\pi}{12}$ rad or 15°. For each tick we locate a point on the radius and plot it on the face of the clock before going on.
- For graphing, we also apply an "r-value" analysis, which looks where r is increasing, decreasing, zero, maximized, and/or minimized.
- If the polar equation is given in terms of sines, the graph will be symmetric to $\theta = \frac{\pi}{2}$.
- If the polar equation is given in terms of cosines, the graph will be symmetric to the polar axis.
- The graphs of several common polar equations are given in Appendix F.

EXERCISES

Sketch using an r-value analysis, symmetry, and any convenient points. Use a graphing calculator to verify your results.

31. $r = 5\sin\theta$ **32.** $r = 4 + 4\cos\theta$ **33.** $r = 2 + 4\cos\theta$ **34.** $r = 8\sin(2\theta)$

SECTION 10.7 More on the Conic Sections: Rotation of Axes and Polar Form

KEY CONCEPTS

- Using a rotation, the conic equation $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$ in the xy-plane can be transformed into $aX^2 + cY^2 + dX + eY + f = 0$ in the XY-plane, in which the mixed xy-term is absent.
- The required angle of rotation β is found using $\tan(2\beta) = \frac{B}{A - C}$; $0 < 2\beta < 180°$.
- The change in coordinates from the xy-plane to the XY-plane is accomplished using the rotation formulas:

$$x = X\cos\beta - Y\sin\beta \qquad y = X\sin\beta + Y\cos\beta$$

- In the process of this conversion, certain quantities, called invariants, remain unchanged and can be used to check that the conversion was correctly performed. These invariants are (1) $F = f$, (2) $A + C = a + c$, and (3) $B^2 - 4AC = b^2 - 4ac$.
- The invariant $B^2 - 4AC = b^2 - 4ac$ is called the discriminant and can be used to classify the type of graph the equation will give, except in degenerate cases:
  - If $B^2 - 4AC = 0$, the equation is that of a parabola.
  - If $B^2 - 4AC < 0$, the equation is that of a circle or an ellipse.
  - If $B^2 - 4AC > 0$, the equation is that of a hyperbola.
  - All conics (not only the parabola) can be stated in terms of a focus/directrix definition. This is done using the concept of eccentricity, symbolized by the letter e.
- If F is a fixed point and $\mathcal{L}$ a fixed line in the plane with the point D on $\mathcal{L}$, the set of all points P such that $\dfrac{\overline{FP}}{\overline{DP}} = e$ (e a constant) is the graph of a conic section. If $e = 1$, the graph is a parabola. If $0 < e < 1$, the graph is an ellipse. If $e > 1$, the graph is a hyperbola.
- Given a conic section with eccentricity e, one focus at the pole of the $r\theta$-plane, and directrix $\mathcal{L}$ located d units from this focus, then the polar equations $r = \dfrac{de}{1 \pm e\cos\theta}$ and $r = \dfrac{de}{1 \pm e\sin\theta}$ represent one of the conic sections as determined by the value of e.

EXERCISES

For the given conics in the xy-plane, use a rotation of axes to find the corresponding equation in the XY-plane, then sketch its graph.

35. $2x^2 - 4xy + 2y^2 - 8\sqrt{2}y - 24 = 0$ **36.** $x^2 + 6\sqrt{3}xy + 7y^2 - 160 = 0$

For the conic equations given, determine if the equation represents a parabola, ellipse, or hyperbola. Then determine the eccentricity e and sketch the graphs using polar graph paper. Verify solutions by graphing them on a calculator.

37. $r = \dfrac{9}{3 - 2\cos\theta}$ **38.** $r = \dfrac{8}{4 - 6\cos\theta}$ **39.** $r = \dfrac{4}{3 + 3\sin\theta}$

40. Mars has a perihelion of 128.4 million miles and an aphelion of 154.9 million miles. Use this information to find a polar equation that models the elliptical orbit, then find the length of the focal chord.

SECTION 10.8 Parametric Equations and Graphs

KEY CONCEPTS

- If we consider the set of points $P(x, y)$ such that the x-values are generated by $f(t)$ and the y-values are generated by $g(t)$ (assuming f and g are both defined on an interval of the domain), the equations $x = f(t)$ and $y = g(t)$ are called parametric equations, with parameter t.
- Parametric equations can be converted to rectangular form by eliminating the parameter. This can sometimes be done by solving for t in one equation and substituting in the other, or by using trigonometric forms.
- A function can be written in parametric form many different ways, by altering the parameter or using trigonometric identities.
- The cycloids are an important family of curves, with equations $x = r(t - \sin t)$ and $y = r(1 - \cos t)$.
- The solutions to dependent systems of equations are often expression in parametric form, with the points $(t, f(t), g(t))$ given by the parametric equations generating solutions to the system.

EXERCISES

Graph the curves defined by the parametric equations over the specified interval and identify the graph. Then eliminate the parameter and write the corresponding rectangular form.

41. $x = t - 4$: $t \in [-3, 3]$: $y = -2t^2 + 3$

42. $x = (2 - t)^2$: $t \in [0, 5]$: $y = (t - 3)^2$

43. $x = -3\sin t$: $t \in [0, 2\pi)$: $y = 4\cos t$

44. Write the function in three different forms by altering the parameter: $y = 2(x - 5)^2 - 1$

45. Use a graphing calculator to graph the Lissajous figure indicated, then state the size of the rectangle needed to frame it: $x = 4\sin(5t)$; $y = 8\cos t$

PRACTICE TEST

By inspection only (no graphing), match each equation to its correct description.

1. $x^2 + y^2 - 6x + 4y + 9 = 0$ _____

2. $4y^2 + x^2 - 4x + 8y + 20 = 0$ _____

3. $x^2 - 4y^2 - 4x + 12y + 20 = 0$ _____

4. $y - x^2 - 4x + 20 = 0$ _____

a. Parabola **b.** Hyperbola **c.** Circle **d.** Ellipse

Identify and then graph each of the following conic sections. State the center, vertices, foci, asymptotes, and other important points when applicable.

5. $x^2 + y^2 - 4x + 10y + 20 = 0$

6. $25(x + 2)^2 + 4(y - 1)^2 = 100$

7. $r = \dfrac{10}{5 - 4\cos\theta}$ **8.** $r = \dfrac{12}{5 - 5\cos\theta}$

9. $\dfrac{(y + 3)^2}{9} - \dfrac{(x - 2)^2}{16} = 1$

10. $4(x - 1)^2 - 25(y + 2)^2 = 100$

Use the equation $80x^2 + 120xy + 45y^2 - 100y - 44 = 0$ to complete Exercises 11 and 12.

11. Use the discriminant $B^2 - 4AC$ to identify the graph, and $\tan(2\beta) = \dfrac{B}{A - C}$ to find $\cos\beta$ and $\sin\beta$.

12. Find the equation in the xy-plane and use a rotation of axes to draw a neat sketch of the graph in the XY-plane.

Graph each polar equation. Verify your results with a graphing calculator.

13. $r = 3 + 3\cos\theta$ **14.** $r = 4 + 8\cos\theta$

15. $r = 6\sin(2\theta)$

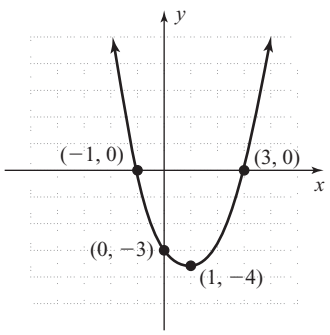
For Exercises 16 and 17, identify and graph each conic section from the parametric equations given. Then remove the parameter and convert to rectangular form.

16. $x = 4\sin t$, $y = 5\cos t$ **17.** $x = (t - 3)^2 + 1$, $y = t + 2$

18. Use a graphing calculator to graph the cycloid, then identify the maximum and minimum values, and the period. $x = 4T - 4\sin T$, $y = 4 - 4\cos T$

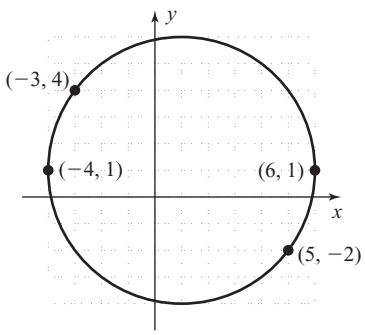
19. Solve each nonlinear system using any method.

a. $\begin{cases} 4x^2 - y^2 = 16 \\ y - x = 2 \end{cases}$ **b.** $\begin{cases} 2y^2 - x^2 = 4 \\ x^2 + y^2 = 8 \end{cases}$



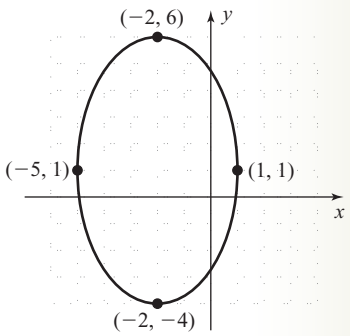
20. Halley's comet has a perihelion of 54.5 million miles and an aphelion of 3253 million miles. Use this information to find a polar equation that models its elliptical orbit. How does its eccentricity compare with that of the planets in our solar system?

21. The soccer match is tied, with time running out. In a desperate attempt to win, the opposing coach pulls his goalie and substitutes a forward. Suddenly, Marques gets a break-away and has an open shot at the empty net, 165 ft away. If the kick is on-line and leaves his foot at an angle of 28° with an initial velocity of 80 ft/sec, is the ball likely to go in the net and score the winning goal?



22. The orbit of Mars around the Sun is elliptical, with the Sun at one focus. When the orbit is expressed as a central ellipse on the coordinate grid, its equation is $\dfrac{x^2}{(141.65)^2} + \dfrac{y^2}{(141.03)^2} = 1$. Use this information to find the *aphelion* of Mars and the *perihelion* of Mars in millions of miles.

Determine the equation of each relation and state its domain and range. For the parabola and the ellipse, also give the location of the foci.



23.

24.

25.

CALCULATOR EXPLORATION AND DISCOVERY

Elongation and Eccentricity

Technically speaking, a circle is an ellipse with both foci at the center. As the distance between foci increases, the ellipse becomes more elongated. We saw other instances of elongation in stretches and compressions of parabolic graphs, and in hyperbolic graphs where the asymptotic slopes varied depending on the values a and b. The measure used to quantify this elongation is called the *eccentricity* e, and is determined by the ratio $e = \frac{c}{a}$. For this *Exploration and Discovery,* we'll use the **repeat graph** feature of a graphing calculator to explore the eccentricity of the graph of a conic. The "repeat graph" feature enables you to graph a family of curves by enclosing changes in a parameter in braces "{ }." For instance, entering $\{-2, -1, 0, 1, 2\}X + 3$ as Y_1 on the Y= screen will automatically graph these five lines:

$$y = -2x + 3,\ y = -x + 3,\ y = 3,$$
$$y = x + 3, \text{ and } y = 2x + 3.$$

We'll use this feature to graph a family of ellipses, observing the result and calculating the eccentricity for each curve in the family. The standard form is $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, which we'll solve for y and enter as Y_1 and Y_2. After simplification the result is $y = \pm b\sqrt{1 - \frac{x^2}{a^2}}$, but for this investigation we'll use the constant $b = 2$ and vary the parameter a using the values $a = 2$, 4, 6, and 8. The result is $y = 2\sqrt{1 - \frac{x^2}{\{4, 16, 36, 64\}}}$. Note from Figure 10.121 that we've set $Y_2 = -Y_1$ to graph the lower half of the ellipse. Using the "friendly" window shown (Figure 10.122) gives the result shown in Figure 10.123, where we see the ellipse is increasingly elongated in the horizontal direction (note when $a = 2$ the result is a circle since $a = b$).

Figure 10.121

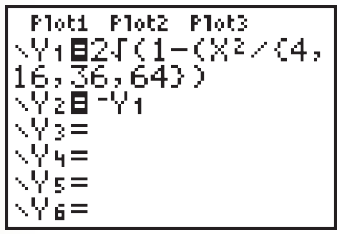


Figure 10.122

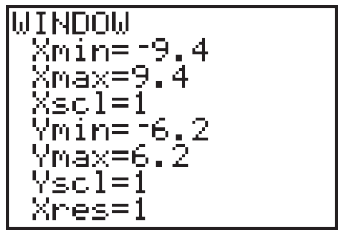

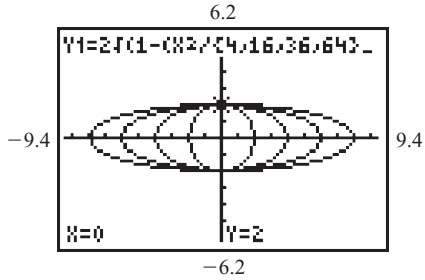

Figure 10.123

Using $a = 2$, 4, 6, and 8 with $b = 2$ in the foci formula $c = \sqrt{a^2 - b^2}$ gives $c = 0, 2\sqrt{3}, 4\sqrt{2}$, and $2\sqrt{15}$, respectively, with these eccentricities: $e = \frac{0}{2}, \frac{2\sqrt{3}}{4}, \frac{4\sqrt{2}}{6}$, and $\frac{2\sqrt{15}}{8}$. While difficult to see in radical form, we find that the eccentricity of an ellipse always satisfies the inequality $0 < e < 1$ (excluding the circle = ellipse case). To two decimal places, the values are $e = 0$, 0.87, 0.94, and 0.97, respectively.

As a final note, it's interesting how the $e = \frac{c}{a}$ definition of eccentricity relates to our everyday use of the word "eccentric." A normal or "noneccentric" person is thought to be well-rounded, and sure enough $e = 0$ produces a well-rounded figure—a circle. A person who is highly eccentric is thought to be far from the norm, deviating greatly from the center, and greater values of e produce very elongated ellipses.

Exercise 1: Perform a similar exploration using a family of *hyperbolas.* What do you notice about the eccentricity?

Exercise 2: Perform a similar exploration using a family of *parabolas.* What do you notice about the eccentricity?

STRENGTHENING CORE SKILLS

Ellipses and Hyperbolas with Rational/Irrational Values of *a* and *b*

Using the process known as completing the square, we were able to convert from the polynomial form of a conic section to the standard form. However, for some equations, values of a and b are somewhat difficult to identify, since the coefficients are not factors. Consider the equation $20x^2 + 120x + 27y^2 - 54y + 192 = 0$, the equation of an ellipse.

$$\begin{aligned}
20x^2 + 120x + 27y^2 - 54y + 192 &= 0 && \text{original equation}\\
20(x^2 + 6x + ___) + 27(y^2 - 2y + ___) &= -192 && \text{subtract 192}\\
20(x^2 + 6x + 9) + 27(y^2 - 2y + 1) &= -192 + 27 + 180 && \text{complete the square in } x \text{ and } y\\
20(x + 3)^2 + 27(y - 1)^2 &= 15 && \text{factor and simplify}\\
\frac{4(x + 3)^2}{3} + \frac{9(y - 1)^2}{5} &= 1 && \text{standard form}
\end{aligned}$$

Unfortunately, we cannot easily identify the values of a and b, since the coefficients of each binomial square are not "1." In these cases, we can write the equation in standard form by using a simple property of fractions—the numerator and denominator of any fraction can be divided by the same quantity to obtain an equivalent fraction. Although the result may look odd, it can nevertheless be applied here, giving a result of $\dfrac{(x + 3)^2}{\frac{3}{4}} + \dfrac{(y - 1)^2}{\frac{5}{9}} = 1$.

We can now identify a and b by writing these denominators in squared form, which gives the following expression: $\dfrac{(x + 3)^2}{\left(\frac{\sqrt{3}}{2}\right)^2} + \dfrac{(y - 1)^2}{\left(\frac{\sqrt{5}}{3}\right)^2} = 1$. The values of a and b are now easily seen as $a = \dfrac{\sqrt{3}}{2} \approx 0.866$ and $b = \dfrac{\sqrt{5}}{3} \approx 0.745$.

Use this idea to complete the following exercises.

Exercise 1: Write the equation in standard form, then identify the values of a and b and use them to graph the ellipse.

$$\frac{4(x + 3)^2}{49} + \frac{25(y - 1)^2}{36} = 1$$

Exercise 2: Write the equation in standard form, then identify the values of a and b and use them to graph the hyperbola.

$$\frac{9(x + 3)^2}{80} - \frac{4(y - 1)^2}{81} = 1$$

Exercise 3: Identify the values of a and b by writing the equation $100x^2 - 400x - 18y^2 - 108y + 230 = 0$ in standard form.

Exercise 4: Identify the values of a and b by writing the equation $28x^2 - 56x + 48y^2 + 192y + 195 = 0$ in standard form.

CUMULATIVE REVIEW CHAPTERS 1–10

1. Find the equation of the parabola with vertex at (2, 3) and directrix $x = 0$.

Solve each equation.

2. $x^2 - 6x + 13 = 0$

3. $4 \cdot 2^{x+1} = \frac{1}{8}$

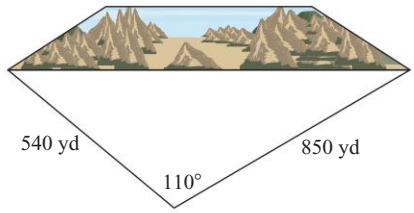
4. $3^{x-2} = 7$

5. $\log_3 81 = x$

6. $\log x + \log(x - 3) = 1$

7. $-6 \tan x = 2\sqrt{3}$

8. $25 \sin\left(\frac{\pi}{3}x - \frac{\pi}{6}\right) + 3 = 15.5$



9. $\frac{\sin 27°}{18} = \frac{\sin x}{35}$

10. Use De Moivre's theorem to find the three cube roots of $-8i$. Write the roots in $a + bi$ form.

11. The price of beef in Argentina varies directly with demand and inversely with supply. In the small town of Chascomus, the tender-cut lomito was selling for 18 pesos/kg last week. There were 1000 kg available, and 850 kg were bought. Next week there is a 3-day weekend, so the demand is expected to be closer to 1400 kg, but the butchers will only be able to supply 1200 kg. What will a kilogram of tender-cut lomito cost next week?

12. Find the inverse of $f(x) = 3 \sin(2x + 1)$.

13. A surveyor needs to estimate the width of a large rock formation in Canyonlands National Park. From her current position she is 540 yd from one edge of the formation and 850 yd from the other edge. If the included angle is 110°, how wide is the formation?

Graph each relation. Include vertices, x- and y-intercepts, asymptotes, and other features.

14. $f(x) = |x - 2| + 3$

15. $y = \sqrt{x - 3} + 1$

16. $g(x) = (x - 3)(x + 1)(x + 4)$

17. $h(x) = \frac{x - 2}{x^2 - 9}$

18. $y = 2^x + 3$

19. $f(x) = \log_2(x + 1)$

20. $x^2 + y^2 + 10x - 4y + 20 = 0$

21. $4(x - 1)^2 - 36(y + 2)^2 = 144$

22. $y = -2 \cos\left(x - \frac{\pi}{4}\right) + 1$

23. $r = 4 \cos(2\theta)$

24. $x = 2 \sin t$, $y = \tan t$

25. Use the dot product to find the angle between the vectors $\mathbf{u} = \langle -4, 5 \rangle$ and $\mathbf{v} = \langle 3, 7 \rangle$.

Solve each system of equations with a graphing calculator. Use a matrix equation for Exercise 26, and the intersection-of-graphs method for Exercise 27.

26. $\begin{cases} 4x + 3y = 13 \\ -9y + 5z = 19 \\ x - 4z = -4 \end{cases}$

27. $\begin{cases} x^2 + y^2 = 25 \\ 64x^2 + 12y^2 = 768 \end{cases}$

28. Use a graphing calculator to solve $\sqrt{x + 2} + 2 = \sqrt{3x + 4}$

29. Use a graphing calculator to decompose $\frac{3x^3 - 2x^2 + x - 3}{x^4 + x^2}$ into partial fractions.

30. In the summer, Hollywood releases its big budget, big star, big money movies. Suppose the weekly summer revenue generated by ticket sales was modeled by the function $R(w) = -w^4 + 25w^3 - 200w^2 + 560w - 234$, where $R(w)$ represents the revenue generated in week w and $1 \le w \le 12$. Use a calculator to determine the amount of revenue generated in week 5.

CONNECTIONS TO CALCULUS

As with other relations and functions we've studied in precalculus, there is a high level of interest in finding rates of change in polar functions, and in solving systems of polar equations. From their use in architecture to their application in studies of planetary motion, both skills play a fundamental role in our continuing study.

Polar Graphs and Instantaneous Rates of Change

Using the tools of calculus, it can be shown that the slope of the tangent line for many different polar graphs can be generated from a specific template. It can also be shown that under certain conditions, the zeroes of the numerator will give the location of horizontal tangent lines, while the zeroes of the denominator will given the location of vertical tangent lines.

EXAMPLE 1 ▶ **Finding Slopes of Tangent Lines**

For the cardioid $r = 1 + \sin\theta$, it can be shown that $\dfrac{\cos\theta\sin\theta + (1+\sin\theta)\cos\theta}{\cos\theta\cos\theta - (1+\sin\theta)\sin\theta}$ gives the slope of the tangent line at θ.

a. Simplify the expression using double-angle identities.

b. Use the result to find the slope of the tangent line at $\theta = \dfrac{2\pi}{3}$.

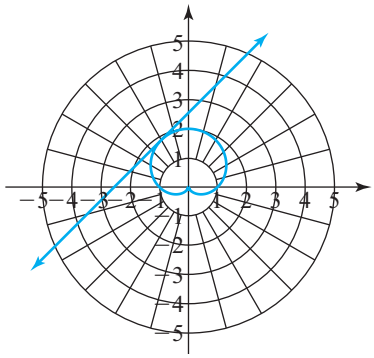
Then, determine the value(s) of θ for which a tangent line is

c. Horizontal.

d. Vertical.

Solution ▶ **a.** After using the distributive property in the numerator and denominator, we have

$$\frac{\cos\theta\sin\theta + (1+\sin\theta)\cos\theta}{\cos\theta\cos\theta - (1+\sin\theta)\sin\theta} = \frac{\cos\theta\sin\theta + \cos\theta + \sin\theta\cos\theta}{\cos^2\theta - \sin\theta - \sin^2\theta} \quad \text{distribute}$$



$$= \frac{2\sin\theta\cos\theta + \cos\theta}{\cos^2\theta - \sin^2\theta - \sin\theta} \quad \text{combine terms}$$

$$= \frac{\sin(2\theta) + \cos\theta}{\cos(2\theta) - \sin\theta} \quad \text{double angle identities}$$

b. For $\theta = \dfrac{2\pi}{3}$, the expression gives $\dfrac{\sin\left(\frac{4\pi}{3}\right) + \cos\left(\frac{2\pi}{3}\right)}{\cos\left(\frac{4\pi}{3}\right) - \sin\left(\frac{2\pi}{3}\right)} = \dfrac{-\frac{\sqrt{3}}{2} - \frac{1}{2}}{-\frac{1}{2} - \frac{\sqrt{3}}{2}} = 1.$

For the cardioid $r = 1 + \sin\theta$, the slope of the tangent line at $\theta = \dfrac{2\pi}{3}$ is 1 (Figure 10.124).

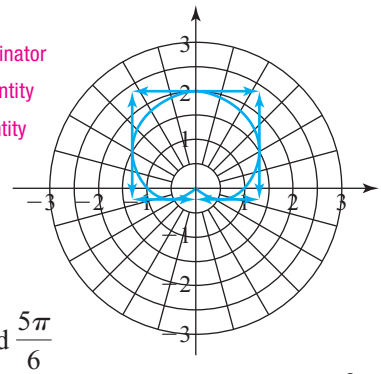
Figure 10.124

c. For horizontal tangents, set the numerator equal to zero and solve.

$$\sin(2\theta) + \cos\theta = 0 \quad \text{zeroes of numerator}$$

$$2\sin\theta\cos\theta + \cos\theta = 0 \quad \text{double angle identity}$$

$$\cos\theta\,(2\sin\theta + 1) = 0 \quad \text{factor } \cos\theta$$



$$\cos\theta = 0 \quad \text{or} \quad \sin\theta = -\frac{1}{2}$$

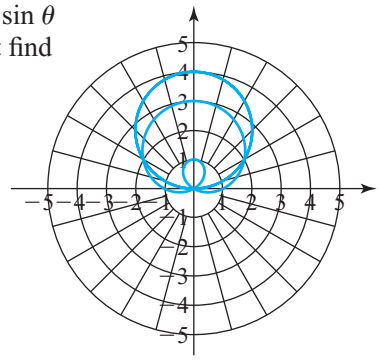
Horizontal tangent lines will occur at $\theta = \frac{\pi}{2}, \frac{7\pi}{6}$, and $\frac{11\pi}{6}$. Note that a horizontal tangent does not occur at $\theta = \frac{3\pi}{2}$, as this value also makes the denominator of the expression equal to zero.

d. For vertical tangents, set the denominator equal to zero and solve.

$$\begin{aligned}
\cos(2\theta) - \sin\theta &= 0 && \text{zeroes of denominator}\\
\cos^2\theta - \sin^2\theta - \sin\theta &= 0 && \text{double angle identity}\\
1 - \sin^2\theta - \sin^2\theta - \sin\theta &= 0 && \text{Pythagorean identity}\\
1 - \sin\theta - 2\sin^2\theta &= 0 && \text{combine terms}\\
(1 - 2\sin\theta)(1 + \sin\theta) &= 0 && \text{factor}\\
\sin\theta = \frac{1}{2} \quad \text{or} \quad \sin\theta &= -1
\end{aligned}$$

Figure 10.125

Vertical tangent lines will occur at $\theta = \frac{\pi}{6}$ and $\frac{5\pi}{6}$ (see enlargement in Figure 10.125). A vertical tangent does not occur at $\theta = \frac{3\pi}{2}$, as this value makes both the numerator and denominator of the expression equal to zero.



Now try Exercises 1 through 4 ▶

Systems of Polar Equations

In the "Connections" feature from Chapter 3, we investigated the area bounded by a given curve, the x-axis, and given vertical lines. In many applications, we need to find the area bounded *between two curves,* which requires that we find where the curves intersect. This can be accomplished by solving a system consisting of the two given functions. For polar equations, the system takes the form $\begin{cases} r = f(\theta) \\ r = g(\theta) \end{cases}$.

EXAMPLE 2 ▶ Finding Intersections of Polar Curves

To find the area of the region inside the circle $r = 4\sin\theta$ and outside the limacon $r = 1 + 2\sin\theta$, we must find where the curves intersect. Set up and solve the required system (see figure).

Solution ▶ For $r = 4\sin\theta$ and $r = 1 + 2\sin\theta$, the system is $\begin{cases} r = 4\sin\theta \\ r = 1 + 2\sin\theta \end{cases}$. Substituting $4\sin\theta$ for r in the second equation gives

$$\begin{aligned}
4\sin\theta &= 1 + 2\sin\theta, && \text{substitute } 4\sin\theta \text{ for } r\\
2\sin\theta &= 1 && \text{subtract } 2\sin\theta\\
\sin\theta &= \frac{1}{2} && \text{divide by 2}\\
\theta &= \sin^{-1}\left(\frac{1}{2}\right) && \text{apply inverse sine}
\end{aligned}$$

This shows the graphs intersect at $\theta = \frac{\pi}{6}$ and $\theta = \frac{5\pi}{6}$. It appears we're finished, but an inspection of the equations (or the graph) shows there must be a third point of intersection at the pole (0, 0). The reason we missed it is that in polar coordinates each point can be represented many different ways. Solutions using a system of polar equations finds only the intersections *represented by the identical ordered pair,* and a separate analysis is needed for the case where $r = 0$. Solving the equation $0 = 4 \sin\theta$ gives $\theta = \pi k$, while $0 = 1 + 2 \sin\theta$ gives $\theta = \frac{7\pi}{6} + 2\pi k$ and $\theta = \frac{11\pi}{6} + 2\pi k$. Although the ordered pairs are different, both represent the pole (0, 0) and the graphs must intersect there.

Now try Exercises 5 through 10 ▶

Connections to Calculus Exercises

For each polar function given, the expression for the slope of the tangent line is also given. (a) Simplify the expression. (b) Find the slope of the tangent line at the values of θ shown. Then determine the value(s) of θ in $[0, 2\pi)$ for which a tangent line is (c) horizontal, and (d) vertical.

1. $r = 1 + \cos\theta$ (cardioid), slope of the tangent line:

$$\frac{\cos\theta + \sin\theta(-\sin\theta) + \cos\theta\cos\theta}{-\sin\theta + 2\cos\theta(-\sin\theta)}; \theta = \frac{\pi}{2}, \frac{11\pi}{6}$$

2. $r = 6\cos\theta$ (circle), slope of the tangent line:

$$\frac{-6\sin\theta\sin\theta + 6\cos\theta\cos\theta}{-6\sin\theta\cos\theta - 6\cos\theta\sin\theta}; \theta = \frac{\pi}{6}, \frac{2\pi}{3}$$

3. $r = \cos\theta - \sin\theta$ (circle), slope of the tangent line:

$$\frac{\cos\theta\cos\theta + \sin\theta(-\sin\theta) - 2\sin\theta\cos\theta}{2\cos\theta(-\sin\theta) - [\sin\theta(-\sin\theta) + \cos\theta\cos\theta]}$$

$\theta = \frac{\pi}{4}, \frac{3\pi}{4}$

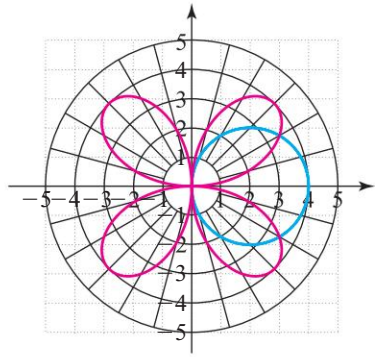
4. $r = \sin\theta - \cos\theta$ (circle), slope of the tangent line:

$$\frac{2\sin\theta(\cos\theta) - [\cos\theta\cos\theta + \sin\theta(-\sin\theta)]}{\cos\theta\cos\theta + \sin\theta(-\sin\theta) - 2\cos\theta(-\sin\theta)}$$

$\theta = \frac{\pi}{2}, \frac{3\pi}{2}$

Solve each system. For Exercises 7 and 8, identify the graph of each function before you begin. Verify results using a graphing calculator.

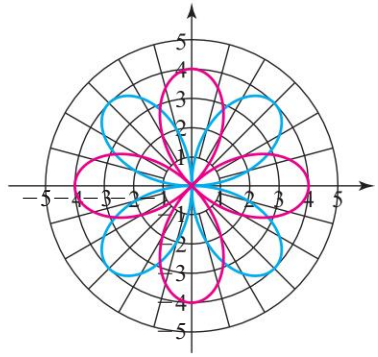
5. $\begin{cases} r = \frac{3}{2} \\ r = 1 + \cos^2\theta \end{cases}$



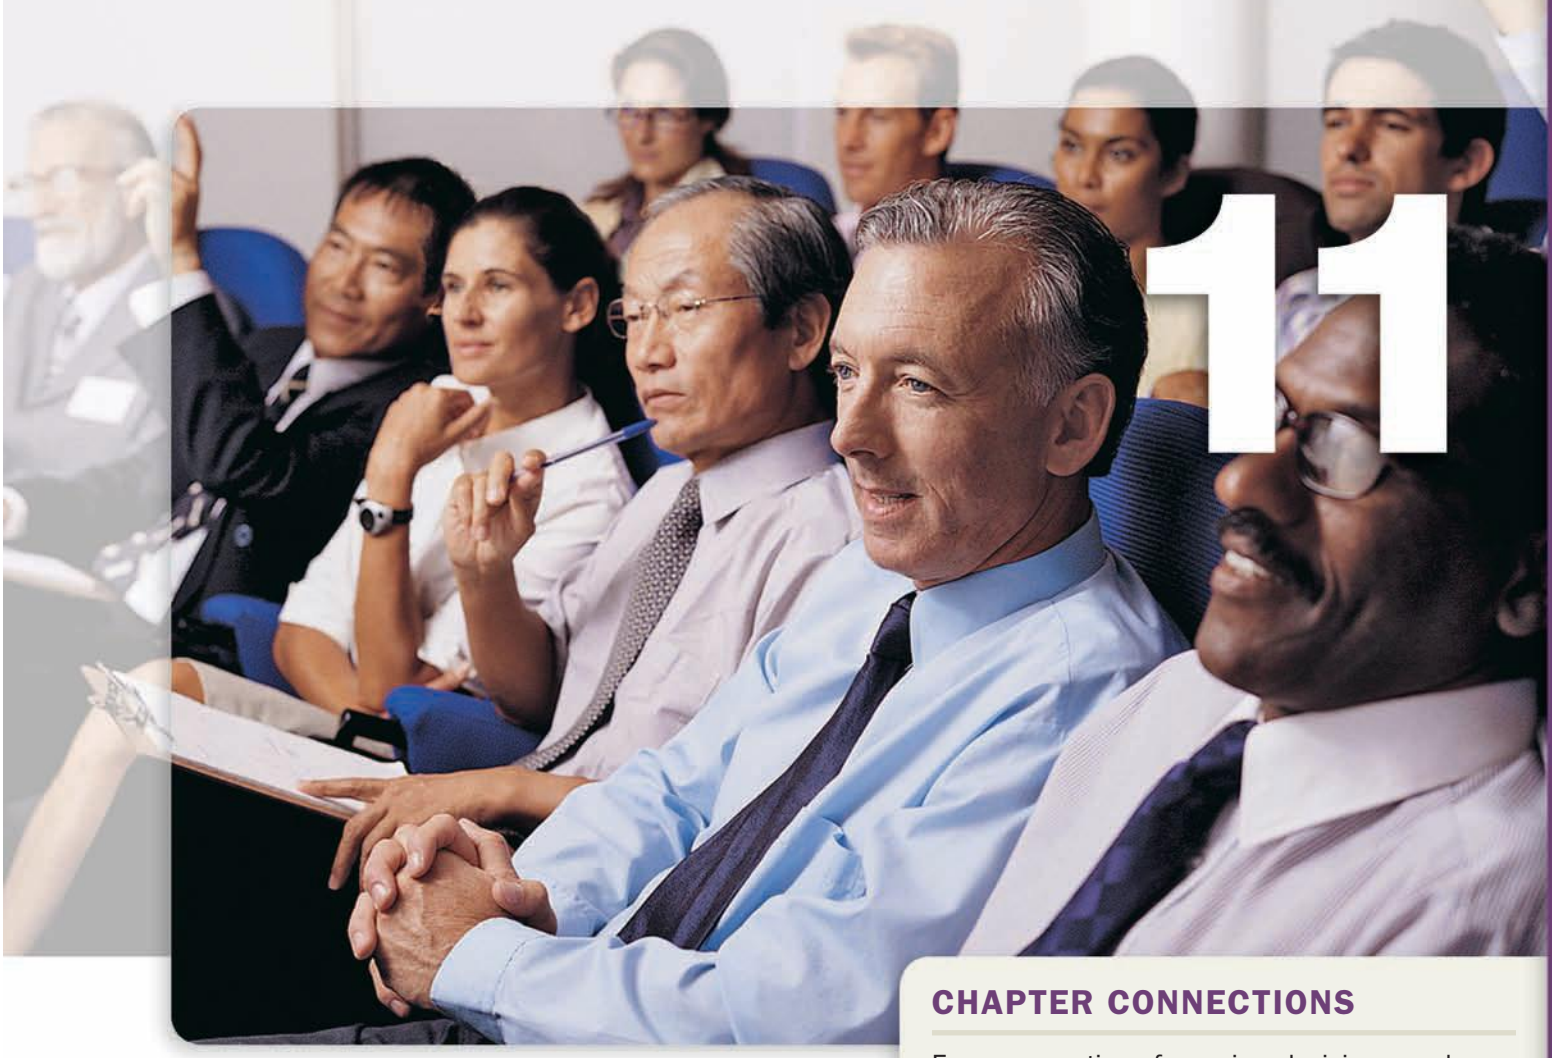
6. $\begin{cases} r = 2\sin^2\theta \\ r = 1 + \sin\theta \end{cases}$

7. $\begin{cases} r = \sin(2\theta) \\ r = \cos\theta \end{cases}$

8. $\begin{cases} r = 2\sin(2\theta) \\ r = 2\sin\theta \end{cases}$



9. Find the points of intersection for the circle $r = 4\cos\theta$ and the curve $r = 4\sin(2\theta)$, by solving the system $\begin{cases} r = 4\cos\theta \\ r = 8\sin\theta\cos\theta \end{cases}$. State your answer in both (r, θ) form and (x, y) form. Note from the graph there are three points of intersection, and that a polar grid has been superimposed on a rectangular grid.



Exercise 9

10. Find the points of intersection of the two four-leaf roses formed by $r = -4\sin(2\theta)$ and $r = 4\cos(2\theta)$, by solving the system $\begin{cases} r = -4\sin(2\theta) \\ r = 4\cos(2\theta) \end{cases}$ (there are nine in all). Some of these points can be found by solving $4\cos(2\theta) = -4\sin(2\theta)$, others can be found using symmetry [since r can be positive or negative, we consider the possibility $r_1 = -r_2$, or $4\cos(2\theta) = 4\sin(2\theta)$]. Be sure to include an analysis of the case where $r = 0$. Answer in (r, θ) form.

Exercise 10

CHAPTER CONNECTIONS

For a corporation of any size, decisions made by upper management often depend on a large number of factors, with the desired outcome attainable in many different ways. For instance, consider a legal firm that specializes in family law, with a support staff of 15 employees—6 paralegals and 9 legal assistants. Due to recent changes in the law, the firm wants to send some combination of five support staff to a conference dedicated to the new changes. In Chapter 11, we'll see how counting techniques and probability can be used to determine the various ways such a group can be randomly formed, even if certain constraints are imposed.

▶ This application appears as Exercise 34 in Section 11.6.

Connections to Calculus

While the notation and properties of summation were introduced as tools to work with finite sums, in Section 11.3 we will note that under certain conditions, consideration of an infinite sum is possible. The process will involve an ever larger sum of ever smaller pieces, a process further illustrated in the *Connections to Calculus* feature following Chapter 11.

11.1 Sequences and Series

LEARNING OBJECTIVES

In Section 11.1 you will see how we can:

- ❑ **A.** Write out the terms of a sequence given the general or *n*th term
- ❑ **B.** Work with recursive sequences and sequences involving a factorial
- ❑ **C.** Find the partial sum of a series
- ❑ **D.** Use summation notation to write and evaluate series
- ❑ **E.** Use sequences to solve applications

A *sequence* can be thought of as a pattern of numbers listed in a prescribed order. A *series* is the sum of the numbers in a sequence. Sequences and series come in countless varieties, and we'll introduce some general forms here. In following sections we'll focus on two special types: arithmetic and geometric sequences. These are used in a number of different fields, with a wide variety of significant applications.

A. Finding the Terms of a Sequence Given the General Term

Suppose a person had \$10,000 to invest, and decided to place the money in government bonds that guarantee an annual return of 7%. From our work in Chapter 5, we know the amount of money in the account after x years can be modeled by the function $f(x) = 10{,}000(1.07)^x$. If you reinvest your earnings each year, the amount in the account would be (rounded to the nearest dollar):

Year:	$f(1)$	$f(2)$	$f(3)$	$f(4)$	$f(5)\ldots$
	↓	↓	↓	↓	↓
Value:	\$10,700	\$11,449	\$12,250	\$13,108	\$14,026 …

Note the relationship (year, value) is a function that pairs 1 with \$10,700, 2 with \$11,449, 3 with \$12,250, and so on. This is an example of a **sequence.** To distinguish sequences from other algebraic functions, we commonly name the functions a instead of f, use the variable n instead of x, and employ a subscript notation. The function $f(x) = 10{,}000(1.07)^x$ would then be written $a_n = 10{,}000(1.07)^n$. Using this notation $a_1 = 10{,}700$, $a_2 = 11{,}449$, and so on.

The values $a_1, a_2, a_3, a_4, \ldots$ are called the **terms** of the sequence. If the account were closed after a certain number of years (for example, after the fifth year) we have a **finite sequence.** If we let the investment grow indefinitely, the result is called an **infinite sequence.** The expression a_n that defines the sequence is called the **general** or ***n*th term** and the terms immediately preceding it are called the $(n-1)$st term, the $(n-2)$nd term, and so on.

WORTHY OF NOTE

Sequences can actually start with any natural number. For instance, the sequence $a_n = \dfrac{2}{n-1}$ must start at $n = 2$ to avoid division by zero. In addition, we will sometimes use a_0 to indicate a preliminary or inaugural element, as in $a_0 = \$10{,}000$ for the amount of money initially held, prior to investing it.

Sequences

A *finite sequence* is a function a_n whose domain is the set of natural numbers from 1 to n. The terms of the sequence are labeled

$$a_1, a_2, a_3, \ldots, a_k, a_{k+1}, \ldots, a_{n-1}, a_n$$

where a_k represents an arbitrary "interior" term and a_n also represents the last term of the sequence.

An *infinite sequence* is a function a_n whose domain is the set of all natural numbers.

EXAMPLE 1A ▶ Computing Specified Terms of a Sequence

For $a_n = \dfrac{n+1}{n^2}$, find a_1, a_3, a_6, and a_7.

Solution ▶

$$a_1 = \frac{1+1}{1^2} = 2 \qquad a_3 = \frac{3+1}{3^2} = \frac{4}{9}$$

$$a_6 = \frac{6+1}{6^2} = \frac{7}{36} \qquad a_7 = \frac{7+1}{7^2} = \frac{8}{49}$$

EXAMPLE 1B ▶ Computing the First *k* Terms of a Sequence

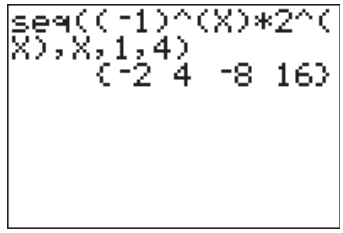
Find the first four terms of the sequence $a_n = (-1)^n 2^n$. Write the terms of the sequence as a list.

Solution ▶

$a_1 = (-1)^1 2^1 = -2$ $\quad a_2 = (-1)^2 2^2 = 4$

$a_3 = (-1)^3 2^3 = -8$ $\quad a_4 = (-1)^4 2^4 = 16$

The sequence can be written $-2, 4, -8, 16, \ldots$, or more generally as $-2, 4, -8, 16, \ldots, (-1)^n 2^n, \ldots$ to show how each term was generated.



WORTHY OF NOTE

When the terms of a sequence *alternate in sign* as in Example 1B, we call it an **alternating sequence.**

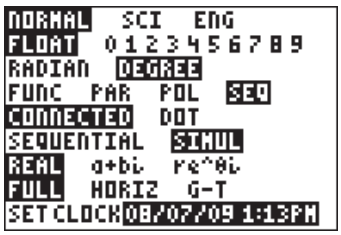
Now try Exercises 7 through 22 ▶

Much of the beauty and power of studying sequences comes from patterns detected within the sequence, or the ability to find a particular term quickly. Here, the calculator becomes an invaluable tool, aiding computations to be sure … but also enabling explorations not generally possible with paper and pencil alone. Most graphing calculators offer a **"seq("** feature (often in a **STAT** or **LIST** menu), where the left parenthesis indicates we need to enter the following four items of information: the nth term formula defining the sequence, the variable in use, the starting value, and the ending value. The sequence generated can be seen on the home screen, or stored in a list for future use. In Figure 11.1, this feature was used to generate the first four terms of the sequence defined in Example 1B using the keystrokes 2nd STAT **(LIST)** ▸ **(OPS) 5:seq(**.

Figure 11.1

In addition to the **seq(** feature, most calculators have a sequence MODE, which is especially useful when working with several sequences simultaneously. In sequence MODE (Figure 11.2A), the Y= screen presents a very different look (Figure 11.2B), first of all showing that the minimum value of n is 1, then naming the functions u(n), v(n), and w(n) instead of Y_1, Y_2, and Y_3. The entries following each, for example "u(nMin) =," are used in a study of the recursive sequences, which are covered later. Note that function names for the sequences (u, v, and w) are the 2nd function for the numbers 7, 8, and 9, respectively.

Figure 11.2A



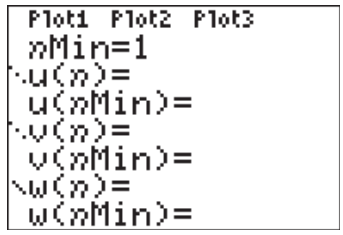


Figure 11.2B

EXAMPLE 2 ▶ **Finding the Terms of a Sequence Using Technology**

Use a calculator in sequence MODE to

a. Find the sixth term (as a fraction) for the sequence defined in Example 1A.

b. Generate the first five terms for the sequence defined in Example 1B and store the results in a list.

Solution ▶

a. On the Y= screen, define the sequence u(n) as $u(n) = \dfrac{n+1}{n^2}$ (Figure 11.3), leaving the second line blank. Then go to the home screen, access the **"seq("** feature as before, and supply the information required. Since we only want the sixth term (a_6), we enter **seq(u(*n*), *n*, 6, 6) ▶Frac,** and after pressing ENTER, we obtain the expected result $\dfrac{7}{36}$ (Figure 11.4).

Figure 11.3

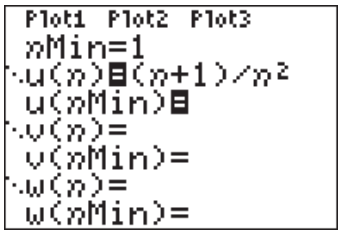

Figure 11.4

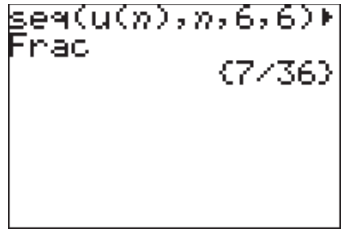

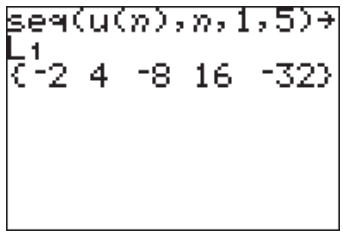

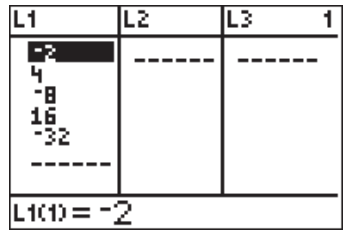

Figure 11.5

A. You've just seen how we can write out the terms of a sequence given the general or *n*th term

b. For the first five terms, we change u(n) to u(n) $= (-1)^n \cdot 2^n$ then go to the home screen and use the **"5:seq("** command once again, this time for terms one through five. Knowing that we want the results stored in a list, we follow the command with STO▸ 2nd 1 **(L1)** (Figure 11.5). The list is shown in Figure 11.6.

Figure 11.6

Now try Exercises 23 through 32 ▶

B. Recursive Sequences and Factorial Notation

Sometimes the formula defining a sequence uses the preceding term or terms to generate those that follow. These are called **recursive sequences** and are particularly useful in writing computer programs. Because of how they are defined, recursive sequences must give an inaugural term or **seed element(s),** to begin the recursion process.

Perhaps the most famous recursive sequence is associated with the work of Leonardo of Pisa (A.D. 1180–1250), better known to history as *Fibonacci.* In the Fibonacci sequence, each successive term is the sum of the previous two, beginning with 1, 1, ...

EXAMPLE 3 ▶ Computing the Terms of a Recursive Sequence

Write out the first eight terms of the Fibonacci sequence, which is defined by $c_1 = 1$, $c_2 = 1$, and $c_n = c_{n-1} + c_{n-2}$.

Solution ▶ The first two terms are given, so we begin with $n = 3$.

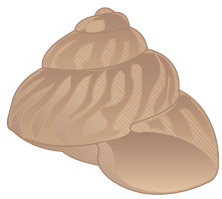
$$\begin{aligned} c_3 &= c_{3-1} + c_{3-2} \\ &= c_2 + c_1 \\ &= 1 + 1 \\ &= 2 \end{aligned} \qquad \begin{aligned} c_4 &= c_{4-1} + c_{4-2} \\ &= c_3 + c_2 \\ &= 2 + 1 \\ &= 3 \end{aligned} \qquad \begin{aligned} c_5 &= c_{5-1} + c_{5-2} \\ &= c_4 + c_3 \\ &= 3 + 2 \\ &= 5 \end{aligned}$$

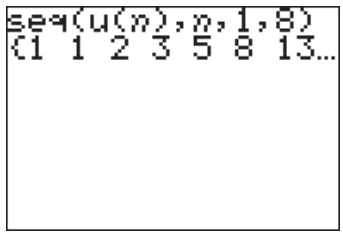
At this point we can simply use the fact that each successive term is simply the sum of the preceding two, and find that $c_6 = 3 + 5 = 8$, $c_7 = 5 + 8 = 13$, and $c_8 = 8 + 13 = 21$. The first eight terms are 1, 1, 2, 3, 5, 8, 13, and 21.

Now try Exercises 33 through 38 ▶

WORTHY OF NOTE

One application of the Fibonacci sequence involves the Fibonacci spiral, found in the growth of many ferns and the spiral shell of many mollusks.





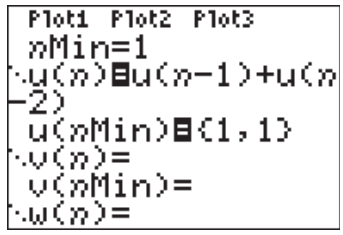


Figure 11.8

Since a recursive sequence is defined using a preceding term or terms, the *first term*(*s*) must be given in order to determine those that follow. To generate the sequence using technology, we enter these initial terms as "u(nMin) =" on the Y= screen, enclosed in braces. For the Fibonacci sequence from Example 3, we would enter u(nMin) = {1, 1}" as shown in Figure 11.7, with the result shown in Figure 11.8 (use the right arrow to view any remaining terms).

Figure 11.7

Some sequences may involve the computation of a **factorial,** which is the product of a given natural number with all those that precede it. The expression **5!** is read, "five factorial," and is evaluated as: $5! = 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1 = 120$.

Factorials

For any natural number n,

$$n! = n \cdot (n - 1) \cdot (n - 2) \cdot \ldots \cdot 3 \cdot 2 \cdot 1$$

Rewriting a factorial in equivalent forms often makes it easier to simplify certain expressions. For example, we can rewrite 5! as $5 \cdot 4!$ or $5! = 5 \cdot 4 \cdot 3!$, and so on. Consider Example 4.

EXAMPLE 4 ▶ **Simplifying Expressions Using Factorial Notation**

Simplify by writing the numerator in an equivalent form.

a. $\dfrac{9!}{7!}$ **b.** $\dfrac{11!}{8!2!}$ **c.** $\dfrac{6!}{3!5!}$

Solution ▶

a. $\dfrac{9!}{7!} = \dfrac{9 \cdot 8 \cdot \cancel{7!}}{\cancel{7!}}$

$= 9 \cdot 8$

$= 72$

b. $\dfrac{11!}{8!2!} = \dfrac{11 \cdot 10 \cdot 9 \cdot \cancel{8!}}{\cancel{8!}2!}$

$= \dfrac{990}{2}$

$= 495$

c. $\dfrac{6!}{3!5!} = \dfrac{6 \cdot \cancel{5!}}{3!\cancel{5!}}$

$= \dfrac{6}{6}$

$= 1$

Now try Exercises 39 through 44 ▶

Most calculators have a factorial option or key. On many calculator models it is located on a submenu of the MATH key: MATH ◀ **PRB 4: !**.

EXAMPLE 5 ▶ **Computing a Specified Term from a Sequence Defined Using Factorials**

Find and simplify the third term of each sequence.

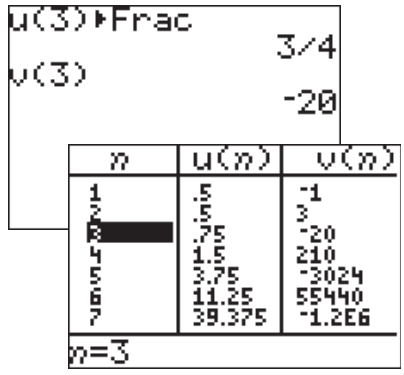
a. $a_n = \dfrac{n!}{2^n}$ **b.** $c_n = \dfrac{(-1)^n(2n-1)!}{n!}$

Algebraic Solution ▶

a. $a_3 = \dfrac{3!}{2^3}$

$= \dfrac{6}{8} = \dfrac{3}{4}$

b. $c_3 = \dfrac{(-1)^3[2(3)-1]!}{3!}$



$= \dfrac{(-1)(5!)}{3!} = \dfrac{(-1)[5 \cdot 4 \cdot \cancel{3!}]}{\cancel{3!}}$

$= -20$

Technology Solution ▶

For this exercise we enter $\dfrac{n!}{2^n}$ as u(n), and $\dfrac{(-1)^n(2n-1)!}{n!}$ as v(n). Once these functions have been defined on the Y= screen, we can evaluate them on the home screen as with other functions (Figure 11.9), or use the **TABLE** feature (Figure 11.10).

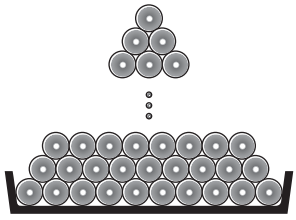


Figure 11.9, 11.10

Now try Exercises 45 through 50 ▶

B. You've just seen how we can work with recursive sequences and sequences involving a factorial

Figure 11.11

C. Series and Partial Sums

Sometimes the terms of a sequence are dictated by context rather than a formula. Consider the stacking of large pipes in a storage yard. If there are 10 pipes in the bottom row, then 9 pipes, then 8 (see Figure 11.11), how many pipes are in the stack if there is a single pipe at the top? The sequence generated is 10, 9, 8, … , 3, 2, 1 and to answer the question we would have to *compute the sum of all terms in the sequence.* When the terms of a finite sequence are added, the result is called a **finite series.**

Finite Series

Given the sequence $a_1, a_2, a_3, a_4, \ldots, a_n$, the sum of the terms is called a **finite series** or **partial sum** and is denoted S_n:

$$S_n = a_1 + a_2 + a_3 + \cdots + a_{n-1} + a_n$$

EXAMPLE 6 ▶ **Computing a Partial Sum**

Given $a_n = 2n$, find the value of **a.** S_4 **b.** S_7.

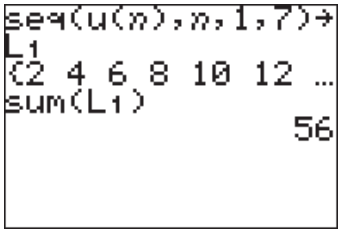
Solution ▶ Since we eventually need the sum of the first seven terms, begin by writing out these terms: 2, 4, 6, 8, 10, 12, and 14.

a. $S_4 = a_1 + a_2 + a_3 + a_4$
$= 2 + 4 + 6 + 8$
$= 20$

b. $S_7 = a_1 + a_2 + a_3 + a_4 + a_5 + a_6 + a_7$
$= 2 + 4 + 6 + 8 + 10 + 12 + 14$
$= 56$

Now try Exercises 51 through 56 ▶

Figure 11.12



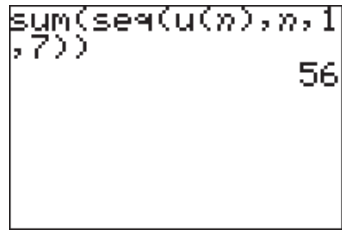


Figure 11.13

There are several ways of computing a partial sum using technology, with the most common being (1) storing the sequence in a list then computing the sum of the list elements, or (2) computing the sum of a sequence directly on the home screen using the appropriate commands. On many calculators, the **"sum("** option is in a **MATH** submenu, accessed using 2nd STAT **(LIST)** ‹ **(MATH) 5:sum(.** For the sum in Example 6(b), we have u$(n) = 2n$, with option (1) demonstrated in Figure 11.12 and option (2) in Figure 11.13.

C. You've just seen how we can find the partial sum of a series

D. Summation Notation

When the general term of a sequence is known, the Greek letter *sigma* Σ can be used to write the related series as a formula. For instance, to indicate the sum of the first four terms of $a_n = 3n + 2$, we write $\sum_{i=1}^{4}(3i + 2)$ with this notation indicating we are to compute the sum of all terms generated as i cycles from 1 through 4. This result is called **summation** or **sigma notation** and the letter i is called the **index of summation.** The letters j, k, l, and m are also used as index numbers, and the summation need not start at 1.

EXAMPLE 7 ▶ **Computing a Partial Sum**

Compute each sum:

a. $\sum_{i=1}^{4}(3i + 2)$ **b.** $\sum_{j=1}^{5}\frac{1}{j}$ **c.** $\sum_{k=3}^{6}(-1)^k k^2$

d. Check each sum using a graphing calculator.

Solution ▶

a. $\sum_{i=1}^{4}(3i + 2) = (3 \cdot 1 + 2) + (3 \cdot 2 + 2) + (3 \cdot 3 + 2) + (3 \cdot 4 + 2)$
$= 5 + 8 + 11 + 14 = 38$

b. $\sum_{j=1}^{5}\frac{1}{j} = \frac{1}{1} + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5}$
$= \frac{60}{60} + \frac{30}{60} + \frac{20}{60} + \frac{15}{60} + \frac{12}{60} = \frac{137}{60}$

c. $\sum_{k=3}^{6}(-1)^k k^2 = (-1)^3 \cdot 3^2 + (-1)^4 \cdot 4^2 + (-1)^5 \cdot 5^2 + (-1)^6 \cdot 6^2$

$= -9 + 16 + (-25) + 36 = 18$

d. Begin by entering the functions in parts (a), (b), and (c) as u(n), v(n), and w(n) respectively on the Y= screen (Figure 11.14). Note that while different indices are used in this example, all are entered into the calculator using the variable n. The results are shown in Figures 11.15 and 11.16.

Figure 11.14

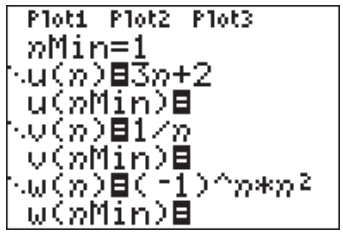

Figure 11.15

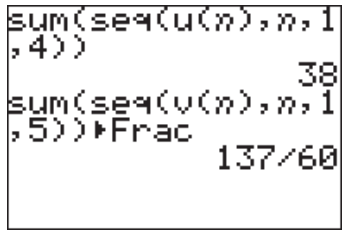

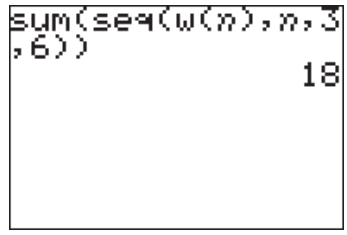

Figure 11.16

Now try Exercises 57 through 68 ▶

If a definite pattern is noted in a given series expansion, this process can be reversed, with the expanded form being expressed in summation notation using the nth term.

EXAMPLE 8 ▶ Writing a Sum in Sigma Notation

Write each of the following sums in summation (sigma) notation.

a. $1 + 3 + 5 + 7 + 9$ **b.** $6 + 9 + 12 + 15 + \cdots$

Solution ▶

a. The series has five terms and each term is an odd number, or 1 less than a multiple of 2. The general term is $a_n = 2n - 1$, and the series is $\sum_{n=1}^{5}(2n - 1)$.

b. The raised ellipsis "$\cdots$" indicates the sum continues infinitely. Since the terms are multiples of 3, we identify the general term as $a_n = 3n$, while noting the series starts at $n = 2$ (instead of $n = 1$). Since the sum continues indefinitely, we use the infinity symbol ∞ as the "ending" value in sigma notation. The series is $\sum_{n=2}^{\infty} 3n$.

WORTHY OF NOTE

By varying the function given and/or where the sum begins, more than one acceptable form is possible.

For Example 8(b) $\sum_{k=1}^{\infty}(3 + 3k)$ also works.

Now try Exercises 69 through 78 ▶

Since the commutative and associative laws hold for the addition of real numbers, summations have the following properties:

Properties of Summation

Given any real number c and natural number n,

(I) $\sum_{i=1}^{n} c = cn$

If you add a constant c "n" times the result is cn.

(II) $\sum_{i=1}^{n} ca_i = c\sum_{i=1}^{n} a_i$

A constant can be factored out of a sum.

(III) $\sum_{i=1}^{n}(a_i \pm b_i) = \sum_{i=1}^{n} a_i \pm \sum_{i=1}^{n} b_i$

A summation can be distributed to two (or more) sequences.

(IV) $\sum_{i=1}^{m} a_i + \sum_{i=m+1}^{n} a_i = \sum_{i=1}^{n} a_i;\ 1 \le m < n$

A summation is cumulative and can be written as a sum of smaller parts.

The verification of property II depends solely on the distributive property.

Proof:

$$\sum_{i=1}^{n} ca_i = ca_1 + ca_2 + ca_3 + \cdots + ca_n \quad \text{expand sum}$$

$$= c(a_1 + a_2 + a_3 + \cdots + a_n) \quad \text{factor out } c$$

$$= c\sum_{i=1}^{n} a_i \quad \text{write series in summation form}$$

The verifications of properties III and IV simply use the commutative and associative properties. You are asked to prove property III in **Exercise 94.**

EXAMPLE 9 ▶ **Computing a Sum Using Summation Properties**

Recompute the sum $\sum_{i=1}^{4}(3i + 2)$ from Example 7(a) using summation properties.

Solution ▶

$$\sum_{i=1}^{4}(3i + 2) = \sum_{i=1}^{4} 3i + \sum_{i=1}^{4} 2 \quad \text{property III}$$

$$= 3\sum_{i=1}^{4} i + \sum_{i=1}^{4} 2 \quad \text{property II}$$

$$= 3(10) + 2(4) \quad 1 + 2 + 3 + 4 = 10\text{; property I}$$

$$= 38 \quad \text{result}$$

D. You've just seen how we can use summation notation to write and evaluate series

Now try Exercises 79 through 82 ▶

E. Applications of Sequences

To solve applications of sequences, (1) identify where the sequence begins (the initial term), (2) write out the first few terms to help identify the nth term, and (3) decide on an appropriate approach or strategy.

EXAMPLE 10 ▶ **Solving an Application—Accumulation of Stock**

Hydra already owned 1420 shares of stock when her company began offering employees the opportunity to purchase 175 discounted shares per year. If she made no purchases other than these discounted shares each year, how many shares will she have 9 yr later? If this continued for the 25 yr she will work for the company, how many shares will she have at retirement?

Solution ▶ To begin, it helps to simply write out the first few terms of the sequence. Since she already had 1420 shares before the company made this offer, we let $a_0 = 1420$ be the inaugural element, showing $a_1 = 1595$ (after 1 yr, she owns $1420 + 175 = 1595$ shares). The first few terms are 1595, 1770, 1945, 2120, and so on. This supports a general term of $a_n = 1595 + 175(n - 1)$.

After 9 years	After 25 years
$a_9 = 1595 + 175(8)$	$a_{25} = 1595 + 175(24)$
$= 2995$	$= 5795$

After 9 yr she would have 2995 shares. Upon retirement she would own 5795 shares of company stock.

Now try Exercises 85 through 90 ▶

Surprisingly, sequences and series have a number of other interesting properties, applications, and mathematical connections. For instance, some of the most celebrated numbers in mathematics can be approximated using a series, as demonstrated in Example 11.

EXAMPLE 11 ▶ Use a calculator to find the partial sums S_4, S_8, and S_{12} for the sequences given. If any sum seems to be approaching a fixed number, name that number.

a. $a_n = \dfrac{1}{n!}$ **b.** $a_n = \dfrac{1}{3^n}$

Solution ▶

a. Begin by entering $\dfrac{1}{n!}$ as u(n) on the Y= screen. Using the **"sum("** and **"seq("** commands as before produces the results shown in Figures 11.17 through 11.19, where it appears the sum becomes very close to $e - 1$ for larger values of n.

Figure 11.17

```
sum(seq(u(n),n,1
,4))
      1.708333333
```

Figure 11.18

```
sum(seq(u(n),n,1
,8))
      1.71827877
```

Figure 11.19

```
sum(seq(u(n),n,1
,12))
      1.718281828
```

b. After entering $\dfrac{1}{3^n}$ as v(n) on the Y= screen, we once again compute the sums indicated as shown in Figures 11.20 through 11.22. It appears the sum becomes very close to $\dfrac{1}{2}$ for larger values of n.

Figure 11.20

```
sum(seq(v(n),n,1
,4))
      .4938271605
```

Figure 11.21

```
sum(seq(v(n),n,1
,8))
      .4999237921
```

Figure 11.22

```
sum(seq(v(n),n,1
,12))
      .4999990592
```

☑ **E.** You've just seen how we can use sequences to solve applications

Now try Exercises 91 and 92 ▶

11.1 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. A sequence is a(n) _____ of numbers listed in a specific _____.
2. A series is the _____ of the numbers from a given sequence.
3. A sequence that uses the preceding term(s) to generate those that follow is called a _____ sequence.
4. The notation $n!$ represents the _____ of the natural number n, with all those _____ n.
5. Describe the characteristics of a recursive sequence and give one example.
6. Describe the characteristics of an alternating sequence and give one example.

▶ DEVELOPING YOUR SKILLS

Find the first four terms, then find the 8th and 12th term for each *n*th term given.

7. $a_n = 2n - 1$
8. $a_n = 2n + 3$
9. $a_n = 3n^2 - 3$
10. $a_n = 2n^3 - 12$
11. $a_n = (-1)^n n$
12. $a_n = \dfrac{(-1)^n}{n}$
13. $a_n = \dfrac{n}{n+1}$
14. $a_n = \left(1 + \dfrac{1}{n}\right)^n$
15. $a_n = \left(\dfrac{1}{2}\right)^n$
16. $a_n = \left(\dfrac{2}{3}\right)^n$
17. $a_n = \dfrac{1}{n}$
18. $a_n = \dfrac{1}{n^2}$
19. $a_n = \dfrac{(-1)^n}{n(n+1)}$
20. $a_n = \dfrac{(-1)^{n+1}}{2n^2 - 1}$
21. $a_n = (-1)^n 2^n$
22. $a_n = (-1)^n 2^{-n}$

Use a calculator to: (a) find the indicated term for each sequence, and (b) generate the first five terms of each sequence and store the results in a list. Use fractions if possible; round to tenths when necessary.

23. $a_n = n^2 - 2;\ a_9$
24. $a_n = (n-2)^2;\ a_9$
25. $a_n = \dfrac{(-1)^{n+1}}{n};\ a_5$
26. $a_n = \dfrac{(-1)^{n+1}}{2n-1};\ a_5$
27. $a_n = 2\left(\dfrac{1}{2}\right)^{n-1};\ a_7$
28. $a_n = 3\left(\dfrac{1}{3}\right)^{n-1};\ a_7$
29. $a_n = \left(1 + \dfrac{1}{n}\right)^n;\ a_{10}$
30. $a_n = \left(n + \dfrac{1}{n}\right)^n;\ a_9$
31. $a_n = \dfrac{1}{n(2n+1)};\ a_4$
32. $a_n = \dfrac{1}{(2n-1)(2n+1)};\ a_5$

Find the first five terms of each recursive sequence.

33. $\begin{cases} a_1 = 2 \\ a_n = 5a_{n-1} - 3 \end{cases}$
34. $\begin{cases} a_1 = 3 \\ a_n = 2a_{n-1} - 3 \end{cases}$
35. $\begin{cases} a_1 = -1 \\ a_n = (a_{n-1})^2 + 3 \end{cases}$
36. $\begin{cases} a_1 = -2 \\ a_n = a_{n-1} - 16 \end{cases}$
37. $\begin{cases} c_1 = 64, c_2 = 32 \\ c_n = \dfrac{c_{n-2} - c_{n-1}}{2} \end{cases}$
38. $\begin{cases} c_1 = 1, c_2 = 2 \\ c_n = c_{n-1} + (c_{n-2})^2 \end{cases}$

Simplify each factorial expression.

39. $\dfrac{8!}{5!}$
40. $\dfrac{12!}{10!}$
41. $\dfrac{9!}{7!2!}$
42. $\dfrac{6!}{3!3!}$
43. $\dfrac{8!}{2!6!}$
44. $\dfrac{10!}{3!7!}$

Write out the first four terms in each sequence.

45. $a_n = \dfrac{n!}{(n+1)!}$
46. $a_n = \dfrac{n!}{(n+3)!}$
47. $a_n = \dfrac{(n+1)!}{(3n)!}$
48. $a_n = \dfrac{(n+3)!}{(2n)!}$

49. $a_n = \dfrac{n^n}{n!}$ **50.** $a_n = \dfrac{2^n}{n!}$

Find the indicated partial sum for each sequence.

51. $a_n = n$; S_5 **52.** $a_n = n^2$; S_7

53. $a_n = 2n - 1$; S_8 **54.** $a_n = 3n - 1$; S_6

55. $a_n = \dfrac{1}{n}$; S_5 **56.** $a_n = \dfrac{n}{n+1}$; S_4

Expand and evaluate each series. Verify results using a graphing calculator.

57. $\sum_{i=1}^{4}(3i - 5)$ **58.** $\sum_{i=1}^{5}(2i - 3)$ **59.** $\sum_{k=1}^{5}(2k^2 - 3)$

60. $\sum_{k=1}^{5}(k^2 + 1)$ **61.** $\sum_{k=1}^{7}(-1)^k k$ **62.** $\sum_{k=1}^{5}(-1)^k 2^k$

63. $\sum_{i=1}^{4}\dfrac{i^2}{2}$ **64.** $\sum_{i=2}^{4} i^2$ **65.** $\sum_{j=3}^{7} 2j$

66. $\sum_{j=3}^{7}\dfrac{j}{2^j}$ **67.** $\sum_{k=3}^{8}\dfrac{(-1)^k}{k(k-2)}$ **68.** $\sum_{k=2}^{6}\dfrac{(-1)^{k+1}}{k^2 - 1}$

Write each sum using sigma notation. Answers are not necessarily unique.

69. a. $4 + 8 + 12 + 16 + 20$

b. $5 + 10 + 15 + 20 + 25$

70. a. $-1 + 4 - 9 + 16 - 25 + 36$

b. $1 - 8 + 27 - 64 + 125 - 216$

71. a. $1 + 3 + 5 + 7 + 9 + 11 + \cdots$

b. $1 + \dfrac{1}{2} + \dfrac{1}{4} + \dfrac{1}{8} + \dfrac{1}{16} + \dfrac{1}{32} + \cdots$

72. a. $0.1 + 0.01 + 0.001 + 0.0001 + \cdots$

b. $1 + \dfrac{1}{2} + \dfrac{1}{6} + \dfrac{1}{24} + \dfrac{1}{120} + \dfrac{1}{720} + \cdots$

For the given general term a_n, write the indicated sum using sigma notation.

73. $a_n = n + 3$; S_5

74. $a_n = \dfrac{n^2 + 1}{n + 1}$; S_4

75. $a_n = \dfrac{n^2}{3}$; third partial sum

76. $a_n = 2n - 1$; sixth partial sum

77. $a_n = \dfrac{n}{2^n}$; sum for $n = 3$ to 7

78. $a_n = n^2$; sum for $n = 2$ to 6

Compute each sum by applying properties of summation.

79. $\sum_{i=1}^{5}(4i - 5)$ **80.** $\sum_{i=1}^{6}(3 + 2i)$

81. $\sum_{k=1}^{4}(3k^2 + k)$ **82.** $\sum_{k=1}^{4}(2k^3 + 5)$

▶ WORKING WITH FORMULAS

83. Sum of $a_n = 3n - 2$: $S_n = \dfrac{n(3n-1)}{2}$

The sum of the first n terms of the sequence defined by $a_n = 3n - 2 = 1, 4, 7, 10, \ldots, (3n - 2), \ldots$ is given by the formula shown. Find S_5 using the formula, then verify by direct calculation.

84. Sum of $a_n = 3n - 1$: $S_n = \dfrac{n(3n+1)}{2}$

The sum of the first n terms of the sequence defined by $a_n = 3n - 1 = 2, 5, 8, 11, \ldots, (3n - 1), \ldots$ is given by the formula shown. Find S_8 using the formula, then verify by direct calculation. Observing the formulas from Exercises 83 and 84, can you now state the sum formula for $a_n = 3n - 0$?

▶ APPLICATIONS

Use the information given in each exercise to determine the nth term a_n for the sequence described. Then use the nth term to list the specified number of terms.

85. Wage increases: Latisha gets \$7.25 an hour for filling candy machines for Archtown Vending. Each year she receives a \$0.50 hourly raise. List Latisha's hourly wage for the first 5 yr. How much will she make in the fifth year if she works 8 hr per day for 240 working days?

86. Average birth weight: The average birth weight of a certain animal species is 900 g, with the baby gaining 125 g each day for the first 10 days. List the infant's weight for the first 10 days. How much does the infant weigh on the 10th day?

87. Blue-book value: Steve's car has a blue-book value of \$6000. Each year it loses 20% of its value (its value each year is 80% of the year before). List the value of Steve's car for the next 5 yr. (*Hint:* $a_0 = 6000$.)

88. Effects of inflation: Suppose inflation (an increase in value) will average 4% for the next 5 yr. List the growing cost (year by year) of a DVD that costs \$15 right now. (*Hint:* $a_0 = 15$.)

89. Stocking a lake: A local fishery stocks a large lake with 1500 bass and then adds an additional 100 mature bass per month until the lake nears maximum capacity. If the bass population grows at a rate of 5% per month through natural reproduction, the number of bass in the pond after n months is given by the recursive sequence $b_0 = 1500$, $b_n = 1.05b_{n-1} + 100$. How many bass will be in the lake after 6 months?

90. Species preservation: The Interior Department introduces 50 wolves (male and female) into a large wildlife area in an effort to preserve the species. Each year about 12 additional adult wolves are added from capture and relocation programs. If the wolf population grows at a rate of 10% per year through natural reproduction, the number of wolves in the area after n years is given by the recursive sequence $w_0 = 50$, $w_n = 1.10w_{n-1} + 12$. How many wolves are in the wildlife area after 6 years?

Use your calculator to find the partial sums for $n = 4$, $n = 8$, and $n = 12$ for the summations given, and attempt to name the number the summation approximates:

91. $\displaystyle\sum_{k=1}^{n} \frac{1}{2^k}$

92. $\displaystyle\sum_{k=1}^{n} \frac{2^k + 3^k}{6^k}$

▶ EXTENDING THE CONCEPT

93. Verify that a constant can be factored out of a sum. That is, verify that the following statement is true:

$$\sum_{j=1}^{n} ca_j = c\sum_{j=1}^{n} a_j$$

94. Verify that a summation may be distributed to two (or more) sequences. That is, verify that the following statement is true:

$$\sum_{i=1}^{n} (a_i \pm b_i) = \sum_{i=1}^{n} a_i \pm \sum_{i=1}^{n} b_i.$$

Regarding Exercises 91 and 92, sometimes a series will approach a fixed number very slowly, and many more terms must be added before this value is recognized. Use your graphing calculator to compute the sums S_{10}, S_{25}, and S_{50} for the following sequences to see if you can recognize the number. Add more terms if necessary.

95. $a_n = \dfrac{1}{n(n+1)(n+2)}$

96. $a_n = \dfrac{1}{(2n-1)(2n+1)}$

▶ MAINTAINING YOUR SKILLS

97. (7.7) Solve $\csc x \sin\left(\dfrac{\pi}{2} - x\right) = -1$

98. (3.6) Set up the difference quotient for $f(x) = \sqrt{x}$, then rationalize the numerator.

99. (8.2) Given a triangle where $a = 0.4$ m, $b = 0.3$ m, and $c = 0.5$ m, find the three corresponding angles.

100. (9.7) Solve the system using a matrix equation.

$$\begin{cases} 25x + y - 2z = -14 \\ 2x - y + z = 40 \\ -7x + 3y - z = -13 \end{cases}$$

11.2 Arithmetic Sequences

LEARNING OBJECTIVES

In Section 11.2 you will see how we can:

- ❑ **A.** Identify an arithmetic sequence and its common difference
- ❑ **B.** Find the nth term of an arithmetic sequence
- ❑ **C.** Find the nth partial sum of an arithmetic sequence
- ❑ **D.** Solve applications involving arithmetic sequences

Similar to the way polynomials fall into certain groups or families (linear, quadratic, cubic, etc.), sequences and series with common characteristics are likewise grouped. In this section, we focus on sequences where each successive term is generated by adding a constant value, as in the sequence 1, 8, 15, 22, 29, … , where 7 is added to a given term in order to produce the next term.

A. Identifying an Arithmetic Sequence and Finding the Common Difference

An **arithmetic sequence** is one where each successive term is found by adding a fixed constant to the preceding term. For instance 3, 7, 11, 15, … is an arithmetic sequence, since adding 4 to any given term produces the next term. This also means if you take the difference of any two consecutive terms, the result will be 4 and in fact, 4 is called the **common difference** d for this sequence. Using the notation developed earlier, we can write $d = a_{k+1} - a_k$, where a_k represents any term of the sequence and a_{k+1} represents the term that follows a_k.

Arithmetic Sequences

Given a sequence $a_1, a_2, a_3, \ldots, a_k, a_{k+1}, \ldots, a_n$, where $k, n \in \mathbb{N}$ and $k < n$, if there exists a common difference d such that $a_{k+1} - a_k = d$ for all k, then the sequence is an *arithmetic sequence.*

The difference of successive terms can be rewritten as $a_{k+1} = a_k + d$ (for $k \geq 1$) to highlight that each following term is found by adding d to the previous term.

EXAMPLE 1 ▶ **Identifying an Arithmetic Sequence**

Determine if the given sequence is arithmetic. If yes, name the common difference. If not, try to determine the pattern that forms the sequence.

a. 2, 5, 8, 11, … **b.** $\frac{1}{2}, \frac{5}{6}, \frac{13}{12}, \frac{77}{60}, \frac{29}{20}, \ldots$

Solution ▶

a. Begin by looking for a common difference $d = a_{k+1} - a_k$. Checking each pair of consecutive terms we have

$$5 - 2 = 3 \qquad 8 - 5 = 3 \qquad 11 - 8 = 3 \quad \text{and so on.}$$

This is an arithmetic sequence with common difference $d = 3$.

b. Checking each pair of consecutive terms yields

$$\frac{5}{6} - \frac{1}{2} = \frac{5}{6} - \frac{3}{6} = \frac{2}{6} = \frac{1}{3} \qquad \frac{13}{12} - \frac{5}{6} = \frac{13}{12} - \frac{10}{12} = \frac{3}{12} = \frac{1}{4} \qquad \frac{77}{60} - \frac{13}{12} = \frac{77}{60} - \frac{65}{60} = \frac{12}{60} = \frac{1}{5}$$

Since the difference is not constant, this is not an arithmetic sequence. It appears the sequence is formed by adding $\frac{1}{k}$ to each previous term, for natural numbers k.

Now try Exercises 7 through 18 ▶

EXAMPLE 2 ▶ **Writing the First *k* Terms of an Arithmetic Sequence**

Write the first five terms of the arithmetic sequence, given the first term a_1 and the common difference d.

a. $a_1 = 12$ and $d = -4$ **b.** $a_1 = \frac{1}{2}$ and $d = \frac{1}{3}$

Solution ▶

a. $a_1 = 12$ and $d = -4$. Starting at $a_1 = 12$, add -4 to each new term to generate the sequence: 12, 8, 4, 0, -4.

b. $a_1 = \frac{1}{2}$ and $d = \frac{1}{3}$. Starting at $a_1 = \frac{1}{2}$ and adding $\frac{1}{3}$ to each new term will generate the sequence: $\frac{1}{2}, \frac{5}{6}, \frac{7}{6}, \frac{3}{2}, \frac{11}{6}$. Note that since the common denominator is 6, terms of the sequence can quickly be found by adding $\frac{1}{3} = \frac{2}{6}$ to the previous term and reducing if possible.

A. You've just seen how we can identify an arithmetic sequence and its common difference

Now try Exercises 19 through 30 ▶

B. Finding the *n*th Term of an Arithmetic Sequence

If the values a_1 and d from an arithmetic sequence are known, we could generate the terms of the sequence by adding *multiples of d to the first term,* instead of adding d to each new term. For example, we can generate the sequence 3, 8, 13, 18, 23 by adding multiples of 5 to the first term $a_1 = 3$:

$$\begin{aligned} 3 &= 3 + (0)5 & a_1 &= a_1 + 0d \\ 8 &= 3 + (1)5 & a_2 &= a_1 + 1d \\ 13 &= 3 + (2)5 & a_3 &= a_1 + 2d \\ 18 &= 3 + (3)5 & a_4 &= a_1 + 3d \\ 23 &= 3 + (4)5 & a_5 &= a_1 + 4d \end{aligned}$$

current term; initial term; coefficient of common difference

It's helpful to note the coefficient of d is 1 less than the subscript of the current term (as shown): $5 - 1 = 4$. This observation leads us to a formula for the nth term.

The *n*th Term of an Arithmetic Sequence

The nth term of an *arithmetic sequence* is given by

$$a_n = a_1 + (n - 1)d$$

where d is the common difference.

EXAMPLE 3 ▶ **Finding a Specified Term in an Arithmetic Sequence**

Find the 24th term of the sequence 0.1, 0.4, 0.7, 1, ...

Solution ▶ Instead of creating all terms up to the 24th, we determine the constant d and use the nth term formula. By inspection we note $a_1 = 0.1$ and $d = 0.3$.

$$\begin{aligned} a_n &= a_1 + (n - 1)d && \text{nth term formula} \\ &= 0.1 + (n - 1)0.3 && \text{substitute 0.1 for } a_1 \text{ and 0.3 for } d \\ &= 0.1 + 0.3n - 0.3 && \text{eliminate parentheses} \\ &= 0.3n - 0.2 && \text{simplify} \end{aligned}$$

To find the 24th term we substitute 24 for n:

$$\begin{aligned} a_{24} &= 0.3(24) - 0.2 && \text{substitute 24 for } n \\ &= 7.0 && \text{result} \end{aligned}$$

Now try Exercises 31 through 42 ▶

EXAMPLE 4 ▶ Determining the Number of Terms in an Arithmetic Sequence

Find the number of terms in the arithmetic sequence $2, -5, -12, -19, \ldots, -411$.

Solution ▶ By inspection we see that $a_1 = 2$ and $d = -7$. As before,

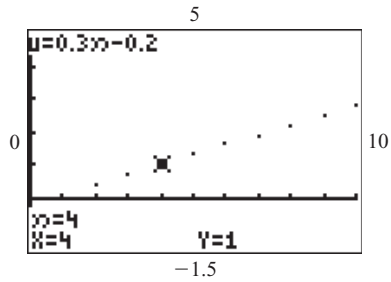
$$\begin{aligned} a_n &= a_1 + (n-1)d && n\text{th term formula} \\ &= 2 + (n-1)(-7) && \text{substitute 2 for } a_1 \text{ and } -7 \text{ for } d \\ &= 2 - 7n + 7 && \text{distribute } -7 \\ &= -7n + 9 && \text{simplify} \end{aligned}$$

Although we don't know the number of terms in the sequence, we *do* know the last or nth term is -411. Substituting -411 for a_n gives

$$\begin{aligned} -411 &= -7n + 9 && \text{substitute } -411 \text{ for } a_n \\ 60 &= n && \text{solve for } n \end{aligned}$$

There are 60 terms in this sequence.

Now try Exercises 43 through 50 ▶



Note that in both Examples 3 and 4, the nth term had the form of a linear equation ($y = mx + b$) after simplifying: $a_n = 0.3n - 0.2$ and $a_n = -7n + 9$. This is a characteristic of arithmetic sequences, with the common difference d corresponding to the slope m. This means the graph of an arithmetic sequence will always be a set of discrete points that lie on a straight line. After entering $u(n) = 0.3n - 0.2$ (from Example 3), Figure 11.23 shows the table of values for $a_n = 0.3n - 0.2$, with the graph in Figure 11.24.

Figure 11.23

n	u(n)
1	.1
2	.4
3	.7
4	1
5	1.3
6	1.6
7	1.9

n=1

Figure 11.24

In sequence MODE, we still set the size of the viewing window as before, but we can also stipulate the range of values of n to be used (nMin and nMax), which term we want to plot as a beginning (PlotStart), and whether we want all following terms graphed (PlotStep = 1), every second term graphed (PlotStep = 2), and so on. The graph in Figure 11.24 was generated using the values shown in Figure 11.25 (Ymin = −1.5, Ymax = 5, and Yscl = 1 cannot be seen).

Figure 11.25

```
WINDOW
 nMin=1
 nMax=10
 PlotStart=1
 PlotStep=1
 Xmin=0
 Xmax=10
↓Xscl=1
```

To see the graph of a sequence more distinctly, we can enter the natural numbers 1 through 10 in L1, then define L2 as u(L1) (Figures 11.26 and 11.27) and plot these points (Figure 11.28).

Figure 11.26

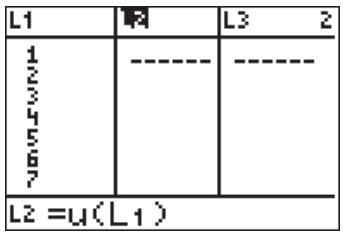


Figure 11.27

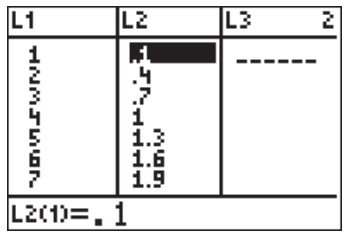

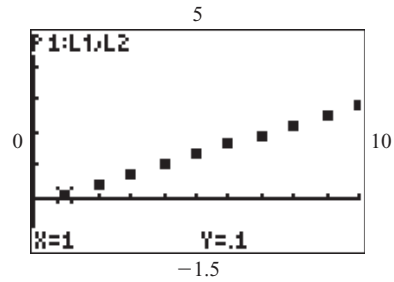

Figure 11.28

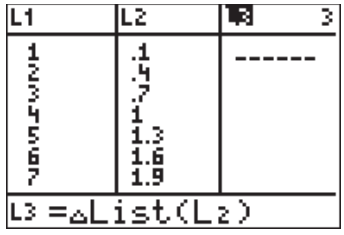
One additional advantage of this approach is that we can easily verify the common difference is d using the **"ΔList("** feature, which automatically computes the difference between each successive term in a specified list. This option is located in the same submenu as the **"seq("** option, accessed using 2nd STAT **(LIST)** ▸ **(OPS) 7:ΔList(L2)** ENTER. See Figures 11.29 and 11.30.

Figure 11.29



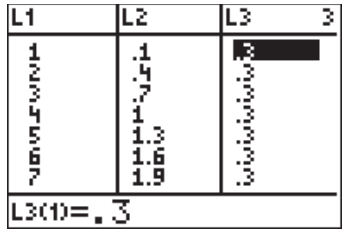


Figure 11.30

EXAMPLE 5 ▸ **Graphing Arithmetic Sequences**

Enter the natural numbers 1 through 6 in L1, and the terms of the sequence -0.45, -0.1, 0.25, 0.6, 0.95, 1.3 in L2. Then verify the sequence in L2 is arithmetic by

a. Graphing the related points to see if they appear linear.

b. Using the **ΔList(** feature.

c. Finding the nth term that defines the sequence and graph the sequence.

Solution ▸

a. The plotted points are shown in Figure 11.31 and appear to be linear.

b. The **ΔList(** feature shows there is a common difference of 0.35 (Figure 11.32).

c. With $a_1 = -0.45$ and $d = 0.35$, the nth term must be

$$\begin{aligned} a_n &= a_1 + (n-1)d && \text{nth term formula} \\ &= -0.45 + (n-1)(0.35) && \text{substitute for } a_1 \text{ and } d \\ &= 0.35n - 0.8 && \text{simplify} \end{aligned}$$

The nth term for this sequence is $a_n = 0.35n - 0.8$. The graph is shown in Figure 11.33.

Figure 11.31

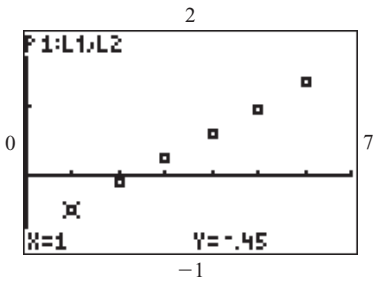

Figure 11.32

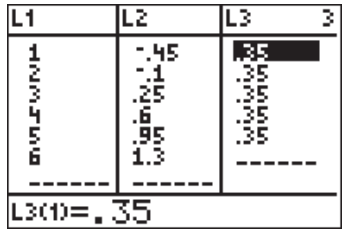

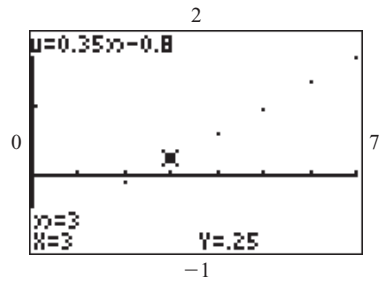

Figure 11.33

Now try Exercises 51 through 54 ▸

If the term a_1 is unknown but a term a_k is given, the nth term can be written

$$a_n = a_k + (n - k)d$$

(the subscript of the term a_k and coefficient of d sum to n).

EXAMPLE 6 ▶ Finding the First Term of an Arithmetic Sequence

Given an arithmetic sequence where $a_6 = 0.55$ and $a_{13} = 0.9$, find the common difference d and the value of a_1.

Solution ▶ At first it seems that not enough information is given, but recall we can express a_{13} as the sum of any earlier term and the appropriate multiple of d. Since a_6 is known, we write $a_{13} = a_6 + 7d$ (note $13 = 6 + 7$ as required).

$$\begin{aligned} a_{13} &= a_6 + 7d && a_1 \text{ is unknown} \\ 0.9 &= 0.55 + 7d && \text{substitute 0.9 for } a_{13} \text{ and 0.55 for } a_6 \\ 0.35 &= 7d && \text{subtract 0.55} \\ d &= 0.05 && \text{solve for } d \end{aligned}$$

Having found d, we can now solve for a_1.

$$\begin{aligned} a_{13} &= a_1 + 12d && n\text{th term formula for } n = 13 \\ 0.9 &= a_1 + 12(0.05) && \text{substitute 0.9 for } a_{13} \text{ and 0.05 for } d \\ 0.9 &= a_1 + 0.6 && \text{simplify} \\ a_1 &= 0.3 && \text{solve for } a_1 \end{aligned}$$

The first term is $a_1 = 0.3$ and the common difference is $d = 0.05$.

Now try Exercises 55 through 60 ▶

B. You've just seen how we can find the nth term of an arithmetic sequence

C. Finding the nth Partial Sum of an Arithmetic Sequence

Using sequences and series to solve applications often requires computing the sum of a given number of terms. To develop and understand the approach used, consider the sum of the first 10 natural numbers. Using S_{10} to represent this sum, we have $S_{10} = 1 + 2 + 3 + 4 + 5 + 6 + 7 + 8 + 9 + 10$. We could just use brute force, but if we rewrite the sum a second time *but in reverse order,* then add it to the first, we find that each column adds to 11.

$$\begin{array}{rcccccccccccccccccc} S_{10} &=& 1 &+& 2 &+& 3 &+& 4 &+& 5 &+& 6 &+& 7 &+& 8 &+& 9 &+& 10 \\ S_{10} &=& 10 &+& 9 &+& 8 &+& 7 &+& 6 &+& 5 &+& 4 &+& 3 &+& 2 &+& 1 \\ \hline 2S_{10} &=& 11 &+& 11 &+& 11 &+& 11 &+& 11 &+& 11 &+& 11 &+& 11 &+& 11 &+& 11 \end{array}$$

Since there are 10 columns, the total is $11 \times 10 = 110$ but this is twice the actual sum and we find that $2S_{10} = 110$, so $S_{10} = 55$.

Now consider the sequence $a_1, a_2, a_3, a_4, \ldots, a_n$ with common difference d. Use S_n to represent the sum of the first n terms and write the original series, then the series in reverse order underneath. Since one row increases at the same rate the other decreases, the sum of each column remains constant, and for simplicity's sake we choose $a_1 + a_n$ to represent this sum.

$$\begin{array}{rcccccccccccccc} S_n &=& a_1 &+& a_2 &+& a_3 &+ \cdots +& a_{n-2} &+& a_{n-1} &+& a_n \\ S_n &=& a_n &+& a_{n-1} &+& a_{n-2} &+ \cdots +& a_3 &+& a_2 &+& a_1 \\ \hline 2S_n &=& (a_1 + a_n) &+& (a_1 + a_n) &+& (a_1 + a_n) &+ \cdots +& (a_1 + a_n) &+& (a_1 + a_n) &+& (a_1 + a_n) \end{array} \quad \downarrow \text{ add columns vertically}$$

To understand why each column adds to $a_1 + a_n$, consider the sum in the second column: $a_2 + a_{n-1}$. From $a_2 = a_1 + d$ and $a_{n-1} = a_n - d$, we obtain $a_2 + a_{n-1} = (a_1 + d) + (a_n - d)$ by adding the equations, which gives a result of $a_1 + a_n$. Since there are n columns, we end up with $2S_n = n(a_1 + a_n)$, and solving for S_n gives the formula for the first n terms of an arithmetic sequence.

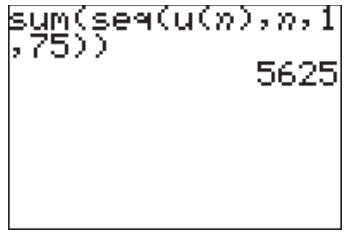
The *n*th Partial Sum of an Arithmetic Sequence

Given an arithmetic sequence with first term a_1, the nth partial sum is given by

$$S_n = \frac{n}{2}(a_1 + a_n).$$

In words: The sum of an arithmetic sequence is one-half the number of terms times the sum of the first and last term.

EXAMPLE 7 ▶ **Computing the Sum of an Arithmetic Sequence**



Use the summation formula to find the sum of the first 75 positive odd integers: $\sum_{n=1}^{75}(2n - 1)$. Verify the result using a graphing calculator.

Solution ▶ The initial terms of the sequence are 1, 3, 5, … and we note $a_1 = 1$, $d = 2$, and $n = 75$. To use the sum formula, we need the value of a_{75}: $2(75) - 1 = 149$.

$$\begin{aligned} S_n &= \frac{n}{2}(a_1 + a_n) && \text{sum formula} \\ S_{75} &= \frac{75}{2}(a_1 + a_{75}) && \text{substitute 75 for } n \\ &= \frac{75}{2}(1 + 149) && \text{substitute 1 for } a_1, \text{ 149 for } a_{75} \\ &= 5625 && \text{result} \end{aligned}$$

The sum of the first 75 positive odd integers is 5625.

To verify, we enter $u(n) = 2n - 1$ on the Y= screen, and find the sum of the first 75 terms of the sequence on the home screen as before. See figure.

Now try Exercises 61 through 66 ▶

By substituting the nth term formula directly into the formula for partial sums, we're able to find a partial sum without actually having to find the nth term:

$$\begin{aligned} S_n &= \frac{n}{2}(a_1 + a_n) && \text{sum formula} \\ &= \frac{n}{2}(a_1 + [a_1 + (n - 1)d]) && \text{substitute } a_1 + (n - 1)d \text{ for } a_n \\ &= \frac{n}{2}[2a_1 + (n - 1)d] && \textit{alternative formula for the nth partial sum} \end{aligned}$$

See Exercises 67 through 72 for more on this alternative formula.

☑ **C.** You've just seen how we can find the nth partial sum of an arithmetic sequence

D. Applications

Figure 11.34

spiral fern

In the evolution of certain plants and shelled animals, sequences and series seem to have been one of nature's favorite tools. The sprials found on many ferns and other plants are excellent examples of sequences in nature, as are the size of the chambers in nautilus shells (see Figures 11.34 and 11.35). Sequences and series also provide a good mathematical model for a variety of other situations as well.

Figure 11.35

nautilus

EXAMPLE 8 ▶ **Solving an Application of Arithmetic Sequences: Seating Capacity**

Cox Auditorium is an amphitheater that has 40 seats in the first row, 42 seats in the second row, 44 in the third, and so on. If there are 75 rows in the auditorium, what is the auditorium's seating capacity?

Solution ▶ The number of seats in each row gives the terms of an arithmetic sequence with $a_1 = 40$, $d = 2$, and $n = 75$. To find the seating capacity, we need to find the total number of seats, which is the sum of this arithmetic sequence. Since the value of a_{75} is unknown, we opt for the alternative formula $S_n = \frac{n}{2}[2a_1 + (n - 1)d]$.

$$S_n = \frac{n}{2}[2a_1 + (n - 1)d] \quad \text{sum formula}$$

$$S_{75} = \frac{75}{2}[2(40) + (75 - 1)(2)] \quad \text{substitute 40 for } a_1\text{, 2 for } d\text{, and 75 for } n$$

$$= \frac{75}{2}(228) \quad \text{simplify}$$

$$= 8550 \quad \text{result}$$

The seating capacity of Cox Auditorium is 8550.

Now try Exercises 75 through 80 ▶

☑ **D.** You've just seen how we can solve applications involving arithmetic sequences

11.2 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. Consecutive terms in an arithmetic sequence differ by a constant called the _____ _____.

2. The sum of the first n terms of an arithmetic sequence is called the nth _____ _____.

3. The formula for the nth partial sum of an arithmetic sequence is $S_n =$ _____, where a_n is the _____ term.

4. The nth term formula for an arithmetic sequence is $a_n =$ _____, where a_1 is the _____ term and d is the _____ _____.

5. Discuss how the terms of an arithmetic sequence can be written in various ways using the relationship $a_n = a_k + (n - k)d$.

6. Describe how the formula for the nth partial sum was derived, and illustrate its application using a sequence from the exercise set.

▶ DEVELOPING YOUR SKILLS

Determine if the sequence given is arithmetic. If yes, name the common difference. If not, try to determine the pattern that forms the sequence.

7. $-5, -2, 1, 4, 7, 10, \ldots$

8. $1, -2, -5, -8, -11, -14, \ldots$

9. $0.5, 3, 5.5, 8, 10.5, \ldots$

10. $1.2, 3.5, 5.8, 8.1, 10.4, \ldots$

11. $2, 3, 5, 7, 11, 13, 17, \ldots$

12. $1, 4, 8, 13, 19, 26, 34, \ldots$

13. $\frac{1}{24}, \frac{1}{12}, \frac{1}{8}, \frac{1}{6}, \frac{5}{24}, \ldots$

14. $\frac{1}{12}, \frac{1}{15}, \frac{1}{20}, \frac{1}{30}, \frac{1}{60}, \ldots$

15. $1, 4, 9, 16, 25, 36, \ldots$

16. $-125, -64, -27, -8, -1, \ldots$

17. $\pi, \frac{5\pi}{6}, \frac{2\pi}{3}, \frac{\pi}{2}, \frac{\pi}{3}, \frac{\pi}{6}, \ldots$

18. $\pi, \frac{7\pi}{8}, \frac{3\pi}{4}, \frac{5\pi}{8}, \frac{\pi}{2}, \ldots$

Write the first four terms of the arithmetic sequence with the given first term and common difference.

19. $a_1 = 2, d = 3$

20. $a_1 = 8, d = 3$

21. $a_1 = 7, d = -2$

22. $a_1 = 60, d = -12$

23. $a_1 = 0.3, d = 0.03$

24. $a_1 = 0.5, d = 0.25$

25. $a_1 = \frac{3}{2}, d = \frac{1}{2}$

26. $a_1 = \frac{1}{5}, d = \frac{1}{10}$

27. $a_1 = \frac{3}{4}, d = -\frac{1}{8}$

28. $a_1 = \frac{1}{6}, d = -\frac{1}{3}$

29. $a_1 = -2, d = -3$

30. $a_1 = -4, d = -4$

Identify the first term and the common difference, then write the expression for the general term a_n and use it to find the 6th, 10th, and 12th terms of the sequence.

31. $2, 7, 12, 17, \ldots$

32. $7, 4, 1, -2, -5, \ldots$

33. $5.10, 5.25, 5.40, \ldots$

34. $9.75, 9.40, 9.05, \ldots$

35. $\frac{3}{2}, \frac{9}{4}, 3, \frac{15}{4}, \ldots$

36. $\frac{5}{7}, \frac{3}{14}, -\frac{2}{7}, -\frac{11}{14}, \ldots$

Find the indicated term using the information given.

37. $a_1 = 5, d = 4$; find a_{15}

38. $a_1 = 9, d = -2$; find a_{17}

39. $a_1 = \frac{3}{2}, d = -\frac{1}{12}$; find a_7

40. $a_1 = \frac{12}{25}, d = -\frac{1}{10}$; find a_9

41. $a_1 = -0.025, d = 0.05$; find a_{50}

42. $a_1 = 3.125, d = -0.25$; find a_{20}

Find the number of terms in each sequence.

43. $a_1 = 2, a_n = -22, d = -3$

44. $a_1 = 4, a_n = 42, d = 2$

45. $a_1 = 0.4, a_n = 10.9, d = 0.25$

46. $a_1 = -0.3, a_n = -36, d = -2.1$

47. $-3, -0.5, 2, 4.5, 7, \ldots, 47$

48. $-3.4, -1.1, 1.2, 3.5, \ldots, 38$

49. $\frac{1}{12}, \frac{1}{8}, \frac{1}{6}, \frac{5}{24}, \frac{1}{4}, \ldots, \frac{9}{8}$

50. $\frac{1}{12}, \frac{1}{15}, \frac{1}{20}, \frac{1}{30}, \ldots, -\frac{1}{4}$

For Exercises 51 through 54, enter the natural numbers 1 through 6 in L1 on a graphing calculator, and the terms of the given sequence in L2. Then determine if the sequence is arithmetic by (a) graphing the related points to see if they appear linear, and (b) using the ΔList(feature. If an arithmetic sequence, (c) find the *n*th term and graph the sequence.

51. $1.5, 2.25, 3, 3.75, 4.5, 5.25, \ldots$

52. $\frac{47}{18}, \frac{19}{9}, \frac{29}{18}, \frac{10}{9}, \frac{11}{18}, \frac{1}{9}, \ldots$

53. $9, 8, 6, 3, -1, -6, \ldots$

54. $\frac{1}{1}, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \frac{1}{6}, \ldots$

Find the common difference *d* and the value of a_1 using the information given.

55. $a_3 = 7, a_7 = 19$

56. $a_5 = -17, a_{11} = -2$

57. $a_2 = 1.025, a_{26} = 10.025$

58. $a_6 = -12.9, a_{30} = 1.5$

59. $a_{10} = \frac{13}{18}, a_{24} = \frac{27}{2}$

60. $a_4 = \frac{5}{4}, a_8 = \frac{9}{4}$

Evaluate each sum. For Exercises 65 and 66, use the summation properties from Section 11.1. Verify all results on a graphing calculator.

61. $\sum_{n=1}^{30} (3n - 4)$

62. $\sum_{n=1}^{29} (4n - 1)$

63. $\sum_{n=1}^{37} \left(\frac{3}{4}n + 2\right)$

64. $\sum_{n=1}^{20} \left(\frac{5}{2}n - 3\right)$

65. $\sum_{n=4}^{15} (3 - 5n)$

66. $\sum_{n=7}^{20} (7 - 2n)$

Use the alternative formula for the *n*th partial sum to compute the sums indicated.

67. The sum S_{15} for the sequence $-12 + (-9.5) + (-7) + (-4.5) + \cdots$

68. The sum S_{20} for the sequence $\frac{9}{2} + \frac{7}{2} + \frac{5}{2} + \frac{3}{2} + \cdots$

69. The sum S_{30} for the sequence $0.003 + 0.173 + 0.343 + 0.513 + \cdots$

70. The sum S_{50} for the sequence $(-2) + (-7) + (-12) + (-17) + \cdots$

71. The sum S_{20} for the sequence $\sqrt{2} + 2\sqrt{2} + 3\sqrt{2} + 4\sqrt{2} + \cdots$

72. The sum S_{10} for the sequence $12\sqrt{3} + 10\sqrt{3} + 8\sqrt{3} + 6\sqrt{3} + \cdots$

▶ WORKING WITH FORMULAS

73. Sum of the first *n* natural numbers: $S_n = \dfrac{n(n+1)}{2}$

The sum of the first n natural numbers can be found using the formula shown, where n represents the number of terms in the sum. Verify the formula by adding the first six natural numbers by hand, and then evaluating S_6. Then find the sum of the first 75 natural numbers.

74. Sum of the squares of the first *n* natural numbers: $S_n = \dfrac{n(n+1)(2n+1)}{6}$

If the first n natural numbers are squared, the sum of these squares can be found using the formula shown, where n represents the number of terms in the sum. Verify the formula by computing the sum of the squares of the first six natural numbers by hand, and then evaluating S_6. Then find the sum of the squares of the first 20 natural numbers: $(1^2 + 2^2 + 3^2 + \cdots + 20^2)$.

▶ APPLICATIONS

75. Temperature fluctuation: At 5 P.M. in Coldwater, the temperature was a chilly 36°F. If the temperature decreased by 3°F every half-hour for the next 7 hr, at what time did the temperature hit 0°F?

76. Arc of a baby swing: When Mackenzie's baby swing is started, the first swing (one way) is a 30-in. arc. As the swing slows down, each successive arc is $\frac{3}{2}$ in. less than the previous one. Find (a) the length of the tenth swing and (b) how far Mackenzie has traveled during the 10 swings.

77. Computer animations: The animation on a new computer game initially allows the hero of the game to jump a (screen) distance of 10 in. over booby traps and obstacles. Each successive jump is limited to $\frac{3}{4}$ in. less than the previous one. Find (a) the length of the seventh jump and (b) the total distance covered after seven jumps.

78. Seating capacity: The Fox Theater creates a "theater in the round" when it shows any of Shakespeare's plays. The first row has 80 seats, the second row has 88, the third row has 96, and so on. How many seats are in the 10th row? If there is room for 25 rows, how many chairs will be needed to set up the theater?

79. Sales goals: *At the time that I was newly hired, 100 sales per month was what I required. Each following month—the last plus 20 more, as I work for the goal of top sales award. When 2500 sales are thusly made, it's Tahiti, Hawaii, and piña coladas in the shade.* How many sales were made by this person in the seventh month? What were the total sales after the 12th month? Was the goal of 2500 total sales met?

80. Bequests to charity: *At the time our mother left this Earth, she gave $9000 to her children of birth. This we kept and each year added $3000 more, as a lasting memorial from the children she bore. When $42,000 is thusly attained, all goes to charity that her memory be maintained.* What was the balance in the sixth year? In what year was the goal of $42,000 met?

▶ EXTENDING THE CONCEPT

81. From a study of numerical analysis, a function is known to be linear if its "first differences" (differences between successive outputs) are constant. Likewise, a function is known to be quadratic if its "first differences" form an *arithmetic sequence.* Use this information to determine if the following sets of output come from a linear or quadratic function:

a. 19, 11.8, 4.6, −2.6, −9.8, −17, −24.2, …

b. −10.31, −10.94, −11.99, −13.46, −15.35, …

82. From elementary geometry it is known that the interior angles of a triangle sum to 180°, the interior angles of a quadrilateral sum to 360°, the interior angles of a pentagon sum to 540°, and so on. Use the pattern created by the relationship between the number of sides and the number of angles to develop a formula for the sum of the interior angles of an n-sided polygon. The interior angles of a decagon (10 sides) sum to how many degrees?

▶ MAINTAINING YOUR SKILLS

83. (6.5) Identify the amplitude (A), period (P), horizontal shift (HS), vertical shift (VS) and endpoints of the translated interval corresponding to $[0, 2\pi)$ for $f(t) = 7\sin\left(\frac{\pi}{3}t - \frac{\pi}{6}\right) + 10$.

84. (3.3) Graph by completing the square. Label all important features: $y = x^2 - 2x - 3$.

85. (1.4) In 2000, the deer population was 972. By 2005 it had grown to 1217. Assuming the growth is linear, find the function that models this data and use it to estimate the deer population in 2008.

86. (7.1) Verify $\frac{\tan x}{\csc x} - \frac{\sin x}{\cos x} = \frac{\sin x - 1}{\cot x}$ is an identity.

11.3 Geometric Sequences

LEARNING OBJECTIVES

In Section 11.3 you will see how we can:

- ❑ **A.** Identify a geometric sequence and its common ratio
- ❑ **B.** Find the nth term of a geometric sequence
- ❑ **C.** Find the nth partial sum of a geometric sequence
- ❑ **D.** Find the sum of an infinite geometric series
- ❑ **E.** Solve application problems involving geometric sequences and series

Recall that arithmetic sequences are those where each term is found by *adding* a constant value to the preceding term. In this section, we consider **geometric sequences,** where each term is found by *multiplying* the preceding term by a constant value. Geometric sequences have many interesting applications, as do **geometric series.**

A. Geometric Sequences

A geometric sequence is one where each successive term is found by multiplying the preceding term by a fixed constant. Consider growth of a bacteria population, where a single cell splits in two every hour over a 24-hr period. Beginning with a single bacterium ($a_0 = 1$), after 1 hr there are 2, after 2 hr there are 4, and so on. Writing the number of bacteria as a sequence we have:

hours:	a_1	a_2	a_3	a_4	a_5	…
	↓	↓	↓	↓	↓	
bacteria:	2	4	8	16	32	…

The sequence 2, 4, 8, 16, 32, … is a geometric sequence since each term is found by multiplying the previous term by the constant factor 2. This also means that the ratio of any two consecutive terms must be 2 and in fact, 2 is called the **common ratio** r for this sequence. Using the notation from Section 11.1 we can write $r = \frac{a_{k+1}}{a_k}$, where a_k represents any term of the sequence and a_{k+1} represents the term that follows a_k.

Geometric Sequences

Given a sequence $a_1, a_2, a_3, \ldots, a_k, a_{k+1}, \ldots, a_n$, where $k, n \in \mathbb{N}$ and $k < n$,

if there exists a common ratio r such that $\dfrac{a_{k+1}}{a_k} = r$ for all k,

then the sequence is a *geometric sequence.*

The ratio of successive terms can be rewritten as $a_{k+1} = a_k r$ (for $k \geq 1$) to highlight that each term is found by multiplying the preceding term by r.

EXAMPLE 1 ▶ **Testing a Sequence for a Common Ratio**

Determine if the given sequence is geometric. If not geometric, try to determine the pattern that forms the sequence.

a. $1, 0.5, 0.25, 0.125, \ldots$ **b.** $\frac{1}{7}, \frac{2}{7}, \frac{6}{7}, \frac{24}{7}, \frac{120}{7}, \ldots$

Solution ▶ Apply the definition to check for a common ratio $r = \dfrac{a_{k+1}}{a_k}$.

a. For $1, 0.5, 0.25, 0.125, \ldots$, the ratio of consecutive terms gives

$$\frac{0.5}{1} = 0.5, \qquad \frac{0.25}{0.5} = 0.5, \qquad \frac{0.125}{0.25} = 0.5, \qquad \text{and so on.}$$

This is a geometric sequence with common ratio $r = 0.5$.

b. For $\frac{1}{7}, \frac{2}{7}, \frac{6}{7}, \frac{24}{7}, \frac{120}{7}, \ldots$, we have:

$$\frac{2}{7} \div \frac{1}{7} = \frac{2}{7} \cdot \frac{7}{1} = 2 \qquad \frac{6}{7} \div \frac{2}{7} = \frac{6}{7} \cdot \frac{7}{2} = 3 \qquad \frac{24}{7} \div \frac{6}{7} = \frac{24}{7} \cdot \frac{7}{6} = 4 \qquad \text{and so on.}$$

Since the ratio is not constant, this is not a geometric sequence. The sequence appears to be formed by dividing $n!$ by 7: $a_n = \dfrac{n!}{7}$.

Now try Exercises 7 through 24 ▶

EXAMPLE 2 ▶ **Writing the Terms of a Geometric Sequence**

Write the first five terms of the geometric sequence, given the first term $a_1 = -16$ and the common ratio $r = 0.25$.

Solution ▶ Given $a_1 = -16$ and $r = 0.25$. Starting at $a_1 = -16$, multiply each term by 0.25 to generate the sequence.

$$a_2 = -16 \cdot 0.25 = -4 \qquad a_3 = -4 \cdot 0.25 = -1$$
$$a_4 = -1 \cdot 0.25 = -0.25 \qquad a_5 = -0.25 \cdot 0.25 = -0.0625$$

The first five terms of this sequence are $-16, -4, -1, -0.25$, and -0.0625.

Now try Exercises 25 through 32 ▶

☑ **A.** You've just seen how we can identify a geometric sequence and its common ratio

B. Find the *n*th Term of a Geometric Sequence

If the values a_1 and r from a geometric sequence are known, we could generate the terms of the sequence by applying *additional factors of r to the first term,* instead of multiplying each new term by r. If $a_1 = 3$ and $r = 2$, we simply begin at a_1, and

continue applying additional factors of r for each successive term.

$$\begin{aligned} 3 &= 3 \cdot 2^0 & a_1 &= a_1 r^0 \\ 6 &= 3 \cdot 2^1 & a_2 &= a_1 r^1 \\ 12 &= 3 \cdot 2^2 & a_3 &= a_1 r^2 \\ 24 &= 3 \cdot 2^3 & a_4 &= a_1 r^3 \\ 48 &= 3 \cdot 2^4 & a_5 &= a_1 r^4 \end{aligned}$$

current term → a_5; initial term → a_1; exponent on common ratio → 4

From this pattern, we note the exponent on r is always 1 less than the subscript of the current term: $5 - 1 = 4$, which leads us to the formula for the nth term of a geometric sequence.

The nth Term of a Geometric Sequence

The nth term of a *geometric sequence* is given by

$$a_n = a_1 r^{n-1}$$

where r is the common ratio.

EXAMPLE 3 ▶ Finding a Specific Term in a Sequence

Identify the common ratio r, and use it to write the expression for the nth term. Then find the 10th term of the sequence: $3, -6, 12, -24, \ldots$.

Solution ▶ By inspection we note that $a_1 = 3$ and $r = -2$. This gives

$$\begin{aligned} a_n &= a_1 r^{n-1} && \text{nth term formula} \\ &= 3(-2)^{n-1} && \text{substitute 3 for } a_1 \text{ and } -2 \text{ for } r \end{aligned}$$

To find the 10th term we substitute $n = 10$:

$$\begin{aligned} a_{10} &= 3(-2)^{10-1} && \text{substitute 10 for } n \\ &= 3(-2)^9 = -1536 && \text{simplify} \end{aligned}$$

Now try Exercises 33 through 46 ▶

EXAMPLE 4 ▶ Determining the Number of Terms in a Geometric Sequence

Find the number of terms in the geometric sequence $4, 2, 1, \ldots, \frac{1}{64}$.

Solution ▶ Observing that $a_1 = 4$ and $r = \frac{1}{2}$, we have

$$\begin{aligned} a_n &= a_1 r^{n-1} && \text{nth term formula} \\ &= 4\left(\frac{1}{2}\right)^{n-1} && \text{substitute 4 for } a_1 \text{ and } \frac{1}{2} \text{ for } r \end{aligned}$$

Although we don't know the number of terms in the sequence, we *do* know the last or nth term is $\frac{1}{64}$. Substituting $a_n = \frac{1}{64}$ gives

$$\begin{aligned} \frac{1}{64} &= 4\left(\frac{1}{2}\right)^{n-1} && \text{substitute } \frac{1}{64} \text{ for } a_n \\ \frac{1}{256} &= \left(\frac{1}{2}\right)^{n-1} && \text{divide by 4 } \left(\text{multiply by } \frac{1}{4}\right) \end{aligned}$$

From our work in Chapter 5, we attempt to write both sides as exponentials with a like base, or apply logarithms. Since $256 = 2^8$, we equate bases.

$$\left(\frac{1}{2}\right)^8 = \left(\frac{1}{2}\right)^{n-1} \quad \text{write } \frac{1}{256} \text{ as } \left(\frac{1}{2}\right)^8$$
$$\rightarrow 8 = n - 1 \quad \text{like bases imply exponents must be equal}$$
$$9 = n \quad \text{solve for } n$$

This shows there are nine terms in the sequence.

Now try Exercises 47 through 58 ▶

WORTHY OF NOTE

The sequence from Example 3 is an *alternating sequence,* and the exponential characteristics of its graph can be seen by taking a look at the graph of $a_n = |3(-2)^{n-1}|$.

Note that in both Examples 3 and 4, the nth term had the form of an exponential equation ($y = a \cdot b^n$) after simplifying: $a_n = 3(-2)^{n-1}$ and $a_n = 4\left(\frac{1}{2}\right)^{n-1}$. This is in fact a characteristic of geometric sequences, with the common ratio r corresponding to the base b. This means the graph of a geometric sequence will always be a set of discrete points that lie on an exponential graph (see *Worthy of Note*). After entering $u(n) = 4\left(\frac{1}{2}\right)^{n-1}$ (from Example 4), Figure 11.36 shows the table of values for this sequence, with the graph in Figure 11.37.

As before, we can see the graph of the sequence more distinctly by entering the natural numbers 1 through 8 in L1, then defining L2 as u(L1). The resulting graph is shown in Figure 11.38.

Figure 11.36

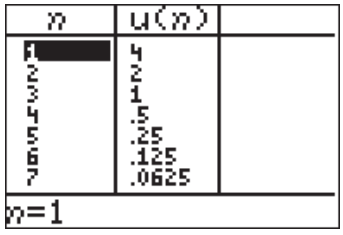


Figure 11.37

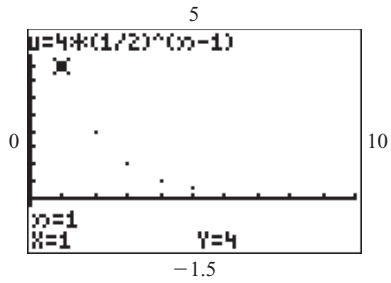

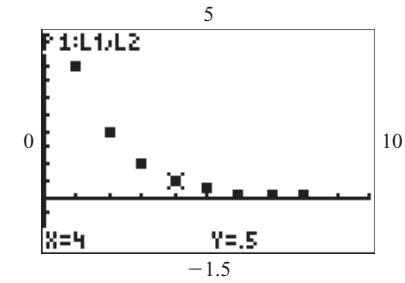

Figure 11.38

One additional advantage of using a list is that we can easily verify whether or not a common ratio r exists. We do this by duplicating L2 in L3 (define L3 = L2), then deleting *the first entry of L3* and *the last entry of L2* (to keep the same number of terms in each list). See Figure 11.39. This enables us to find the ratio $\frac{a_{k+1}}{a_k}$ for the entire list by defining L4 as the ratio L3/L2 (which automatically computes the ratio of successive terms). See Figures 11.40 and 11.41.

Figure 11.39

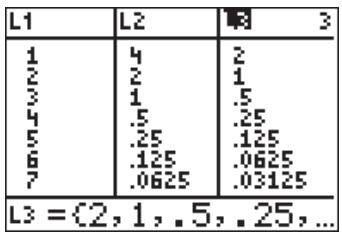

Figure 11.40

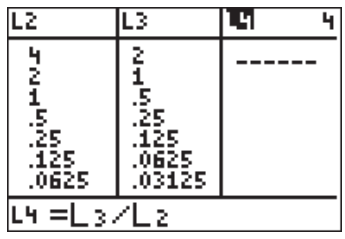

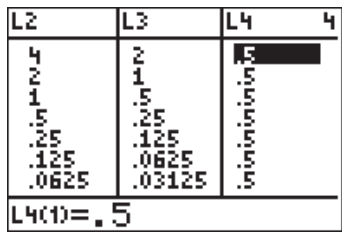

Figure 11.41

EXAMPLE 5 ▶ Graphing Geometric Sequences

Enter the natural numbers 1 through 6 in L1, and the terms of the sequence 0.25, 1.25, 6.25, 31.25, 156.25, 781.25 in L2. Then determine if the sequence is geometric by

a. Graphing the related points to see if they appear to form along an exponential graph.

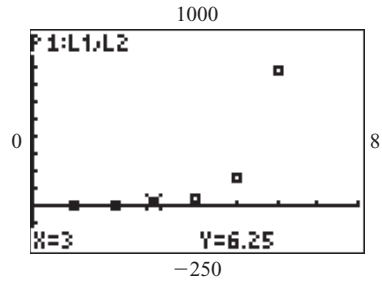
b. Finding the successive ratios between terms.

c. If the sequence is geometric, find the nth term and graph the sequence.

Solution ▶

a. The plotted points are shown in Figure 11.42 and appear to lie along an exponential graph.

Figure 11.42



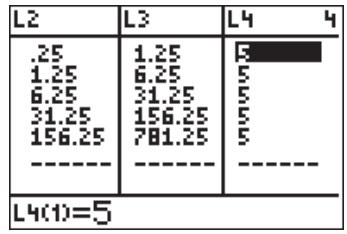


Figure 11.43

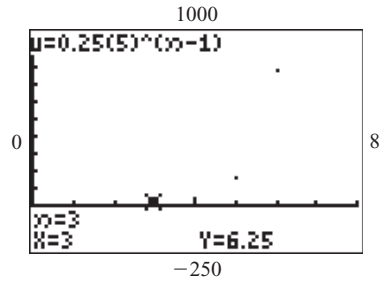


b. Using the approach described prior to Example 5, we find there is a common ratio of $r = 5$ (Figure 11.43).

c. With $a_1 = 0.25$ and $r = 5$, the nth term must be

$$\begin{aligned} a_n &= a_1 r^{n-1} && n\text{th term formula} \\ &= 0.25(5)^{n-1} && \text{substitute for } a_1 \text{ and } r \end{aligned}$$

The nth term for this sequence is $a_n = 0.25(5)^{n-1}$. The graph is shown in Figure 11.44.

Figure 11.44

Now try Exercises 59 through 62 ▶

If the term a_1 is unknown but a term a_k is given, the nth term can be written

$$a_n = a_k r^{n-k},$$

(the subscript on the term a_k and the exponent on r sum to n).

EXAMPLE 6 ▶ Finding the First Term of a Geometric Sequence

Given a geometric sequence where $a_4 = 0.075$ and $a_7 = 0.009375$, find the common ratio r and the value of a_1.

Solution ▶ Since a_1 is not known, we express a_7 as the product of a known term and the appropriate number of common ratios: $a_7 = a_4 r^3$ ($7 = 4 + 3$, as required).

$$\begin{aligned} a_7 &= a_4 \cdot r^3 && a_1 \text{ is unknown} \\ 0.009375 &= 0.075 r^3 && \text{substitute 0.009375 for } a_7 \text{ and 0.075 for } a_4 \\ 0.125 &= r^3 && \text{divide by 0.075} \\ r &= 0.5 && \text{solve for } r \end{aligned}$$

Having found r, we can now solve for a_1

$$\begin{aligned} a_7 &= a_1 r^6 && \text{nth term formula} \\ 0.009375 &= a_1(0.5)^6 && \text{substitute 0.009375 for } a_7 \text{ and 0.5 for } r \\ 0.009375 &= a_1(0.015625) && \text{simplify} \\ a_1 &= 0.6 && \text{solve for } a_1 \end{aligned}$$

The first term is $a_1 = 0.6$ and the common ratio is $r = 0.5$.

B. You've just seen how we can find the nth term of a geometric sequence

Now try Exercises 63 through 68 ▶

C. Find the nth Partial Sum of a Geometric Sequence

As with arithmetic series, applications of geometric series often involve computing sums of consecutive terms. We can adapt the method for finding the sum of an arithmetic sequence to develop a formula for adding the first n terms of a geometric sequence.

For the nth term $a_n = a_1 r^{n-1}$, we have $S_n = a_1 + a_1 r + a_1 r^2 + a_1 r^3 + \cdots + a_1 r^{n-1}$. If we multiply S_n by $-r$ then add the original series, the "interior terms" sum to zero.

$$\begin{aligned} -rS_n &= -a_1 r + (-a_1 r^2) + (-a_1 r^3) + \cdots + (-a_1 r^{n-1}) + (-a_1 r^n) \\ +\ S_n &= a_1 + a_1 r + a_1 r^2 + \cdots + a_1 r^{n-2} + a_1 r^{n-1} \\ \hline S_n - rS_n &= a_1 + 0 + 0 + 0 + \cdots + 0 + 0 + (-a_1 r^n) \end{aligned}$$

We then have $S_n - rS_n = a_1 - a_1 r^n$, and can now solve for S_n:

$$\begin{aligned} S_n(1 - r) &= a_1 - a_1 r^n && \text{factor out } S_n \\ S_n &= \frac{a_1 - a_1 r^n}{1 - r} && \text{solve for } S_n \text{ (divide by } 1 - r) \end{aligned}$$

The result is a formula for the nth partial sum of a geometric sequence.

The nth Partial Sum of a Geometric Sequence

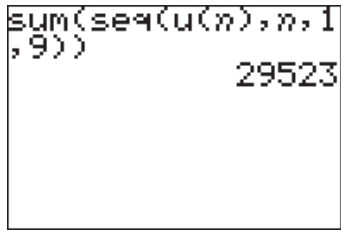
Given a geometric sequence with first term a_1 and common ratio r, the nth partial sum (the sum of the first n terms) is

$$S_n = \frac{a_1 - a_1 r^n}{1 - r} = \frac{a_1(1 - r^n)}{1 - r}, \quad r \neq 1$$

In words: The sum of the first n terms of a geometric sequence is the difference of the first and $(n + 1)$st term, divided by 1 minus the common ratio.

EXAMPLE 7 ▶ Computing a Partial Sum

Use the preceding summation formula to find the sum: $\sum_{i=1}^{9} 3^i$ (the first nine powers of 3). Verify the result on a graphing calculator.



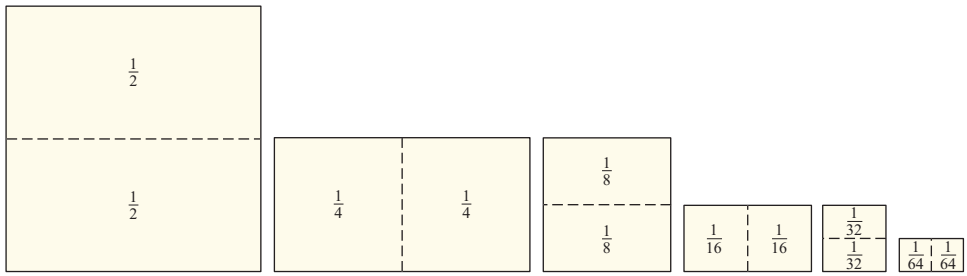
Solution ▶ The initial terms of this series are $3 + 9 + 27 + \cdots$, and we note $a_1 = 3$, $r = 3$, and $n = 9$. We could find the first nine terms and add, but using the partial sum formula is much faster and gives

$$\begin{aligned} S_n &= \frac{a_1(1 - r^n)}{1 - r} && \text{sum formula} \\ S_9 &= \frac{3(1 - 3^9)}{1 - 3} && \text{substitute 3 for } a_1, 9 \text{ for } n, \text{ and 3 for } r \end{aligned}$$

$$= \frac{3(-19{,}682)}{-2} \quad \text{simplify}$$

$$= 29{,}523 \quad \text{result}$$

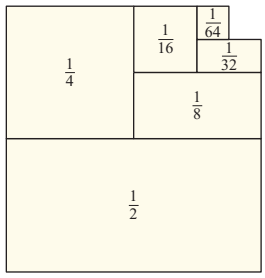
To verify, we enter $u(n) = 3^n$ on the Y= screen, and find the sum of the first nine terms of the sequence on the home screen as before. See figure.



C. You've just seen how we can find the *n*th partial sum of a geometric sequence

Now try Exercises 69 through 92 ▶

D. The Sum of an Infinite Geometric Series



To this point we've considered only partial sums of a geometric series. While it is impossible to add an infinite number of these terms, some of these "infinite sums" appear to have what is called a **limiting value.** The sum appears to get ever closer to this value but never exceeds it—much like the asymptotic behavior of some graphs. We will define the sum of this **infinite geometric series** to be this limiting value, if it exists. Consider the illustration in Figure 11.45, where a standard sheet of typing paper is cut in half. One of the halves is again cut in half and the process is continued indefinitely, as shown. Notice the "halves" create an infinite sequence $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{1}{16}, \frac{1}{32}, \cdots$ with $a_1 = \frac{1}{2}$ and $r = \frac{1}{2}$. The corresponding infinite series is $\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \frac{1}{32} + \cdots + \frac{1}{2^n} + \cdots$.

Figure 11.45

and so on

Figure 11.46

If we arrange one of the halves from each stage as shown in Figure 11.46, we would be rebuilding the original sheet of paper. As we add more and more of these halves together, we get closer and closer to the size of the original sheet. We gain an intuitive sense that this series must add to 1, because the *pieces* of the original sheet of paper must add to 1 whole sheet. To explore this idea further, consider what happens to $(\frac{1}{2})^n$ as n becomes large.

$$n = 4: \left(\frac{1}{2}\right)^4 = 0.0625 \qquad n = 8: \left(\frac{1}{2}\right)^8 \approx 0.004 \qquad n = 12: \left(\frac{1}{2}\right)^{12} \approx 0.0002$$

Further exploration with a calculator seems to support the idea that as $n \to \infty$, $(\frac{1}{2})^n \to 0$, although a definitive proof is left for a future course. In fact, it can be shown that for any $|r| < 1$, r^n becomes very close to zero as n becomes large. In symbols: as $n \to \infty$, $r^n \to 0$. For $S_n = \dfrac{a_1 - a_1 r^n}{1 - r} = \dfrac{a_1}{1 - r} - \dfrac{a_1 r^n}{1 - r}$, note that if $|r| < 1$ and "we sum an infinite number of terms," the second term becomes zero, leaving only the first term. In other words, the limiting value (represented by S_∞) is $S_\infty = \dfrac{a_1}{1 - r}$.

WORTHY OF NOTE

The formula for the sum of an infinite geometric series can also be derived by noting that $S_\infty = a_1 + a_1 r + a_1 r^2 + a_1 r^3 + \cdots$ can be rewritten as $S_\infty = a_1 + r(a_1 + a_1 r + a_1 r^2 + a_1 r^3 + \cdots) = a_1 + rS_\infty$.

$$S_\infty - rS_\infty = a_1$$
$$S_\infty(1 - r) = a_1$$
$$S_\infty = \frac{a_1}{1 - r}.$$

Infinite Geometric Series

Given a geometric sequence with first term a_1 and $|r| < 1$, the sum of the related infinite series is given by

$$S_\infty = \frac{a_1}{1 - r}; \; r \neq 1$$

If $|r| > 1$, no finite sum exists.

EXAMPLE 8 ▶ **Computing an Infinite Sum**

Find the limiting value of each infinite geometric series (if it exists).

a. $1 + 2 + 4 + 8 + \cdots$ **b.** $3 + 2 + \frac{4}{3} + \frac{8}{9} + \cdots$

c. $0.185 + 0.000185 + 0.000000185 + \cdots$

Solution ▶ Begin by determining if the infinite series is geometric with $|r| < 1$. If so, use $S_\infty = \dfrac{a_1}{1 - r}$.

a. Since $r = 2$ (by inspection), a finite sum does not exist.

b. Using the ratio of consecutive terms we find $r = \frac{2}{3}$ and the infinite sum exists. With $a_1 = 3$, we have

$$S_\infty = \frac{3}{1 - \frac{2}{3}} = \frac{3}{\frac{1}{3}} = 9$$

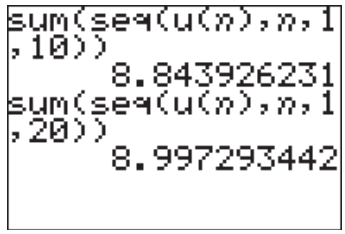
c. This series is equivalent to the repeating decimal $0.185185185\ldots = 0.\overline{185}$. The common ratio is $r = \frac{0.000185}{0.185} = 0.001$ and the infinite sum exists:

$$S_\infty = \frac{0.185}{1 - 0.001} = \frac{5}{27}$$

Now try Exercises 93 through 108 ▶

While it is impossible for us to sum an infinite number of terms, we can often see a pattern that strongly suggests a limiting value exists. As in Section 11.2, we do this by increasing the number terms we sum, until such a limiting value seems apparent. But be very careful to note that such a calculator approach *is far from an actual proof,* and a more definitive means must be used to actually prove a limiting value exists. For the sequence in Example 8(b), we enter $3\left(\frac{2}{3}\right)^{n-1}$ as u(n), and compute the sums S_{10}, S_{20}, S_{30}, and S_{40} (Figures 11.47 and 11.48), where it indeed appears the limiting value is 9.

Figure 11.47



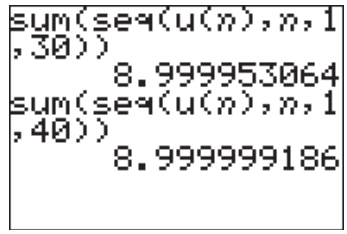


Figure 11.48

☑ **D.** You've just seen how we can find the sum of an infinite geometric series

E. Applications Involving Geometric Sequences and Series

Here are a few of the ways these ideas can be put to use.

EXAMPLE 9 ▶ **Solving an Application of Geometric Sequences: Pendulums**

A pendulum is any object attached to a fixed point and allowed to swing freely under the influence of gravity. Suppose each swing is 0.9 the length of the previous one. Gradually the swings become shorter and shorter and at some point the pendulum will appear to have stopped (although *theoretically* it never does).

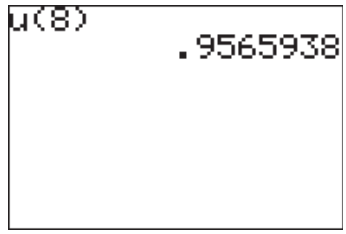
a. How far does the pendulum travel on its eighth swing, if the first was 2 m?

b. What is the total distance traveled by the pendulum for these eight swings?

c. How many swings until the length of each swing falls below 0.5 m?

d. What total distance does the pendulum travel before coming to rest?

Verify your response to parts (a) through (c) using a graphing calculator.



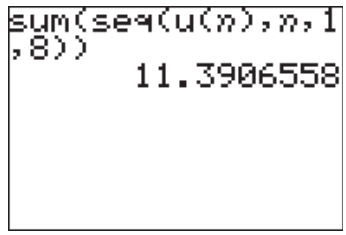
Solution ▶

a. The lengths of each swing form the terms of a geometric sequence with $a_1 = 2$ and $r = 0.9$. The first few terms are 2, 1.8, 1.62, 1.458, and so on. For the 8th term we have:

$$a_n = a_1 r^{n-1} \quad \text{nth term formula}$$
$$a_8 = 2(0.9)^{8-1} \quad \text{substitute 8 for } n\text{, 2 for } a_1\text{, and 0.9 for } r$$
$$\approx 0.957$$

The pendulum travels about 0.957 m on its 8th swing. See Figure 11.49.

Figure 11.49

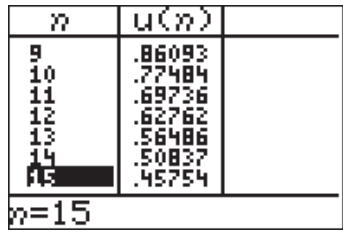


b. For the total distance traveled after eight swings, we compute the value of S_8.

$$S_n = \frac{a_1(1 - r^n)}{1 - r} \quad \text{nth partial sum formula}$$
$$S_8 = \frac{2(1 - 0.9^8)}{1 - 0.9} \quad \text{substitute 2 for } a_1\text{, 0.9 for } r\text{, and 8 for } n$$
$$\approx 11.4$$

The pendulum has traveled about 11.4 m by the end of the 8th swing. See Figure 11.50.

Figure 11.50

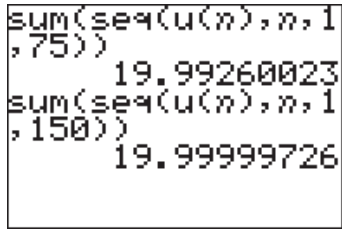


c. To find the number of swings until the length of each swing is less than 0.5 m, we solve for n in the equation $0.5 = 2(0.9)^{n-1}$. This yields

$$0.25 = (0.9)^{n-1} \quad \text{divide by 2}$$
$$\ln 0.25 = (n - 1)\ln 0.9 \quad \text{take the natural log, apply power property}$$
$$\frac{\ln 0.25}{\ln 0.9} + 1 = n \quad \text{solve for } n \text{ (exact form)}$$
$$14.16 \approx n \quad \text{solve for } n \text{ (approximate form)}$$

After the 14th swing, each successive swing will be less than 0.5 m. See Figure 11.51.

Figure 11.51



d. For the total distance traveled before coming to rest, we consider the related infinite geometric series, with $a_1 = 2$ and $r = 0.9$.

$$S_\infty = \frac{a_1}{1 - r} \quad \text{infinite sum formula}$$
$$S_\infty = \frac{2}{1 - 0.9} \quad \text{substitute 2 for } a_1 \text{ and 0.9 for } r$$
$$= 20 \quad \text{result}$$

The pendulum would travel 20 m before coming to rest. Note that summing a larger number of terms on a calculator takes an increasing amount of time. The values for S_{15} and S_{150} are shown in Figure 11.52.

Figure 11.52

Now try Exercises 111 and 112 ▶

As mentioned in Section 11.1, sometimes the sequence or series for a particular application will use the preliminary or inaugural term a_0. For example, we might consider an initial amount of money that is deposited before any interest is earned, or the efficiency of a new machine after purchase—prior to any wear and tear.

EXAMPLE 10 ▶ **Equipment Efficiency—Furniture Manufacturing**

The manufacturing of mass-produced furniture requires robotic machines to drill numerous holes for the bolts used in the assembly process. When new, the drill bits are capable of drilling through hardwood at a rate of 6 cm/sec. As the bit becomes worn, it loses 4% of its drilling speed per day.

a. How many cm/sec can the bit drill through after a 5-day workweek?

b. When the drilling speed falls below 3.6 cm/sec, the bit must be replaced. After how many days must the bit be replaced?

Solution ▶ The efficiency of a new drill bit (prior to use) is given as $a_0 = 6$ cm/sec. Since the bit *loses* $4\% = 0.04$ of its efficiency per day, it maintains $96\% = 0.96$ of its efficiency, showing that after 1 day of use $a_1 = 0.96(6) = 5.76$. This means the nth term formula will be $a_n = 5.76(0.96)^{n-1}$.

a. At the end of day 5 we have

$$\begin{aligned} a_5 &= 5.76(0.96)^{5-1} \\ &= 5.76(0.96)^4 \\ &\approx 4.9 \end{aligned}$$

After 5 days, the bit can drill through the hardwood at about 4.9 cm/sec.

b. To find the number of days until the efficiency falls below 3.6 cm/sec, we replace a_n with 3.6 and solve for n.

$$\begin{aligned} 3.6 &= 5.76(0.96)^{n-1} && \text{substitute 3.6 for } a_n \\ 0.625 &= 0.96^{n-1} && \text{divide} \\ \ln 0.625 &= \ln 0.96^{n-1} && \text{take the natural log of both sides} \\ \ln 0.625 &= (n-1)\ln 0.96 && \text{power property} \\ \frac{\ln 0.625}{\ln 0.96} &= n-1 && \text{divide} \\ \frac{\ln 0.625}{\ln 0.96} + 1 &= n && \text{solve for } n \text{ (exact form)} \\ 12.5 &\approx n && \text{solution (approximate form)} \end{aligned}$$

The drill bit must be replaced after approximately 12.5 days of use.

E. You've just seen how we can solve application problems involving geometric sequences and series

Now try Exercises 113 through 126 ▶

11.3 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. In a geometric sequence, each successive term is found by _____ the preceding term by a fixed value r.

2. In a geometric sequence, the common ratio r can be found by computing the _____ of any two consecutive terms.

3. The nth term of a geometric sequence is given by $a_n =$ _____, for any $n \geq 1$.

4. For the general sequence $a_1, a_2, a_3, \ldots, a_k, \ldots$, the fifth partial sum is given by $S_5 =$ _____.

5. Describe/Discuss how the formula for the nth partial sum is related to the formula for the sum of an infinite geometric series.

6. Describe the difference(s) between an arithmetic and a geometric sequence. How can a student prevent confusion between the formulas?

▶ DEVELOPING YOUR SKILLS

Determine if the sequence given is geometric. If yes, name the common ratio. If not, try to determine the pattern that forms the sequence.

7. $4, 8, 16, 32, \ldots$

8. $2, 6, 18, 54, 162, \ldots$

9. $3, -6, 12, -24, 48, \ldots$

10. $128, -32, 8, -2, \ldots$

11. $2, 5, 10, 17, 26, \ldots$

12. $-13, -9, -5, -1, 3, \ldots$

13. $3, 0.3, 0.03, 0.003, \ldots$

14. $12, 0.12, 0.0012, 0.000012, \ldots$

15. $-1, 3, -12, 60, -360, \ldots$

16. $-\frac{2}{3}, 2, -8, 40, -240, \ldots$

17. $25, 10, 4, \frac{8}{5}, \ldots$

18. $-36, 24, -16, \frac{32}{3}, \ldots$

19. $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{1}{16}, \ldots$

20. $\frac{2}{3}, \frac{4}{9}, \frac{8}{27}, \frac{16}{81}, \ldots$

21. $3, \frac{12}{x}, \frac{48}{x^2}, \frac{192}{x^3}, \ldots$

22. $5, \frac{10}{a}, \frac{20}{a^2}, \frac{40}{a^3}, \ldots$

23. $240, 120, 40, 10, 2, \ldots$

24. $-120, -60, -20, -5, -1, \ldots$

Write the first four terms of the sequence, given a_1 and r.

25. $a_1 = 5, r = 2$

26. $a_1 = 2, r = -4$

27. $a_1 = -6, r = -\frac{1}{2}$

28. $a_1 = \frac{2}{3}, r = \frac{1}{5}$

29. $a_1 = 4, r = \sqrt{3}$

30. $a_1 = \sqrt{5}, r = \sqrt{5}$

31. $a_1 = 0.1, r = 0.1$

32. $a_1 = 0.024, r = 0.01$

Write the expression for the nth term, then find the indicated term for each sequence.

33. $a_1 = -24, r = \frac{1}{2}$; find a_7

34. $a_1 = 48, r = -\frac{1}{3}$; find a_6

35. $a_1 = -\frac{1}{20}, r = -5$; find a_4

36. $a_1 = \frac{3}{20}, r = 4$; find a_5

37. $a_1 = 2, r = \sqrt{2}$; find a_7

38. $a_1 = \sqrt{3}, r = \sqrt{3}$; find a_8

Identify a_1 and r, then write the expression for the nth term $a_n = a_1 r^{n-1}$ and use it to find a_6, a_{10}, and a_{12}.

39. $\frac{1}{27}, -\frac{1}{9}, \frac{1}{3}, -1, 3, \ldots$

40. $-\frac{7}{8}, \frac{7}{4}, -\frac{7}{2}, 7, -14, \ldots$

41. $729, 243, 81, 27, 9, \ldots$

42. $625, 125, 25, 5, 1, \ldots$

43. $\frac{1}{2}, \frac{\sqrt{2}}{2}, 1, \sqrt{2}, 2, \ldots$

44. $36\sqrt{3}, 36, 12\sqrt{3}, 12, 4\sqrt{3}, \ldots$

45. $0.2, 0.08, 0.032, 0.0128, \ldots$

46. $0.5, -0.35, 0.245, -0.1715, \ldots$

Find the number of terms in each sequence.

47. $a_1 = 9, a_n = 729, r = 3$

48. $a_1 = 1, a_n = -128, r = -2$

49. $a_1 = 16, a_n = \frac{1}{64}, r = \frac{1}{2}$

50. $a_1 = 4, a_n = \frac{1}{512}, r = \frac{1}{2}$

51. $a_1 = -1, a_n = -1296, r = \sqrt{6}$

52. $a_1 = 2, a_n = 1458, r = -\sqrt{3}$

53. $2, -6, 18, -54, \ldots, -4374$

54. $3, -6, 12, -24, \ldots, -6144$

55. $64, 32\sqrt{2}, 32, 16\sqrt{2}, \ldots, 1$

56. $243, 81\sqrt{3}, 81, 27\sqrt{3}, \ldots, 1$

57. $\frac{3}{8}, -\frac{3}{4}, \frac{3}{2}, -3, \ldots, 96$

58. $-\frac{5}{27}, \frac{5}{9}, -\frac{5}{3}, -5, \ldots, -135$

For Exercises 59 through 62, enter the natural numbers 1 through 6 in L1 on a graphing calculator, and the terms of the given sequence in L2. Then determine if the sequence is geometric by (a) graphing the related points to see if they appear to lie on an exponential curve, and (b) computing the successive ratios of all terms. If a geometric sequence, find the nth term and graph the sequence.

59. $131.25, 26.25, 5.25, 1.05, 0.21, 0.042, \ldots$

60. $2, 2\sqrt{5}, 10, 10\sqrt{5}, 50, 50\sqrt{5}, \ldots$

61. $20, 16, 12, 8, 4, 0, \ldots$

62. $\frac{1}{6}, \frac{1}{3}, \frac{1}{2}, \frac{2}{3}, \frac{5}{6}, 1, \ldots$

Find the common ratio r and the value of a_1 using the information given (assume $r > 0$).

63. $a_3 = 324, a_7 = 64$

64. $a_5 = 6, a_9 = 486$

65. $a_4 = \frac{4}{9}, a_8 = \frac{9}{4}$

66. $a_2 = \frac{16}{81}, a_5 = \frac{2}{3}$

67. $a_4 = \frac{32}{3}, a_8 = 54$

68. $a_3 = \frac{16}{25}, a_7 = 25$

Find the partial sum indicated.

69. $a_1 = 8, r = -2$; find S_{12}

70. $a_1 = 2, r = -3$; find S_8

71. $a_1 = 96, r = \frac{1}{3}$; find S_5

72. $a_1 = 12, r = \frac{1}{2}$; find S_8

73. $a_1 = 8, r = \frac{3}{2}$; find S_7

74. $a_1 = -1, r = -\frac{3}{2}$; find S_{10}

75. $2 + 6 + 18 + \cdots$; find S_6

76. $2 + 8 + 32 + \cdots$; find S_7

77. $16 - 8 + 4 - \cdots$; find S_8

78. $4 - 12 + 36 - \cdots$; find S_8

79. $\frac{4}{3} + \frac{2}{9} + \frac{1}{27} + \cdots$; find S_9

80. $\frac{1}{18} - \frac{1}{6} + \frac{1}{2} - \cdots$; find S_7

Find the partial sum indicated, and verify the result using a graphing calculator. For Exercises 85 and 86, use the summation properties from Section 11.1.

81. $\sum_{j=1}^{5} 4^j$

82. $\sum_{k=1}^{10} 2^k$

83. $\sum_{k=1}^{8} 5\left(\frac{2}{3}\right)^{k-1}$

84. $\sum_{j=1}^{7} 3\left(\frac{1}{5}\right)^{j-1}$

85. $\sum_{i=4}^{10} 9\left(-\frac{1}{2}\right)^{i-1}$

86. $\sum_{i=3}^{8} 5\left(-\frac{1}{4}\right)^{i-1}$

Find the indicated partial sum using the information given. Write all results in simplest form.

87. $a_2 = -5, a_5 = \frac{1}{25}$; find S_5

88. $a_3 = 1, a_6 = -27$; find S_6

89. $a_3 = \frac{4}{9}, a_7 = \frac{9}{64}$; find S_6

90. $a_2 = \frac{16}{81}, a_5 = \frac{2}{3}$; find S_8

91. $a_3 = 2\sqrt{2}, a_6 = 8$; find S_7

92. $a_2 = 3, a_5 = 9\sqrt{3}$; find S_7

Determine whether the infinite geometric series has a finite sum. If so, find the limiting value.

93. $9 + 3 + 1 + \cdots$

94. $36 + 24 + 16 + \cdots$

95. $3 + 6 + 12 + 24 + \cdots$

96. $4 + 8 + 16 + 32 + \cdots$

97. $25 + 10 + 4 + \frac{8}{5} + \cdots$

98. $10 + 2 + \frac{2}{5} + \frac{2}{25} + \cdots$

99. $6 + 3 + \frac{3}{2} + \frac{3}{4} + \cdots$

100. $-49 + (-7) + (-\frac{1}{7}) + \cdots$

101. $6 - 3 + \frac{3}{2} - \frac{3}{4} + \cdots$

102. $10 - 5 + \frac{5}{2} - \frac{5}{4} + \cdots$

103. $0.3 + 0.03 + 0.003 + \cdots$

104. $0.63 + 0.0063 + 0.000063 + \cdots$

105. $\sum_{k=1}^{\infty} \frac{3}{4}\left(\frac{2}{3}\right)^k$

106. $\sum_{i=1}^{\infty} 5\left(\frac{1}{2}\right)^i$

107. $\sum_{j=1}^{\infty} 9\left(-\frac{5}{4}\right)^j$

108. $\sum_{k=1}^{\infty} 12\left(\frac{4}{3}\right)^k$

▶ WORKING WITH FORMULAS

109. Sum of the cubes of the first n natural numbers:

$$S_n = \frac{n^2(n+1)^2}{4}$$

Compute $1^3 + 2^3 + 3^3 + \cdots + 8^3$ using the formula given. Then confirm the result by direct calculation.

110. Student loan payment: $A_n = P(1 + r)^n$

If P dollars is borrowed at an annual interest rate r with interest compounded annually, the amount of money to be paid back after n years is given by the indicated formula. Find the total amount of money that the student must repay to clear the loan, if \$8000 is borrowed at 4.5% interest and the loan is paid back in 10 yr.

▶ APPLICATIONS

Write the *n*th term formula for each application, then solve.

111. **Pendulum movement:** On each swing, a pendulum travels only 80% as far as it did on the previous swing. If the first swing is 24 ft, how far does the pendulum travel on the 7th swing? What total distance is traveled before the pendulum comes to rest?

112. **Tire swings:** Ernesto is swinging to and fro on his backyard tire swing. Using his legs and body, he pumps each swing until reaching a maximum height, then suddenly relaxes until the swing comes to a stop. With each swing, Ernesto travels 75% as far as he did on the previous swing. If the first arc (or swing) is 30 ft, find the distance Ernesto travels on the 5th arc. What total distance will he travel before coming to rest?

Identify the inaugural term and write the *n*th term formula for each application, then solve.

113. **Depreciation—automobiles:** A certain new SUV depreciates in value about 20% per year (meaning it holds 80% of its value each year). If the SUV is purchased for $46,000, how much is it worth 4 yr later? How many years until its value is less than $5000?

114. **Depreciation—business equipment:** A new photocopier under heavy use will depreciate about 25% per year (meaning it holds 75% of its value each year). If the copier is purchased for $7000, how much is it worth 4 yr later? How many years until its value is less than $1246?

115. **Equipment aging—industrial oil pumps:** Tests have shown that the pumping power of a heavy-duty oil pump decreases by 3% per month. If the pump can move 160 gallons per minute (gpm) new, how many gpm can the pump move 8 months later? If the pumping rate falls below 118 gpm, the pump must be replaced. How many months until this pump is replaced?

116. **Equipment aging—lumber production:** At the local mill, a certain type of saw blade can saw approximately 2 log-feet/sec when it is new. As time goes on, the blade becomes worn, and loses 6% of its cutting speed each week. How many log-feet/sec can the saw blade cut after 6 weeks? If the cutting speed falls below 1.2 log-feet/sec, the blade must be replaced. During what week of operation will this blade be replaced?

117. **Population growth—United States:** At the beginning of the year 2000, the population of the United States was approximately 277 million. If the population is growing at a rate of 2.3% per year, what was the population in 2010, 10 yr later?

118. **Population growth—space colony:** The population of the Zeta Colony on Mars is 1000 people. Determine the population of the Colony 20 yr from now, if the population is growing at a constant rate of 5% per year.

119. **Creating a vacuum:** To create a vacuum, a hand pump is used to remove the air from an air-tight cube with a volume of 462 in^3. With each stroke of the pump, two-fifths of the air that remains in the cube is removed. How much air remains inside after the 5th stroke? How many strokes are required to remove all but 12.9 in^3 of the air?

120. **Atmospheric pressure:** In 1654, scientist Otto Von Guericke performed his famous demonstration of atmospheric pressure and the strength of a vacuum in front of Emperor Ferdinand III of Hungary. After joining two hemispheres with mating rims, he used a vacuum pump to remove all of the air from the sphere formed. He then attached a team of 15 horses to each hemisphere and despite their efforts, they could not pull the hemispheres apart. If the sphere held a volume of 4200 in^3 of air and one-tenth of the remaining air was removed with each stroke of the pump, how much air was still in the sphere after the 11th stroke? How many strokes were required to remove 85% of the air?

121. **Treating swimming pools:** In preparation for the summer swim season, chlorine is added to swimming pools to control algae and bacteria. However, careful measurements must be taken as levels above 5 ppm (parts per million) can be highly irritating to the eyes and throat, while levels below 1 ppm will be ineffective (3.0 to 3.5 ppm is ideal). In addition, the water must be treated daily since within a 24-hr period, about 25% of the chlorine will dissipate into the air. If the chlorine

level in a swimming pool is 8 ppm after its initial treatment, how many days should the County Pool Supervisor wait before opening it up to the public? If left untreated, how many days until the chlorine level drops below 1 ppm?

122. Venting landfill gases: The gases created from the decomposition of waste in landfills must be carefully managed, as their release can cause terrible odors, harm the landfill structure, damage vegetation, or even cause an explosion. Suppose the accumulated volume of gas is 50,000 ft^3, and civil engineers are able to vent 2.5% of this gas into the atmosphere daily. What volume of gas remains after 21 days? How many days until the volume of gas drops below 10,000 ft^3?

123. Population growth—bacteria: A biologist finds that the population of a certain type of bacteria doubles *each half-hour.* If an initial culture has 50 bacteria, what is the population after 5 hr? How long will it take for the number of bacteria to reach 204,800?

124. Population growth—boom towns: Suppose the population of a "boom town" in the old west doubled *every 2 months* after gold was discovered. If the initial population was 219, what was the population 8 months later? How many months until the population exceeded 28,000?

125. Elastic rebound—super balls: Megan discovers that a rubber ball dropped from a height of 2 m rebounds four-fifths of the distance it has previously fallen. How high does it rebound on the 7th bounce? How far does the ball travel before coming to rest?

126. Elastic rebound—computer animation: The screen saver on my computer is programmed to send a colored ball vertically down the middle of the screen so that it rebounds 95% of the distance it last traversed. If the ball always begins at the top and the screen is 36 cm tall, how high does the ball bounce on its 8th rebound? How far does the ball travel before coming to rest (and a new screen saver starts)?

▶ EXTENDING THE CONCEPT

127. A standard piece of typing paper is approximately 0.001 in. thick. Suppose you were able to fold this piece of paper in half 26 times. How thick would the result be? As tall as a hare, as tall as a hen, as tall as a horse, as tall as a house, or over 1 mi high? Find the actual height by computing the 27th term of a geometric sequence. Discuss what you find.

128. As part of a science experiment, identical rubber balls are dropped from a given height onto these surfaces: slate, cement, and asphalt. When dropped onto slate, the ball rebounds 80% of the height from which it last fell. Onto cement the figure is 75% and onto asphalt the figure is 70%. The ball is dropped from 130 m onto the slate, 175 m onto the cement, and 200 m onto the asphalt. Which ball has traveled the shortest total distance at the time of the fourth bounce? Which ball will travel farthest before coming to rest?

129. Consider the following situation. A person is hired at a salary of $40,000 per year, with a guaranteed raise of $1750 per year. At the same time, inflation is running about 4% per year. How many years until this person's salary is overtaken and eaten up by the actual cost of living?

130. Find an alternative formula for the sum

$S_n = \sum_{k=1}^{n} \log k$, that does not use the sigma notation.

131. Verify the following statements:

a. If $a_1, a_2, a_3, \ldots, a_n$ is a geometric sequence with r and a_1 greater than zero, then $\log a_1, \log a_2, \log a_3, \ldots, \log a_n$ is an arithmetic sequence.

b. If $a_1, a_2, a_3, \ldots, a_n$ is an arithmetic sequence, then $10^{a_1}, 10^{a_2}, \ldots, 10^{a_n}$, is a geometric sequence.

▶ MAINTAINING YOUR SKILLS

132. (3.2) Find the zeroes of f using the quadratic formula: $f(x) = x^2 + 5x + 9$.

133. (8.3) Find a unit vector in the same direction as $3\mathbf{i} - 7\mathbf{j}$.

134. (4.5) Graph the rational function:

$h(x) = \dfrac{x^2}{x - 1}$

135. (6.1) The cars on the Millenium Ferris Wheel are 100 ft from the center axle. If the top speed of the wheel is 1.5 revolutions per minute, find the linear velocity of a passenger in a car. Round your answer to the nearest whole number. Also, give the velocity in miles per hour.

11.4 Mathematical Induction

LEARNING OBJECTIVES

In Section 11.4 you will see how we can:

- ❑ **A.** Use subscript notation to evaluate and compose functions
- ❑ **B.** Apply the principle of mathematical induction to sum formulas involving natural numbers
- ❑ **C.** Apply the principle of mathematical induction to general statements involving natural numbers

Since middle school (or even before) we have accepted that, "The product of two negative numbers is a positive number." But have you ever been asked to *prove* it? It's not as easy as it seems. We may think of several patterns that yield the result, analogies that indicate its truth, or even number line illustrations that lead us to believe the statement. But most of us have never seen a *proof* (see www.mhhe.com/coburn). In this section, we introduce one of mathematics' most powerful tools for proving a statement, called **proof by induction.**

A. Subscript Notation and Function Notation

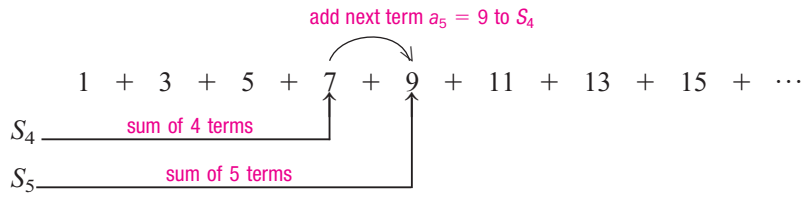
One of the challenges in understanding a proof by induction is working with the notation. Earlier in the chapter, we introduced subscript notation as an alternative to function notation, since it is more commonly used when the functions are defined by a sequence. But regardless of the notation used, the functions can still be simplified, evaluated, composed, and even graphed. Consider the function $f(x) = 3x^2 - 1$ and the sequence defined by $a_n = 3n^2 - 1$. Both can be evaluated and graphed, with the only difference being that $f(x)$ is continuous with domain $x \in \mathbb{R}$, while a_n is discrete (made up of distinct points) with domain $n \in \mathbb{N}$.

EXAMPLE 1 ▶ **Using Subscript Notation for a Composition**

For $f(x) = 3x^2 - 1$ and $a_n = 3n^2 - 1$, find $f(k + 1)$ and a_{k+1}.

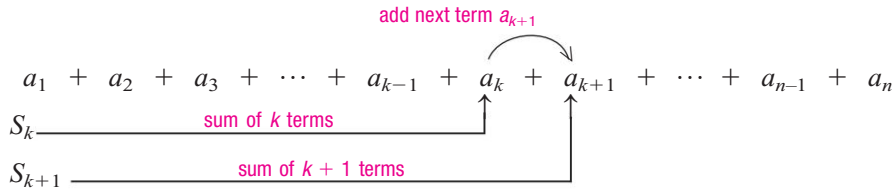
Solution ▶

$$\begin{aligned} f(k+1) &= 3(k+1)^2 - 1 \\ &= 3(k^2 + 2k + 1) - 1 \\ &= 3k^2 + 6k + 2 \end{aligned} \qquad \begin{aligned} a_{k+1} &= 3(k+1)^2 - 1 \\ &= 3(k^2 + 2k + 1) - 1 \\ &= 3k^2 + 6k + 2 \end{aligned}$$



Now try Exercises 7 through 18 ▶

☑ **A.** You've just seen how we can use subscript notation to evaluate and compose functions



No matter which notation is used, every occurrence of the input variable is replaced by the new value or expression indicated by the composition.

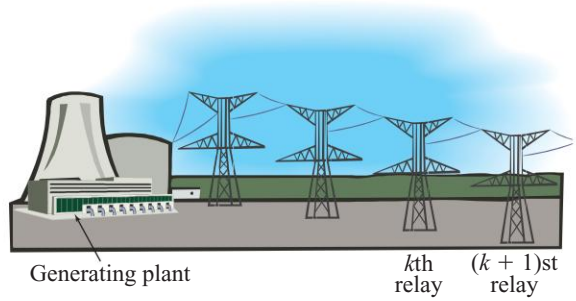
B. Mathematical Induction Applied to Sums

Consider the sum of odd numbers $1 + 3 + 5 + 7 + 9 + 11 + 13 + \cdots$. The sum of the first four terms is $1 + 3 + 5 + 7 = 16$, or $S_4 = 16$. If we now add a_5 (the next term in line), would we get the same answer as if we had simply computed S_5? Common sense would say, "Yes!" since $S_5 = 1 + 3 + 5 + 7 + 9 = 25$ and $S_4 + a_5 = 16 + 9 = 25$✓. In diagram form, we have

Our goal is to develop this same degree of clarity in the *notational scheme* of things. For a given series, if we find the kth partial sum S_k (shown next) and then add the next term a_{k+1}, would we get the same answer if we had simply computed S_{k+1}? In other words, is $S_k + a_{k+1} = S_{k+1}$ true?

Now, let's return to the sum $1 + 3 + 5 + 7 + \cdots + (2n - 1)$. This is an arithmetic series with $a_1 = 1$, $d = 2$, and nth term $a_n = 2n - 1$. Using the sum formula for an arithmetic sequence, an alternative formula for *this sum* can be established.

$$\begin{aligned} S_n &= \frac{n(a_1 + \boldsymbol{a_n})}{2} && \text{summation formula for an arithmetic sequence} \\ &= \frac{n(1 + \boldsymbol{2n - 1})}{2} && \text{substitute } 1 \text{ for } a_1 \text{ and } \boldsymbol{2n-1} \text{ for } \boldsymbol{a_n} \\ &= \frac{n(2n)}{2} && \text{simplify} \\ &= n^2 && \text{result} \end{aligned}$$



This shows that the sum of the first n positive odd integers is given by $S_n = n^2$. As a check we compute $S_5 = 1 + 3 + 5 + 7 + 9 = 25$ and compare to $S_5 = 5^2 = 25$✓. We also note $S_6 = 6^2 = 36$, and $S_5 + a_6 = 25 + 11 = 36$, showing $S_6 = S_5 + a_6$. For more on this relationship, **see Exercises 19 through 24.** While it may seem simplistic now, showing $S_5 + a_6 = S_6$ and $S_k + a_{k+1} = S_{k+1}$ (in general) is a critical component of a proof by induction.

Unfortunately, general summation formulas for many sequences cannot be established from known formulas. In addition, just because a formula works for the first few values of n, we cannot assume that it will hold true for *all* values of n (there are infinitely many). As an illustration, the formula $a_n = n^2 - n + 41$ yields a prime number for *every natural number n from 1 to 40,* but fails to yield a prime for $n = 41$. This helps demonstrate the need for a more conclusive proof, particularly when a relationship appears to be true, and can be "verified" in a finite number of cases, but whether it is true in *all* cases remains in doubt.

WORTHY OF NOTE

No matter how distant the city or how many relay stations are involved, if the generating plant is working and the kth station relays to the $(k + 1)$st station, the city will get its power.

Proof by induction is based on a relatively simple idea. To help understand how it works, consider n relay stations that are used to transport electricity from a generating plant to a distant city. If we know the generating plant is operating, and if we assume that the kth relay station (any station in the series) is making the transfer to the $(k + 1)$st station (the next station in the series), then we're sure the city will have electricity.

This idea can be applied mathematically as follows. Consider the statement, "The sum of the first n positive even integers is $n^2 + n$." In other words, $2 + 4 + 6 + 8 + \cdots + 2n = n^2 + n$. We can certainly verify the statement for the first few even numbers:

The first even number is 2 and…	$(1)^2 + 1 = 2$
The sum of the first *two* even numbers is $2 + 4 = 6$ and…	$(2)^2 + 2 = 6$
The sum of the first *three* even numbers is $2 + 4 + 6 = 12$ and…	$(3)^2 + 3 = 12$
The sum of the first *four* even numbers is $2 + 4 + 6 + 8 = 20$ and…	$(4)^2 + 4 = 20$

While we could continue this process for a very long time (or even use a computer), *no finite number of checks can prove a statement is universally true.* To prove the statement true for *all* positive integers, we use a reasoning similar to that applied in the relay stations example. If we are sure the formula works for $n = 1$ (the generating station is operating), and if the truth of $n = k$ implies that $n = k + 1$ is true [the kth relay station is transferring electricity to the $(k + 1)$st station], then the statement is true for all n (the city will get its electricity). The case where $n = 1$ is called the **base case** of an inductive proof, and the assumption that the formula is true for $n = k$ is called the **induction hypothesis.** When the induction hypothesis is applied to a sum formula, we attempt to show that $S_k + a_{k+1} = S_{k+1}$. Since k and $k + 1$ are arbitrary, the statement must be true for all n.

Mathematical Induction Applied to Sums

Let S_n be a sum formula involving positive integers.

If **1.** S_1 is true, and

2. the truth of S_k implies that S_{k+1} is true,

then S_n must be true for all positive integers n.

WORTHY OF NOTE

To satisfy our finite minds, it might help to show that S_n is true for the first few cases, prior to extending the ideas to the infinite case.

Both parts 1 and 2 must be verified for the proof to be complete. Since the process requires the terms S_k, a_{k+1}, and S_{k+1}, we will usually compute these first.

EXAMPLE 2 ▶ Proving a Statement Using Mathematical Induction

Use induction to prove that *the sum of the first n perfect squares is given by*

$$1 + 4 + 9 + 16 + 25 + \cdots + n^2 = \frac{n(n + 1)(2n + 1)}{6}.$$

Solution ▶ Given $a_n = n^2$ and $S_n = \dfrac{n(n + 1)(2n + 1)}{6}$, the needed components are …

For $a_n = n^2$: $a_k = k^2$ and $a_{k+1} = (k + 1)^2$

For $S_n = \dfrac{n(n + 1)(2n + 1)}{6}$: $S_k = \dfrac{k(k + 1)(2k + 1)}{6}$ and $S_{k+1} = \dfrac{(k + 1)(k + 2)(2k + 3)}{6}$

1. Show S_n is true for $n = 1$.

$$S_n = \frac{n(n + 1)(2n + 1)}{6} \quad \text{sum formula}$$

$$S_1 = \frac{1(2)(3)}{6} \quad \textit{base case: } n = 1$$

$$= 1\checkmark \quad \text{result checks, the first term is 1}$$

2. Assume S_k is true,

$$1 + 4 + 9 + 16 + \cdots + k^2 = \frac{k(k + 1)(2k + 1)}{6} \quad \text{induction hypothesis: } S_k \text{ is true}$$

and use it to show the truth of S_{k+1} follows. That is,

$$\underbrace{1 + 4 + 9 + 16 + \cdots + k^2}_{S_k} + \underbrace{(k + 1)^2}_{a_{k+1}} = \underbrace{\frac{(k + 1)(k + 2)(2k + 3)}{6}}_{S_{k+1}}$$

Working with the left-hand side, we have

$$\underbrace{1 + 4 + 9 + 16 + \cdots + k^2}_{} + (k + 1)^2$$

$$= \frac{k(k + 1)(2k + 1)}{6} + (k + 1)^2 \quad \text{induction hypothesis: substitute } \frac{k(k + 1)(2k + 1)}{6} \text{ for } 1 + 4 + 9 + 16 + 25 + \cdots + k^2$$

$$= \frac{k(k + 1)(2k + 1) + 6(k + 1)^2}{6} \quad \text{common denominator}$$

$$= \frac{(k+1)[k(2k+1)+6(k+1)]}{6} \quad \text{factor out } k+1$$

$$= \frac{(k+1)[2k^2+7k+6]}{6} \quad \text{multiply and combine terms}$$

$$= \frac{(k+1)(k+2)(2k+3)}{6} \quad \text{factor the trinomial, result is } S_{k+1}$$

Since the truth of S_{k+1} follows from S_k, the formula is true for all n.

B. You've just seen how we can apply the principle of mathematical induction to sum formulas involving natural numbers

Now try Exercises 27 through 38 ▶

C. The General Principle of Mathematical Induction

Proof by induction can be used to verify many other kinds of relationships involving a natural number n. In this regard, the basic principles remain the same but are stated more broadly. Rather than using S_n to represent a sum, we will use P_n to represent *any proposed statement or relationship* we might wish to verify. This broadens the scope of the proof and makes it more widely applicable, while maintaining its connection to the sum formulas verified earlier.

The General Principle of Mathematical Induction

Let P_n be a statement involving natural numbers.

If **1.** P_1 is true, and

2. the truth of P_k implies that P_{k+1} is also true

then P_n must be true for all natural numbers n.

EXAMPLE 3 ▶ **Proving a Statement Using the General Principle of Mathematical Induction**

Use the general principle of mathematical induction to show the statement P_n is true for all natural numbers n. P_n: $2^n \geq n + 1$

Solution ▶ The statement P_n is defined as $2^n \geq n + 1$. This means that P_k is represented by $2^k \geq k + 1$ and P_{k+1} by $2^{k+1} \geq k + 2$.

1. Show P_n is true for $n = 1$:

P_n: $2^n \geq n + 1$ given statement

P_1: $2^1 \geq 1 + 1$ base case: $n = 1$

$2 \geq 2$✓ true

Although not a part of the formal proof, a table of values can help to illustrate the relationship we're trying to establish. It *appears* that the statement is true.

n	1	2	3	4	5
2^n	2	4	8	16	32
$n + 1$	2	3	4	5	6

2. Assume that P_k is true.

P_k: $2^k \geq k + 1$ induction hypothesis

and use it to show the truth of P_{k+1}. That is,

P_{k+1}: $2^{k+1} \geq (k + 1) + 1$

$\geq k + 2$

Begin by working with the left-hand side of the inequality, 2^{k+1}.

$2^{k+1} = 2(\mathbf{2^k})$ properties of exponents

$\geq 2(\mathbf{k+1})$ *induction hypothesis:* substitute $k+1$ for 2^k (symbol changes since 2^k is greater than or equal to $k+1$)

$\geq 2k+2$ distribute

Since k is a positive integer, $2^{k+1} \geq 2k+2 \geq k+2$,

showing $2^{k+1} \geq k+2$.

Since the truth of P_{k+1} follows from P_k, the formula is true for all n.

WORTHY OF NOTE

Note there is no reference to a_n, a_k, or a_{k+1} in the statement of the general principle of mathematical induction.

Now try Exercises 39 through 42 ▶

EXAMPLE 4 ▶ Proving Divisibility Using Mathematical Induction

Let P_n be the statement, "$4^n - 1$ *is divisible by* 3 *for all positive integers* n." Use mathematical induction to prove that P_n is true.

Solution ▶ If a number is evenly divisible by three, it can be written as the product of 3 and some positive integer we will call p.

1. Show P_n is true for $n = 1$:

P_n: $4^n - 1 = 3p$ given statement, $p \in \mathbb{Z}$

P_1: $4^{(1)} - 1 = 3p$ substitute 1 for n

$3 = 3p$ ✓ statement is true for $n = 1$

2. Assume that P_k is true.

P_k: $4^k - 1 = 3p$ induction hypothesis

$4^k = 3p + 1$ isolate 4^k

and use it to show the truth of P_{k+1}. That is,

P_{k+1}: $4^{k+1} - 1 = 3q$ for $q \in \mathbb{Z}$ is also true.

Beginning with the left-hand side we have:

$4^{k+1} - 1 = 4 \cdot \mathbf{4^k} - 1$ properties of exponents

$= 4 \cdot (\mathbf{3p+1}) - 1$ induction hypothesis: substitute $3p+1$ for 4^k

$= 12p + 3$ distribute and simplify

$= 3(4p+1) = 3q$ factor

The last step shows $4^{k+1} - 1$ is divisible by 3. Since the original statement is true for $n = 1$, and the truth of P_k implies the truth of P_{k+1}, the statement, "$4^n - 1$ *is divisible by* 3" is true for all positive integers n.

Now try Exercises 43 through 47 ▶

C. You've just seen how we can apply the principle of mathematical induction to general statements involving natural numbers

We close this section with some final notes. Although the base step of a proof by induction seems trivial, both the base step and the induction hypothesis are necessary parts of the proof. For example, the statement $\frac{1}{3^n} < \frac{1}{3n}$ is false for $n = 1$, but true for all other positive integers. Finally, for a fixed natural number p, some statements are false for all $n < p$, but true for all $n \geq p$. By modifying the base case to begin at p, we can use the induction hypothesis to prove the statement is true for all n greater than p. For example, $n < \frac{1}{3}n^2$ is false for $n < 4$, but true for all $n \geq 4$.

11.4 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. No _____ number of verifications can prove a statement _____ true.
2. Showing a statement is true for $n = 1$ is called the _____ _____ of an inductive proof.
3. Assuming that a statement/formula is true for $n = k$ is called the _____ _____.
4. The graph of a sequence is _____, meaning it is made up of distinct points.
5. Explain the equation $S_k + a_{k+1} = S_{k+1}$. Begin by saying, "Since the kth term is arbitrary…" (continue from here).
6. Discuss the similarities and differences between mathematical induction applied to sums and the general principle of mathematical induction.

▶ DEVELOPING YOUR SKILLS

For the given nth term a_n, find a_4, a_5, a_k, and a_{k+1}.

7. $a_n = 10n - 6$
8. $a_n = 6n - 4$
9. $a_n = n$
10. $a_n = 7n$
11. $a_n = 2^{n-1}$
12. $a_n = 2(3^{n-1})$

For the given sum formula S_n, find S_4, S_5, S_k, and S_{k+1}.

13. $S_n = n(5n - 1)$
14. $S_n = n(3n - 1)$
15. $S_n = \dfrac{n(n + 1)}{2}$
16. $S_n = \dfrac{7n(n + 1)}{2}$
17. $S_n = 2^n - 1$
18. $S_n = 3^n - 1$

Verify that $S_4 + a_5 = S_5$ for each exercise. Note that each S_n is identical to those in Exercises 13 through 18.

19. $a_n = 10n - 6$; $S_n = n(5n - 1)$
20. $a_n = 6n - 4$; $S_n = n(3n - 1)$
21. $a_n = n$; $S_n = \dfrac{n(n + 1)}{2}$
22. $a_n = 7n$; $S_n = \dfrac{7n(n + 1)}{2}$
23. $a_n = 2^{n-1}$; $S_n = 2^n - 1$
24. $a_n = 2(3^{n-1})$; $S_n = 3^n - 1$

▶ WORKING WITH FORMULAS

25. **Sum of the first n cubes (alternative form): $(1 + 2 + 3 + 4 + \cdots + n)^2$**

    Earlier we noted the formula for the sum of the first n cubes was $\dfrac{n^2(n + 1)^2}{4}$. An alternative is given by the formula shown.

    a. Verify the formula for $n = 1$, 5, and 9.

    b. Verify the formula using
    $$1 + 2 + 3 + \cdots + n = \frac{n(n + 1)}{2}.$$

26. **Powers of the imaginary unit: $i^{n+4} = i^n$, where $i = \sqrt{-1}$**

    Use a proof by induction to prove that powers of the imaginary unit are cyclic. That is, that they cycle through the numbers i, -1, $-i$, and 1 for consecutive powers.

▶ APPLICATIONS

Use mathematical induction to prove the indicated sum formula is true for all natural numbers n.

27. $2 + 4 + 6 + 8 + 10 + \cdots + 2n$; $a_n = 2n$, $S_n = n(n + 1)$
28. $3 + 7 + 11 + 15 + 19 + \cdots + (4n - 1)$; $a_n = 4n - 1$, $S_n = n(2n + 1)$
29. $5 + 10 + 15 + 20 + 25 + \cdots + 5n$; $a_n = 5n$, $S_n = \dfrac{5n(n + 1)}{2}$
30. $1 + 4 + 7 + 10 + 13 + \cdots + (3n - 2)$; $a_n = 3n - 2$, $S_n = \dfrac{n(3n - 1)}{2}$

31. $5 + 9 + 13 + 17 + \cdots + (4n + 1)$;
$a_n = 4n + 1, S_n = n(2n + 3)$

32. $4 + 12 + 20 + 28 + 36 + \cdots + (8n - 4)$;
$a_n = 8n - 4, S_n = 4n^2$

33. $3 + 9 + 27 + 81 + 243 + \cdots + 3^n$;
$a_n = 3^n, S_n = \dfrac{3(3^n - 1)}{2}$

34. $5 + 25 + 125 + 625 + \cdots + 5^n$;
$a_n = 5^n, S_n = \dfrac{5(5^n - 1)}{4}$

35. $2 + 4 + 8 + 16 + 32 + 64 + \cdots + 2^n$;
$a_n = 2^n, S_n = 2^{n+1} - 2$

36. $1 + 8 + 27 + 64 + 125 + 216 + \cdots + n^3$;
$a_n = n^3, S_n = \dfrac{n^2(n + 1)^2}{4}$

37. $\dfrac{1}{1(3)} + \dfrac{1}{3(5)} + \dfrac{1}{5(7)} + \cdots + \dfrac{1}{(2n - 1)(2n + 1)}$;
$a_n = \dfrac{1}{(2n - 1)(2n + 1)}, S_n = \dfrac{n}{2n + 1}$

38. $\dfrac{1}{1(2)} + \dfrac{1}{2(3)} + \dfrac{1}{3(4)} + \cdots + \dfrac{1}{n(n + 1)}$;
$a_n = \dfrac{1}{n(n + 1)}, S_n = \dfrac{n}{n + 1}$

Use the principle of mathematical induction to prove that each statement is true for all natural numbers *n*.

39. $3^n \geq 2n + 1$

40. $2^n \geq n + 1$

41. $3 \cdot 4^{n-1} \leq 4^n - 1$

42. $4 \cdot 5^{n-1} \leq 5^n - 1$

43. $n^2 - 7n$ is divisible by 2

44. $n^3 - n + 3$ is divisible by 3

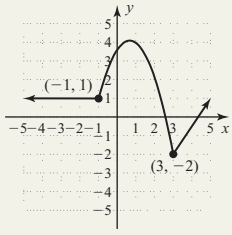
45. $n^3 + 3n^2 + 2n$ is divisible by 3

46. $5^n - 1$ is divisible by 4

47. $6^n - 1$ is divisible by 5

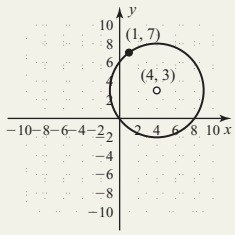
▶ EXTENDING THE CONCEPT

48. You may have noticed that the sum formula for the first n integers was *quadratic,* and the formula for the first n integer squares was *cubic.* Is the formula for the first n integer cubes, if it exists, a quartic (degree four) function? Use your calculator to run a quartic regression on the first five perfect cubes (enter 1 through 5 in L1 and the cumulative sums in L2). What did you find? How is this exercise related to Exercise 36?



49. Use mathematical induction to prove that $\dfrac{x^n - 1}{x - 1} = (1 + x + x^2 + x^3 + \cdots + x^{n-1})$.

50. Use mathematical induction to prove that for $1^4 + 2^4 + 3^4 + \cdots + n^4$, where $a_n = n^4$,
$S_n = \dfrac{n(n + 1)(2n + 1)(3n^2 + 3n - 1)}{30}$.



▶ MAINTAINING YOUR SKILLS

51. **(7.2)** Verify the identity
$(\sin\theta + \cos\theta)^2 + (\sin\theta - \cos\theta)^2 = 2$.

52. **(2.5)** State the domain and range of the piecewise function shown here.

53. **(1.1)** State the equation of the circle whose graph is shown here.

54. **(8.4)** Given $\mathbf{p} = \langle\sqrt{3}, -1\rangle$ and $\mathbf{q} = \langle 1, 1\rangle$, find

a. the dot product $\mathbf{p} \cdot \mathbf{q}$

b. the angle between the vectors

MID-CHAPTER CHECK

In Exercises 1 through 3, the nth term is given. Write the first three terms of each sequence and find a_9.

1. $a_n = 7n - 4$

2. $a_n = n^2 + 3$

3. $a_n = (-1)^n(2n - 1)$

4. Evaluate the sum $\sum_{n=1}^{4} 3^{n+1}$

5. Rewrite using sigma notation.
$1 + 4 + 7 + 10 + 13 + 16$

Match each formula to its correct description.

6. $S_n = \dfrac{n(a_1 + a_n)}{2}$

7. $a_n = a_1 r^{n-1}$

8. $S_\infty = \dfrac{a_1}{1 - r}$

9. $a_n = a_1 + (n - 1)d$

10. $S_n = \dfrac{a_1(1 - r^n)}{1 - r}$

a. sum of an infinite geometric series

b. nth term formula for an arithmetic series

c. sum of a finite geometric series

d. summation formula for an arithmetic series

e. nth term formula for a geometric series

11. Identify a_1 and the common difference d. Then find an expression for the general term a_n.

a. 2, 5, 8, 11, …

b. $\frac{3}{2}, \frac{9}{4}, 3, \frac{15}{4}, \ldots$

Find the number of terms in each series and then find the sum. Verify results on a graphing calculator.

12. $2 + 5 + 8 + 11 + \cdots + 74$

13. $\frac{1}{2} + \frac{3}{2} + \frac{5}{2} + \frac{7}{2} + \cdots + \frac{31}{2}$

14. For an arithmetic series, $a_3 = -8$ and $a_7 = 4$. Find S_{10}.

15. For a geometric series, $a_3 = -81$ and $a_6 = 3$. Find S_{10}.

16. Identify a_1 and the common ratio r. Then find an expression for the general term a_n.

a. 2, 6, 18, 54, …

b. $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{1}{16}, \ldots$

17. Find the number of terms in the series then compute the sum. $\frac{1}{54} + \frac{1}{18} + \frac{1}{6} + \cdots + \frac{81}{2}$

18. Find the infinite sum (if it exists).
$-49 + (-7) + (-1) + (-\frac{1}{7}) + \cdots$

19. Barrels of toxic waste are stacked at a storage facility in pyramid form, with 60 barrels in the first row, 59 in the second row, and so on, until there are 10 barrels in the top row. How many barrels are in the storage facility? Verify results using a graphing calculator.

20. As part of a conditioning regimen, a drill sergeant orders her platoon to do 25 continuous standing broad jumps. The best of these recruits was able to jump 96% of the distance from the previous jump, with a first jump distance of 8 ft. Use a sequence/series to determine the distance the recruit jumped on the 15th try, and the total distance traveled by the recruit after all 25 jumps. Verify results using a graphing calculator.

REINFORCING BASIC CONCEPTS

Applications of Summation

The properties of summation play a large role in the development of key ideas in a first semester calculus course, and the following summation formulas are an integral part of these ideas. The first three formulas were verified in Section 11.4, while proof of the fourth was part of Exercise 48 on page 1118.

(1) $\sum_{i=1}^{n} c = cn$ **(2)** $\sum_{i=1}^{n} i = \dfrac{n(n + 1)}{2}$ **(3)** $\sum_{i=1}^{n} i^2 = \dfrac{n(n + 1)(2n + 1)}{6}$ **(4)** $\sum_{i=1}^{n} i^3 = \dfrac{n^2(n + 1)^2}{4}$

To see the various ways they can be applied consider the following.

Illustration 1 ▶ Over several years, the owner of Morgan's LawnCare has noticed that the company's monthly profits (in thousands) can be approximated by the sequence $a_n = 0.0625n^3 - 1.25n^2 + 6n$, with the points plotted in Figure 11.53 (the continuous graph is shown for effect only). Find the company's approximate annual profit.

Solution ▶ The most obvious approach would be to simply compute terms a_1 through a_{12} (January through December) and find their sum: **sum(seq(Y1, X, 1, 12)**, which gives a result of 35.75 or \$35,750.

As an alternative, we could add the amount of profit earned by the company in the first 8 months, then add the amount the company lost (or broke even) during the last 4 months. In other words, we could apply summation property IV: $\sum_{i=1}^{12} a_n = \sum_{i=1}^{8} a_n + \sum_{i=9}^{12} a_n$ [(see Figure 11.54), which gives the same result:

$$42 + (-6.25) = 35.75 \text{ or } \$35{,}750].$$

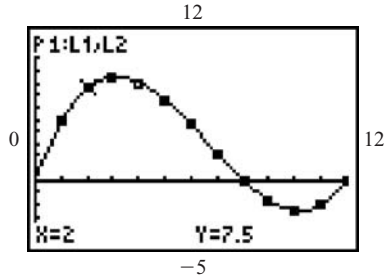
As a third option, we could use summation properties along with the appropriate summation formulas, and compute the result manually. Note the function is now written in terms of "*i*." *Distribute summation and factor out constants* (properties II and III):

$$\sum_{i=1}^{12}(0.0625i^3 - 1.25i^2 + 6i) = 0.0625\sum_{i=1}^{12} i^3 - 1.25\sum_{i=1}^{12} i^2 + 6\sum_{i=1}^{12} i$$

Replace each summation with the appropriate summation formula, then substitute 12 for n:

$$= 0.0625\left[\frac{n^2(n+1)^2}{4}\right] - 1.25\left[\frac{n(n+1)(2n+1)}{6}\right] + 6\left[\frac{n(n+1)}{2}\right]$$
$$= 0.0625\left[\frac{(12)^2(13)^2}{4}\right] - 1.25\left[\frac{(12)(13)(25)}{6}\right] + 6\left[\frac{(12)(13)}{2}\right]$$
$$= 0.0625(6084) - 1.25(650) + 6(78)$$
$$= 35.75$$

Figure 11.53



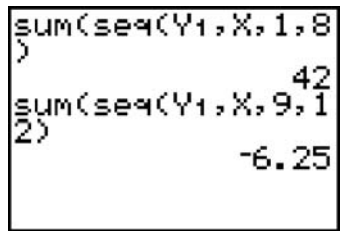


Figure 11.54

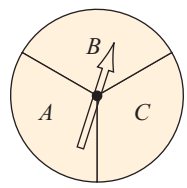
As we expected, the result shows profit was \$35,750. While some approaches seem "easier" than others, all have great value, are applied in different ways at different times, and are necessary to adequately develop key concepts in future classes.

Exercise 1: Repeat Illustration 1 if the profit sequence is $a_n = 0.125x^3 - 2.5x^2 + 12x$.

11.5 Counting Techniques

LEARNING OBJECTIVES

In Section 11.5 you will see how we can:



- ❑ **A.** Count possibilities using lists and tree diagrams
- ❑ **B.** Count possibilities using the fundamental principle of counting

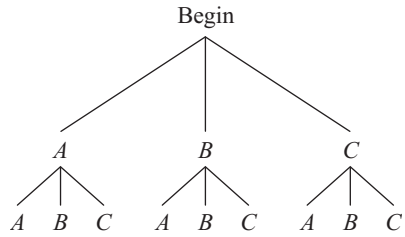
How long would it take to estimate the number of fans sitting shoulder-to-shoulder at a sold-out basketball game? Well, it depends. You could actually begin counting 1, 2, 3, 4, 5, …, which would take a very long time, or you could try to simplify the process by counting the number of fans in the first row and multiplying by the number of rows. Techniques for "quick-counting" the objects in a set or various subsets of a large set play an important role in a study of probability.

A. Counting by Listing and Tree Diagrams



Consider the simple spinner shown in Figure 11.55, which is divided into three equal parts. What are the different possible outcomes for two spins, spin 1 followed by spin 2? We might begin by organizing the possibilities using a **tree diagram.** As the name implies, each choice or possibility appears as the branch of a tree, with the total possibilities being equal to the number of (unique)

Figure 11.55

paths from the beginning point to the end of a branch. Figure 11.56 shows how the spinner exercise would appear (possibilities for two spins). Moving from top to bottom we can trace nine possible paths: *AA*, *AB*, *AC*, *BA*, *BB*, *BC*, *CA*, *CB*, and *CC*.

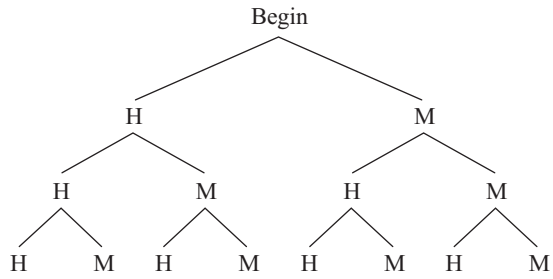


Figure 11.56

EXAMPLE 1 ▶ **Listing Possibilities Using a Tree Diagram**

A basketball player is fouled and awarded three free throws. Let H represent the possibility of a hit (basket is made), and M the possibility of a miss. Determine the possible outcomes for the three shots using a tree diagram.

Solution ▶ Each shot has two possibilities, hit (H) or miss (M), so the tree will branch in two directions at each level. As illustrated in the figure, there are a total of eight possibilities: HHH, HHM, HMH, HMM, MHH, MHM, MMH, and MMM.

Now try Exercises 7 through 10 ▶

WORTHY OF NOTE

Sample spaces may vary depending on how we define the experiment, and for simplicity's sake we consider only those experiments having outcomes that are equally likely.

To assist our discussion, an **experiment** is any task that can be done repeatedly and has a well-defined set of possible outcomes. Each repetition of the experiment is called a **trial.** A **sample outcome** is any potential outcome of a trial, and a **sample space** is a set of all possible outcomes.

In our first illustration, the *experiment* was spinning a spinner, there were *three sample outcomes* (*A*, *B*, or *C*), the experiment had *two trials* (spin 1 and spin 2), and there were *nine* elements in the *sample space.* Note that after the first trial, each of the three sample outcomes will again have three possibilities (*A*, *B*, and *C*). For two trials we have $3^2 = 9$ possibilities, while three trials would yield a sample space with $3^3 = 27$ possibilities. In general, for N equally likely outcomes we have

A "Quick-Counting" Formula for a Sample Space

If an experiment has N sample outcomes that are equally likely and the experiment is repeated t times, the number of elements in the sample space is

$$N^t.$$

EXAMPLE 2 ▶ **Counting the Outcomes in a Sample Space**

Many combination locks have the digits 0 through 39 arranged along a circular dial. Opening the lock requires stopping at a sequence of three numbers within this range, going counterclockwise to the first number, clockwise to the second, and counterclockwise to the third. How many three-number combinations are possible?

Solution ▶ There are 40 sample outcomes ($N = 40$) in this experiment, and three trials ($t = 3$). The number of possible combinations is identical to the number of elements in the sample space. The quick-counting formula gives $40^3 = 64{,}000$ possible combinations.

A. You've just seen how we can count possibilities using lists and tree diagrams

Now try Exercises 11 and 12 ▶

B. Fundamental Principle of Counting

The number of possible outcomes may differ depending on how the event is defined. For example, some security systems, license plates, and telephone numbers exclude certain numbers. For example, phone numbers cannot begin with 0 or 1 because these are reserved for operator assistance, long distance, and international calls. Constructing a three-digit area code is like filling in three blanks $\underset{\text{digit}}{___}\ \underset{\text{digit}}{___}\ \underset{\text{digit}}{___}$ with three digits. Since the area code must start with a number between 2 and 9, there are eight choices for the first blank. Since there are 10 choices for the second digit and 10 choices for the third, there are $8 \cdot 10 \cdot 10 = 800$ possibilities in the sample space.

EXAMPLE 3 ▶ **Counting Possibilities for a Four-Digit Security Code**

A digital security system requires that you enter a four-digit PIN (personal identification number), using only the digits 1 through 9. How many codes are possible if

a. Repetition of digits is allowed?

b. Repetition is not allowed?

c. The first digit must be even and repetitions are not allowed?

Solution ▶

a. Consider filling in the four blanks $\underset{\text{digit}}{___}\ \underset{\text{digit}}{___}\ \underset{\text{digit}}{___}\ \underset{\text{digit}}{___}$ with the number of ways the digit can be chosen. If repetition is allowed, the experiment is similar to that of Example 2 and there are $N^t = 9^4 = 6561$ possible PINs.

b. If repetition is not allowed, there are only eight possible choices for the second digit of the PIN, then seven for the third, and six for the fourth. The number of possible PIN numbers decreases to $9 \cdot 8 \cdot 7 \cdot 6 = 3024$.

c. There are four choices for the first digit (2, 4, 6, 8). Once this choice has been made there are eight choices for the second digit, seven for the third, and six for the last: $4 \cdot 8 \cdot 7 \cdot 6 = 1344$ possible codes.

Now try Exercises 13 through 16 ▶

Given *any* experiment involving a sequence of tasks, if the first task can be completed in p possible ways, the second task has q possibilities, and the third task has r possibilities, a tree diagram will show that the number of possibilities in the sample space for task_1–task_2–task_3 is $p \cdot q \cdot r$. This situation is simply a variation of the previous quick-counting formula. Even though the examples we've considered to this point have varied a great deal, this idea was fundamental to counting all possibilities in a sample space and is, in fact, known as the **fundamental principle of counting** (FPC).

Fundamental Principle of Counting (Applied to Three Tasks)

Given any experiment with three defined tasks, if there are p possibilities for the first task, q possibilities for the second, and r possibilities for the third, the total number of ways the experiment can be completed is

$$p \cdot q \cdot r.$$

This fundamental principle can be extended to include any number of tasks, and can be applied in many different ways. **See Exercises 17 through 20.**

EXAMPLE 4 ▶ **Counting Possibilities for Seating Arrangements**

Adrienne, Bob, Carol, Dax, Earlene, and Fabian bought tickets to see *The Marriage of Figaro.* Assuming they sat together in a row of six seats, how many different seating arrangements are possible if

a. Bob and Carol are sweethearts and must sit together?

b. Bob and Carol are enemies and must not sit together?

Solution ▶

a. Since a restriction has been placed on the seating arrangement, it will help to divide the experiment into a sequence of tasks: *task 1:* they sit together; *task 2:* either Bob is on the left or Bob is on the right; and *task 3:* the other four are seated. Bob and Carol can sit together in five different ways, as shown in Figure 11.57, so there are five possibilities for task 1. There are two ways they can be side-by-side: Bob on the left and Carol on the right, as shown, or Carol on the left and Bob on the right. The remaining four people can be seated randomly, so task 3 has $4! = 24$ possibilities. Under these conditions they can be seated $5 \cdot 2 \cdot 4! = 240$ ways.

b. This is similar to part (a), but now we have to count the number of ways they can be separated by *at least one seat: task 1:* Bob and Carol are in nonadjacent seats; *task 2:* either Bob is on the left or Bob is on the right; and *task 3:* the other four are seated. For tasks 1 and 2, be careful to note there is no multiplication involved, just a simple counting. If Bob sits in seat 1 (to the left of Carol), there are four nonadjacent seats on the right. If Bob sits in seat 2, there are three nonadjacent seats on the right. With Bob in seat 3, there are two nonadjacent seats to his right. Similar reasoning for the remaining seats shows there are $10 \cdot 2 = 20$ possibilities for Bob and Carol not sitting together (by symmetry, Bob could also sit to the right of Carol). Multiplying by the number of ways the other four can be seated (task 3) gives $20 \cdot 4! = 480$ possible seating arrangements. We could also reason that since there are $6! = 720$ random seating arrangements and 240 of them consist of Bob and Carol sitting together, the remaining $720 - 240 = 480$ must consist of Bob and Carol *not* sitting together. More will be said about this type of reasoning in Section 11.6.

Figure 11.57

☑ **B.** You've just seen how we can count possibilities using the fundamental principle of counting

Now try Exercises 21 through 28 ▶

C. Distinguishable Permutations

In the game of Scrabble® (Milton Bradley), players attempt to form words by rearranging letters. Suppose a player has the letters P, S, T, and O at the end of the game. These letters could be rearranged or *permuted* to form the words POTS, SPOT, TOPS, OPTS, POST, or STOP. These arrangements are called permutations of the four letters. A permutation is any new arrangement, listing, or sequence of objects obtained by changing an existing order. A **distinguishable permutation** is a permutation that produces a result different from the original. For example, a distinguishable permutation of the digits in the number 1989 is 8199.

Example 4 considered six people, six seats, and the various ways they could be seated. But what if there were fewer seats than people? By the FPC, with six people and four seats there could be $6 \cdot 5 \cdot 4 \cdot 3 = 360$ different arrangements, with six people and three seats there are $6 \cdot 5 \cdot 4 = 120$ different arrangements, and so on. These rearrangements are called distinguishable permutations. You may have noticed that for six people and six seats, we will use all six factors of 6!, while for six people and four seats we used the first four, six people and three seats required only the first three, and so on. Generally, for n people and r seats, the first r factors of $n!$ will be used. The notation and formula for *distinguishable permutations of n objects taken r at a time* is ${}_nP_r = \dfrac{n!}{(n-r)!}$. By defining $0! = 1$, the formula includes the case where all n objects are selected, which of course results in ${}_nP_n = \dfrac{n!}{(n-n)!} = \dfrac{n!}{0!} = \dfrac{n!}{1} = n!$.

Distinguishable Permutations: Unique Elements

If r objects are selected from a set containing n unique elements ($r \le n$) and placed in an ordered arrangement, the number of distinguishable permutations is

$$ {}_nP_r = \frac{n!}{(n-r)!} \quad \text{or} \quad {}_nP_r = n(n-1)(n-2)\cdots(n-r+1) $$

EXAMPLE 5 ▶ Computing a Permutation

Compute each value of ${}_nP_r$ using the methods described previously.

a. ${}_7P_4$ **b.** ${}_{10}P_3$

Solution ▶ Begin by evaluating each expression using the formula ${}_nP_r = \dfrac{n!}{(n-r)!}$, noting the third line (in bold) gives the first r factors of $n!$.

a. ${}_7P_4 = \dfrac{7!}{(7-4)!}$

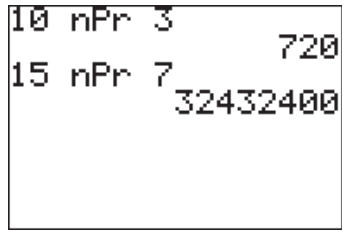
$= \dfrac{7 \cdot 6 \cdot 5 \cdot 4 \cdot \cancel{3!}}{\cancel{3!}}$

$= \mathbf{7 \cdot 6 \cdot 5 \cdot 4}$

$= 840$

b. ${}_{10}P_3 = \dfrac{10!}{(10-3)!}$

$= \dfrac{10 \cdot 9 \cdot 8 \cdot \cancel{7!}}{\cancel{7!}}$



$= \mathbf{10 \cdot 9 \cdot 8}$

$= 720$

Now try Exercises 29 through 36 ▶

When the number of objects is very large, the formula for permutations can become somewhat unwieldy and the computed result is often a very large number. When needed, most graphing calculators have the ability to compute permutations, with this option accessed using MATH ‹ **(PRB) 2:nPr.** Figure 11.58 verifies the computation for Example 5(b), and also shows that if there were 15 people and 7 chairs, the number of possible seating arrangements exceeds 32 million! Note that the value of n is entered first, followed by the **nPr** command and the value of r.

Figure 11.58

EXAMPLE 6 ▶ Counting the Possibilities for Finishing a Race

As part of a sorority's initiation process, the nine new inductees must participate in a 1-mi race. Assuming there are no ties, how many first- through fifth-place finishes are possible if it is well known that Mediocre Mary will finish fifth and Lightning Louise will finish first?

Solution ▶ To help understand the situation, we can diagram the possibilities for finishing first through fifth. Since Louise will finish first, this slot can be filled in only one way, by Louise herself. The same goes for Mary and her fifth-place finish:

Louise				Mary
1st	2nd	3rd	4th	5th

The remaining three slots can be filled in ${}_7P_3 = 7 \cdot 6 \cdot 5$ different ways, indicating that under these conditions, there are $1 \cdot 7 \cdot 6 \cdot 5 \cdot 1 = 210$ different ways to finish.

C. You've just seen how we can quick-count distinguishable permutations

Now try Exercises 37 through 42 ▶

D. Nondistinguishable Permutations

As the name implies, certain permutations are nondistinguishable, meaning you cannot tell one apart from another. Such is the case when the original set contains elements or sample outcomes that are identical. Consider a family with four children, Lyddell, Morgan, Michael, and Mitchell, who are at the photo studio for a family picture. Michael and Mitchell are identical twins and cannot be told apart. In how many ways can they be lined up for the picture? Since this is an ordered arrangement of four children taken from a group of four, there are ${}_4P_4 = 24$ ways to line them up. A few of them are

Lyddell	Morgan	Michael	Mitchell		Lyddell	Morgan	Mitchell	Michael
Lyddell	Michael	Morgan	Mitchell		Lyddell	Mitchell	Morgan	Michael
Michael	Lyddell	Morgan	Mitchell		Mitchell	Lyddell	Morgan	Michael

But of these six arrangements, half will appear to be the same picture, since the difference between Michael and Mitchell cannot be distinguished. In fact, of the 24 total permutations, every picture where Michael and Mitchell have switched places will be nondistinguishable. To find the *distinguishable* permutations, we need to take the total permutations $({}_4P_4)$ *and divide by* 2!, *the number of ways the twins can be permuted:* $\frac{{}_4P_4}{(2)!} = \frac{24}{2} = 12$ distinguishable pictures.

These ideas can be generalized and stated in the following way.

Nondistinguishable Permutations: Nonunique Elements

In a set containing n elements where one element is repeated p times, another is repeated q times, and another is repeated r times $(p + q + r = n)$, the number of nondistinguishable permutations is

$$\frac{{}_nP_n}{p!q!r!} = \frac{n!}{p!q!r!}$$

The idea can be extended to include any number of repeated elements.

EXAMPLE 7 ▶ **Counting Nondistinguishable Permutations**

A Scrabble player starts the game with the seven letters S, A, O, O, T, T, and T in her rack. How many distinguishable arrangements can be formed as she attempts to play a word?

Solution ▶ Essentially the exercise asks for the number of distinguishable permutations of the seven letters, given T is repeated three times and O is repeated twice (for S and A, $1! = 1$). There are $\frac{{}_7P_7}{3!2!} = 420$ distinguishable permutations.

Now try Exercises 43 through 54 ▶

D. You've just seen how we can quick-count nondistinguishable permutations

WORTHY OF NOTE

In Example 7, if a Scrabble player is able to play all seven letters in one turn, he or she "bingos" and is awarded 50 extra points. The player in Example 7 did just that. Can you determine what word was played?

E. Combinations

Similar to nondistinguishable permutations, there are other times the total number of permutations must be reduced to quick-count the elements of a desired subset. Consider a vending machine that offers a variety of 40¢ candies. If you have a quarter (Q), dime (D), and nickel (N), the machine wouldn't care about the order the coins are deposited. Even though QDN, QND, DQN, DNQ, NQD, and NDQ give the ${}_3P_3 = 6$ possible permutations, the machine considers them as equal and will vend your snack. Using sets, this is similar to saying the set $A = \{X, Y, Z\}$ has only one subset with three elements, since $\{X, Z, Y\}$, $\{Y, X, Z\}$, $\{Y, Z, X\}$, and so on, all represent the same set. Similarly, there are six two-letter permutations of X, Y, and Z $({}_3P_2 = 6)$: XY, XZ, YX,

YZ, ZX, and ZY, but only three two-letter subsets: $\{X, Y\}$, $\{X, Z\}$ and $\{Y, Z\}$. When permutations having the same elements are considered identical, the result is the number of possible **combinations** and is denoted ${}_nC_r$. Since the r objects can be selected in $r!$ ways, we divide ${}_nP_r$ by $r!$ to "quick-count" the number of possibilities: ${}_nC_r = \frac{{}_nP_r}{r!}$, which can be thought of as *the first r factors of n!, divided by r!*. By substituting $\frac{n!}{(n-r)!}$ for ${}_nP_r$ in this formula, we find an alternative method for computing ${}_nC_r$ is $\frac{n!}{r!(n-r)!}$. Take special note that when r objects are selected from a set with n elements and the order they're listed is unimportant (because you end up with the same subset), the result is a *combination*, not a permutation.

Combinations

The number of combinations of n objects taken r at a time is given by

$$ {}_nC_r = \frac{{}_nP_r}{r!} \quad \text{or} \quad {}_nC_r = \frac{n!}{r!(n-r)!} $$

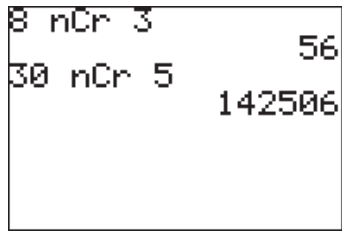
EXAMPLE 8 ▶ **Computing Combinations Using a Formula**

Compute each value of ${}_nC_r$ given.

a. ${}_7C_4$ **b.** ${}_8C_3$ **c.** ${}_5C_2$

Solution ▶

a. ${}_7C_4 = \frac{7 \cdot 6 \cdot 5 \cdot 4}{4!} = 35$



b. ${}_8C_3 = \frac{8 \cdot 7 \cdot 6}{3!} = 56$

c. ${}_5C_2 = \frac{5 \cdot 4}{2!} = 10$

Now try Exercises 55 through 64 ▶

As with permutations, when the number of objects is very large, the formula for combinations can also become somewhat cumbersome. Most graphing calculators have the ability to compute combinations, with this option accessed on the same submenu as **nPr:** MATH ◀ **(PRB) 3:nCr.** Figure 11.59 verifies the computation from Example 8(b), and also shows that in a Political Science class with 30 students, 5 can be picked at random to attend a seminar in the nation's capitol 142,506 ways.

Figure 11.59

EXAMPLE 9 ▶ **Applications of Combinations-Lottery Results**

A small city is getting ready to draw five Ping-Pong balls of the nine they have numbered 1 through 9 to determine the winner(s) for its annual raffle. If a ticket holder has the same five numbers, they win. In how many ways can the winning numbers be drawn?

Solution ▶ Since the winning numbers can be drawn in any order, we have a combination of 9 things taken 5 at a time. The five numbers can be

drawn in ${}_9C_5 = \frac{9 \cdot 8 \cdot 7 \cdot 6 \cdot 5}{5!} = 126$ ways.

Now try Exercises 65 and 66 ▶

Somewhat surprisingly, there are many situations where the order things are listed is not important. Such situations include

- The formation of committees, since the order people volunteer is unimportant
- Card games with a standard deck, since the order cards are dealt is unimportant
- Playing BINGO, since the order the winning numbers are called is unimportant

When the order in which people or objects are selected from a group is unimportant, the number of possibilities is a *combination,* not a permutation.

Another way to tell the difference between permutations and combinations is the following memory device: *P*ermutations have *P*riority or *P*recedence; in other words, the *P*osition of each element matters. By contrast, a *C*ombination is like a *C*ommittee of *C*olleagues or *C*ollection of *C*ommoners; all members have equal rank. For permutations, *a*-*b*-*c* is different from *b*-*a*-*c*. For combinations, *a*-*b*-*c* is the same as *b*-*a*-*c*.

EXAMPLE 10 ▶ **Applications of Quick-Counting—Committees and Governance**

The Sociology Department of Lakeside Community College has 12 dedicated faculty members. (a) In how many ways can a three-member textbook selection committee be formed? (b) If the department is in need of a Department Chair, Curriculum Chair, and Technology Chair, in how many ways can the positions be filled?

Solution ▶

a. Since textbook selection depends on a *C*ommittee of *C*olleagues, the order members are chosen is not important. This is a *C*ombination of 12 people taken 3 at a time, and there are ${}_{12}C_3 = 220$ ways the committee can be formed.

b. Since those selected will have *P*osition or *P*riority, this is a *P*ermutation of 12 people taken 3 at a time, giving ${}_{12}P_3 = 1320$ ways the positions can be filled.

Now try Exercises 67 through 78 ▶

☑ **E.** You've just seen how we can quick-count using combinations

The Exercise Set contains a wide variety of additional applications. **See Exercises 81 through 107.**

11.5 EXERCISES

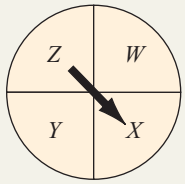
▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. A(n) _____ is any task that can be repeated and has a(n) _____ set of possible outcomes.

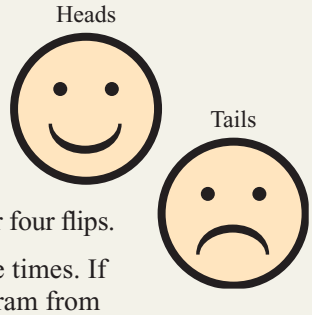
2. When unique elements of a set are rearranged, the result is called a(n) _____ permutation.

3. If an experiment has N equally likely outcomes and is repeated t times, the number of elements in the sample space is given by _____.



4. If some elements of a group are identical, certain rearrangements are identical and the result is a(n) _____ permutation.

5. A three-digit number is formed from digits 1 to 9. Explain how forming the number with repetition differs from forming it without repetition.



6. Discuss/Explain the difference between a permutation and a combination. Try to think of new ways to help remember the distinction.

▶ DEVELOPING YOUR SKILLS

7. For the spinner shown here, (a) draw a tree diagram illustrating all possible outcomes for two spins and (b) create an ordered list showing all possible outcomes for two spins.

8. For the fair coin shown here, (a) draw a tree diagram illustrating all possible outcomes for four flips and (b) create an ordered list showing the possible outcomes for four flips.

9. A fair coin is flipped five times. If you extend the tree diagram from Exercise 8, how many possibilities are there?

10. A spinner has the two equally likely outcomes *A* or *B* and is spun four times. How is this experiment related to the one in Exercise 8? How many possibilities are there?

11. An inexpensive lock uses the numbers 0 to 24 for a three-number combination. How many different combinations are possible?

12. Grades at a local college consist of A, B, C, D, F, and W. If four classes are taken, how many different report cards are possible?

License plates. In a certain (English-speaking) country, license plates for automobiles consist of two letters followed by one of four symbols (■, ◆, ○, **or** ●), followed by three digits. How many license plates are possible if

13. Repetition is allowed?

14. Repetition is not allowed?

15. A remote access door opener requires a five-digit (1–9) sequence. How many sequences are possible if (a) repetition is allowed? (b) repetition is not allowed?

16. An instructor is qualified to teach Math 020, 030, 140, and 160. How many different four-course schedules are possible if (a) repetition is allowed? (b) repetition is not allowed?

Use the fundamental principle of counting and other quick-counting techniques to respond.

17. **Menu items:** At Joe's Diner, the manager is offering a dinner special that consists of one choice of entree (chicken, beef, soy meat, or pork), two vegetable servings (corn, carrots, green beans, peas, broccoli, or okra), and one choice of pasta, rice, or potatoes. How many different meals are possible?

18. **Getting dressed:** A frugal businessman has five shirts, seven ties, four pairs of dress pants, and three pairs of dress shoes. Assuming that all possible arrangements are appealing, how many different shirt-tie-pants-shoes outfits are possible?

19. **Number combinations:** How many four-digit numbers can be formed using the even digits 0, 2, 4, 6, 8, if (a) no repetitions are allowed; (b) repetitions are allowed; (c) repetitions are not allowed and the number must be less than 6000 and divisible by 10.

20. **Number combinations:** If I was born in March, April, or May, after the 19th but before the 30th, and after 1949 but before 1981, how many different MM–DD–YYYY dates are possible for my birthday?

Seating arrangements: William, Xayden, York, and Zelda decide to sit together at the movies. How many ways can they be seated if

21. They sit in random order?

22. York must sit next to Zelda?

23. York and Zelda must be on the outside?

24. William must have the aisle seat?

Course schedule: A college student is trying to set her schedule for the next semester and is planning to take five classes: English, art, math, fitness, and science. How many different schedules are possible if

25. The classes can be taken in any order.

26. She wants her science class to immediately follow her math class.

27. She wants her English class to be first and her fitness class to be last.

28. She can't decide on the best order and simply takes the classes in alphabetical order.

Find the value of ${}_nP_r$ in two ways: (a) compute r factors of $n!$ and (b) use the formula ${}_nP_r = \dfrac{n!}{(n-r)!}$.

29. ${}_{10}P_3$ 30. ${}_{12}P_2$ 31. ${}_9P_4$

32. ${}_5P_3$ 33. ${}_8P_7$ 34. ${}_8P_1$

Determine the number of three-letter permutations of the letters given, then use an organized list to write them all out. How many of them are actually words or common names?

35. T, R, and A **36.** P, M, and A

37. The regional manager for an office supply store needs to replace the manager and assistant manager at the downtown store. In how many ways can this be done if she selects the personnel from a group of 10 qualified applicants?

38. The local chapter of Mu Alpha Theta will soon be electing a president, vice-president, and treasurer. In how many ways can the positions be filled if the chapter has 15 members?

39. The local school board is going to select a principal, vice-principal, and assistant vice-principal from a pool of eight qualified candidates. In how many ways can this be done?

40. From a pool of 32 applicants, a board of directors must select a president, vice-president, labor relations liaison, and a director of personnel for the company's day-to-day operations. Assuming all applicants are qualified and willing to take on any of these positions, how many ways can this be done?

41. A hugely popular chess tournament now has six finalists. Assuming there are no ties, (a) in how many ways can the finalists place in the final round? (b) In how many ways can they finish first, second, and third? (c) In how many ways can they finish if it's sure that Roberta Fischer is going to win the tournament and that Geraldine Kasparov will come in sixth?

42. A field of 10 horses has just left the paddock area and is heading for the gate. Assuming there are no ties in the big race, (a) in how many ways can the horses place in the race? (b) In how many ways can they finish in the win, place, or show positions? (c) In how many ways can they finish if it's sure that John Henry III is going to win, Seattle Slew III will come in second (place), and either Dumb Luck II or Calamity Jane I will come in tenth?

Assuming all multiple births are identical and the children cannot be told apart, how many distinguishable photographs can be taken of a family of six, if they stand in a single row and there is

43. one set of twins

44. one set of triplets

45. one set of twins and one set of triplets

46. one set of quadruplets

47. How many distinguishable numbers can be made by rearranging the digits of 105,001?

48. How many distinguishable numbers can be made by rearranging the digits in the palindrome 1,234,321?

How many distinguishable permutations can be formed from the letters of the given word?

49. logic **50.** leave

51. lotto **52.** levee

A Scrabble player (see Example 7) has the six letters shown remaining in her rack. How many distinguishable, six-letter permutations can be formed? (If all six letters are played, what was the word?)

53. A, A, A, N, N, B

54. D, D, D, N, A, E

Find the value of ${}_nC_r$: (a) using ${}_nC_r = \dfrac{{}_nP_r}{r!}$ (r factors of $n!$ over $r!$) and (b) using ${}_nC_r = \dfrac{n!}{r!(n-r)!}$.

55. ${}_9C_4$ **56.** ${}_{10}C_3$ **57.** ${}_8C_5$

58. ${}_6C_3$ **59.** ${}_6C_6$ **60.** ${}_6C_0$

Use a calculator to verify that each pair of combinations is equal.

61. ${}_9C_4$, ${}_9C_5$ **62.** ${}_{10}C_3$, ${}_{10}C_7$

63. ${}_8C_5$, ${}_8C_3$ **64.** ${}_7C_2$, ${}_7C_5$

65. A platoon leader needs to send four soldiers to do some reconnaissance work. There are 12 soldiers in the platoon and each soldier is assigned a number between 1 and 12. The numbers 1 through 12 are placed in a helmet and drawn randomly. If a soldier's number is drawn, then that soldier goes on the mission. In how many ways can the reconnaissance team be chosen?

66. Seven colored balls (red, indigo, violet, yellow, green, blue, and orange) are placed in a bag and three are then withdrawn. In how many ways can the three colored balls be drawn?

67. When the company's switchboard operators went on strike, the company president asked for three volunteers from among the managerial ranks to temporarily take their place. In how many ways can the three volunteers "step forward," if there are 14 managers and assistant managers in all?

68. Becky has identified 12 books she wants to read this year and decides to take four with her to read while on vacation. She chooses *Pastwatch* by Orson Scott Card for sure, then decides to randomly choose any three of the remaining books. In how many ways can she select the four books she'll end up taking?

69. A new garage band has built up their repertoire to 10 excellent songs that really rock. Next month they'll be playing in a *Battle of the Bands* contest, with the winner getting some guaranteed gigs at the city's most popular hot spots. In how many ways can the band select 5 of their 10 songs to play at the contest?

70. Pierre de Guirré is an award-winning chef and has just developed 12 delectable, new main-course recipes for his restaurant. In how many ways can he select three of the recipes to be entered in an international culinary competition?

For each exercise, determine whether a permutation, a combination, counting principles, or a determination of the number of subsets is the most appropriate tool for obtaining a solution, then solve. Some exercises can be completed using more than one method.

71. In how many ways can eight second-grade children line up for lunch?

72. If you flip a fair coin five times, how many different outcomes are possible?

73. Eight sprinters are competing for the gold, silver, and bronze medals. In how many ways can the medals be awarded?

74. Motorcycle license plates are made using two letters followed by three numbers. How many plates can be made if repetition of letters (only) is allowed?

75. A committee of five students is chosen from a class of 20 to attend a seminar. How many different ways can this be done?

76. If onions, cheese, pickles, and tomatoes are available to dress a hamburger, how many different hamburgers can be made?

77. A caterer offers eight kinds of fruit to make various fruit trays. How many different trays can be made using four different fruits?

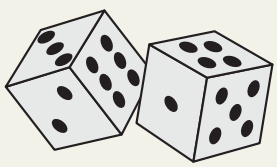
78. Eighteen females try out for the basketball team, but the coach can only place 15 on her roster. How many different teams can be formed?

▶ WORKING WITH FORMULAS

79. Stirling's Formula: $n! \approx \sqrt{2\pi} \cdot (n^{n+0.5}) \cdot e^{-n}$
Values of $n!$ grow very quickly as n gets larger (13! is already in the billions). For some applications, scientists find it useful to use the approximation for $n!$ shown, called Stirling's Formula.

a. Compute the value of 7! on your calculator, then use Stirling's Formula with $n = 7$. By what percent does the approximate value differ from the true value?

b. Compute the value of 10! on your calculator, then use Stirling's Formula with $n = 10$. By what percent does the approximate value differ from the true value?



80. Factorial formulas: For $n, k \in \mathbb{W}$, where $n > k$, $\dfrac{n!}{(n-k)!} = n(n-1)(n-2)\cdots(n-k+1)$

a. Verify the formula for $n = 7$ and $k = 5$.

b. Verify the formula for $n = 9$ and $k = 6$.

▶ APPLICATIONS

81. Yahtzee: In the game of "Yahtzee"® (Milton Bradley) five dice are rolled simultaneously on the first turn in an attempt to obtain various arrangements (worth various point values). How many different arrangements are possible?

82. Twister: In the game of "Twister"® (Milton Bradley) a simple spinner is divided into four quadrants designated Left Foot (LF), Right Hand (RH), Right Foot (RF), and Left Hand (LH), with four different color possibilities in each quadrant (red, green, yellow, blue). Determine the number of possible outcomes for three spins.

83. Clue: In the game of "Clue"® (Parker Brothers) a crime is committed in one of nine rooms, with one of six implements, by one of six people. In how many different ways can the crime be committed?

Phone numbers in North America have 10 digits: a three-digit area code, a three-digit exchange number, and the four final digits that make each phone number unique. Neither area codes nor exchange numbers can start with 0 or 1. Prior to 1994 the second digit of the area code *had to be* a 0 or 1. Sixteen area codes are reserved for special services (such as 911 and 411). In 1994, the last area code was used up and the rules were changed to allow the digits 2 through 9 as the middle digit in area codes.

84. How many different area codes were possible prior to 1994?

85. How many different exchange numbers were possible prior to 1994?

86. How many different phone numbers were possible *prior to* 1994?

87. How many different phone numbers were possible *after* 1994?

Aircraft N-Numbers: In the United States, private aircraft are identified by an "N-Number," which is generally the letter "N" followed by five characters and includes these restrictions: (1) the N-Number can consist of five digits, four digits followed by one letter, or three digits followed by two letters; (2) the first digit cannot be a zero; (3) to avoid confusion with the numbers zero and one, the letters O and I cannot be used; and (4) repetition of digits and letters is allowed. How many unique N-Numbers can be formed

88. that have four digits and one letter?

89. that have three digits and two letters?

90. that have five digits?

91. that have three digits, two letters with no repetitions of any kind allowed?

Seating arrangements: Eight people would like to be seated. Assuming some will have to stand, in how many ways can the seats be filled if the number of seats available is

92. eight

93. five

94. three

95. one

Seating arrangements: In how many different ways can eight people (six students and two teachers) sit in a row of eight seats if

96. the teachers must sit on the ends

97. the teachers must sit together

Television station programming: A television station needs to fill eight half-hour slots for its Tuesday evening schedule with eight programs. In how many ways can this be done if

98. there are no constraints

99. *Seinfeld* must have the 8:00 P.M. slot

100. *Seinfeld* must have the 8:00 P.M. slot and *The Drew Carey Show* must be shown at 6:00 P.M.

101. *Friends* can be aired at 7:00 or 9:00 P.M. and *Everybody Loves Raymond* can be aired at 6:00 or 8:00 P.M.

Scholarship awards: Fifteen students at Roosevelt Community College have applied for six available scholarship awards. How many ways can the awards be given if

102. there are six different awards given to six different students

103. there are six identical awards given to six different students

Committee composition: The local city council has 10 members and is trying to decide if they want to be governed by a committee of three people or by a president, vice-president, and secretary.

104. If they are to be governed by committee, how many unique committees can be formed?

105. How many different president, vice-president, and secretary possibilities are there?

106. Team rosters: A soccer team has three goalies, eight defensive players, and eight forwards on its roster. How many different starting line-ups can be formed (one goalie, three defensive players, and three forwards)?

107. e-mail addresses: A business wants to standardize the e-mail addresses of its employees. To make them easier to remember and use, they consist of two letters and two digits (followed by @esmtb.com), with zero being excluded from use as the first digit and no repetition of letters or digits allowed. Will this provide enough unique addresses for their 53,000 employees worldwide?

▶ EXTENDING THE CONCEPT

Tic-Tac-Toe: In the game *Tic-Tac-Toe,* players alternately write an "X" or an "O" in one of nine squares on a 3×3 grid. If either player gets three in a row horizontally, vertically, or diagonally, that player wins. If all nine squares are played with neither person winning, the game is a draw. Assuming "X" always goes first,

108. How many different "ending boards" are possible if the game ends after five plays?

109. How many different "ending boards" are possible if the game ends after six plays?

▶ MAINTAINING YOUR SKILLS

110. (9.3) Solve the given system of linear inequalities by graphing. Shade the feasible region.

$$\begin{cases} 2x + y < 6 \\ x + 2y < 6 \\ x \geq 0 \\ y \geq 0 \end{cases}$$

111. (6.2) Given $\sin\theta = \dfrac{12}{13}$, determine the other five trig functions of the acute angle θ.

112. (7.3) Rewrite $\cos(2\alpha)\cos(3\alpha) - \sin(2\alpha)\sin(3\alpha)$ as a single expression.

113. (10.3) Graph the hyperbola that is defined by

$$\frac{(x-2)^2}{4} - \frac{(y+3)^2}{9} = 1.$$

11.6 Introduction to Probability

LEARNING OBJECTIVES

In Section 11.6 you will see how we can:

- ❑ **A.** Define an event on a sample space
- ❑ **B.** Compute elementary probabilities
- ❑ **C.** Use certain properties of probability
- ❑ **D.** Compute probabilities using quick-counting techniques
- ❑ **E.** Compute probabilities involving nonexclusive events

There are few areas of mathematics that give us a better view of the world than **probability** and **statistics.** Unlike statistics, which seeks to analyze and interpret data, probability (for our purposes) attempts to use observations and data to make statements concerning the likelihood of future events. Such predictions of what *might* happen have found widespread application in such diverse fields as politics, manufacturing, gambling, opinion polls, product life, and many others. In this section, we develop the basic elements of probability.

A. Defining an Event

In Section 11.5 we defined the following terms: experiment and sample outcome. Flipping a coin twice in succession is an *experiment,* and two sample outcomes are HH and HT. An **event *E*** is *any designated set of sample outcomes,* and is a subset of the sample space. One event might be E_1: (two heads occur), another possibility is E_2: (at least one tail occurs).

EXAMPLE 1 ▶ Stating a Sample Space and Defining an Event

Consider the experiment of rolling one standard, six-sided die (plural is dice). State the sample space S and define any two events relative to S.

Solution ▶ S is the set of all possible outcomes, so $S = \{1, 2, 3, 4, 5, 6\}$. Two possible events are E_1: (a 5 is rolled) and E_2: (an even number is rolled).

Now try Exercises 7 through 10 ▶

☑ **A.** You've just seen how we can define an event on a sample space

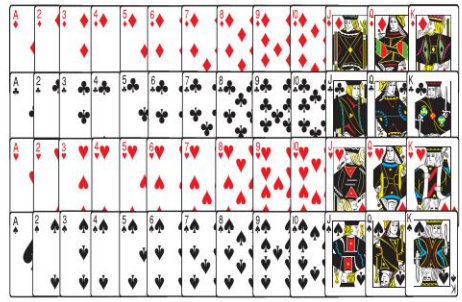
B. Elementary Probability

When rolling a die, we know the result can be any of the six equally likely outcomes in the sample space, so the chance of E_1:(a five is rolled) is $\frac{1}{6}$. Since three of the elements in S are even numbers, the chance of E_2:(an even number is rolled) is $\frac{3}{6} = \frac{1}{2}$. This suggests the following definition.

The Probability of an Event *E*

Given S is a sample space of equally likely events and E is an event relative to S, the probability of E, written $P(E)$, is computed as

$$P(E) = \frac{n(E)}{n(S)}$$



where $n(E)$ represents the number of elements in E, and $n(S)$ represents the number of elements in S.

WORTHY OF NOTE

Our study of probability will involve only those sample spaces with events that are equally likely.

A standard deck of playing cards consists of 52 cards divided in four groups or *suits*. There are 13 hearts (♥), 13 diamonds (◆), 13 spades (♠), and 13 clubs (♣). As you can see in Figure 11.60, each of the 13 cards in a suit is labeled A, 2, 3, 4, 5, 6, 7, 8, 9, 10, J, Q, and K. Also notice that 26 of the cards are red (hearts and diamonds), 26 are black (spades and clubs), and 12 of the cards are "face cards" (J, Q, K of each suit).

Figure 11.60

EXAMPLE 2 ▶ **Stating a Sample Space and the Probability of a Single Outcome**

A single card is drawn from a well-shuffled deck. Define S and state the probability of any single outcome. Then define E as *a King is drawn* and find $P(E)$.

Solution ▶ Sample space: $S = \{\text{the 52 cards}\}$. There are 52 equally likely outcomes, so the probability of any one outcome is $\frac{1}{52}$. Since S has four Kings,

$$P(E) = \frac{n(E)}{n(S)} = \frac{4}{52} \text{ or about } 0.077.$$

Now try Exercises 11 through 14 ▶

EXAMPLE 3 ▶ **Stating a Sample Space and the Probability of a Single Outcome**

A family of five has two girls and three boys named Sophie, Maria, Albert, Isaac, and Pythagoras. Their ages are 21, 19, 15, 13, and 9, respectively. One is to be selected randomly. Find the probability a teenager is chosen.

Solution ▶ The sample space is $S = \{9, 13, 15, 19, 21\}$. Three of the five are teenagers, meaning the probability is $\frac{3}{5}$, 0.6, or 60%.

Now try Exercises 15 and 16 ▶

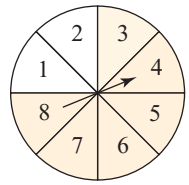
☑ **B.** You've just seen how we can compute elementary probabilities

C. Properties of Probability

WORTHY OF NOTE
In probability studies, the tilde "~" acts as a negation symbol. For any event E defined on the sample space, $\sim E$ means the event does not occur.

A study of probability necessarily includes recognizing some basic and fundamental properties. For example, when a fair die is rolled, what is $P(E)$ if E is defined as a *1, 2, 3, 4, 5, or 6* is rolled? The event E will occur 100% of the time, since 1, 2, 3, 4, 5, 6 are the only possibilities. In symbols we write P(outcome is in the sample space) or simply $P(S) = 1$ (100%).

What percent of the time will a result *not* in the sample space occur? Since the die has only the six sides numbered 1 through 6, the probability of rolling something else is zero. In symbols, P(outcome is not in sample space) $= 0$ or simply $P(\sim S) = 0$.



Properties of Probability

Given sample space S and any event E defined relative to S.

1. $P(S) = 1$ **2.** $P(\sim S) = 0$ **3.** $0 \le P(E) \le 1$

EXAMPLE 4 ▶ **Determining the Probability of an Event**

A game is played using a spinner like the one shown. Determine the probability of the following events:

E_1: A nine is spun. E_2: An integer greater than 0 and less than 9 is spun.

Solution ▶ The sample space consists of eight equally likely outcomes.

$$P(E_1) = \frac{0}{8} = 0 \qquad P(E_2) = \frac{8}{8} = 1.$$

Technically, E_1: A nine is spun is not an "event," since it is not in the sample space and cannot occur, while E_2 contains the entire sample space and must occur.

Now try Exercises 17 and 18 ▶

Because we know $P(S) = 1$ and all sample outcomes are equally likely, the probabilities of all single events defined on the sample space must sum to 1. For the experiment of rolling a fair die, the sample space has six outcomes that are equally likely. Note that $P(1) = P(2) = P(3) = P(4) = P(5) = P(6) = \frac{1}{6}$, and $\frac{1}{6} + \frac{1}{6} + \frac{1}{6} + \frac{1}{6} + \frac{1}{6} + \frac{1}{6} = 1$.

Probability and Sample Outcomes

Given a sample space S with n equally likely sample outcomes $s_1, s_2, s_3, \ldots, s_n$.

$$\sum_{i=1}^{n} P(s_i) = P(s_1) + P(s_2) + P(s_3) + \cdots + P(s_n) = 1$$

The **complement** of an event E is the set of sample outcomes in S not contained in E. Symbolically, $\sim E$ is the complement of E.

Probability and Complementary Events

Given sample space S and any event E defined relative to S, the complement of E, written $\sim E$, is the set of all outcomes not in E and:

1. $P(E) = 1 - P(\sim E)$ **2.** $P(E) + P(\sim E) = 1$

EXAMPLE 5 ▶ **Stating a Probability Using Complements**

Use complementary events to answer the following questions:

a. A single card is drawn from a well-shuffled deck. What is the probability that it is not a diamond?

b. A single letter is picked at random from the letters in the word "divisibility." What is the probability it is not an "i"?

Solution ▶

a. Since there are 13 diamonds in a standard 52-card deck:
$P(\sim D) = 1 - P(D) = 1 - \frac{13}{52} = \frac{39}{52} = 0.75$.

b. Of the 12 letters in d-i-v-i-s-i-b-i-l-i-t-y, 5 are "i's." This means $P(\sim i) = 1 - P(i)$, or $1 - \frac{5}{12} = \frac{7}{12}$. The probability of choosing a letter other than i is $0.58\overline{3}$.

WORTHY OF NOTE

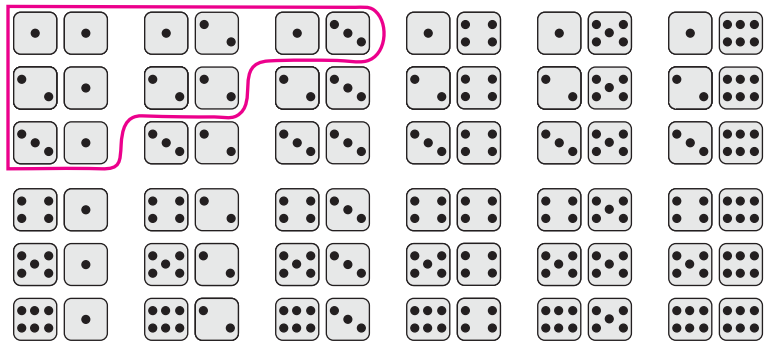
Probabilities can be written in fraction form, decimal form, or as a percent. For $P(\sim D)$ from Example 5(a), the probability could be written $\frac{3}{4}$, 0.75, or 75%.

Now try Exercises 19 through 22 ▶

EXAMPLE 6 ▶ **Stating a Probability Using Complements**

Inter-Island Waterways has just opened hydrofoil service between several islands. The hydrofoil is powered by two engines, one forward and one aft, and will operate if either of its two engines is functioning. Due to testing and past experience, the company knows the probability of the aft engine failing is $P(\text{aft engine fails}) = 0.05$, the probability of the forward engine failing is $P(\text{forward engine fails}) = 0.03$, and the probability that both fail is $P(\text{both engines simultaneously fail}) = 0.012$. What is the probability the hydrofoil completes its next trip?

Solution ▶ Although the answer may *seem* complicated, note that $P(\text{trip is completed})$ and $P(\text{both engines simultaneously fail})$ are complements.



$$\begin{aligned} P(\text{trip is completed}) &= 1 - P(\text{both engines simultaneously fail}) \\ &= 1 - 0.012 \\ &= 0.988 \end{aligned}$$

There is close to a 99% probability the trip will be completed.

Now try Exercises 23 and 24 ▶

The chart in Figure 11.61 shows all 36 possible outcomes (the sample space) from the experiment of rolling two fair dice.

Figure 11.61

EXAMPLE 7 ▶ **Stating a Probability Using Complements**

Two fair dice are rolled. What is the probability the sum of both dice is greater than or equal to 5, $P(\text{sum} \geq 5)$?

Solution ▶ See Figure 11.61. For $P(\text{sum} \geq 5)$ it may be easier to use complements as there are far fewer possibilities: $P(\text{sum} \geq 5) = 1 - P(\text{sum} < 5)$, which gives

$$1 - \frac{6}{36} = 1 - \frac{1}{6} = \frac{5}{6} = 0.8\overline{3}.$$

C. You've just seen how we can use certain properties of probability

Now try Exercises 25 and 26 ▶

D. Probability and Quick-Counting

Quick-counting techniques were introduced earlier to help count the number of elements in a large or more complex sample space, and the number of sample outcomes in an event.

EXAMPLE 8A ▶ **Stating a Probability Using Combinations**

Five cards are drawn from a shuffled 52-card deck. Calculate the probability of E_1:(*all five cards are face cards*) or E_2:(*all five cards are hearts*).

Solution ▶ The sample space for both events consists of all five-card groups that can be formed from the 52 cards or ${}_{52}C_5$. For E_1 we are to select five face cards from the 12 that are available (three from each suit), or ${}_{12}C_5$. The probability of five face cards is $\dfrac{n(E)}{n(S)} = \dfrac{{}_{12}C_5}{{}_{52}C_5}$, which gives $\dfrac{792}{2{,}598{,}960} \approx 0.0003$. For E_2 we are to select five hearts from the 13 available, or ${}_{13}C_5$. The probability of five hearts is $\dfrac{n(E)}{n(S)} = \dfrac{{}_{13}C_5}{{}_{52}C_5}$, which is $\dfrac{1287}{2{,}598{,}960} \approx 0.0005$.

WORTHY OF NOTE
It seems reasonable that the probability of 5 hearts is slightly higher, as 13 of the 52 cards are hearts, while only 12 are face cards.

EXAMPLE 8B ▶ **Stating a Probability Using Combinations and the Fundamental Principle of Counting**

Of the 42 seniors at Jacoby High School, 23 are female and 19 are male. A group of five students is to be selected at random to attend a conference in Reno, Nevada. What is the probability the group will have exactly three females?

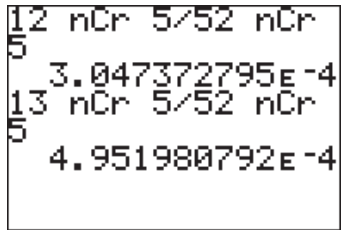
Solution ▶ The sample space consists of all five-person groups that can be formed from the 42 seniors or ${}_{42}C_5$. The event consists of selecting 3 females from the 23 available (${}_{23}C_3$) and 2 males from the 19 available (${}_{19}C_2$). Using the fundamental principle of counting $n(E) = {}_{23}C_3 \cdot {}_{19}C_2$ and the probability the group has 3 females is $\dfrac{n(E)}{n(S)} = \dfrac{{}_{23}C_3 \cdot {}_{19}C_2}{{}_{42}C_5}$, which gives $\dfrac{302{,}841}{850{,}668} \approx 0.356$. There is approximately a 35.6% probability the group will have exactly 3 females.

Now try Exercises 27 through 34 ▶

While the fundamentals of probability are usually introduced using dice, cards, and very basic applications, this should not take away from its true power and utility. We use probability to help us to analyze things quantitatively (with numbers) so that important decisions can be made. In manufacturing, the probability a product becomes defective during its warranty period is crucial to the company's financial stability. Health organizations rely heavily on probability to plan against the anticipated spread

of a symptom through a given population. In these and many other situations, the sample spaces are very large and the defined events likewise large, making the use of technology an integral part of probability studies. The computed result of Example 8A is shown in Figure 11.62 (in scientific notation—shift the decimal four places to the left). The computed result of Example 8B appears in Figure 11.63.

Figure 11.62



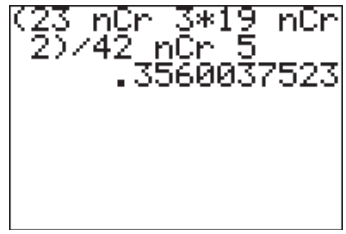


Figure 11.63

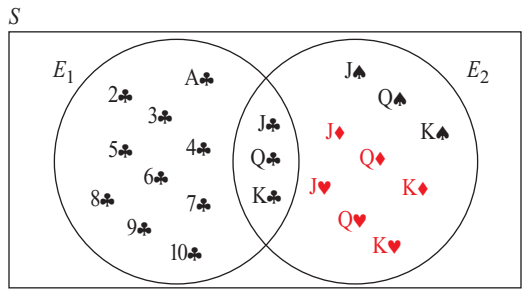


☑ **D.** You've just seen how we can compute probabilities using quick-counting techniques

E. Probability and Nonexclusive Events

Sometimes the way events are defined causes them to share sample outcomes. Using a standard deck of playing cards once again, if we define the events E_1:(a club is drawn) and E_2:(a face card is drawn), they share the outcomes J♣, Q♣, and K♣ as shown in Figure 11.64. This overlapping region is the intersection of the events, or $E_1 \cap E_2$. If we compute $n(E_1 \cup E_2)$ as $n(E_1) + n(E_2)$ as before, this intersecting region gets counted *twice*!

Figure 11.64

WORTHY OF NOTE

This can be verified by simply counting the elements involved: $n(E_1) = 13$ and $n(E_2) = 12$ so $n(E_1) + n(E_2) = 25$. However, there are only 22 possibilities in $E_1 \cup E_2$—the J♣, Q♣, and K♣ got counted twice.

In cases where the events are **nonexclusive** (not mutually exclusive), we maintain the correct count by subtracting one of the two intersections, obtaining $n(E_1 \cup E_2) = n(E_1) + n(E_2) - n(E_1 \cap E_2)$. This leads to the following calculation for the probability of nonexclusive events:

$$P(E_1 \cup E_2) = \frac{n(E_1) + n(E_2) - n(E_1 \cap E_2)}{n(S)} \quad \text{definition of probability}$$

$$= \frac{n(E_1)}{n(S)} + \frac{n(E_1)}{n(S)} - \frac{n(E_1 \cap E_2)}{n(S)} \quad \text{property of rational expressions}$$

$$= P(E_1) + P(E_2) - P(E_1 \cap E_2) \quad \text{definition of probability}$$

Probability and Nonexclusive Events

Given sample space S and *nonexclusive events* E_1 and E_2 defined relative to S, the probability of E_1 *or* E_2 is given by

$$P(E_1 \cup E_2) = P(E_1) + P(E_2) - P(E_1 \cap E_2)$$

EXAMPLE 9A ▶ Stating the Probability of Nonexclusive Events

What is the probability that a club or a face card is drawn from a standard deck of 52 well-shuffled cards?

Solution ▶ As before, define the events E_1:(a club is drawn) and E_2:(a face card is drawn). Since there are 13 clubs and 12 face cards, $P(E_1) = \frac{13}{52}$ and $P(E_2) = \frac{12}{52}$. But three of the face cards are clubs, so $P(E_1 \cap E_2) = \frac{3}{52}$. This leads to

$$\begin{aligned} P(E_1 \cup E_2) &= P(E_1) + P(E_2) - P(E_1 \cap E_2) && \text{nonexclusive events} \\ &= \frac{13}{52} + \frac{12}{52} - \frac{3}{52} && \text{substitute} \\ &= \frac{22}{52} \approx 0.423 && \text{combine terms} \end{aligned}$$

There is about a 42% probability that a club or face card is drawn.

EXAMPLE 9B ▶ **Stating the Probability of Nonexclusive Events**

A survey of 100 voters was taken to gather information on critical issues and the demographic information collected is shown in the table. One out of the 100 voters is to be drawn at random to be interviewed on the 5 P.M. News. What is the probability the person is a woman (W) or a Republican (R)?

	Women	Men	Totals
Republican	17	20	37
Democrat	22	17	39
Independent	8	7	15
Green Party	4	1	5
Tax Reform	2	2	4
Totals	53	47	100

Solution ▶ Since there are 53 women and 37 Republicans, $P(W) = 0.53$ and $P(R) = 0.37$. The table shows 17 people are both female and Republican so $P(W \cap R) = 0.17$.

$$\begin{aligned} P(W \cup R) &= P(W) + P(R) - P(W \cap R) && \text{nonexclusive events} \\ &= 0.53 + 0.37 - 0.17 && \text{substitute} \\ &= 0.73 && \text{combine} \end{aligned}$$

There is a 73% probability the person is a woman or a Republican.

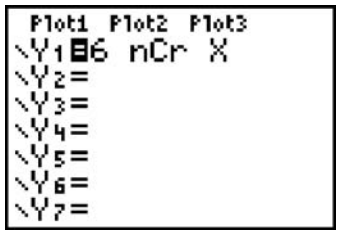
Now try Exercises 35 through 48 ▶

Two events that have no common outcomes are called **mutually exclusive** events (one excludes the other and vice versa). For example, in rolling one die, E_1:(*a 2 is rolled*) and E_2:(*an odd number is rolled*) are mutually exclusive, since 2 is not an odd number. For the probability of E_3:(*a 2 is rolled* or *an odd number is rolled*), we note that $n(E_1 \cap E_2) = 0$ and the previous formula simply reduces to $P(E_1) + P(E_2)$. **See Exercises 49 and 50.** There is a large variety of additional applications in the Exercise Set. **See Exercises 53 through 68.**

When probability calculations require a repeated use of permutations or combinations, tables can make the work more efficient and help to explore the patterns they generate. For instance, to choose r children from a group of six children ($n = 6$), we can set **TBLSET** to **AUTO,** then press Y= and enter $6\ {}_nC_r\ X$ as Y_1 (Figure 11.65). Access the **TABLE** (2nd GRAPH) and note that the calculator has automatically computed the value of ${}_6C_0$, ${}_6C_1$, ${}_6C_2$, … , ${}_6C_6$ (Figure 11.66) and the pattern of outputs is symmetric. For calculations like those required in Example 8B (${}_{23}C_3 \cdot {}_{19}C_2$), we can enter $Y_1 = 23\ {}_nC_r\ X$, $Y_2 = 19\ {}_nC_r\ (5 - X)$, and $Y_3 = Y_1 \cdot Y_2$ to further explore the number of ways groups with different numbers of females can be chosen. Also **see Exercise 70.**

☑ **E.** You've just seen how we can compute probabilities involving nonexclusive events

Figure 11.65



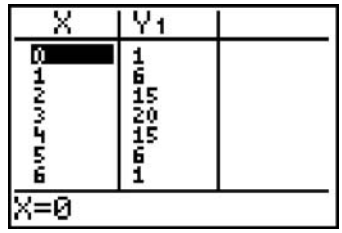


Figure 11.66

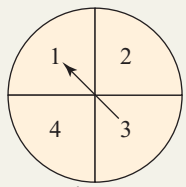
11.6 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.



1. Given a sample space S and an event E defined relative to S, $P(E) = \frac{\quad}{n(S)}$.
2. In elementary probability, we consider all events in the sample space to be _____ likely.
3. Given a sample space S and an event E defined relative to S: ___ $\le P(E) \le$ ___, $P(S) =$ ___, and $P(\sim S) =$ ___.
4. The _____ of an event E is the set of sample outcomes in S which are not contained in E.
5. Discuss/Explain the difference between mutually exclusive events and nonexclusive events. Give an example of each.
6. A single die is rolled. With no calculations, explain why the probability of rolling an even number is greater than rolling a number greater than four.

▶ DEVELOPING YOUR SKILLS

State the sample space *S* and the probability of a single outcome. Then define any two events *E* relative to *S* (many answers possible).

7. Two fair coins (heads and tails) are flipped.
8. The simple spinner shown is spun.

Exercise 8

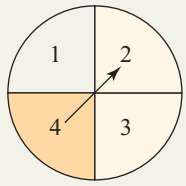
9. The head coaches for six little league teams (the Patriots, Cougars, Angels, Sharks, Eagles, and Stars) have gathered to discuss new changes in the rule book. One of them is randomly chosen to ask the first question.
10. Experts on the planets Mercury, Venus, Mars, Jupiter, Saturn, Uranus, Neptune, and the Kuiper object formerly known as the planet Pluto have gathered at a space exploration conference. One group of experts is selected at random to speak first.

Find *P*(*E*) for the events defined.

11. Nine index cards numbered 1 through 9 are shuffled and placed in an envelope, then one of the cards is randomly drawn. Define event E as *the number drawn is even.*
12. Eight flash cards used for studying basic geometric shapes are shuffled and one of the cards is drawn at random. The eight cards include information on circles, squares, rectangles, kites, trapezoids, parallelograms, pentagons, and triangles. Define event E as *a quadrilateral is drawn.*
13. One card is drawn at random from a standard deck of 52 cards. What is the probability of
    - **a.** drawing a Jack
    - **b.** drawing a spade
    - **c.** drawing a black card
    - **d.** drawing a red three

14. Pinochle is a card game played with a deck of 48 cards consisting of 2 Aces, 2 Kings, 2 Queens, 2 Jacks, 2 Tens, and 2 Nines in each of the four standard suits [hearts (♥), diamonds (◆), spades (♠), and clubs (♣)]. If one card is drawn at random from this deck, what is the probability of

a. drawing an Ace **b.** drawing a club



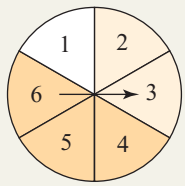
c. drawing a red card

d. drawing a face card (Jack, Queen, King)

15. A group of finalists on a game show consists of three males and five females. Hank has a score of 520 points, with Harry and Hester having 490 and 475 points, respectively. Madeline has 532 points, with Mackenzie, Morgan, Maggie, and Melanie having 495, 480, 472, and 470 points, respectively. One of the contestants is randomly selected to start the final round. Define E_1 as *Hester is chosen,* E_2 as *a female is chosen,* and E_3 as *a contestant with fewer than 500 points is chosen.* Find the probability of each event.

16. Soccer coach Maddox needs to fill the last spot on his starting roster for the opening day of the season and has to choose between three forwards and five defenders. The forwards have jersey numbers 5, 12, and 17, while the defenders have jersey numbers 7, 10, 11, 14, and 18. Define E_1 as *a forward is chosen,* E_2 as *a defender is chosen,* and E_3 as *a player whose jersey number is greater than 10 is chosen.* Find the probability of each event.

17. A game is played using a spinner like the one shown. For each spin,



a. What is the probability the arrow lands in a shaded region?

b. What is the probability your spin is less than 5?

c. What is the probability you spin a 2?

d. What is the probability the arrow points to prime number?

18. A game is played using a spinner like the one shown here. For each spin,

a. What is the probability the arrow lands in a lightly shaded region?

b. What is the probability your spin is greater than 2?

c. What is the probability the arrow lands in a shaded region?

d. What is the probability you spin a 5?

Use the complementary events to complete Exercises 19 through 22.

19. One card is drawn from a standard deck of 52. What is the probability it is not a club?

20. Four standard dice are rolled. What is the probability the sum is less than 24?

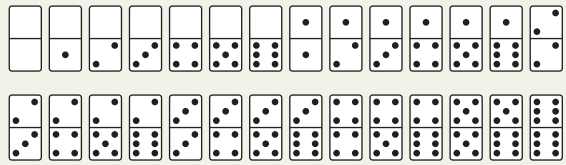
21. A single digit is randomly selected from among the digits of 10!. What is the probability the digit is not a 2?

22. A corporation will be moving its offices to Los Angeles, Miami, Atlanta, Dallas, or Phoenix. If the site is randomly selected, what is the probability Dallas is not chosen?

23. A large manufacturing plant can remain at full production as long as one of its two generators is functioning. Due to past experience and the age difference between the systems, the plant manager estimates the probability of the main generator failing is 0.05, the probability of the secondary generator failing is 0.01, and the probability of both failing is 0.009. What is the probability the plant remains in full production today?

24. A fire station gets an emergency call from a shopping mall in the mid-afternoon. From a study of traffic patterns, Chief Nozawa knows the probability the most direct route is clogged with traffic is 0.07, while the probability of the secondary route being clogged is 0.05. The probability both are clogged is 0.02. What is the probability they can respond to the call unimpeded using one of these routes?

25. Two fair dice are rolled (see Figure 11.61). What is the probability of



a. a sum less than four

b. a sum less than eleven

c. the sum is not nine

d. a roll is not a "double" (both dice the same)

"Double-six" dominos is a game played with the 28 numbered tiles shown in the diagram.

26. The 28 dominos are placed in a bag, shuffled, and then one domino is randomly drawn. What is the probability the total number of dots on the domino

a. is three or less

b. is greater than three

c. does not have a blank half

d. is not a "double" (both sides the same)

Find $P(E)$ given the values for $n(E)$ and $n(S)$ shown.

27. $n(E) = {}_6C_3 \cdot {}_4C_2$; $n(S) = {}_{10}C_5$

28. $n(E) = {}_{12}C_9 \cdot {}_8C_7$; $n(S) = {}_{20}C_{16}$

29. $n(E) = {}_9C_6 \cdot {}_5C_3$; $n(S) = {}_{14}C_9$

30. $n(E) = {}_7C_6 \cdot {}_3C_2$; $n(S) = {}_{10}C_8$

31. Five cards are drawn from a well-shuffled, standard deck of 52 cards. Which has the greater probability: (a) all five cards are red or (b) all five cards are numbered cards? How much greater?

32. Five cards are drawn from a well-shuffled pinochle deck of 48 cards (see Exercise 14). Which has the greater probability, (a) all five cards are face cards (King, Queen, or Jack) or (b) all five cards are black? How much greater?

33. A dietetics class has 24 students. Of these, 9 are vegetarians and 15 are not. The instructor receives enough funding to send six students to a conference. If the students are selected randomly, what is the probability the group will have

a. exactly two vegetarians

b. exactly four nonvegetarians

c. at least three vegetarians

34. A large law firm has a support staff of 15 employees: six paralegals and nine legal assistants. Due to recent changes in the law, the firm wants to send five of them to a forum on the new changes. If the selection is done randomly, what is the probability the group will have

a. exactly three paralegals

b. exactly two legal assistants

c. at least two paralegals

Find the probability indicated using the information given.

35. Given $P(E_1) = 0.7$, $P(E_2) = 0.5$, and $P(E_1 \cap E_2) = 0.3$, compute $P(E_1 \cup E_2)$.

36. Given $P(E_1) = 0.6$, $P(E_2) = 0.3$, and $P(E_1 \cap E_2) = 0.2$, compute $P(E_1 \cup E_2)$.

37. Given $P(E_1) = \frac{3}{8}$, $P(E_2) = \frac{3}{4}$, and $P(E_1 \cup E_2) = \frac{5}{6}$; compute $P(E_1 \cap E_2)$.

38. Given $P(E_1) = \frac{1}{2}$, $P(E_2) = \frac{3}{5}$, and $P(E_1 \cup E_2) = \frac{17}{20}$; compute $P(E_1 \cap E_2)$.

39. Given $P(E_1 \cup E_2) = 0.72$, $P(E_2) = 0.56$, and $P(E_1 \cap E_2) = 0.43$; compute $P(E_1)$.

40. Given $P(E_1 \cup E_2) = 0.85$, $P(E_1) = 0.4$, and $P(E_1 \cap E_2) = 0.21$; compute $P(E_2)$.

41. Two fair dice are rolled. What is the probability the sum of the dice is

a. a multiple of 3 and an odd number

b. a sum greater than 5 and a 3 on one die

c. an even number and a number greater than 9

d. an odd number and a number less than 10

42. *Eight Ball* is a game played on a pool table with 15 balls numbered 1 through 15 and a cue ball that is solid white. Of the 15 numbered balls, 8 are a solid (nonwhite) color and numbered 1 through 8, and seven are striped balls numbered 9 through 15. The fifteen numbered pool balls (no cueball) are placed in a large bowl and mixed, then one is drawn out. What is the probability of drawing

a. the eight ball

b. a number greater than fifteen

c. an even number

d. a multiple of three

e. a solid color and an even number

f. a striped ball and an odd number

g. an even number and a number divisible by 3

h. an odd number and a number divisible by 4

43. A survey of 50 veterans was taken to gather information on their service career and what life is like out of the military. A breakdown of those surveyed is shown in the table. One out of the 50 will be selected at random for an interview and a biographical sketch. What is the probability the person chosen is

	Women	Men	Totals
Private	6	9	15
Corporal	10	8	18
Sergeant	4	5	9
Lieutenant	2	1	3
Captain	2	3	5
Totals	24	26	50

a. a woman and a sergeant
b. a man and a private
c. a private and a sergeant
d. a woman and an officer
e. a person in the military

44. Referring to Exercise 43, what is the probability the person chosen is
a. a woman or a sergeant
b. a man or a private
c. a woman or a man
d. a woman or an officer
e. a captain or a lieutenant

A computer is asked to randomly generate a three-digit number. What is the probability the

45. ten's digit is odd or the one's digit is even

46. first digit is prime and the number is a multiple of 10

A computer is asked to randomly generate a four-digit number. What is the probability the number is

47. at least 4000 or a multiple of 5

48. less than 7000 and an odd number

49. Two fair dice are rolled. What is the probability of
a. boxcars (sum of 12) or snake eyes (sum of 2)
b. a sum of 7 or a sum of 11
c. an even-numbered sum or a prime sum
d. an odd-numbered sum or a sum that is a multiple of 4
e. a sum of 15 or a multiple of 12
f. a sum that is a prime number

50. Suppose all 16 balls from a game of pool (see Exercise 42) are placed in a large leather bag and mixed, then one is drawn out. Consider the cue ball as "0." What is the probability of drawing
a. a striped ball
b. a solid-colored ball
c. a polka-dotted ball
d. the cue ball
e. the cue ball or the eight ball
f. a striped ball or a number less than five
g. a solid color or a number greater than 12
h. an odd number or a number divisible by 4

▶ WORKING WITH FORMULAS

51. Games involving a fair spinner (with numbers 1 through 4): $P(n) = (\frac{1}{4})^n$

Games that involve moving pieces around a board using a fair spinner are fairly common. If a fair spinner has the numbers 1 through 4, the probability that any one number is spun n times in succession is given by the formula shown, where n represents the number of spins. What is the probability (a) the first player spins a two? (b) all four players spin a two? (c) Discuss the graph of $P(n)$ and explain the connection between the graph and the probability of consistently spinning a two.

52. Games involving a fair coin (heads and tails): $P(n) = (\frac{1}{2})^n$

When a fair coin is flipped, the probability that heads (or tails) is flipped n times in a row is given by the formula shown, where n represents the number of flips. What is the probability (a) the first flip is heads? (b) the first four flips are heads? (c) Discuss the graph of $P(n)$ and explain the connection between the graph and the probability of consistently flipping heads.

▶ APPLICATIONS

53. To improve customer service, a company tracks the number of minutes a caller is "on hold" and waiting for a customer service representative. The table shows the probability that a caller will wait m minutes. Based on the table, what is the probability a caller waits
a. at least 2 minutes
b. less than 2 minutes
c. 4 minutes or less
d. over 4 minutes
e. less than 2 or more than 4 minutes
f. 3 or more minutes

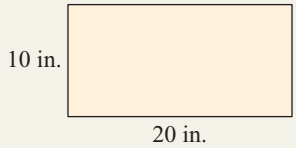
Wait Time (minutes m)	Probability
0	0.07
$0 < m < 1$	0.28
$1 \le m < 2$	0.32
$2 \le m < 3$	0.25
$3 \le m < 4$	0.08

54. To study the impact of technology on American families, a researcher first determines the probability that a family has n computers at home. Based on the table, what is the probability a home

a. has at least one computer

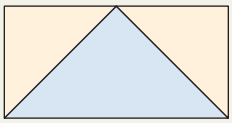
b. has two or more computers

c. has fewer than four computers



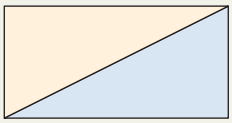
d. has five computers

e. has one, two, or three computers

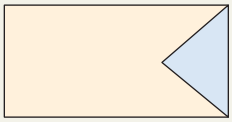


f. does not have two computers

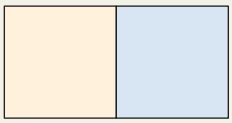
Number of Computers	Probability
0	9%
1	51%
2	28%
3	9%
4	3%



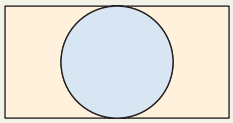
55. Jolene is an experienced markswoman and is able to hit a 10 in. by 20 in. target 100% of the time at a range of 100 yd. Assuming the probability she hits a target is related to its area, what is the probability she hits the shaded portions shown?



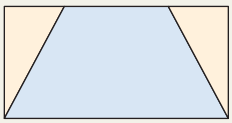
a. isosceles triangle



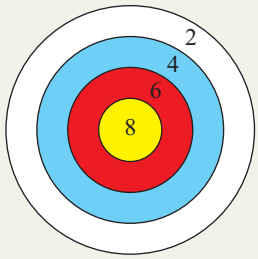
b. right triangle



c. isosceles right triangle

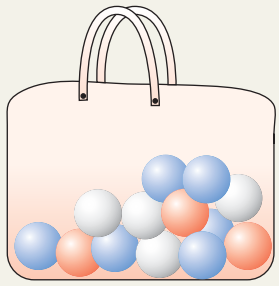


56. **a.** square



b. circle

c. isosceles trapezoid with $b = \frac{B}{2}$



57. A circular dartboard has a total radius of 8 in., with circular bands that are 2 in. wide, as shown. You are skilled enough to hit this board 100% of the time so you always score at least two points each time you throw a dart. Assuming the probabilities are related to area, on the next dart that you throw what is the probability you

a. score at least a 4? **b.** score at least a 6?

c. hit the bull's-eye? **d.** score exactly 4 points?

58. Three red balls, six blue balls, and four white balls are placed in a bag. What is the probability the first ball you draw out is

a. red **b.** blue

c. not white

d. purple

e. red or white

f. red and white

59. Three red balls, six blue balls, and four white balls are placed in a bag, then two are drawn out and placed in a rack. What is the probability the balls drawn are

a. first red, second blue

b. first blue, second red

c. both white

d. first blue, second not red

e. first white, second not blue

f. first not red, second not blue

60. Consider the 210 discrete points found in the first and second quadrants where $-10 \le x \le 10$, $1 \le y \le 10$, and x and y are integers. The coordinates of each point is written on a slip of paper and placed in a box. One of the slips is then randomly drawn. What is the probability the point (x, y) drawn

a. is on the graph of $y = |x|$

b. is on the graph of $y = 2|x|$

c. is on the graph of $y = 0.5|x|$

d. has coordinates $(x, y > -2)$

e. has coordinates $(x \le 5, y > -2)$

f. is between the branches of $y = x^2$

61. Your instructor surprises you with a True/False quiz for which you are totally unprepared and must guess randomly. What is the probability you pass the quiz with an 80% or better if there are

a. three questions

b. four questions

c. five questions

62. A robot is sent out to disarm a timed explosive device by randomly changing some switches from a neutral position to a *positive flow* or *negative flow* position. The problem is, the switches are independent and unmarked, and it is unknown which direction is positive and which direction is negative. The bomb is harmless if a majority of the switches yield a positive flow. All switches must be thrown. What is the probability the device is disarmed if there are

a. three switches

b. four switches

c. five switches

63. A survey of 100 retirees was taken to gather information concerning how they viewed the Vietnam War back in the early 1970s. A breakdown of those surveyed is shown in the table. One out of the hundred will be selected at random for a personal, taped interview. What is the probability the person chosen had a

a. career of any kind and opposed the war

b. medical career and supported the war

c. military career and opposed the war

d. legal or business career and opposed the war

e. academic or medical career and supported the war

Career	Support	Opposed	Total
Military	9	3	12
Medical	8	16	24
Legal	15	12	27
Business	18	6	24
Academics	3	10	13
Totals	53	47	100

64. Referring to Exercise 63, what is the probability the person chosen

a. had a career of any kind or opposed the war

b. had a medical career or supported the war

c. supported the war or had a military career

d. had a medical or a legal career

e. supported or opposed the war

65. The Board of Directors for a large hospital has 15 members. There are six doctors of nephrology (kidneys), five doctors of gastroenterology (stomach and intestines), and four doctors of endocrinology (hormones and glands). Eight of them will be selected to visit the nation's premier hospitals on a 3-week, expenses-paid tour. What is the probability the group of eight selected consists of exactly

a. four nephrologists and four gastroenterologists

b. three endocrinologists and five nephrologists

66. A support group for hodophobics (an irrational fear of travel) has 32 members. There are 15 aviophobics (fear of air travel), eight siderodrophobics (fear of train travel), and nine thalassophobics (fear of ocean travel) in the group. Twelve of them will be randomly selected to participate in a new therapy. What is the probability the group of 12 selected consists of exactly

a. two aviophobics, six siderodrophobics, and four thalassophobics

b. five thalassophobics, four aviophobics, and three siderodrophobics

67. A trained chimpanzee is given a box containing eight wooden cubes with the letters p, a, r, a, l, l, e, l printed on them (one letter per block). Assuming the chimp can't read or spell, what is the probability he draws the eight blocks in order and actually forms the word "parallel"?

68. A number is called a "perfect number" if the sum of its proper factors is equal to the number itself. Six is the first perfect number since the sum of its proper factors is six: $1 + 2 + 3 = 6$. Twenty-eight is the second since: $1 + 2 + 4 + 7 + 14 = 28$. A young child is given a box containing eight wooden blocks with the following numbers (one per block) printed on them: four 3's, two 5's, one 0, and one 6. What is the probability she draws the eight blocks in order and forms the fifth perfect number: 33,550,336?

▶ EXTENDING THE CONCEPT

69. The function $f(x) = (\frac{1}{2})^x$ gives the probability that x number of flips will all result in heads (or tails). Compute the probability that 20 flips results in *20 heads in a row,* then use the Internet or some other resource to find the probability of winning a state lottery. Which is more likely to happen (which has the greater probability)? Were you surprised?

70. Recall that a function is a relation in which each element of the domain is paired with only one element from the range. Is the relation defined by $C(x) = {}_nC_x$ (n is a constant) a function? To investigate, plot the points generated by $C(x) = {}_8C_x$ for $x = 0$ to $x = 8$ using a "friendly" window ($x \in [0, 9.4]$, $y \in [0, 93]$) and answer the following questions:

a. Is the resulting graph continuous or discrete (made up of distinct points)?

b. Does the resulting graph pass the vertical line test?

c. Discuss the features of the relation and its graph, including the domain, range, maximum or minimum values, and symmetries observed.

▶ MAINTAINING YOUR SKILLS

71. **(6.2)** Given $\csc\theta = 3$ and $\cos\theta < 0$, find the values of the remaining five trig functions of θ.

72. **(5.4)** Complete the following logarithmic properties:

$\log_b b =$ __ $\log_b 1 =$ __

$\log_b b^n =$ __ $b^{\log_b n} =$ __

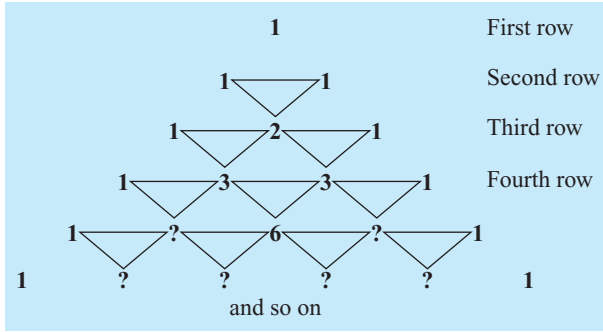
73. **(7.4)** Find exact values for $\sin(2\theta)$, $\cos(2\theta)$, and $\tan(2\theta)$ given $\cos\theta = -\frac{21}{29}$ and θ is in Quadrant II.

74. **(11.3)** A rubber ball is dropped from a height of 25 ft onto a hard surface. With each bounce, it rebounds 60% of the height from which it last fell. Use sequences/series to find (a) the height of the sixth bounce, (b) the total distance traveled up to the sixth bounce, and (c) the distance the ball will travel before coming to rest.

11.7 The Binomial Theorem

LEARNING OBJECTIVES

In Section 11.7 you will see how we can:



- ❑ **A.** Use Pascal's triangle to find $(a + b)^n$
- ❑ **B.** Find binomial coefficients using $\binom{n}{k}$ notation
- ❑ **C.** Use the binomial theorem to find $(a + b)^n$
- ❑ **D.** Find a specific term of a binomial expansion
- ❑ **E.** Solve applications of binomial powers

Strictly speaking, a binomial is a polynomial with two terms. This limits us to terms with real number coefficients and whole number powers on variables. In this section, we will loosely regard a binomial as the sum or difference of *any* two terms. Hence $3x^2 - y^4$, $\sqrt{x} + 4$, $x + \frac{1}{x}$, and $-\frac{1}{2} + \frac{\sqrt{3}}{2}i$ are all "binomials." Our goal is to develop an ability to raise a binomial to any natural number power, with the results having important applications in genetics, probability, polynomial theory, and other areas. The tool used for this purpose is called the *binomial theorem*.

A. Binomial Powers and Pascal's Triangle

Much of our mathematical understanding comes from a study of patterns. One area where the study of patterns has been particularly fruitful is **Pascal's triangle** (Figure 11.67), named after the French scientist Blaise Pascal (although the triangle was well known before his time). It begins with a "1" at the vertex of the triangle, with 1's extending diagonally downward to the left and right as shown. The entries on the interior of the triangle are found by adding the two entries directly above and to the left and right of each new position.

Figure 11.67

There are a variety of patterns hidden within the triangle. In this section, we'll use the *horizontal rows* of the triangle to help us raise a binomial to various powers. To begin, recall that $(a + b)^0 = 1$ and $(a + b)^1 = 1a + 1b$ (unit coefficients are included for emphasis). In our earlier work, we saw that a binomial square (a binomial raised to the second power) always followed the pattern $(a + b)^2 = 1a^2 + 2ab + 1b^2$. Observe the overall pattern that is developing as we include $(a + b)^3$:

$(a + b)^0$	$\mathbf{1}$	row 1
$(a + b)^1$	$\mathbf{1}a + \mathbf{1}b$	row 2
$(a + b)^2$	$\mathbf{1}a^2 + \mathbf{2}ab + \mathbf{1}b^2$	row 3
$(a + b)^3$	$\mathbf{1}a^3 + \mathbf{3}a^2b + \mathbf{3}ab^2 + \mathbf{1}b^3$	row 4

Apparently the coefficients of $(a + b)^n$ will occur in row $n + 1$ of Pascal's triangle. Also observe that in each term of the expansion, the exponent of the first term *a decreases by 1* as the exponent on the second term *b increases by 1,* keeping the degree of each term constant (recall the degree of a term with more than one variable is the sum of the exponents).

$$1a^3b^0 + 3a^2b^1 + 3a^1b^2 + 1a^0b^3$$

3 + 0	2 + 1	1 + 2	0 + 3
degree 3	degree 3	degree 3	degree 3

These observations help us to quickly expand a binomial power.

EXAMPLE 1 ▶ Expanding a Binomial Using Pascal's Triangle

Use Pascal's triangle and the patterns noted to expand $(x + \frac{1}{2})^4$.

Solution ▶ Working step-by-step we have

1. The coefficients will be in the fifth row of Pascal's triangle.

   1 4 6 4 1

2. The exponents on x begin at 4 and *decrease,* while the exponents on $\frac{1}{2}$ begin at 0 and *increase.*

$$\mathbf{1}x^4\left(\frac{1}{2}\right)^0 + \mathbf{4}x^3\left(\frac{1}{2}\right)^1 + \mathbf{6}x^2\left(\frac{1}{2}\right)^2 + \mathbf{4}x^1\left(\frac{1}{2}\right)^3 + \mathbf{1}x^0\left(\frac{1}{2}\right)^4$$

3. Simplify each term.

   The result is $x^4 + 2x^3 + \frac{3}{2}x^2 + \frac{1}{2}x + \frac{1}{16}$.

Now try Exercises 7 through 10 ▶

If the exercise involves a difference rather than a sum, we simply rewrite the expression using algebraic addition and proceed as before.

EXAMPLE 2 ▶ **Raising a Complex Number to a Power Using Pascal's Triangle**

Use Pascal's triangle and the patterns noted to compute $(3 - 2i)^5$.

Solution ▶ Begin by rewriting $(3 - 2i)^5$ as $[3 + (-2i)]^5$.

1. The coefficients will be in the sixth row of Pascal's triangle.

$$1 \qquad 5 \qquad 10 \qquad 10 \qquad 5 \qquad 1$$

2. The exponents on 3 begin at 5 and *decrease,* while the exponents on $(-2i)$ begin at 0 and *increase*.

$$\mathbf{1}(3^5)(-2i)^0 + \mathbf{5}(3^4)(-2i)^1 + \mathbf{10}(3^3)(-2i)^2 + \mathbf{10}(3^2)(-2i)^3 + \mathbf{5}(3^1)(-2i)^4 + \mathbf{1}(3^0)(-2i)^5$$

3. Simplify each term.

$$243 - 810i - 1080 + 720i + 240 - 32i$$

The result is $-597 - 122i$.

Now try Exercises 11 and 12 ▶

Expanding Binomial Powers $(a + b)^n$

1. The coefficients will be in row $n + 1$ of Pascal's triangle.
2. The exponents on *the first term* begin at n and *decrease,* while the exponents on *the second term* begin at 0 and *increase.*
3. For any binomial difference $(a - b)^n$, rewrite the base as $[a + (-b)]^n$ using algebraic addition and proceed as before, then simplify each term.

☑ **A.** You've just seen how we can use Pascal's triangle to find $(a + b)^n$

B. Binomial Coefficients and Factorials

Pascal's triangle can easily be used to find the coefficients of $(a + b)^n$, as long as the exponent is relatively small. If we needed to expand $(a + b)^{25}$, writing out the first 26 rows of the triangle would be rather tedious. To overcome this limitation, we introduce a *formula* that enables us to find the coefficients of any binomial expansion.

The Binomial Coefficients

For natural numbers n and r where $n \geq r$, the expression $\binom{n}{r}$, read "n choose r," is called the **binomial coefficient** and evaluated as:

$$\binom{n}{r} = \frac{n!}{r!(n - r)!}$$

Notice the formula for determining binomial coefficients is identical to that for ${}_nC_r$, and it turns out the coefficients are actually found using a combination, with the new notation used primarily as a convenience. In Example 1, we found the coefficients of $(a + b)^4$ using the fifth or $(n + 1)$st row of Pascal's triangle. In Example 3, these coefficients are found using the formula for binomial coefficients.

EXAMPLE 3 ▶ **Computing Binomial Coefficients**

Evaluate $\binom{n}{r} = \frac{n!}{r!(n - r)!}$ as indicated:

a. $\binom{4}{1}$ **b.** $\binom{4}{2}$ **c.** $\binom{4}{3}$

Solution ▶

a. $\binom{4}{1} = \frac{4!}{1!(4-1)!} = \frac{4 \cdot 3!}{1!3!} = 4$

b. $\binom{4}{2} = \frac{4!}{2!(4-2)!} = \frac{4 \cdot 3 \cdot 2!}{2!2!} = \frac{4 \cdot 3}{2} = 6$

c. $\binom{4}{3} = \frac{4!}{3!(4-3)!} = \frac{4 \cdot 3!}{3!1!} = 4$

Now try Exercises 13 through 20 ▶

Note $\binom{4}{1} = 4, \binom{4}{2} = 6$, and $\binom{4}{3} = 4$ give the *interior entries* in the fifth row of Pascal's triangle: 1 4 6 4 1. For consistency and symmetry, we define $0! = 1$, which enables the formula to generate all entries of the triangle, including the "1's."

$$\binom{4}{0} = \frac{4!}{0!(4-0)!} \quad \text{apply formula}$$
$$= \frac{4!}{1 \cdot 4!} = 1 \quad 0! = 1$$

$$\binom{4}{4} = \frac{4!}{4!(4-4)!} = \frac{4!}{4! \cdot 0!} \quad \text{apply formula}$$
$$= \frac{4!}{4! \cdot 1} = 1 \quad 0! = 1$$

The formula for $\binom{n}{r}$ with $0 \le r \le n$ now gives all coefficients in the $(n+1)$st row. For $n = 5$, we have

$\binom{5}{0}$	$\binom{5}{1}$	$\binom{5}{2}$	$\binom{5}{3}$	$\binom{5}{4}$	$\binom{5}{5}$
1	5	10	10	5	1

EXAMPLE 4 ▶ Computing Binomial Coefficients

Compute the binomial coefficients:

a. $\binom{9}{0}$ **b.** $\binom{9}{1}$ **c.** $\binom{6}{5}$ **d.** $\binom{6}{6}$

Solution ▶

a. $\binom{9}{0} = \frac{9!}{0!(9-0)!} = \frac{9!}{9!} = 1$

b. $\binom{9}{1} = \frac{9!}{1!(9-1)!} = \frac{9!}{8!} = 9$

c. $\binom{6}{5} = \frac{6!}{5!(6-5)!} = \frac{6!}{5!} = 6$

d. $\binom{6}{6} = \frac{6!}{6!(6-6)!} = \frac{6!}{6!} = 1$

Now try Exercises 21 through 24 ▶

B. You've just seen how we can find binomial coefficients using $\binom{n}{k}$ notation

As mentioned, the formulas for $\binom{n}{r}$ and ${}_nC_r$ yield like results for given values of n and r. For future use, it will help to commit the general results from Example 4 to memory: $\binom{n}{0} = 1, \binom{n}{1} = n, \binom{n}{n-1} = n$, and $\binom{n}{n} = 1$.

C. The Binomial Theorem

Using $\binom{n}{r}$ notation and the observations made regarding binomial powers, we can now state the **binomial theorem.**

Binomial Theorem

For any binomial $(a + b)$ and natural number n,

$$(a + b)^n = \binom{n}{0}a^n b^0 + \binom{n}{1}a^{n-1}b^1 + \binom{n}{2}a^{n-2}b^2 + \cdots + \binom{n}{n-1}a^1 b^{n-1} + \binom{n}{n}a^0 b^n$$

The theorem can also be stated in summation form as

$$(a + b)^n = \sum_{r=0}^{n}\binom{n}{r}a^{n-r}b^r$$

The expansion actually looks overly impressive in this form, and it helps to summarize the process in words, as we did earlier. The exponents on the first term a begin at n and decrease, while the exponents on the second term b begin at 0 and increase, keeping the degree of each term constant. The $\binom{n}{r}$ notation simply gives the coefficients of each term. As a final note, observe that the r in $\binom{n}{r}$ gives the exponent on b.

EXAMPLE 5 ▶ **Expanding a Binomial Using the Binomial Theorem**

Expand $(a + b)^6$ using the binomial theorem.

Solution ▶

$$\begin{aligned}(a + b)^6 &= \binom{6}{0}a^6b^0 + \binom{6}{1}a^5b^1 + \binom{6}{2}a^4b^2 + \binom{6}{3}a^3b^3 + \binom{6}{4}a^2b^4 + \binom{6}{5}a^1b^5 + \binom{6}{6}a^0b^6\\ &= \frac{6!}{0!6!}a^6 + \frac{6!}{1!5!}a^5b^1 + \frac{6!}{2!4!}a^4b^2 + \frac{6!}{3!3!}a^3b^3 + \frac{6!}{4!2!}a^2b^4 + \frac{6!}{5!1!}a^1b^5 + \frac{6!}{6!0!}b^6\\ &= 1a^6 + 6a^5b + 15a^4b^2 + 20a^3b^3 + 15a^2b^4 + 6ab^5 + 1b^6\end{aligned}$$

Now try Exercises 25 through 32 ▶

EXAMPLE 6 ▶ **Using the Binomial Theorem to Find the Initial Terms of an Expansion**

Find the first three terms of $(2x + y^2)^{10}$.

Solution ▶ Use the binomial theorem with $a = 2x$, $b = y^2$, and $n = 10$.

$$\begin{aligned}(2x + y^2)^{10} &= \binom{10}{0}(2x)^{10}(y^2)^0 + \binom{10}{1}(2x)^9(y^2)^1 + \binom{10}{2}(2x)^8(y^2)^2 + \cdots && \text{first three terms}\\ &= (1)1024x^{10} + (10)512x^9y^2 + \frac{10!}{2!8!}256x^8y^4 + \cdots && \binom{10}{0} = 1, \binom{10}{1} = 10\\ &= 1024x^{10} + 5120x^9y^2 + (45)256x^8y^4 + \cdots && \frac{10!}{2!8!} = 45\\ &= 1024x^{10} + 5120x^9y^2 + 11{,}520x^8y^4 + \cdots && \text{result}\end{aligned}$$

Now try Exercises 33 through 36 ▶

☑ **C.** You've just seen how we can use the binomial theorem to find $(a + b)^n$

D. Finding a Specific Term of the Binomial Expansion

In some applications of the binomial theorem, our main interest is a *specific term* of the expansion, rather than the expansion as a whole. To find a specified term, it helps to consider that the expansion of $(a + b)^n$ has $n + 1$ terms: $(a + b)^0$ has one term, $(a + b)^1$ has two terms, $(a + b)^2$ has three terms, and so on. Because the notation $\binom{n}{r}$ always begins at $r = 0$ for the first term, the value of r will be *1 less than the term we are seeking.* In other words, for the seventh term of $(a + b)^9$, we use $r = 6$.

The kth Term of a Binomial Expansion

For the binomial expansion $(a + b)^n$, the kth term is given by

$$\binom{n}{r}a^{n-r}b^r, \text{ where } r = k - 1.$$

EXAMPLE 7 ▶ **Finding a Specific Term of a Binomial Expansion**

Find the eighth term in the expansion of $(x + 2y)^{12}$.

Solution ▶ By comparing $(x + 2y)^{12}$ to $(a + b)^n$ we have $a = x$, $b = 2y$, and $n = 12$. Since we want the eighth term, $k = 8$ and $r = 7$. The eighth term of the expansion is

$$\begin{aligned}\binom{12}{7}x^5(2y)^7 &= \frac{12!}{7!5!}128x^5y^7 && 2^7 = 128\\ &= (792)(128x^5y^7) && \tbinom{12}{7} = 792\\ &= 101{,}376x^5y^7 && \text{result}\end{aligned}$$

D. You've just seen how we can find a specific term of a binomial expansion

Now try Exercises 37 through 42 ▶

E. Applications

One application of the binomial theorem involves a **binomial experiment** and **binomial probability.** For binomial probabilities, the following must be true: (1) The experiment must have only two possible outcomes, typically called success and failure, and (2) if the experiment has n trials, the probability of success must be constant for all n trials. If the probability of success for each trial is p, the formula $\binom{n}{k}(1 - p)^{n-k}p^k$ gives the probability that exactly k trials will be successful.

Binomial Probability

Given a binomial experiment with n trials, where the probability for success in each trial is p. The probability that exactly k trials are successful is given by

$$\binom{n}{k}(1 - p)^{n-k}p^k.$$

EXAMPLE 8 ▶ **Applying the Binomial Theorem—Binomial Probability**

Paula Rodrigues has a free-throw shooting average of 85%. On the last play of the game, with her team behind by three points, she is fouled at the three-point line, and is awarded two additional free throws via technical fouls on the opposing coach (a total of five free-throws). What is the probability she makes *at least three* (meaning they at least tie the game)?

Solution ▶ Here we have $p = 0.85$, $1 - p = 0.15$, and $n = 5$. The key idea is to recognize the phrase *at least three* means "3 or 4 or 5." So $P(\text{at least } 3) = P(3 \cup 4 \cup 5)$.

$$\begin{aligned} P(\text{at least } 3) &= P(3 \cup 4 \cup 5) && \text{“or” implies a union} \\ &= P(3) + P(4) + P(5) && \text{sum of probabilities (mutually exclusive events)} \\ &= \binom{5}{3}(0.15)^2(0.85)^3 + \binom{5}{4}(0.15)^1(0.85)^4 + \binom{5}{5}(0.15)^0(0.85)^5 \\ &\approx 0.1382 + 0.3915 + 0.4437 \\ &= 0.9734 \end{aligned}$$

Paula's team has an excellent chance (≈97.3%) of at least tying the game.

Now try Exercises 45 and 46 ▶

As you can see, calculations involving binomial probabilities can become quite extensive. Here again, a conceptual understanding of what the numbers mean can be combined with the use of technology to solve significant applications of the idea. Most graphing calculators provide a *binomial probability distribution function,* abbreviated **"binompdf("** and accessed using 2nd VARS **(DISTR) 0:binompdf(.** The function requires three inputs: the number of trials n, the probability of success p for each trial, and the value of k. As with the evaluation of other functions, k can be a single value or a list of values enclosed in braces: "{ }." The resulting calculation for Example 8 is shown in Figure 11.68, and verifies each of the individual probabilities, although we must use the right arrow to see them all. To find the sum of these probabilities, we simply precede the **"binompdf("** command with the **"sum("** feature used previously. The final result is shown in Figure 11.69, and verifies our earlier calculation. **See Exercises 47 and 48.**

11.7 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in the blank with the appropriate word or phrase. Carefully reread the section if needed.

1. In any binomial expansion, there is always _____ more term than the power applied.
2. In all terms in the expanded form of $(a + b)^n$, the exponents on a and b must sum to _____.
3. To expand a binomial *difference* such as $(a - 2b)^5$, we rewrite the binomial as _____ and proceed as before.
4. In a binomial experiment with n trials, the probability there are exactly k successes is given by the formula _____.
5. Discuss why the expansion of $(a + b)^n$ has $n + 1$ terms.
6. For any defined binomial experiment, discuss the relationships between the phrases, "exactly k success," and "at least k successes."

▶ DEVELOPING YOUR SKILLS

Use *Pascal's triangle* and the patterns explored to write each expansion.

7. $(x + y)^5$ **8.** $(a + b)^6$ **9.** $(2x + 3)^4$

10. $(x^2 + \frac{1}{3})^3$ **11.** $(1 - 2i)^5$ **12.** $(2 - 5i)^4$

Evaluate each of the following

13. $\binom{7}{4}$ **14.** $\binom{8}{2}$ **15.** $\binom{5}{3}$

16. $\binom{9}{5}$ **17.** $\binom{20}{17}$ **18.** $\binom{30}{26}$

19. $\binom{40}{3}$ **20.** $\binom{45}{3}$ **21.** $\binom{6}{0}$

22. $\binom{5}{0}$ **23.** $\binom{15}{15}$ **24.** $\binom{10}{10}$

Use the *binomial theorem* to expand each expression. Write the general form first, then simplify.

25. $(c + d)^5$ **26.** $(v + w)^4$ **27.** $(a - b)^6$

28. $(x - y)^7$ **29.** $(2x - 3)^4$ **30.** $(a - 2b)^5$

31. $(1 - 2i)^3$ **32.** $(2 + i\sqrt{3})^5$

Use the *binomial theorem* to write the first three terms.

33. $(x + 2y)^9$ **34.** $(3p + q)^8$ **35.** $(v^2 - \frac{1}{2}w)^{12}$

36. $(\frac{1}{2}a - b^2)^{10}$

Find the indicated term for each binomial expansion.

37. $(x + y)^7$; 4th term **38.** $(m + n)^6$; 5th term

39. $(p - 2)^8$; 7th term **40.** $(a - 3)^{14}$; 10th term

41. $(2x + y)^{12}$; 11th term **42.** $(3n + m)^9$; 6th term

▶ WORKING WITH FORMULAS

43. Binomial probability: $P(k) = \binom{n}{k}\left(\frac{1}{2}\right)^k\left(\frac{1}{2}\right)^{n-k}$

The theoretical probability of getting exactly k heads in n flips of a fair coin is given by the formula above. What is the probability that you would get exactly 5 heads in 10 flips of the coin?

44. Binomial probability: $P(k) = \binom{n}{k}\left(\frac{1}{5}\right)^k\left(\frac{4}{5}\right)^{n-k}$

A multiple choice test has five options per question. The probability of guessing correctly k times out of n questions is found using the formula shown. What is the probability a person scores a 70% by guessing randomly (7 out of 10 questions correct)?

▶ APPLICATIONS

45. Batting averages: Tony Gwynn (San Diego Padres) had a lifetime batting average of 0.347, ranking him as one of the greatest hitters of all time. Suppose he came to bat five times in any given game.

a. What is the probability that he will get exactly three hits?

b. What is the probability that he will get at least three hits?

46. Pollution testing: Erin suspects that a nearby iron smelter is contaminating the drinking water over a large area. A statistical study reveals that 83% of the wells in this area are likely contaminated. If the figure is accurate, find the probability that if another 10 wells are tested

a. exactly 8 are contaminated

b. at least 8 are contaminated

47. Late rental returns: The manager of Victor's DVD Rentals knows that 6% of all DVDs rented are returned *late*. Of the eight videos rented in the last hour, what is the probability that

a. exactly five are returned on time

b. exactly six are returned on time

c. at least six are returned on time

d. none of them will be returned late

48. Opinion polls: From past experience, a research firm knows that 20% of telephone respondents will agree to answer an opinion poll. If 20 people are contacted by phone, what is the probability that

a. exactly 18 refuse to be polled

b. exactly 19 refuse to be polled

c. at least 18 refuse to be polled

d. none of them agree to be polled

▶ EXTENDING THE CONCEPT

49. If you sum the entries in each row of Pascal's triangle, a pattern emerges. Find a formula that generalizes the result for any row of the triangle, and use it to find the sum of the entries in the 12th row of the triangle.

50. The *derived polynomial* of $f(x)$ is $f(x + h)$ or the original polynomial evaluated at $x + h$. Use Pascal's triangle or the binomial theorem to find the derived polynomial for $f(x) = x^3 + 3x^2 + 5x - 11$. Simplify the result completely.

▶ MAINTAINING YOUR SKILLS

51. **(2.5)** Graph the function shown and find $f(3)$:

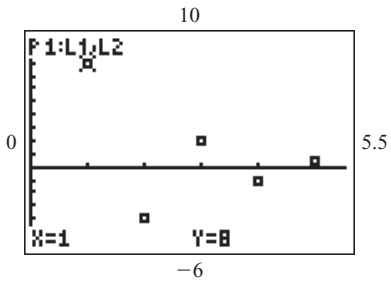
$$f(x) = \begin{cases} x + 2 & x \le 2 \\ (x - 4)^2 & x > 2 \end{cases}$$

52. **(6.2)** Given the point $(-0.6, y)$ is a point on the unit circle in the third quadrant, find y.

53. **(4.3/4.6)** Graph the function $g(x) = x^3 - x^2 - 6x$. Clearly indicate all intercepts and intervals where $g(x) > 0$.

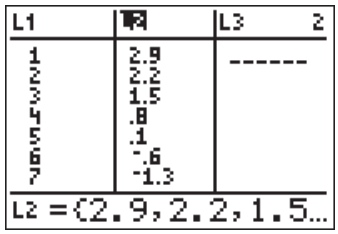
54. **(7.5)** Evaluate $\arcsin\left[\sin\left(\frac{5\pi}{6}\right)\right]$.

MAKING CONNECTIONS



Making Connections: Graphically, Symbolically, Numerically, and Verbally

Eight situations are described in (a) through (h) below. Match the characteristics, formulas, operations, or results indicated in 1 through 16 to one of the eight situations.



(a) $\sum_{i=1}^{7} \frac{3^{i-1}}{18}$

(b) $-2 + 0.5 + 3 + 5.5 + 8 + 10.5 + \cdots + 33$

(c)

(d)

(e) $16a^4 - 32a^3b + 24a^2b^2 - 8ab^3 + b^4$

(f) $-29, -23, -17, -11, \ldots$

(g) $1, 1, 2, 3, 5, 8, 13, \ldots$

(h) $a^4 + 8a^3b + 24a^2b^2 + 32ab^3 + 16b^4$

1. ____ alternating sequence
2. ____ Fibonacci sequence
3. ____ 232.5
4. ____ $d = -0.7$
5. ____ $a_n = 3.6 - 0.7n$
6. ____ $S_{39} = 3315$
7. ____ arithmetic series
8. ____ $(a + 2b)^4$
9. ____ $a_{22} = -11.8$
10. ____ geometric series
11. ____ $r = 3$
12. ____ $S_\infty = \frac{16}{3}$
13. ____ $(2a - b)^4$
14. ____ $a_n = 6n - 35$
15. ____ recursively defined
16. ____ $\frac{1093}{18}$

SUMMARY AND CONCEPT REVIEW

SECTION 11.1 Sequences and Series

KEY CONCEPTS

- A *finite sequence* is a function a_n whose domain is the set of natural numbers from 1 to n.
- The terms of the sequence are labeled $a_1, a_2, a_3, \ldots, a_{k-1}, a_k, a_{k+1}, \ldots, a_{n-2}, a_{n-1}, a_n$.
- The expression a_n, which defines the sequence (generates the terms in order), is called the nth term.
- An *infinite sequence* is a function whose domain is the set of natural numbers.
- When each term of a sequence is larger than the preceding term, it is called an increasing sequence.
- When each term of a sequence is smaller than the preceding term, it is called a decreasing sequence.
- When successive terms of a sequence alternate in sign, it is called an alternating sequence.
- When the terms of a sequence are generated using previous term(s), it is called a recursive sequence.
- Sequences are sometimes defined using factorials, which are the product of a given natural number with all natural numbers that precede it: $n! = n \cdot (n-1) \cdot (n-2) \cdot \cdots \cdot 3 \cdot 2 \cdot 1$.
- Given the sequence $a_1, a_2, a_3, a_4, \ldots, a_n$ the sum is called a finite series and is denoted S_n.
- $S_n = a_1 + a_2 + a_3 + a_4 + \cdots + a_n$. The sum of the first n terms is called a partial sum.
- In sigma notation, the expression $\sum_{i=1}^{k} a_i = a_1 + a_2 + \cdots + a_k$ represents a finite series, and the letter "i" is called the index of summation.

EXERCISES

Write the first four terms that are defined and the value of a_{10}.

1. $a_n = 5n - 4$

2. $a_n = \dfrac{n+1}{n^2+1}$

Find the general term a_n for each sequence, and the value of a_6.

3. $1, 16, 81, 256, \ldots$

4. $-17, -14, -11, -8, \ldots$

Find the eighth partial sum (S_8).

5. $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \ldots$

6. $-21, -19, -17, \ldots$

Evaluate each sum.

7. $\sum_{n=1}^{7} n^2$

8. $\sum_{n=1}^{5} (3n - 2)$

Write the first five terms that are defined.

9. $a_n = \dfrac{n!}{(n-2)!}$

10. $\begin{cases} a_1 = \frac{1}{2} \\ a_{n+1} = 2a_n - \frac{1}{4} \end{cases}$

Write as a single summation and evaluate.

11. $\sum_{i=1}^{7} i^2 + \sum_{i=1}^{7} (3i - 2)$

12. A large wildlife preserve brings in 40 rare hawks (male and female) in an effort to repopulate the species. Each year they are able to add an average of 10 additional hawks in cooperation with other wildlife areas. If the population of hawks grows at a rate of 12% through natural reproduction, the number of hawks in the preserve after x yr is given by the recursive sequence $h_0 = 40$, $h_n = 1.12h_{n-1} + 10$. (a) How many hawks are in the wildlife preserve after 5 yr? (b) How many years before the number of hawks exceeds 200?

SECTION 11.2 Arithmetic Sequences

KEY CONCEPTS

- In an arithmetic sequence, successive terms are found by adding a fixed constant to the preceding term.
- In a sequence, if there exists a number d, called the common difference, such that $a_{k+1} - a_k = d$, then the sequence is arithmetic. Alternatively, $a_{k+1} = a_k + d$ for $k \geq 1$.
- The nth term n of an arithmetic sequence is given by $a_n = a_1 + (n - 1)d$, where a_1 is the first term and d is the common difference.
- If the initial term is unknown or is not a_1 the nth term can be written $a_n = a_k + (n - k)d$, where the subscript of the term a_k and the coefficient of d sum to n.
- For an arithmetic sequence with first term a_1, the nth partial sum (the sum of the first n terms) is given by $S_n = \dfrac{n(a_1 + a_n)}{2}$.

EXERCISES

Find the general term (a_n) for each arithmetic sequence. Then find the indicated term.

13. $2, 5, 8, 11, \ldots$; find a_{40}

14. $3, 1, -1, -3, \ldots$; find a_{35}

Find the sum of each series.

15. $-1 + 3 + 7 + 11 + \cdots + 75$

16. $1 + 4 + 7 + 10 + \cdots + 88$

17. $3 + 6 + 9 + 12 + \cdots$; S_{20}

18. $1 + \frac{3}{4} + \frac{1}{2} + \frac{1}{4} + \cdots$; S_{15}

19. $\displaystyle\sum_{n=1}^{25} (3n - 4)$

20. From a point just behind the cockpit, the width of a modern fighter plane's swept-back wings is 1.25 m. The width of the wings, measured in equal increments, increases according to the pattern 1.25, 2.15, 3.05, 3.95, ... Find the width of the wings on the eighth measurement.

SECTION 11.3 Geometric Sequences

KEY CONCEPTS

- In a geometric sequence, successive terms are found by multiplying the preceding term by a nonzero constant.
- In other words, if there exists a number r, called the common ratio, such that $\dfrac{a_{k+1}}{a_k} = r$, then the sequence is geometric. Alternatively, we can write $a_{k+1} = a_k r$ for $k \geq 1$.
- The nth term a_n of a geometric sequence is given by $a_n = a_1 r^{n-1}$, where a_1 is the first term and a_n represents the general term of a finite sequence.
- If the initial term is unknown or is not a_1, the nth term can be written $a_n = a_k r^{n-k}$, where the subscript of the term a_k and the exponent on r sum to n.
- The nth partial sum of a geometric sequence is $S_n = \dfrac{a_1(1 - r^n)}{1 - r}$.
- If $|r| < 1$, the sum of an infinite geometric series is $S_\infty = \dfrac{a_1}{1 - r}$.

EXERCISES

Find the indicated term for each geometric sequence.

21. $a_1 = 5, r = 3$; find a_7

22. $a_1 = 4, r = \sqrt{2}$; find a_7

23. $a_1 = \sqrt{7}, r = \sqrt{7}$; find a_8

Find the indicated sum, if it exists.

24. $16 - 8 + 4 - \cdots$; find S_7

25. $2 + 6 + 18 + \cdots$; find S_8

26. $\frac{4}{5} + \frac{2}{5} + \frac{1}{5} + \frac{1}{10} + \cdots$; find S_{12}

27. $4 + 8 + 16 + 32 + \cdots$

28. $5 + 0.5 + 0.05 + 0.005 + \cdots$

29. $6 - 3 + \frac{3}{2} - \frac{3}{4} + \cdots$

30. $\sum_{k=1}^{8} 5\left(\frac{2}{3}\right)^k$ **31.** $\sum_{k=1}^{\infty} 12\left(\frac{4}{3}\right)^k$ **32.** $\sum_{k=1}^{\infty} 5\left(\frac{1}{2}\right)^k$

33. Sumpter reservoir contains 121,500 ft^3 of water and is being drained in the following way. Each day one-third of the water is *drained* (and not replaced). Use a sequence/series to compute how much water *remains in the pond* after 7 days.

34. Credit-hours taught at Cody Community College have been increasing at 7% per year since it opened in 2001 and taught 1225 credit-hours. For the new faculty, the college needs to predict the number of credit-hours that will be taught in 2015. Use a sequence/series to compute the credit-hours for 2015 and to find the total number of credit hours taught through the 2015 school year.

SECTION 11.4 Mathematical Induction

KEY CONCEPTS

- Functions written in subscript notation can be evaluated, graphed, and composed with other functions.
- A sum formula involving only natural numbers n as inputs can be proven valid using a proof by induction. Given that S_n represents a sum formula involving natural numbers, if (1) S_1 is true and (2) $S_k + a_{k+1} = S_{k+1}$, then S_n must be true for all natural numbers.
- Proof by induction can also be used to validate other relationships, using a more general statement of the principle. Let P_n be a statement involving the natural numbers n. If (1) P_1 is true (P_n for $n = 1$) and (2) the truth of P_k implies that P_{k+1} is also true, then P_n must be true for all natural numbers n.

EXERCISES

Use the principle of mathematical induction to prove the indicated sum formula is true for all natural numbers n.

35. $1 + 2 + 3 + 4 + 5 + \cdots + n$;

$a_n = n$ and $S_n = \frac{n(n+1)}{2}$.

36. $1 + 4 + 9 + 16 + 25 + 36 + \cdots + n^2$;

$a_n = n^2$ and $S_n = \frac{n(n+1)(2n+1)}{6}$.

Use the principle of mathematical induction to prove that each statement is true for all natural numbers n.

37. $4^n \geq 3n + 1$ **38.** $6 \cdot 7^{n-1} \leq 7^n - 1$ **39.** $3^n - 1$ is divisible by 2

SECTION 11.5 Counting Techniques

KEY CONCEPTS

- An experiment is any task that can be repeated and has a well-defined set of possible outcomes.
- Each repetition of an experiment is called a trial.
- Any potential outcome of an experiment is called a sample outcome.
- The set of all sample outcomes is called the sample space.
- An experiment with N (equally likely) sample outcomes that is repeated t times, has a sample space with N^t elements.
- If a sample outcome can be used more than once, the counting is said to be with repetition. If a sample outcome can be used only once, the counting is said to be without repetition.
- The fundamental principle of counting states: If there are p possibilities for a first task, q possibilities for the second, and r possibilities for the third, the total number of ways the experiment can be completed is pqr. This fundamental principle can be extended to include any number of tasks.
- If the elements of a sample space have precedence or priority (order or rank is important), the number of elements is counted using a permutation, denoted ${}_nP_r$ and read, "the distinguishable permutations of n objects taken r at a time."
- To expand ${}_nP_r$, we can write out the first r factors of $n!$ or use the formula ${}_nP_r = \frac{n!}{(n-r)!}$.

- If any of the sample outcomes are identical, certain permutations will be nondistinguishable. In a set containing n elements where one element is repeated p times, another is repeated q times, and another r times ($p + q + r = n$), the number of distinguishable permutations is given by $\frac{{}_nP_n}{p!q!r!} = \frac{n!}{p!q!r!}$.
- If the elements of a set have no rank, order, or precedence (as in a committee of colleagues) permutations with the same elements are considered identical. The result is the number of combinations, ${}_nC_r = \frac{n!}{r!(n-r)!}$.

EXERCISES

40. Three slips of paper with the letters A, B, and C are placed in a box and randomly drawn one at a time. Show all possible ways they can be drawn using a tree diagram.

41. The combination for a certain bicycle lock consists of three digits. How many combinations are possible if (a) repetition of digits is not allowed and (b) repetition of digits is allowed.

42. Jethro has three work shirts, four pairs of work pants, and two pairs of work shoes. How many different ways can he dress himself (shirt, pants, shoes) for a day's work?

43. From a field of 12 contestants in a pet show, three cats are chosen at random to be photographed for a publicity poster. In how many different ways can the cats be chosen?

44. Compute the following values by hand, showing all work:

a. $7!$ **b.** ${}_7P_4$ **c.** ${}_7C_4$

45. Six horses are competing in a race at the McClintock Ranch. Assuming there are no ties, (a) how many different ways can the horses finish the race? (b) How many different ways can the horses finish first, second, and third place? (c) How many finishes are possible if it is well known that Nellie-the-Nag will finish last and Sea Biscuit will finish first?

46. How many distinguishable permutations can be formed from the letters in the word "tomorrow"?

47. Quality Construction Company has 12 equally talented employees. (a) How many ways can a three-member crew be formed to complete a small job? (b) If the company is in need of a Foreman, Assistant Foreman, and Crew Chief, in how many ways can the positions be filled?

SECTION 11.6 Introduction to Probability

KEY CONCEPTS

- An event E is any designated set of sample outcomes.
- Given S is a sample space of equally likely sample outcomes and E is an event relative to S, the probability of E, written $P(E)$, is computed as $P(E) = \frac{n(E)}{n(S)}$, where $n(E)$ represents the number of elements in E, and $n(S)$ represents the number of elements in S.
- The complement of an event E is the set of sample outcomes in S, but not in E and is denoted $\sim E$.
- Given sample space S and any event E defined relative to S:
  (1) $P(\sim S) = 0$, (2) $0 \le P(E) \le 1$, (3) $P(S) = 1$, (4) $P(E) = 1 - P(\sim E)$, and
  (5) $P(E) + P(\sim E) = 1$.
- Two events that have no outcomes in common are said to be mutually exclusive.
- If two events are not mutually exclusive, $P(E_1 \text{ or } E_2) \rightarrow P(E_1 \cup E_2) = P(E_1) + P(E_2) - P(E_1 \cap E_2)$.
- If two events are mutually exclusive, $P(E_1 \text{ or } E_2) \rightarrow P(E_1 \cup E_2) = P(E_1) + P(E_2)$.

EXERCISES

48. One card is drawn from a standard deck. What is the probability the card is a ten or a face card?

49. One card is drawn from a standard deck. What is the probability the card is a Queen or a face card?

50. One die is rolled. What is the probability the result is not a three?

51. Given $P(E_1) = \frac{3}{8}$, $P(E_2) = \frac{3}{4}$, and $P(E_1 \cup E_2) = \frac{5}{6}$, compute $P(E_1 \cap E_2)$.

52. Find $P(E)$ given that $n(E) = {}_7C_4 \cdot {}_5C_3$ and $n(S) = {}_{12}C_7$.

53. To determine if more physicians should be hired, a medical clinic tracks the number of days between a patient's request for an appointment and the actual appointment date. The table given shows the probability that a patient must wait d days. Based on the table, what is the probability a patient must wait

Wait (days d)	Probability
0	0.002
$0 < d < 10$	0.07
$10 \le d < 20$	0.32
$20 \le d < 30$	0.43
$30 \le d < 40$	0.178

a. at least 20 days **b.** less than 20 days
c. 40 days or less **d.** over 40 days
e. less than 40 and more than 10 days **f.** 30 or more days

SECTION 11.7 The Binomial Theorem

KEY CONCEPTS

- To expand $(a + b)^n$ for n of "moderate size," we can use Pascal's triangle and observed patterns.
- For any natural numbers n and r, where $n \ge r$, the expression $\binom{n}{r}$ (read "n choose r") is called the *binomial coefficient* and evaluated as $\binom{n}{r} = \dfrac{n!}{r!(n-r)!}$.
- If n is large, it is more efficient to expand using the binomial coefficients and binomial theorem.
- The following binomial coefficients are useful/common and should be committed to memory:

$$\binom{n}{0} = 1 \qquad \binom{n}{1} = n \qquad \binom{n}{n-1} = n \qquad \binom{n}{n} = 1$$

- We define $0! = 1$; for example $\binom{n}{n} = \dfrac{n!}{n!(n-n)!} = \dfrac{1}{0!} = \dfrac{1}{1} = 1$.
- The binomial theorem: $(a+b)^n = \binom{n}{0}a^n b^0 + \binom{n}{1}a^{n-1}b^1 + \binom{n}{2}a^{n-2}b^2 + \cdots + \binom{n}{n-1}a^1 b^{n-1} + \binom{n}{n}a^0 b^n$.
- The kth term of $(a+b)^n$ can be found using the formula $\binom{n}{r}a^{n-r}b^r$, where $r = k - 1$.

EXERCISES

54. Evaluate each of the following:

a. $\binom{7}{5}$ **b.** $\binom{8}{3}$

55. Use Pascal's triangle to expand the expressions:

a. $(x - y)^4$ **b.** $(1 + 2i)^5$

Use the binomial theorem to:

56. Write the first four terms of

a. $(a + \sqrt{3})^8$ **b.** $(5a + 2b)^7$

57. Find the indicated term of each expansion.

a. $(x + 2y)^7$; fourth **b.** $(2a - b)^{14}$; 10th

58. Mark Leland is a professional bowler who is able to roll a strike (knocking down all 10 pins on the first ball) 91% of the time. (a) What is the probability he rolls at least four strikes in the first five frames? (b) What is the probability he rolls five strikes (and scares the competition)?

PRACTICE TEST

1. The general term of a sequence is given. Find the first four terms and the 8th term.

a. $a_n = \dfrac{2n}{n+3}$ **b.** $a_n = \dfrac{(n+2)!}{n!}$

c. $a_n = \begin{cases} a_1 = 3 \\ a_{n+1} = \sqrt{(a_n)^2 - 1} \end{cases}$

2. Expand each series and evaluate.

a. $\sum_{k=2}^{6}(2k^2 - 3)$ **b.** $\sum_{j=2}^{6}(-1)^j\left(\dfrac{j}{j+1}\right)$

c. $\sum_{j=1}^{5}(-2)\left(\dfrac{3}{4}\right)^j$ **d.** $\sum_{k=1}^{\infty}7\left(\dfrac{1}{2}\right)^k$

3. Identify the first term and the common difference or common ratio. Then find the general term a_n.

a. $7, 4, 1, -2, \ldots$ **b.** $-8, -6, -4, -2, \ldots$

c. $4, -8, 16, -32, \ldots$ **d.** $10, 4, \frac{8}{5}, \frac{16}{25}, \ldots$

4. Find the indicated value for each sequence.

a. $a_1 = 4, d = 5$; find a_{40}

b. $a_1 = 2, a_n = -22, d = -3$; find n

c. $a_1 = 24, r = \frac{1}{2}$; find a_6

d. $a_1 = -2, a_n = 486, r = -3$; find n

5. Find the sum of each series.

a. $7 + 10 + 13 + \cdots + 100$

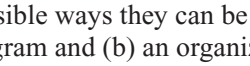
b. $\sum_{k=1}^{37} (3k + 2)$

c. For $4 - 12 + 36 - 108 + \cdots$, find S_7

d. $6 + 3 + \frac{3}{2} + \frac{3}{4} + \cdots$

6. Each swing of a pendulum (in one direction) is 95% of the previous one. If the first swing is 12 ft, (a) find the length of the seventh swing and (b) determine the distance traveled by the pendulum for the first seven swings.

7. A rare coin that cost \$3000 appreciates in value 7% per year. Find the value after 12 yr.



8. A car that costs \$50,000 decreases in value by 15% per year. Find the value of the car after 5 yr.

9. Use mathematical induction to verify that for $a_n = 5n - 3$, the sum formula $S_n = \dfrac{5n^2 - n}{2}$ is true for all natural numbers n.

10. Use the principle of mathematical induction to verify that P_n: $2 \cdot 3^{n-1} \le 3^n - 1$ is true for all natural numbers n.

11. Three colored balls (aqua, brown, and creme) are to be drawn without replacement from a bag. List all possible ways they can be drawn using (a) a tree diagram and (b) an organized list.

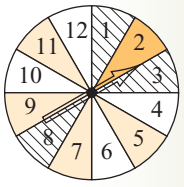
12. Suppose that license plates for motorcycles must consist of three numbers followed by two letters. How many license plates are possible if zero and "Z" cannot be used and no repetition is allowed?

13. If one icon is randomly chosen from the following set, find the probability a mailbox is not chosen: {  }.

14. Compute the following values by hand, showing all work: (a) 6! (b) ${}_6P_3$ (c) ${}_6C_3$

15. An English major has built a collection of rare books that includes two identical copies of *The Canterbury Tales* (Chaucer), three identical copies of *Romeo and Juliet* (Shakespeare), four identical copies of *Faustus* (Marlowe), and four identical copies of *The Faerie Queen* (Spenser). If these books are to be arranged on a shelf, how many distinguishable permutations are possible?

16. A company specializes in marketing various *cornucopia* (traditionally a curved horn overflowing with fruit, vegetables, gourds, and ears of grain) for Thanksgiving table settings. The company has seven fruit, six vegetable, five gourd, and four grain varieties available. If two from each group (without repetition) are used to fill the horn, how many different cornucopia are possible?



17. Use Pascal's triangle to expand/simplify:

a. $(x - 2y)^4$ **b.** $(1 + i)^4$

18. Use the binomial theorem to write the first three terms of (a) $(x + \sqrt{2})^{10}$ and (b) $(a - 2b^3)^8$.

19. Michael and Mitchell are attempting to make a nonstop, 100-mi trip on a tandem bicycle. The probability that Michael cannot continue pedaling for the entire trip is 0.02. The probability that Mitchell cannot continue pedaling for the entire trip is 0.018. The probability that neither one can pedal the entire trip is 0.011. What is the probability that they complete the trip?

20. The spinner shown is spun once. What is the probability of spinning

a. a striped wedge

b. a shaded wedge

c. a clear wedge

d. an even number

e. a two or an odd number

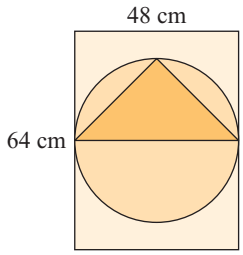
f. a number greater than nine

g. a shaded wedge *or* a number greater than 12

h. a shaded wedge *and* a number greater than 12

21. To improve customer service, a cable company tracks the number of days a customer must wait until their cable service is installed. The table shows the probability that a customer must wait d days. Based on the table, what is the probability a customer waits

Wait (days d)	Probability
0	0.02
$0 < d < 1$	0.30
$1 \le d < 2$	0.60
$2 \le d < 3$	0.05
$3 \le d < 4$	0.03



a. at least 2 days **b.** less than 2 days

c. 4 days or less **d.** over 4 days

e. less than 2 or at least 3 days

f. three or more days

22. An experienced archer can hit the rectangular target shown 100% of the time at a range of 75 m. Assuming the probability the target is hit is related to its area, what is the probability the archer hits within the

a. triangle **b.** circle

c. circle but outside the triangle

d. lower half-circle

e. rectangle but outside the circle

f. lower half-rectangle, outside the circle

23. A survey of 100 union workers was taken to register concerns to be raised at the next bargaining session. A breakdown of those surveyed is shown in the table

Expertise Level	Women	Men	Total
Apprentice	16	18	34
Technician	15	13	28
Craftsman	9	9	18
Journeyman	7	6	13
Contractor	3	4	7
Totals	50	50	100

in the right column. One out of the hundred will be selected at random for a personal interview. What is the probability the person chosen is a

a. woman or a craftsman

b. man or a contractor

c. man and a technician

d. journeyman or an apprentice

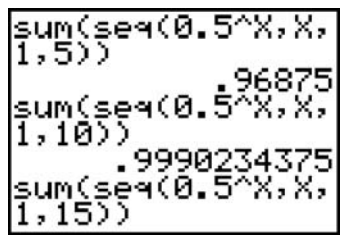
24. Cheddar is a 12-year-old male box turtle. Provolone is an 8-year-old female box turtle. The probability that Cheddar will live another 8 yr is 0.85. The probability that Provolone will live another 8 yr is 0.95. Find the probability that

a. both turtles live for another 8 yr

b. neither turtle lives for another 8 yr

c. at least one of them will live another 8 yr

25. The quality control department at a lightbulb factory has determined that the company is losing money because their manufacturing process produces a defective bulb 12% of the time. If a random sample of 10 bulbs is tested, (a) what is the probability that none are defective? (b) What is the probability that no more than 3 bulbs are defective?



CALCULATOR EXPLORATION AND DISCOVERY

Infinite Series, Finite Results

Although there were many earlier flirtations with infinite processes, it may have been the paradoxes of Zeno of Elea (~450 B.C.) that crystallized certain questions that simultaneously frustrated and fascinated early mathematicians. The first paradox, called the dichotomy paradox, can be summarized by the following question: How can one ever finish a race, seeing that one-half the distance must first be traversed, then one-half the remaining distance, then one-half the distance that then remains, and so on an infinite number of times? Although we easily accept that races can be finished, the subtleties involved in this question stymied mathematicians for centuries and were not satisfactorily resolved until the eighteenth century. In modern notation, Zeno's first paradox says $\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \cdots < 1$. This is a geometric series with $a_1 = \frac{1}{2}$ and $r = \frac{1}{2}$.

Illustration 1 ▶ For the geometric sequence with $a_1 = \dfrac{1}{2}$ and $r = \dfrac{1}{2}$, the nth term is $a_n = \dfrac{1}{2^n}$. Use the **"sum("** and **"seq("** features of your calculator to compute S_5, S_{10}, and S_{15} (see Section 11.1). Does the sum appear to be approaching some "limiting value?" If so, what is this value? Now compute S_{20}, S_{25}, and S_{30}. Does there still appear to be a limit to the sum? What happens when you have the calculator compute S_{35}?

Figure 11.70

Solution ▶ CLEAR the calculator and enter sum(seq (0.5^X, X, 1, 5)) on the home screen. Pressing ENTER gives $S_5 = 0.96875$ (Figure 11.70). Press 2nd ENTER to recall the expression and overwrite the 5, changing it to a 10. Pressing ENTER shows $S_{10} = 0.9990234375$. Repeating these steps gives $S_{15} = 0.9999694824$, and it seems that "1" may be a limiting value. Our conjecture receives further support as S_{20}, S_{25}, and S_{30} are closer and closer to 1, but do not exceed it.

Note that the sum of additional terms will create a longer string of 9's. That the sum of an infinite number of these terms *is* **1** can be understood by converting the repeating decimal $0.\overline{9}$ to its fractional form (as shown). For $x = 0.\overline{9}$, $10x = 9.\overline{9}$ and it follows that

$$\begin{aligned} 10x &= 9.\overline{9} \\ -x &= -0.\overline{9} \\ \hline 9x &= 9 \\ x &= 1 \end{aligned}$$

For a geometric sequence, the result of an infinite sum can be verified using $S_\infty = \dfrac{a_1}{1-r}$. However, there are many nongeometric, infinite series that also have a limiting value. In some cases these require many, many more terms before the limiting value can be observed.

Use a calculator to write the first five terms and to find S_5, S_{10}, and S_{15}. Decide if the sum appears to be approaching some limiting value, then compute S_{20} and S_{25}. Do these sums support your conjecture?

Exercise 1: $a_1 = \frac{1}{3}$ and $r = \frac{1}{3}$ **Exercise 2:** $a_1 = 0.2$ and $r = 0.2$ **Exercise 3:** $a_n = \dfrac{1}{(n-1)!}$

Additional Insight: Zeno's first paradox can also be "resolved" by observing that the "half-steps" needed to complete the race require increasingly shorter (infinitesimally short) amounts of time. Eventually the race is complete.

STRENGTHENING CORE SKILLS

Probability, Quick-Counting, and Card Games

The card game known as *Five Card Stud* is often played for fun and relaxation, using toothpicks, beans, or pocket change as players attempt to develop a winning "hand" from the five cards dealt. The various "hands" are given here with the higher value hands listed first (e.g., a full house is a better/higher hand than a flush).

Five Card Hand	Description	Probability of Being Dealt
royal flush	five cards of the same suit in sequence from 10 to Ace	0.000 001 540
straight flush	any five cards of the same suit in sequence (exclude royal)	0.000 013 900
four of a kind	four cards of the same rank, any fifth card	
full house	three cards of the same rank, with one pair	
flush	five cards of the same suit, no sequence required	0.001 970
straight	five cards in sequence, regardless of suit	
three of a kind	three cards of the same rank, any two other cards	
two pairs	two cards of the one rank, two of another rank, one other card	0.047 500
one pair	two cards of the same rank, any three others	0.422 600

For this study, we will consider the hands that are based on suit (the flushes) and the sample space to be five cards dealt from a deck of 52, or ${}_{52}C_5$.

A flush consists of five cards in the same suit, a straight consists of five cards in sequence. Let's consider that an Ace can be used as either a high card (as in 10, J, Q, K, A) or a low card (as in A, 2, 3, 4, 5). Since the dominant characteristic of a flush is its *suit,* we first consider choosing one suit of the four, then the number of ways that the straight can be formed (if needed).

Illustration 1 ▶ What is the probability of being dealt a royal flush?

Solution ▶ For a royal flush, all cards must be of one suit. Since there are four suits, it can be chosen in ${}_4C_1$ ways. A royal flush must have the cards A, K, Q, J, and 10 and once the suit has been decided, it can happen in only this (one) way or ${}_1C_1$. This means $P\,(\text{royal flush}) = \dfrac{{}_4C_1 \cdot {}_1C_1}{{}_{52}C_5} \approx 0.000\,001\,540$.

Illustration 2 ▶ What is the probability of being dealt a straight flush?

Solution ▶ Once again all cards must be of one suit, which can be chosen in ${}_4C_1$ ways. A straight flush is any five cards in sequence and once the suit has been decided, this can happen in 10 ways (Ace on down, King on down, Queen on down, and so on). By the FCP, there are ${}_4C_1 \cdot {}_{10}C_1 = 40$ ways this can happen, but *four of these will be royal flushes that are of a higher value* and must be subtracted from this total. So in the intended context we have

$$P\,(\text{straight flush}) = \frac{{}_4C_1 \cdot {}_{10}C_1 - 4}{{}_{52}C_5} \approx 0.000\,013\,900$$

Using these examples, determine the probability of being dealt

Exercise 1: a simple flush (no royal or straight flushes)

Exercise 2: three cards of the same suit and any two other (nonsuit) cards

Exercise 3: four cards of the same suit and any one other (nonsuit) card

Exercise 4: a flush having no face cards

CUMULATIVE REVIEW CHAPTERS 1–11

1. Robot Moe is assembling memory cards for computers. At 9:00 A.M., 52 cards had been assembled. At 11:00 A.M., a total of 98 had been made. Assuming the production rate is linear

a. Find the slope of this line and explain what it means in this context.

b. Determine how many cards Moe can assemble in an eight-hour day.

c. Find a linear equation model for this data.

d. Determine the approximate time that Moe began work this morning.

Table for Exercise 3

x	y
0	
$\frac{\pi}{6}$	
$\frac{\pi}{4}$	
$\frac{\pi}{3}$	
$\frac{\pi}{2}$	
$\frac{2\pi}{3}$	
$\frac{5\pi}{6}$	
π	

2. When using a calculator to find $\sin 120°$, you get $\dfrac{\sqrt{3}}{2}$, yet $\sin^{-1}\left(\dfrac{\sqrt{3}}{2}\right) \neq 120°$. Explain why.

3. Complete this table of special values for $y = \cos x$ without using a calculator.

4. Sketch the graph of $y = \sqrt{x+4} - 3$ using transformations of a toolbox function. Label the x- and y-intercepts and state what transformations were used.

5. Solve using the quadratic formula: $3x^2 + 5x - 7 = 0$. State your answer in exact and approximate form.

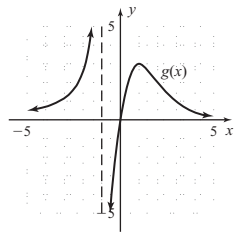
6. The orbit of Venus around the Sun is nearly circular, with a radius of 67 million miles. The planet completes one revolution in about 225 days. Calculate the planet's (a) angular velocity in radians per hour and (b) the planet's orbital velocity in miles per hour.

7. For the graph of $g(x)$ shown, state where

a. $g(x) = 0$ **b.** $g(x) < 0$

c. $g(x) > 0$ **d.** $g(x)\uparrow$

e. $g(x)\downarrow$ **f.** local max



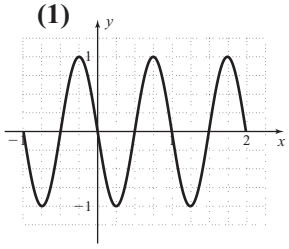
g. local min **h.** $g(x) = 2$

i. $g(4)$ **j.** $g(-1)$

k. as $x \to -1^+$, $g(x) \to$ _____

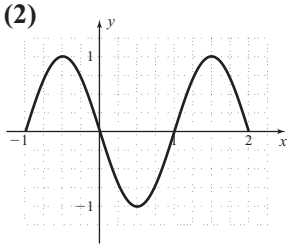
l. as $x \to \infty$, $g(x) \to$ _____

m. the domain of $g(x)$



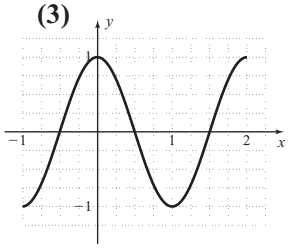
8. Match each equation to its corresponding graph.

a. $y = \sin(\pi x)$ **b.** $y = \sin(\pi x - \pi)$

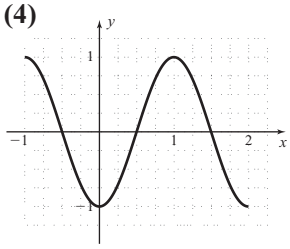


c. $y = \sin(2\pi x - \pi)$ **d.** $y = \sin\left(\pi x - \frac{\pi}{2}\right)$

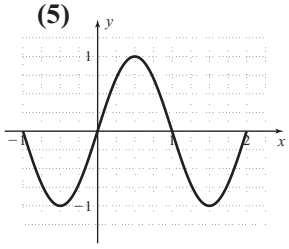
e. $y = \sin(2\pi x)$ **f.** $y = \sin\left(\pi x + \frac{\pi}{2}\right)$



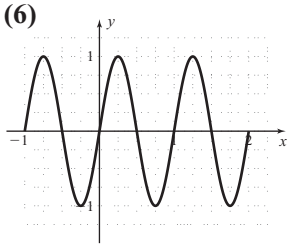
(1)



(2)



(3)



(4)

(5)

(6)

9. Graph the piecewise function and state the domain and range.

$$y = \begin{cases} -2 & -3 \le x \le -1 \\ x & -1 < x < 2 \\ x^2 & 2 \le x \le 3 \end{cases}$$

10. For $\mathbf{u} = 3\mathbf{i} + 4\mathbf{j}$ and $\mathbf{v} = -12\mathbf{i} + 8\mathbf{j}$, find the resultant vector $\mathbf{w} = \mathbf{u} + \mathbf{v}$, then use the dot product to compute the angle between $\mathbf{u}$ and $\mathbf{w}$.

11. Compute the difference quotient for each function given.

a. $f(x) = 2x^2 - 3x$ **b.** $h(x) = \dfrac{1}{x - 2}$

12. Graph the polynomial function given. Clearly indicate all intercepts. $f(x) = x^3 + x^2 - 4x - 4$

13. Graph the rational function $h(x) = \dfrac{2x^2 - 8}{x^2 - 1}$. Clearly indicate all asymptotes and intercepts.

14. Write each expression in logarithmic form:

a. $x = 10^y$ **b.** $\dfrac{1}{81} = 3^{-4}$

15. Write each expression in exponential form:

a. $3 = \log_x(125)$ **b.** $\ln(2x - 1) = 5$

16. What interest rate is required to ensure that \$2000 will double in 10 yr if interest is compounded continuously?

17. Solve for x.

a. $e^{2x-1} = 217$ **b.** $\log(3x - 2) + 1 = 4$

18. Solve using matrices and row reduction:

$$\begin{cases} 2a + 3b - 6c = 15 \\ 4a - 6b + 5c = 35 \\ 3a + 2b - 5c = 24 \end{cases}$$

19. Solve using a calculator and inverse matrices.

$$\begin{cases} 0.7x + 1.2y - 3.2z = -32.5 \\ 1.5x - 2.7y + 0.8z = -7.5 \\ 2.8x + 1.9y - 2.1z = 1.5 \end{cases}$$

20. Find an equation of the hyperbola with foci at $(-6, 0)$ and $(6, 0)$ and vertices at $(-4, 0)$ and $(4, 0)$.

21. Identify the center, vertices, and foci of the conic section defined by $x^2 + 4y^2 - 24y + 6x + 29 = 0$.

22. Use properties of sequences to determine a_{20} and S_{20}.

a. 262,144, 65,536, 16,384, 4096, ...

b. $\frac{7}{8}, \frac{27}{40}, \frac{19}{40}, \frac{11}{40}, \ldots$

23. Use the difference identity for cosine to

a. verify that $\cos\left(\frac{\pi}{2} - \theta\right) = \sin\theta$ and

b. find the value of $\cos 15°$ in exact form.

24. Caleb's grandparents live in a small town that lies 125 mi away at a heading of 110°. Having just received his pilot's license, he sets out on a heading of 110° in a rented plane, traveling at 125 mph (total flight time 1 hr). Unfortunately, he forgets to account for the wind, which is coming from the northeast at 20 mph on a heading of 190°. (a) If Caleb starts out at coordinates (0, 0), what are the coordinates of his grandparent's town? (b) What are the vector coordinates of the plane 1 hr later? (c) How many miles is he actually away from his grandparent's town?

25. Empty 55-gal drums are stacked at a storage facility in the form of a pyramid with 52 barrels in the bottom row, 51 barrels in the next row, and so on, until there are 10 barrels in the top row. Use properties of sequences to determine how many barrels are in this stack.

Exercises 26 through 30 require the use of a graphing calculator.

26. Solve the system. For this system x, y, and z are the variables, with π and e the well-known constants. Round your answer to two decimal places.

$$\begin{cases} \pi x + \sqrt{2}y + ez = 5 \\ \sqrt{2}x + ey + \pi z = 5 \\ ex + \pi y + \sqrt{2}z = 5 \end{cases}$$

27. Find the solution region for the system of linear inequalities. Your answer should include a screen shot or facsimile, and the location of any points of intersection, rounded to four decimal places.

$$\begin{cases} 112x + 39y > 438 \\ 57x - 64y < 101 \\ x \geq 0 \\ y \geq 0 \end{cases}$$

28. A triangle has vertices at (112.3, 98.5), (67.7, −39), and $(-27\pi, 21.5)$. Use the determinant formula to determine its area, rounded to the nearest tenth.

29. A recursive sequence is defined by $a_1 = 0.3$ and $a_{k+1} = a_k^2 - 0.4a_k$. Find S_{40}, rounded to four decimal places.

30. Solve the equation. Round your answer to two decimal places.
$\log x - 2 \ln x + 3 \log_3 x = 6$.

The properties of summation play an important role in the development of many key ideas in a first semester calculus course. Here, we'll see how the summation properties (Section 11.1) are combined with the summation formulas (Section 11.4) and the concept of the area under a curve (*Connections to Calculus* Chapter 3), to produce some very interesting results. For convenience, the summation formulas are restated here:

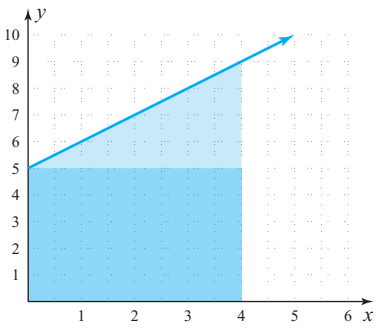
$$(1)\ \sum_{i=1}^{n} c = cn \qquad (2)\ \sum_{i=1}^{n} i = \frac{n^2 + n}{2}$$

$$(3)\ \sum_{i=1}^{n} i^2 = \frac{2n^3 + 3n^2 + n}{6} \qquad (4)\ \sum_{i=1}^{n} i^3 = \frac{n^4 + 2n^3 + n^2}{4}$$

Applications of Summation

For this study, consider the area under the line $f(x) = x + 5$ in the interval $[0, 4]$ (between the y-axis and the vertical line $x = 4$, Figure 11.71). To find the total area, we could add the area of the rectangle and triangle shown, or use $f(0) = 5$ and $f(4) = 9$ as the bases of a trapezoid and simply apply the formula $A = \frac{h}{2}(b_1 + b_2)$ (giving $A = 28$ units^2). Instead of being so direct, we'll use this simple geometric shape to develop some powerful ideas, to be used when the desired area is much more complex. Using what we'll call the **rectangle method,** we first *approximate* the total area by adding the area of the four rectangles shown in Figure 11.72. Note this will give an area greater than the true value, but yields a reasonable estimate.

Figure 11.71



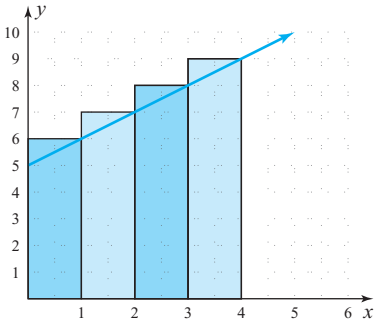


Figure 11.72

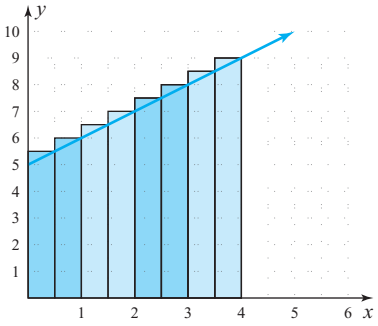


Each rectangle will have a width of 1, since there are four rectangles in an interval four units wide ($\frac{4}{4} = 1$), and the length of each rectangle will be $f(x) = x + 5$ for $x = 1, 2, 3$, and 4. Using the formula $A = LW$, we can write this as $\sum LW = \sum_{i=1}^{4} f(i)(1)$, where the function is written in terms of i $[f(i) = i + 5]$ for the sake of the summation notation.

$$\sum_{i=1}^{4} f(i)(1) = f(1)(1) + f(2)(1) + f(3)(1) + f(4)(1)$$
$$= 6 + 7 + 8 + 9 = 30 \text{ units}^2$$

To refine this estimate, consider the eight rectangles shown in Figure 11.73. The original four-unit interval is now divided into eight parts, so each part is $\frac{4}{8} = \frac{1}{2}$ unit wide. The length of each rectangle is still given by $f(x) = x + 5$, but we now evaluate the function in increments of $\frac{1}{2}$:

Figure 11.73

8 rectangles — one-half unit wide

giving $\sum LW = \sum_{i=1}^{8} f\left(\frac{1}{2}i\right)\left(\frac{1}{2}\right)$

evaluate f each 1/2 unit — for $i = 1, 2, 3, \ldots, 8$

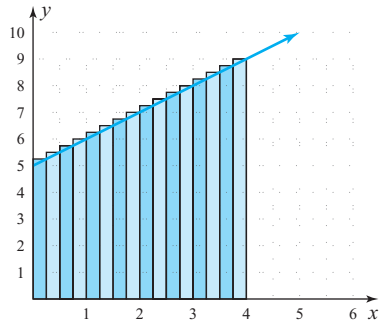
Since the length of each rectangle is multiplied by $W = \frac{1}{2}$, we can factor out $\frac{1}{2}$ and write the expression as $\frac{1}{2}\sum_{i=1}^{8} f\left(\frac{1}{2}i\right)$ for convenience.

EXAMPLE 1 ▶ **Computing a Sum of Rectangular Areas**

Find the sum $\frac{1}{2}\sum_{i=1}^{8} f\left(\frac{1}{2}i\right)$ by writing out each term.

Solution ▶

$$\frac{1}{2}\sum_{i=1}^{8} f\left(\frac{1}{2}i\right) = \frac{1}{2}\left[f\left(\frac{1}{2}\right) + f(1) + f\left(\frac{3}{2}\right) + f(2) + f\left(\frac{5}{2}\right) + f(3) + f\left(\frac{7}{2}\right) + f(4)\right]$$



$$= \frac{1}{2}\left(\frac{11}{2} + 6 + \frac{13}{2} + 7 + \frac{15}{2} + 8 + \frac{17}{2} + 9\right)$$

$$= \frac{11}{4} + 3 + \frac{13}{4} + \frac{7}{2} + \frac{15}{4} + 4 + \frac{17}{4} + \frac{9}{2} = 29 \text{ units}^2$$

Now try Exercises 1 and 2 ▶

This approximation is still too large, but closer to the true value of 28 units^2. At this point, we could get an even better estimate using 16 rectangles (see Figure 11.74), with each width being $\frac{4}{16} = \frac{1}{4}$ unit wide, and the length still computed by $f(x) = x + 5$ but using increments of $\frac{1}{4}$. This would yield $\sum LW = \sum_{i=1}^{16} f\left(\frac{1}{4}i\right)\left(\frac{1}{4}\right) = \frac{1}{4}\sum_{i=1}^{16} f\left(\frac{1}{4}i\right)$. As you might imagine, finding the sum $\frac{1}{4}\sum_{i=1}^{16} f\left(\frac{1}{4}i\right)$ by writing out each term would be tedious and time consuming. Instead, the properties of summation and the summation formulas can be used to develop an expression where we can find *the sum for* $n = 16$ *directly*. The key idea is to note that since $f\left(\frac{1}{4}i\right) = \frac{1}{4}i + 5$, we can write the summation as $\frac{1}{4}\sum_{i=1}^{16}\left(\frac{1}{4}i + 5\right)$ and work as in Example 2.

Figure 11.74

EXAMPLE 2 ▶ **Computing a Sum of Rectangular Areas**

For the sum $\frac{1}{4}\sum_{i=1}^{n}\left(\frac{1}{4}i + 5\right)$, use the summation properties and summation formulas to develop an expression where $\frac{1}{4}\sum_{i=1}^{16}\left(\frac{1}{4}i + 5\right)$ can be found by substituting $n = 16$ directly.

Solution ▶

$$\frac{1}{4}\sum_{i=1}^{n}\left(\frac{1}{4}i+5\right)=\frac{1}{4}\left(\sum_{i=1}^{n}\frac{1}{4}i+\sum_{i=1}^{n}5\right) \quad \text{summation properties (distribute)}$$

$$=\frac{1}{4}\left(\frac{1}{4}\sum_{i=1}^{n}i+\sum_{i=1}^{n}5\right) \quad \text{factor } \frac{1}{4} \text{ from first summation}$$

$$=\frac{1}{4}\left[\frac{1}{4}\left(\frac{n^2+n}{2}\right)+5n\right] \quad \text{use summation formulas}$$

$$=\frac{1}{4}\left[\frac{1}{4}\left(\frac{16^2+16}{2}\right)+5(16)\right] \quad \text{substitute 16 for } n$$

$$=\frac{1}{16}\left(\frac{272}{2}\right)+20 \quad \text{distribute and simplify}$$

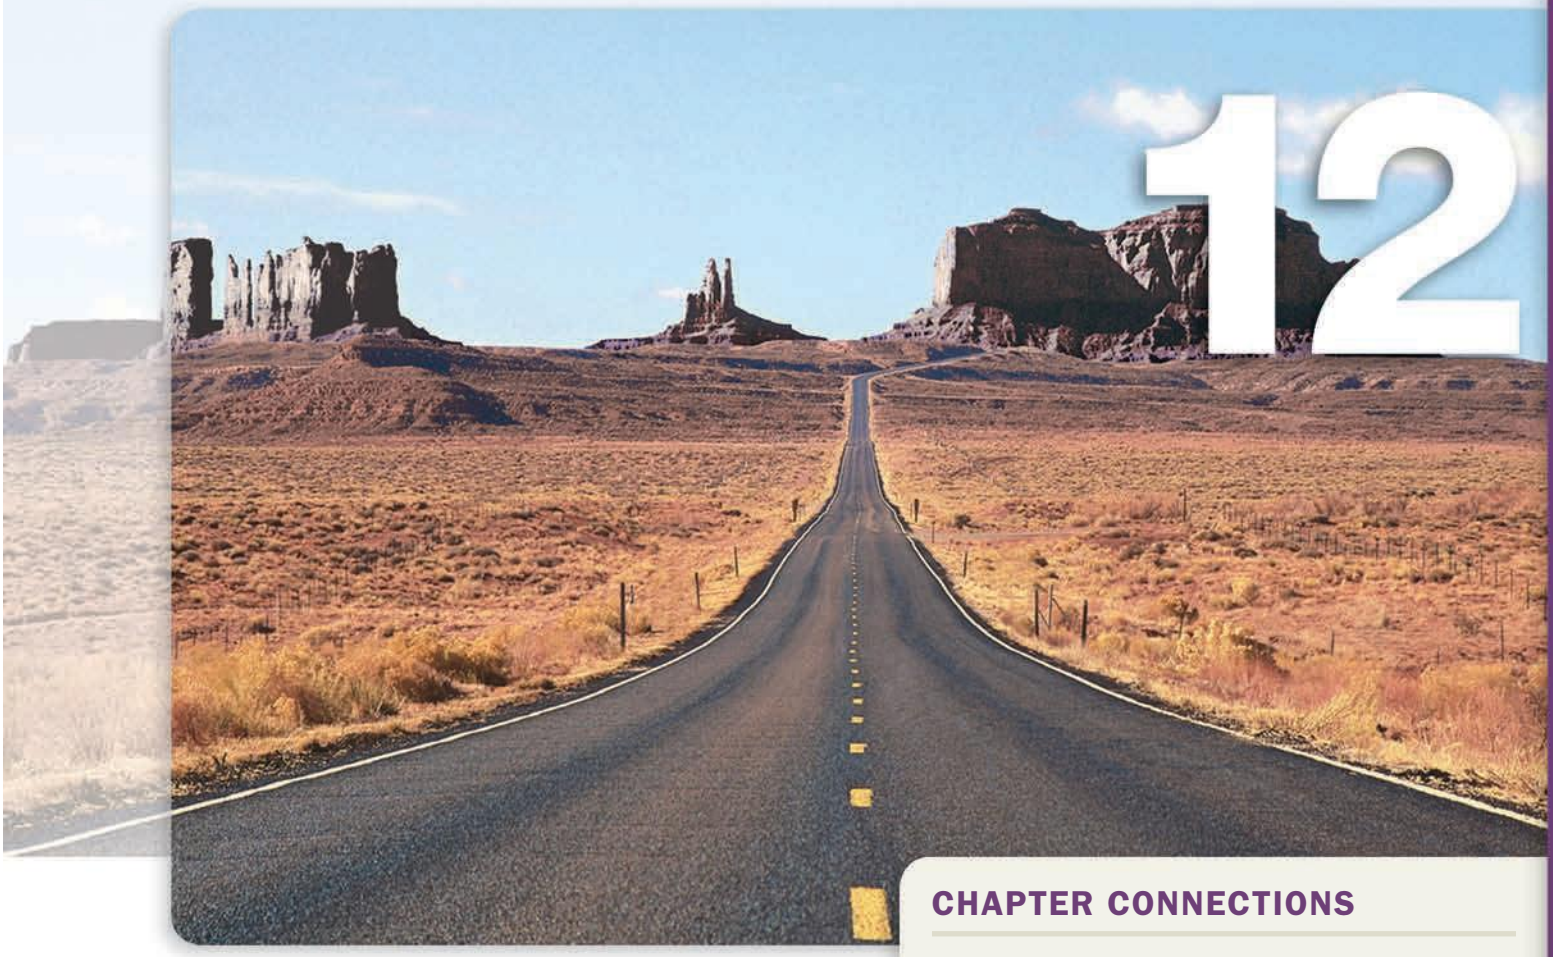
$$=8.5+20=28.5 \quad \text{result}$$

The approximate area is 28.5 units^2.

Now try Exercises 3 and 4 ▶

The significance of this result cannot be overstated. As we'll see in Chapter 12, similar calculations can be used if n rectangles are assumed, with the area easily calculated for *any value of* n. Further, you might imagine the amazement of the early students of mathematics, when they realized that these ideas could still be applied for areas where no elementary formula existed, as for the area under a nonlinear graph.

Connections to Calculus Exercises



1. For $f(x)=-x+6$ and $x\in[0,4]$, (a) graph the function, then approximate the area under the graph in this interval using four rectangles of width 1 and length $f(x)$ for $x=1$, 2, 3, and 4. Begin by developing the summation formula for $\sum LW$, then expand the sum. (b) Repeat part (a) using eight rectangles of width one-half and length $f(x)$. Draw both the graph and the rectangles in each case, and verify the increased number of rectangles gives a better estimate.

2. For $f(x)=x+4$ and $x\in[0,6]$, (a) graph the function, then approximate the area under the graph in this interval using six rectangles of width 1 and length $f(x)$ for $x=1$, 2, 3, 4, 5, and 6. Begin by developing the summation formula for $\sum LW$, then expand the sum. (b) Repeat part (a) using 12 rectangles of width one-half and length $f(x)$. Draw both the graph and the rectangles in each case, and verify the increased number of rectangles gives a better estimate.

For Exercises 3 and 4, show all work requested using a methodical step-by-step process, similar to that illustrated in Example 2.

3. For $f(x)=-x+6$ and $x\in[0,4]$ from Exercise 1, (a) discuss how the area under the graph of f in this interval can be approximated using the rectangle method and $n=32$ rectangles without expanding the sum. (b) Find the area for $n=32$ by applying summation properties and formulas.

4. For $f(x)=x+4$ and $x\in[0,6]$ from Exercise 2, (a) discuss how the area under the graph of f in this interval can be approximated using the rectangle method and $n=36$ rectangles without expanding the sum. (b) Find the area for $n=36$ by applying summation properties and formulas.

Bridges to Calculus: An Introduction to Limits

CHAPTER OUTLINE

12.1 An Introduction to Limits Using Tables and Graphs 1170

12.2 The Properties of Limits 1180

12.3 Continuity and More on Limits 1191

12.4 Applications of Limits: Instantaneous Rates of Change and the Area under a Curve 1203

CHAPTER CONNECTIONS

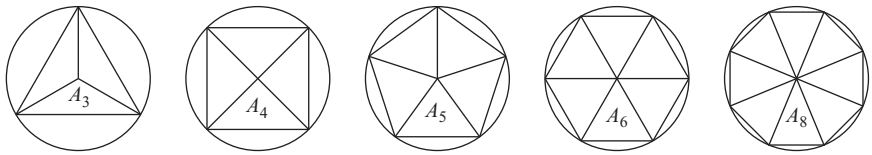
This chapter introduces one of the most central and powerful ideas in calculus, the concept of a limit. While the study of limits isn't a recent phenomenon (Archimedes inscribed a polygon within a circle and considered an ever increasing number of sides to estimate the circumference), a complete development of the idea had to wait for the talents of Augustin-Louis Cauchy (c. 1821) and a maturation of the notation needed to work with the concept effectively. Using a rational function to illustrate, essentially the concept involves recognizing the distinction between the *value* of $g(x) = \dfrac{x^2 + 2x - 3}{x - 1}$ when $x = 1$ (the function is not defined at 1), and the *limit* of $g(x)$ as x becomes very close to 1.

▶ This application appears as Exercise 33 in Section 12.1.

12.1 An Introduction to Limits Using Tables and Graphs

LEARNING OBJECTIVES

In Section 12.1 you will see how we can:



- ❑ **A.** Distinguish between a limit and an approximation
- ❑ **B.** Estimate limits using tables
- ❑ **C.** Evaluate one-sided limits
- ❑ **D.** Determine when a limit does not exist

The concept of a limit is the foundation of all calculus. If the concept is faulty, the conclusions of calculus can be neither supported nor sustained, and the whole becomes a great leap of faith. The inventors of calculus (Isaac Newton and Gottfried Leibniz) tried mightily to bridge the gap between the finite and the infinite, but it was only after a long evolution that the ideas would mature to a point where infinity could be tamed and calculus placed on an unassailable footing.

A. Distinguishing between Limits and Approximations

To begin our study, consider the area of a regular polygon inscribed in a circle of radius r (inscribed: all vertices of the polygon are on the circumference). The radii drawn from the center to each vertex divide the polygons into isosceles triangles, enabling us to approximate the area of the circle by summing the areas of these triangles (Figure 12.1).

Figure 12.1

If we let A_n represent the area of an inscribed polygon with n sides, we note that as the number of sides increases, the area of the polygon gives a better and better approximation of the area of the circle. In fact, it seems intuitive that as n becomes infinitely large, the area of the polygon becomes infinitely close to the area of the circle. Using the notation seen in previous chapters we would say, as $n \to \infty$, $A_n \to \pi r^2$. In a study of limits, **limit notation** is used, and the same statement is written

$$\lim_{n\to\infty} A_n = \pi r^2$$

In words, "the limit of A_n as n becomes infinitely large is πr^2." For practice using the new notation, **see Exercises 7 through 12.**

In a study of limits it becomes extremely important to accept that no finite number of sides for our polygon will give the *exact* area of the circle (even with 100 sides we still have only a very good approximation). But that's not what the concept and notation are saying. They only say that πr^2 is the **limiting value,** and that we can become as close as we like to this limit, by choosing n sufficiently large.

EXAMPLE 1 ▶ **Finding the Area of an Inscribed Polygon**

If an n-sided regular polygon is inscribed in a circle of radius r, its area is given by $A_n = \frac{nr^2}{2}\sin\left(\frac{2\pi}{n}\right)$ (see Worthy of Note). Assume the circle has a radius of $r = 10$ cm. Use the **TABLE** feature of a graphing calculator to determine the number of sides needed (to the nearest 100) for the area of the polygon to approximate the area of the circle rounded to two decimal places ($A \approx 314.16$ units^2 rounded).

WORTHY OF NOTE

From the area formula $A = \frac{1}{2}ab\sin C$, note that for each triangle within the circle, the angle at the center C is $\frac{2\pi}{n}$, and $a = b = r$. This shows each triangle has area $A = \frac{1}{2}r^2\sin\left(\frac{2\pi}{n}\right)$ and there are n of these triangles.

Solution ▶ With $r = 10$, the formula becomes $A_n = 50n \sin\left(\frac{2\pi}{n}\right)$, where n represents the number of sides. Enter this equation as Y_1 in your calculator (in function and radian MODE), and set up a table to start at 100 with $\Delta\text{Tbl} = 100$. In the figure, we note that when $n = 700$, the area of the polygon approximates the area of the circle rounded to two decimal places.

☑ **A.** You've just seen how we can distinguish between a limit and an approximation

Now try Exercises 13 through 16 ▶

B. Estimating Limits Using Tables and Graphs

The limit in the discussion prior to Example 1 ($\lim_{n\to\infty} A_n$) is called a **limit at infinity,** or a limit as n becomes infinitely large. These are discussed in more detail in Section 12.3. Here we turn our attention to limits at a constant c (the limit as $x \to c$), an idea we explored in our study of asymptotic behavior in Section 4.5. Consider the function $f(x) = \frac{\sin x}{x}$ (x in radians), noting that $x = 0$ is not in the domain of f. However, the fact that we could not evaluate $\lim_{n\to\infty} A_n$ for $n = \infty$ in Example 1, did not stop us from evaluating A_n as $n \to \infty$. Similarly, we cannot evaluate $f(x) = \frac{\sin x}{x}$ at $x = 0$, but we can evaluate f for values of x slightly less than zero, or slightly greater than zero, to investigate the limit of $\frac{\sin x}{x}$ as $x \to 0$. For additional practice with the limit notation, **see Exercises 17 through 22.**

EXAMPLE 2 ▶ **Determining Whether a Limiting Value Exists**

Use the **TABLE** feature of a graphing calculator to evaluate $f(x) = \frac{\sin x}{x}$ as $x \to 0$. If the function seems to approach a limiting value, write the relationship in words and using the limit notation.

Solution ▶ For this exercise it seems appropriate to begin a short distance from zero, and approach it in small increments. Enter $Y_1 = \frac{\sin X}{X}$ in your calculator and set up the table to **ASK** for the independent variable values. Noting that 0 can be "approached" from either side, we use values less than zero (from the left-hand side) and values greater than zero (from the right-hand side). Beginning at $x = -0.5$ and approaching 0 from the left, our calculator produces the screen shown in Figure 12.2. Starting at $x = 0.5$ and approaching from the right yields Figure 12.3. Note the calculator rounds each entry in the Y_1 column to five decimal places. Because of this, the final Y_1 value shown in each figure is 1. After using the arrow keys to highlight this value, the calculator displays a more accurate approximation (rounded to 12 decimal places) along the bottom of the screen. These values in both figures seem to indicate that as x becomes very close to 0, $\frac{\sin x}{x}$ becomes very close to 1, or seems to have a limiting value of 1. In limit notation we write $\lim_{x\to 0} \frac{\sin x}{x} = 1$.

Now try Exercises 23 through 28 ▶

Similar to our work with the area of a polygon and circle, note that we can make $\frac{\sin x}{x}$ as close as we like to 1 by using values of x that are sufficiently close to 0. This suggests the following definition of a limit, a definition, however, that will be refined and made more precise as we gain a greater understanding of the limit concept.

The Definition of a Limit

For a fixed real number L and constant c,

$$\lim_{x \to c} f(x) = L$$

means that values of $f(x)$ can be made arbitrarily close (infinitely close) to L, by taking values of x sufficiently close to c, $x \neq c$.

The graph of (1) $f(x) = \frac{\sin x}{x}$ is shown in Figure 12.4. As we did in Section 2.5, we could create a piecewise function that defines $f(x)$ at $x = 0$, and two possibilities are listed here, followed by their graphs (Figures 12.5 and 12.6, respectively).

$$(2)\ f(x) = \begin{cases} \frac{\sin x}{x} & x \neq 0 \\ 2 & x = 0 \end{cases} \qquad (3)\ f(x) = \begin{cases} \frac{\sin x}{x} & x \neq 0 \\ 1 & x = 0 \end{cases}$$

Figure 12.4

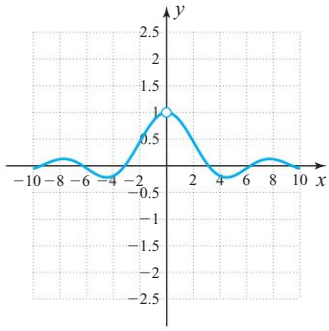

Figure 12.5

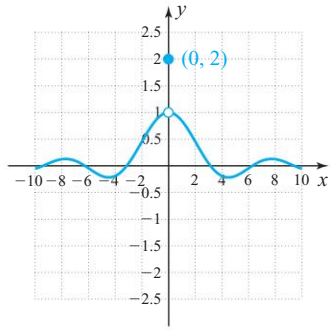

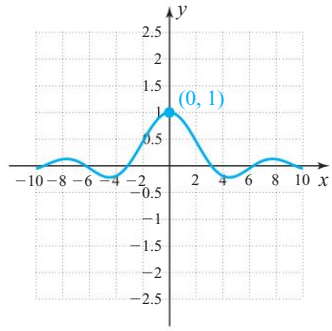

Figure 12.6

In (2), $f(x)$ defines the function at (0, 2) but leaves a hole in the graph at (0, 1), while in (3), $f(x)$ is a continuous function as we can now draw the entire graph without lifting our pencil **(see Exercises 29 and 30).** Note that in all three cases, $\lim_{x \to 0} f(x) = 1$ *remains true,* as the definition of a limit is still satisfied in every respect. In other words, the limit of a function as $x \to c$ can exist even if

(1) the function is not defined at c as in $f(x) = \frac{\sin x}{x}$,

(2) the function is defined at c but $f(c) \neq L$ as in $f(x) = \begin{cases} \frac{\sin x}{x}, & x \neq 0 \\ 2 & x = 0 \end{cases}$,

or (3) the function is defined at c and $f(c) = L$ as in $f(x) = \begin{cases} \frac{\sin x}{x}, & x \neq 0 \\ 1 & x = 0 \end{cases}$.

EXAMPLE 3 ▶ Determining Whether a Limiting Value Exists

Use the **TABLE** feature of a graphing calculator to evaluate $g(x) = \frac{\frac{1}{2}x^2 - x}{x - 2}$, as $x \to 2$. If the function seems to approach a limiting value, write the relationship in words and using the limit notation.

Solution ▶ Similar to Example 2, enter this equation as Y_1 in your calculator, start a short distance from 2 on the left- and right-hand sides, and approach 2 in small increments. Starting from the left at 1.6 produces the table shown in Figure 12.7. Starting from the right at 2.4 yields Figure 12.8.

These screen shots seem to indicate that as x becomes very close to 2, $g(x)$ becomes very close to 1, or seems to have a limiting value of 1. In limit notation, $\lim_{x \to 2} \dfrac{\frac{1}{2}x^2 - x}{x - 2} = 1$. The graph of $y = g(x)$ is shown in Figure 12.9.

☑ **B.** You've just seen how we can estimate limits using tables

Now try Exercises 31 through 36 ▶

C. One-Sided Limits

In Examples 2 and 3 our discussion focused on what are called **two-sided limits,** as we approached the limiting value by selecting inputs to the left *and* to the right of c ($x \neq c$). But what of functions like $y = \sqrt{2 - x}$, $y = \dfrac{x^2 - 2x}{20\sqrt{x - 2}}$ and many others, that may only be defined to the left *or* right of $c = 2$? Can these functions approach a limiting value as x approaches c from only one side?

EXAMPLE 4 ▶ **Determining Whether a Limit Exists for a One-Sided Approach**

Use the **TABLE** feature of a graphing calculator to help determine if $f(x) = \dfrac{x^2 - 2x}{20\sqrt{x - 2}}$ has a limiting value as $x \to 2$ from the right.

Solution ▶ With the radical $\sqrt{x - 2}$ in the denominator, the domain of f is $(2, \infty)$. For $Y_1 = f(x)$, we input values close to 2 but greater than 2, since 2 can only be "approached" from the right-hand side. The result is the **TABLE** shown, and seems to indicate that as x becomes very close to 2 from the right, Y_1 becomes very close to 0. Further, it appears we can make Y_1 as close to zero as we like, by choosing values of x sufficiently close to 2 but greater than 2. This suggests the limit of $f(x)$ as x approaches 2 from the right is 0.

Y1=.00100005

Now try Exercises 37 through 42 ▶

For functions like those in Example 4, we can define a **one-sided limit,** using the general definition as a template and introducing a modified notation to represent the idea more clearly.

Right-Hand Limits

For a fixed real number L and constant c,

$$\lim_{x \to c^+} f(x) = L$$

means that values of $f(x)$ can be made arbitrarily close (infinitely close) to L, by taking values of x sufficiently close to c and to the right of c $(x > c)$.

Left-Hand Limits

For a fixed real number L and constant c,

$$\lim_{x \to c^-} f(x) = L$$

means that values of $f(x)$ can be made arbitrarily close (infinitely close) to L, by taking values of x sufficiently close to c and to the left of c $(x < c)$.

Note how the superscript on c indicates the direction from which x is approaching c (c can be *any* real number). For $x \to c^-$, x is approaching c from the left (the "negative side"), for $x \to c^+$, x is approaching c from the right (the "positive side"). For practice with this notation, **see Exercises 43 through 46.**

EXAMPLE 5 ▶ **Determining Left- and Right-Handed Limits**

For $h(x) = \dfrac{|x-2|}{x-2}$, use the **TABLE** feature of a gaphing calculator to evaluate the expressions

a. $\lim_{x \to 2^-} h(x)$ **b.** $\lim_{x \to 2^+} h(x)$

If a limiting value appears to exist from either side, write the relationship in words and using the limit notation.

Solution ▶ Begin by noting the domain of h is $x \in \mathbb{R}, x \neq 2$.

a. For $\lim_{x \to 2^-} h(x)$, we use a table to track the value of h as x approaches 2 from the left. After entering $h(x)$ as Y_1 (recall the **abs(** command can be found under the MATH **NUM** menu), the **TABLE** produced is shown in Figure 12.10, and suggests $\lim_{x \to 2^-} \dfrac{|x-2|}{x-2} = -1$. In words, the limit of $h(x)$ as x approaches 2 from the left is -1.

Figure 12.10

b. Similarly, Figure 12.11 suggests $\lim_{x \to 2^+} \dfrac{|x-2|}{x-2} = 1$, or the limit of $h(x)$ as x approaches 2 from the right is 1.

The graph of h is shown in Figure 12.12 and seems to support these conclusions.

Figure 12.12

C. You've just seen how we can evaluate one-sided limits

Now try Exercises 47 through 54 ▶

D. Limits That Fail to Exist

Unlike the function in Example 4 (where x could approach 2 only from the right), the functions in Examples 3 and 5 allowed approaches from both the left and right sides. Note that the statement, "taking values of x sufficiently close to c" from the general definition of a limit *implies a two-sided approach to c,* and we must approach c from both sides wherever possible. Since this is not possible in Example 4, we use the notation for one-sided limits to state: $\lim\limits_{x\to 2^+} \dfrac{x^2-2x}{20\sqrt{x-2}} = 0$. For the function $g(x)$ in Example 3, a "two-sided" approach was possible and we saw the value approached from each side was equal to 1. Using the general definition we were able to write $\lim\limits_{x\to 2} g(x) = 1$ (the limit is $L = 1$). For the function $h(x)$ in Example 5, x could also approach c from both sides, but the left-hand limit was not equal to the right, and there is no single number L that $h(x)$ approaches as $x \to 2$. This leads us to the following statement:

The Existence of a Limit

For a fixed real number L and constant c,

$$\lim_{x\to c} f(x) = L \quad \text{if and only if} \quad \lim_{x\to c^-} f(x) = \lim_{x\to c^+} f(x) = L.$$

In words, "the limit of $f(x)$ as x approaches c is L, if and only if the left-hand limit as x approaches c is equal to the right-hand limit as x approaches c, and both are also equal to L."

EXAMPLE 6 ▶ **Determining Whether a Limit Exists**

Use the **TABLE** feature of a graphing calculator to evaluate the expression $\lim\limits_{x\to 3} \dfrac{x^2-3x}{\sqrt{x^2-6x+9}}$.

Solution ▶ Similar to the previous examples, we enter $Y_1 = \dfrac{X^2-3X}{\sqrt{X^2-6X+9}}$ into our calculator. As a matter of choice we first evaluate the left-hand limit, and Figure 12.13 suggests $\lim\limits_{x\to 3^-} \dfrac{x^2-3x}{\sqrt{x^2-6x+9}} = -3$. For the right-hand limit, Figure 12.14 suggests $\lim\limits_{x\to 3^+} \dfrac{x^2-3x}{\sqrt{x^2-6x+9}} = 3$.

Y1 = 3.0001

Since the left-hand limit ≠ right-hand limit, $\lim\limits_{x\to 3} \dfrac{x^2-3x}{\sqrt{x^2-6x+9}}$ does not exist.

Figure 12.15

The graph of $y = \dfrac{x^2-3x}{\sqrt{x^2-6x+9}}$ is shown in Figure 12.15. As a matter of order we will adopt the following notation for the case where the left-hand limit is not equal to the right-hand limit. Using dne as an abbreviation for "does not exist," we will write $\lim\limits_{x\to c} f(x) = \left(\underset{\text{LH}\neq\text{RH}}{\text{dne}}\right)$.

Now try Exercises 55 through 60 ▶

In Example 7 we note a second way that a limit can fail to exist.

EXAMPLE 7 ▶ Determining Whether a Limit Exists

Given $f(x) = \dfrac{9x}{(x-2)^2}$, use a **TABLE** to evaluate $\lim\limits_{x\to 2} f(x)$.

Solution ▶ For the left-hand limit, we obtain the **TABLE** shown and note as $x \to 2^-$, the value of $f(x)$ increases without bound [for $x = 1.999$, $f(x)$ is almost 18,000,000]. A similar check shows that as $x \to 2^+$, the values of $f(x)$ likewise become infinitely large. Since $f(x)$ becomes infinitely large and positive as $x \to 2$, the limit does not exist and we write $\lim\limits_{x\to 2} f(x) = \left(\begin{matrix}\text{dne}\\ \infty\end{matrix}\right)$.

X	Y1
1.5	54
1.6	90
1.7	170
1.8	405
1.9	1710
1.99	179100
1.999	17991000

Y1=17991000

Now try Exercises 61 through 66 ▶

From our work with rational functions in Section 4.5, we know the graph of $f(x) = \dfrac{9x}{(x-2)^2}$ has a vertical asymptote at $x = 2$, verifying it is impossible for the function to have a limit as $x \to 2$.

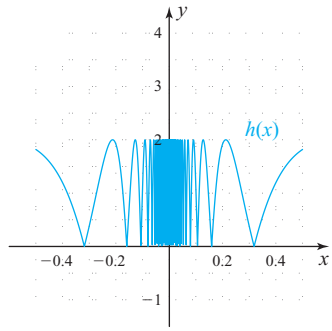
Finally, we consider a third way that a limit can fail to exist.

EXAMPLE 8 ▶ Determining Whether a Limit Exists

For $h(x) = 2\left|\sin\left(\dfrac{1}{x}\right)\right|$, try to find a fixed number L such that $\lim\limits_{x\to 0} f(x) = L$.

Solution ▶ Using an approach from the right gives the result shown in Figure 12.16. This time there is no apparent pattern in the output values, and a graph of the function (Figure 12.17) reveals why. As $x \to 0$, the function begins to oscillate wildly between 0 and 2, with no approach to any fixed number L. A similar thing happens for a left-handed approach. As per our definition, the limit does not exist because L does not exist. In this case, we write $\lim\limits_{x\to 2} h(x) = \left(\begin{matrix}\text{dne}\\ \not\exists\end{matrix}\right)$.

WORTHY OF NOTE



For students and instructors with a sense of humor, Example 8 is sometimes called the Christmas Case, because there's No-el.

12.1 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section, if necessary.

1. The limit of $f(x)$ as $x \to \infty$ is called a limit at _____.

2. $\lim\limits_{x \to c} g(x) = L$ means that values of $g(x)$ can be made _____ to L, by taking values of _____ sufficiently close to _____.

3. To evaluate the limit of a function as $x \to c$, we must find the _____ limit using values of x less than c, and the _____ limit using values of x _____ than c.

4. If a rational function $v(x)$ has a vertical asymptote at $x = c$, the limit as $x \to c$ does not exist and we write $\lim\limits_{x \to c} v(x) =$ _____.

5. Discuss/Explain why $\lim\limits_{x \to 3} g(x) = 5$ for $g(x) = \dfrac{x^2 - x - 6}{x - 3}$, but $g(3) \neq 5$. Can we redefine $g(x)$ to create a piecewise-defined function where $\lim\limits_{x \to 3} g(x) = g(3)$?

6. Discuss/Explain why $\lim\limits_{x \to 1} f(x)$ does not exist for $f(x) = \dfrac{x^2 - x}{\sqrt{(x-1)^2}}$, even though the left-hand limit and the right-hand limit do exist.

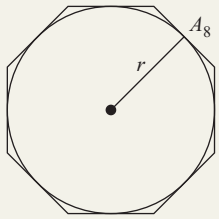
▶ DEVELOPING YOUR SKILLS

Write each of the following statements using limit notation.

7. As n approaches ∞, V_n approaches $\dfrac{4}{3}\pi r^3$.

8. As n approaches ∞, A_n approaches $\dfrac{a}{3}x^3 + \dfrac{b}{2}x^2 + cx + d$.

9. As t approaches $-\infty$, $e^{f(t)}$ approaches 0.



10. As t approaches $-\infty$, $\sin[g(t)]$ approaches 1.

11. As x increases without bound, $\cos\left(\dfrac{1}{x}\right)$ approaches 1.

12. As x decreases without bound, $\dfrac{5x^2 - 3}{2x^2 - x - 1}$ approaches $\frac{5}{2}$.

Use the TABLE feature of a graphing calculator for the following exercises.

13. If an n-sided regular polygon *circumscribes* a circle of radius r (see the figure), its area is given by $A_n = nr^2 \tan\left(\dfrac{\pi}{n}\right)$. For a circle with radius $r = 10$ cm, determine the number of sides needed (to the nearest 100) for the area of the polygon to approximate the area of the circle correct to two decimal places when rounded. Compare your result with that of Example 1.

14. If an n-sided regular polygon is *inscribed* in a circle of radius r, its perimeter is given by $P = 2nr \sin\left(\dfrac{\pi}{n}\right)$. For a circle with radius $r = 50$ mm, determine the number of sides needed (to the nearest 25) for the perimeter of the polygon to approximate the circumference of the circle correct to two decimal places when rounded.

15. If an n-sided regular polygon *circumscribes* a circle of radius r, its perimeter is given by $P = 2nr \tan\left(\dfrac{\pi}{n}\right)$. For a circle with radius $r = 50$ mm, determine the number of sides needed (to the nearest 25) for the perimeter of the polygon to approximate the circumference of the circle correct to two decimal places when rounded. Compare your results with those in Exercise 14.

16. One of the most famous and useful numbers in all of mathematics is the one defined as $\lim\limits_{x \to \infty} \left(1 + \dfrac{1}{x}\right)^x = e$. Determine the smallest x to (the nearest 250) that can be used to approximate the value of e to three decimal places.

Write each of the following statements using limit notation.

17. As t approaches 5, s_t approaches $5r$.

18. As t approaches -3, d_t approaches $\sqrt{9 + r^2}$.

19. As x approaches a, $\tan^{-1}[g(x)]$ approaches $\frac{\pi}{3}$.

20. As x approaches b, $\csc^2[f(x)]$ approaches $\frac{4}{3}$.

21. As $x \to -3$, $\dfrac{x + 3}{x^2 - 9}$ approaches $-\frac{1}{6}$.

22. As $x \to \pi$, $\dfrac{\sin x}{\cos\left(\dfrac{x}{2}\right)}$ approaches 2.

Use the TABLE feature of a graphing calculator to evaluate each function as x approaches the value indicated. If the function seems to approach a limiting value, write the relationship in words and using the limit notation.

23. $p(x) = \cos x + \sin\left(\dfrac{3x}{2}\right); x \to \pi$

24. $q(x) = \tan x + 3 \sin 2x; x \to \dfrac{\pi}{4}$

25. $v(x) = \dfrac{\cos\left(\dfrac{\pi}{x}\right)}{\sin(\pi x)}; x \to 2$

26. $w(x) = \dfrac{\tan(x - 2)}{x - 2}; x \to 2$

27. $s(x) = \dfrac{2 \cos x - 2}{x}; x \to 0$

28. $t(x) = \dfrac{\sin x - 1}{\sin(2x)}; x \to \dfrac{\pi}{2}$

The functions in Exercises 29 and 30 have a hole (discontinuity) in their graphs at $x = 2$. Write a related piecewise-defined function that creates a continuous graph for each.

29. $r(x) = \dfrac{2x^2 - 7x + 6}{\sin(x - 2)}$

30. $s(x) = \dfrac{\sin(x^2 - 4x + 4)}{x - 2}$

Use the TABLE feature of a graphing calculator to evaluate each function as x approaches the value indicated. If the function seems to approach a limiting value, write the relationship in words and using the limit notation.

31. $f(x) = \dfrac{x^2 - 2x}{x^2 - 4}; x \to 2$

32. $v(x) = \dfrac{x^2 - 3x - 10}{2x + 4}; x \to -2$

33. $g(x) = \dfrac{x^2 + 2x - 3}{x - 1}; x \to 1$

34. $w(x) = \dfrac{x(x - 2) - 8}{4(x - 4)}; x \to 4$

35. $f(x) = 3x^2 - x - 2; x \to 1$

36. $g(x) = 10x - x^2; x \to -2$

See if the TABLE feature of a graphing calculator suggests a limit exists for the functions and approaches indicated.

37. $f(x) = 2x^2 - 3x$ as $x \to -3$ from the right.

38. $g(x) = 6x^2 - x$ as $x \to -\dfrac{1}{2}$ from the right.

39. $f(x) = \dfrac{x^3 + 8}{\frac{1}{2}x + 1}$ as $x \to -2$ from the left.

40. $g(x) = \dfrac{x^4 - 1}{x + 1}$ as $x \to -1$ from the left.

41. $f(x) = \dfrac{\sin\sqrt{x}}{\sqrt{x}}$ as $x \to 0$ from the right.

42. $g(x) = \dfrac{x}{\ln x}$ as $x \to 0$ from the right.

Write each statement using limit notation.

43. As x approaches 3 from the left, I_x approaches $3 \cos^2(R_1 + R_2)$.

44. As x approaches -1 from the right, S_x approaches $\log(\varphi + 1)$.

45. As x approaches m from the left, f approaches L.

46. As x approaches n from the right, g approaches L.

Evaluate the following limits using the TABLE feature of a graphing calculator.

47. Given $f(x) = \dfrac{\sin x}{|\sin x|}$, find

a. $\lim\limits_{x \to \pi^-} f(x)$ **b.** $\lim\limits_{x \to \pi^+} f(x)$

48. Given $g(x) = -\dfrac{\cos x}{|\cos x|}$, find

a. $\lim\limits_{x \to \frac{\pi}{2}^-} g(x)$ **b.** $\lim\limits_{x \to \frac{\pi}{2}^+} g(x)$

49. Given $f(x) = \dfrac{x^2 - 10x + 24}{\sqrt{x^2 - 12x + 36}}$, find

a. $\lim\limits_{x \to 6^-} f(x)$ **b.** $\lim\limits_{x \to 6^+} f(x)$

50. Given $g(x) = \dfrac{x^2 + 2x - 3}{\sqrt{x^2 + 6x + 9}}$, find

a. $\lim\limits_{x \to -3^-} g(x)$ **b.** $\lim\limits_{x \to -3^+} g(x)$

51. Given $f(x) = \dfrac{2}{x} - 3x^{\frac{1}{2}}$, find

a. $\lim\limits_{x \to 4^-} f(x)$ **b.** $\lim\limits_{x \to 4^+} f(x)$

52. Given $g(x) = e^x - 5$, find

a. $\lim\limits_{x \to \ln 7.3^-} g(x)$ **b.** $\lim\limits_{x \to \ln 7.3^+} g(x)$

53. For $f(x) = \begin{cases} x^2 - 4 & x < 2 \\ \sin(x^2 - 4) & x \geq 2 \end{cases}$, find

a. $\lim\limits_{x \to 2^-} f(x)$ **b.** $\lim\limits_{x \to 2^+} f(x)$

54. For $g(x) = \begin{cases} 3 \tan\left[\dfrac{\pi}{4}(x + 2)\right] & x \leq -1 \\ \sqrt{x^2 + 8} & x > -1 \end{cases}$, find

a. $\lim\limits_{x \to -1^-} g(x)$ **b.**

55. Given $f(x) = \begin{cases} 2x^2 - 7 & x < -5 \\ 3 - 2x & x \geq -5 \end{cases}$, find

a. $\lim\limits_{x \to -5^-} f(x)$ **b.** $\lim\limits_{x \to -5^+} f(x)$

c. $\lim\limits_{x \to -5} f(x)$

56. Given $g(x) = \begin{cases} -(x + 1) & x \leq 10 \\ \log x & x > 10 \end{cases}$, find

a. $\lim\limits_{x \to 10^-} g(x)$ **b.** $\lim\limits_{x \to 10^+} g(x)$

c. $\lim\limits_{x \to 10} g(x)$

57. Given $f(x) = \dfrac{\sqrt{1 - \cos(2x)}}{\sqrt{2} \sin x}$, find

a. $\lim\limits_{x \to \pi^-} f(x)$ **b.** $\lim\limits_{x \to \pi^+} f(x)$

c. $\lim\limits_{x \to \pi} f(x)$

58. Given $g(x) = \dfrac{\sin[\pi(x - 1)]}{|x|}$, find

a. $\lim\limits_{x \to 0^-} g(x)$ **b.** $\lim\limits_{x \to 0^+} g(x)$

c. $\lim\limits_{x \to 0} g(x)$

59. Given $f(x) = \begin{cases} \sin x & x < \dfrac{\pi}{4} \\ \tan x & x = \dfrac{\pi}{4} \\ \cos x & x > \dfrac{\pi}{4} \end{cases}$, find

a. $\lim\limits_{x \to \frac{\pi}{4}^-} f(x)$ **b.** $\lim\limits_{x \to \frac{\pi}{4}^+} f(x)$

c. $\lim\limits_{x \to \frac{\pi}{4}} f(x)$

60. Given $g(x) = \begin{cases} \sec x & x < \dfrac{5\pi}{4} \\ \cot x & x = \dfrac{5\pi}{4} \\ \csc x & x > \dfrac{5\pi}{4} \end{cases}$, find

a. $\lim\limits_{x \to \frac{5\pi}{4}^-} g(x)$ **b.** $\lim\limits_{x \to \frac{5\pi}{4}^+} g(x)$

c. $\lim\limits_{x \to \frac{5\pi}{4}} g(x)$

61. Given $f(x) = x^2 + \dfrac{3}{(x + 2)^2}$, find $\lim\limits_{x \to -2} f(x)$.

62. Given $g(x) = 2x^2 - 3x + 4x^{-2}$, find $\lim\limits_{x \to 0} g(x)$

63. Given $f(x) = \dfrac{-4 \cos\left(\dfrac{\pi}{4}x\right)}{x - 2}$, find $\lim\limits_{x \to 2} f(x)$.

64. Given $g(x) = |\csc(x^2 - 17x + 52)|$, find $\lim\limits_{x \to 13} g(x)$.

65. Given $f(x) = \dfrac{2x}{|x^3 + 216|}$, find $\lim\limits_{x \to -6} f(x)$.

66. Given $g(x) = \dfrac{6x^2 - x - 1}{2x - 1}$, find $\lim\limits_{x \to \frac{1}{2}} g(x)$.

67. Given $f(x) = \sin\left(\dfrac{x + 1}{x - 1}\right)$, find $\lim\limits_{x \to 1} f(x)$.

68. Given $g(x) = \cos\left(\dfrac{x - 1}{x + 1}\right)$, find $\lim\limits_{x \to 1} g(x)$.

69. Given $f(x) = \tan(\cos x)$, find $\lim\limits_{x \to \frac{\pi}{2}} f(x)$.

70. Given $f(x) = \cos(\tan x)$, find $\lim\limits_{x \to \frac{\pi}{2}} f(x)$.

▶ MAINTAINING YOUR SKILLS

71. **(4.2)** Use the rational zeroes theorem to write the polynomial in completely factored form: $3x^4 - 19x^3 + 15x^2 + 27x - 10$.

72. **(3.1)** Find the sum, difference, product, and quotient of $1 + 3i$ and $1 - 3i$.

73. **(8.2)** Use Heron's formula to find the area of a triangle with sides $a = 5$ in., $b = 8$ in., $c = 9$ in., rounded to two decimal places.

74. **(6.5)** Write a sinusoidal equation given the maximum is 100, the minimum is -20 and the period is 365.

12.2 The Properties of Limits

LEARNING OBJECTIVES

In Section 12.2 you will see how we can:

- ❑ **A.** Establish limit properties using a table
- ❑ **B.** Evaluate limits using the limit properties
- ❑ **C.** Distinguish between a declarative statement and a proof

After the invention of calculus, but before the concept of a limit had been fully developed, the ideas of Newton (the method of fluxions) and Leibniz (the method of differentials) were often met with skepticism and sarcasm even within the academic world. In a tract called *The Analyst* (1734), mathematician and philosopher George Berkeley once said, "he who can digest a second or third fluxion ... need not, methinks, be squeamish about any point in divinity." In this section, we introduce the properties of limits, which helped to place the study of calculus on a sure footing. The plausibility of these properties will be illustrated using a table or graph, with their formal proof left for a future course.

A. Establishing the Limit Properties

While our work in Section 12.1 seems plausible, using a table of values to draw conclusions can sometimes be misleading (see objective C that follows), and it seems we need a more definitive method for evaluating limits. As it turns out, limits possess certain properties that, once established, enable us to evaluate even complicated limits with complete confidence. The properties we're interested in involve the various ways that limits can be combined using basic operations. For instance, from our study of operations on functions, we know $(f + g)(x) = f(x) + g(x)$. Is it similarly true that $\lim\limits_{x\to c}[f(x) + g(x)] = \lim\limits_{x\to c} f(x) + \lim\limits_{x\to c} g(x)$? While a formal proof of the properties that follow will be offered in a first calculus course, for the time being we will accept them as true after demonstrating their plausibility using tables and our intuition (despite their shortcomings).

EXAMPLE 1 ▶ Combining Limits to Establish Limit Properties

Using a table of values and the techniques from Section 12.1, it can be shown that for $f(x) = x$ and $g(x) = -x^2 + 7$, $\lim\limits_{x\to 3} f(x) = 3$ and $\lim\limits_{x\to 3} g(x) = -2$. Create a new function $h(x) = (f + g)(x)$ and use the **TABLE** feature of a graphing calculator to investigate whether $\lim\limits_{x\to c}[f(x) + g(x)] = \lim\limits_{x\to c} f(x) + \lim\limits_{x\to c} g(x)$.

Solution ▶ For f and g as given, we have $h(x) = x + (-x^2 + 7)$. This means we need to investigate $\lim_{x\to 3} h(x) = \lim_{x\to 3} [x + (-x^2 + 7)]$. With $Y_1 = X + (-X^2 + 7)$, the tables shown in Figures 12.18 and 12.19 seem to indicate $\lim_{x\to 3} h(x) = 1$.

Figure 12.18

X	Y1
2.6	2.84
2.7	2.41
2.8	1.96
2.9	1.49
2.99	1.0499
2.999	1.005
2.9999	[illegible]

Y1=1.00049999

Figure 12.19

X	Y1
3.4	-1.16
3.3	-.59
3.2	-.04
3.1	.49
3.01	.9499
3.001	.995
3.0001	[illegible]

Y1=.99949999

It appears that such a property exists, as the tables suggest

$$\lim_{x\to 3} [f(x) + g(x)] = \lim_{x\to 3} f(x) + \lim_{x\to 3} g(x)$$
$$1 = 3 + (-2)$$
$$1 = 1 \checkmark$$

Now try Exercises 7 through 26 ▶

Other investigations might involve whether limits have a "multiplicative" property. In other words, is $\lim_{x\to c} [f(x)g(x)] = \lim_{x\to c} f(x) \lim_{x\to c} g(x)$? Or, is $\lim_{x\to c} \frac{g(x)}{f(x)} = \frac{\lim_{x\to c} g(x)}{\lim_{x\to c} f(x)}$ a true statement? We explore these questions in Example 2.

EXAMPLE 2 ▶ **Combining Limits to Establish Limit Properties**

Using a table of values and the techniques from Section 12.1 suggests that for $f(x) = x^2$ and $g(x) = -3x$, $\lim_{x\to -2} f(x) = 4$ and $\lim_{x\to -2} g(x) = 6$. Note this yields $\lim_{x\to -2} f(x) \cdot \lim_{x\to -2} g(x) = 4(6) = 24$ and $\frac{\lim_{x\to -2} g(x)}{\lim_{x\to -2} f(x)} = \frac{6}{4} = \frac{3}{2}$. Use this information to

a. Create a new function $m(x) = f(x)g(x)$ to investigate whether $\lim_{x\to -2} m(x) = \lim_{x\to -2} f(x) \lim_{x\to -2} g(x)$.

b. Create a new function $v(x) = \frac{g(x)}{f(x)}$ to investigate whether $\lim_{x\to -2} v(x) = \frac{\lim_{x\to -2} g(x)}{\lim_{x\to -2} f(x)}$.

Table 12.1

x	$m(x)$
−1.9	20.577
−1.99	23.642
−1.999	23.964
−2	
−2.001	24.036
−2.01	24.362
−2.1	27.783

Solution ▶ **a.** For the product of f and g we have $m(x) = (x^2)(-3x) = -3x^3$. Now using a single table to view the approach from the left and from the right (indicated by the arrows), Table 12.1 suggests $\lim_{x\to -2} m(x) = \lim_{x\to -2} (-3x^3) = 24$.

WORTHY OF NOTE

While the limits illustrated in Tables 12.1 and 12.2 used functions that were defined at $x = -2$, remember that the limit does not *depend* on the functions being defined there.

b. For the quotient of g and f we have $v(x) = \dfrac{-3x}{x^2} = -\dfrac{3}{x}\,(x \neq 0)$. Table 12.2 indicates

$$\lim_{x\to -2} v(x) = \lim_{x\to -2} \frac{-3}{x} = \frac{3}{2}.$$

The tables seem to indicate that such properties exist, as they suggest $\lim\limits_{x\to -2}[f(x)g(x)] = \lim\limits_{x\to -2} f(x) \cdot \lim\limits_{x\to -2} g(x) = 24$, and $\lim\limits_{x\to -2} \dfrac{g(x)}{f(x)} = \dfrac{\lim\limits_{x\to -2} g(x)}{\lim\limits_{x\to -2} f(x)} = \dfrac{3}{2}$.

Table 12.2

x	$v(x)$
−1.9	1.5789
−1.99	1.5075
−1.999	1.5008
−2	
−2.001	1.4993
−2.01	1.4925
−2.1	1.4286

Now try Exercises 27 through 36 ▶

The preceding observations seem to imply that the limit of a product can be found by taking the limit of each factor, and the limit of a quotient is equal to the quotient of the limits (if the limit of the denominator is not 0). In fact, each of these observations (and others) can be generalized and formally established using the definition of a limit. Based on these observations, we might expect that limit properties exist for the other basic operations, and this is indeed the case. The end result is the following seven properties.

Properties of Limits

Given that the limits $\lim\limits_{x\to c} f(x)$ and $\lim\limits_{x\to c} g(x)$ exist,

(I) $\lim\limits_{x\to c}[f(x) + g(x)] = \lim\limits_{x\to c} f(x) + \lim\limits_{x\to c} g(x)$
the limit of a sum is the sum of the limits

(II) $\lim\limits_{x\to c}[f(x) - g(x)] = \lim\limits_{x\to c} f(x) - \lim\limits_{x\to c} g(x)$
the limit of a difference is the difference of the limits

(III) $\lim\limits_{x\to c}[f(x)g(x)] = \lim\limits_{x\to c} f(x) \lim\limits_{x\to c} g(x)$
the limit of a product is the product of the limits

(IV) $\lim\limits_{x\to c}[kg(x)] = k \lim\limits_{x\to c} g(x)$, k a constant
the limit of a constant times a function is the constant times the limit of the function

(V) $\lim\limits_{x\to c} \dfrac{f(x)}{g(x)} = \dfrac{\lim\limits_{x\to c} f(x)}{\lim\limits_{x\to c} g(x)}$, *provided* $\lim\limits_{x\to c} g(x) \neq 0$
the limit of a quotient is the quotient of the limits

By repeatedly applying property III with $f(x) = g(x)$, we obtain the property related to the limit of a power.

(VI) $\lim\limits_{x\to c}[f(x)]^n = [\lim\limits_{x\to c} f(x)]^n$, for n a natural number
the limit of a power is the power of the limit

A similar property holds for the limit of an nth root.

(VII) $\lim\limits_{x\to c} \sqrt[n]{f(x)} = \sqrt[n]{\lim\limits_{x\to c} f(x)}$, for $n \in \mathbb{N}$, $n > 1$ [if n is even, then $f(x) > 0$]
the limit of an nth root is the nth root of the limit

WORTHY OF NOTE

A formal proof of these properties, requiring a more sophisticated approach to limits, is offered in a calculus course.

☑ **A.** You've just seen how we can establish limit properties using a table

B. Finding Limits Using the Limit Properties

Before we begin applying these properties to evaluate limits, we will accept the validity of the following basic limits, most of which are supported by the previous examples. These are used extensively in our application of the limit properties.

Basic Limits

1. $\lim_{x\to c} k = k$
2. $\lim_{x\to c} x = c$
3. $\lim_{x\to c} x^n = c^n$, n a natural number
4. $\lim_{x\to c} \sqrt[n]{x} = \sqrt[n]{c}$, n a natural number, $n > 1$ (if n is even, then $c > 0$)

EXAMPLE 3 ▶ **Using Limit Properties to Determine a Limit**

Find the following limits using the limit properties. State the property that justifies each step.

a. $\lim_{x\to -3} (x^3 + 3x - 4)$ **b.** $\lim_{x\to 2} \dfrac{x^4 + 3x^2 - 5}{7 - 4x}$

Solution ▶

a.
$$\lim_{x\to -3} (x^3 + 3x - 4) = \lim_{x\to -3} x^3 + \lim_{x\to -3} 3x - \lim_{x\to -3} 4 \quad \text{properties I and II}$$
$$= \lim_{x\to -3} x^3 + 3\lim_{x\to -3} x - \lim_{x\to -3} 4 \quad \text{property IV}$$
$$= (-3)^3 + 3(-3) - 4 \quad \text{basic limits 3, 2, and 1}$$
$$= -40 \quad \text{result}$$

b.
$$\lim_{x\to 2} \frac{x^4 + 3x^2 - 5}{7 - 4x} = \frac{\lim_{x\to 2} (x^4 + 3x^2 - 5)}{\lim_{x\to 2} (7 - 4x)} \quad \text{property V}$$
$$= \frac{\lim_{x\to 2} x^4 + \lim_{x\to 2} 3x^2 - \lim_{x\to 2} 5}{\lim_{x\to 2} 7 - \lim_{x\to 2} 4x} \quad \text{properties I and II}$$
$$= \frac{\lim_{x\to 2} x^4 + 3\lim_{x\to 2} x^2 - \lim_{x\to 2} 5}{\lim_{x\to 2} 7 - 4\lim_{x\to 2} x} \quad \text{property IV}$$
$$= \frac{2^4 + 3(2^2) - 5}{7 - 4(2)} \quad \text{basic limits 3, 2, and 1}$$
$$= \frac{23}{-1} = -23 \quad \text{result}$$

Note the general strategy is to "break-up" the expressions using limit properties, then use the basic limits to evaluate the result.

Now try Exercises 37 through 48 ▶

EXAMPLE 4 ▶ **Using the Limit Properties to Determine a Limit**

Evaluate the following limits using the limit properties.

a. $\lim_{x\to -4} \sqrt[3]{x^3 - 7x + 28}$ **b.** $\lim_{x\to 0} \dfrac{9\sqrt{x^2 + 4}}{x^2 + 5}$

Solution ▶

a. $\lim\limits_{x\to -4}\sqrt[3]{x^3-7x+28}=\sqrt[3]{\lim\limits_{x\to -4}(x^3-7x+28)}$ property VII

$=\sqrt[3]{\lim\limits_{x\to -4}x^3-\lim\limits_{x\to -4}7x+\lim\limits_{x\to -4}28}$ properties I and II

$=\sqrt[3]{\lim\limits_{x\to -4}x^3-7\lim\limits_{x\to -4}x+\lim\limits_{x\to -4}28}$ property IV

$=\sqrt[3]{(-4)^3-7(-4)+28}$ basic limits 3, 2, and 1

$=\sqrt[3]{-8}=-2$ result

b. $\lim\limits_{x\to 0}\dfrac{9\sqrt{x^2+4}}{x^2+5}=\dfrac{\lim\limits_{x\to 0}(9\sqrt{x^2+4})}{\lim\limits_{x\to 0}(x^2+5)}$ property V

$=\dfrac{9\lim\limits_{x\to 0}\sqrt{x^2+4}}{\lim\limits_{x\to 0}(x^2+5)}$ property IV

$=\dfrac{9\sqrt{\lim\limits_{x\to 0}(x^2+4)}}{\lim\limits_{x\to 0}(x^2+5)}$ property VII

$=\dfrac{9\sqrt{\lim\limits_{x\to 0}x^2+\lim\limits_{x\to 0}4}}{\lim\limits_{x\to 0}x^2+\lim\limits_{x\to 0}5}$ properties I and II

$=\dfrac{9\sqrt{0^2+4}}{0^2+5}$ basic limits 3, 2, and 1

$=\dfrac{9(2)}{5}=\dfrac{18}{5}$ result

Now try Exercises 49 through 56 ▶

EXAMPLE 5 ▶ Using Limit Properties to Determine Limits

Find the following limits using the limit properties. If a limit does not exist, use the **TABLE** feature of a graphing calculator to state why.

a. $\lim\limits_{x\to -1}\dfrac{x^2}{x^2+2x+1}$ **b.** $\lim\limits_{x\to -2}\dfrac{x^2+2x}{\sqrt{x^2+4x+4}}$ **c.** $\lim\limits_{x\to 9}\dfrac{x-9}{\sqrt{x}-3}$

Solution ▶

a. $\lim\limits_{x\to -1}\dfrac{x^2}{x^2+2x+1}=\dfrac{\lim\limits_{x\to -1}x^2}{\lim\limits_{x\to -1}(x^2+2x+1)}$ property V

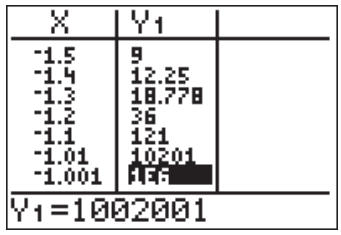
$=\dfrac{\lim\limits_{x\to -1}x^2}{\lim\limits_{x\to -1}x^2+\lim\limits_{x\to -1}2x+\lim\limits_{x\to -1}1}$ property I

$=\dfrac{(-1)^2}{(-1)^2+2(-1)+1}$ property IV and basic limits 3, 2, and 1

$=\dfrac{1}{0}$ result

In this case, applying the limit properties results in an undefined expression, and we resort to a table of values to see what's happening as $x\to -1$.

Figure 12.20



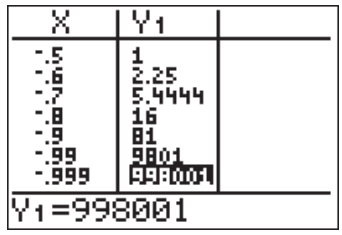


Figure 12.21

Figures 12.20 and 12.21 show that as $x \to -1$, function values grow infinitely large and positive, and we conclude $\lim_{x \to -1} \dfrac{x^2}{x^2 + 2x + 1} = \begin{pmatrix} \text{dne} \\ \infty \end{pmatrix}$.

b.
$$\lim_{x \to -2} \frac{x^2 + 2x}{\sqrt{x^2 + 4x + 4}} = \frac{\lim_{x \to -2} (x^2 + 2x)}{\lim_{x \to -2} \sqrt{x^2 + 4x + 4}} \qquad \text{property V}$$

$$= \frac{\lim_{x \to -2} x^2 + \lim_{x \to -2} 2x}{\sqrt{\lim_{x \to -2} (x^2 + 4x + 4)}} \qquad \text{properties I and VII}$$

$$= \frac{\lim_{x \to -2} x^2 + \lim_{x \to -2} 2x}{\sqrt{\lim_{x \to -2} x^2 + \lim_{x \to -2} 4x + \lim_{x \to -2} 4}} \qquad \text{property I}$$

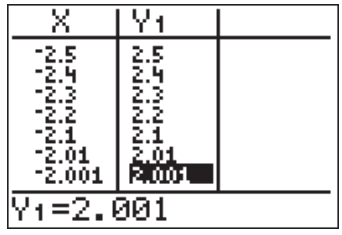
$$= \frac{\left(\lim_{x \to -2} x\right)^2 + 2 \lim_{x \to -2} x}{\sqrt{\left(\lim_{x \to -2} x\right)^2 + 4 \lim_{x \to -2} x + \lim_{x \to -2} 4}} \qquad \text{properties VI and IV}$$

$$= \frac{(-2)^2 + 2(-2)}{\sqrt{(-2)^2 + 4(-2) + 4}} = \frac{0}{\sqrt{0}} \qquad \text{basic limits 2 and 1}$$

$$= \frac{0}{0} \qquad \text{result}$$

Here, application of the limit properties results in an indeterminate expression, and we again resort to a table of values to check the behavior of the function as $x \to -2$.

Figure 12.22



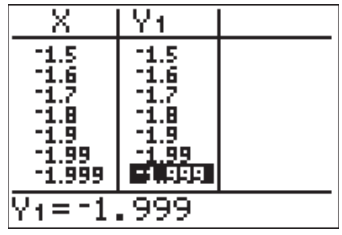


Figure 12.23

Figures 12.22 and 12.23 imply that $\lim_{x \to -2^-} \dfrac{x^2 + 2x}{\sqrt{x^2 + 4x + 4}} = 2$ (the left-hand limit is 2), while $\lim_{x \to -2^+} \dfrac{x^2 + 2x}{\sqrt{x^2 + 4x + 4}} = -2$ (the right-hand limit is -2). Since these do not agree, the limit does not exist and we write

$$\lim_{x \to -2} \frac{x^2 + 2x}{\sqrt{x^2 + 4x + 4}} = \begin{pmatrix} \text{dne} \\ \text{LH} \neq \text{RH} \end{pmatrix}.$$

c. $$\lim_{x\to 9}\frac{x-9}{\sqrt{x}-3}=\frac{\lim\limits_{x\to 9}(x-9)}{\lim\limits_{x\to 9}(\sqrt{x}-3)}$$ property V

$$=\frac{\lim\limits_{x\to 9}x-\lim\limits_{x\to 9}9}{\lim\limits_{x\to 9}\sqrt{x}-\lim\limits_{x\to 9}3}$$ property II

$$=\frac{9-9}{\sqrt{9}-3}=\frac{9-9}{3-3}$$ basic limits 1, 2, and 4

$$=\frac{0}{0}$$ result

Once again the result is an indeterminate expression and we use a table of values to check the behavior of the function as $x\to 9$. To our surprise, the tables in Figures 12.24 and 12.25 indicate that the limit is 6, and we conclude $\lim\limits_{x\to 9}\frac{x-9}{\sqrt{x}-3}=6$.

Now try Exercises 57 through 68 ▶

As a summary note, Example 5(a) demonstrates why expressions of the form $\frac{k}{0}$ are said to be undefined, as any limit resulting in this form will approach positive or negative infinity. Similarly, Examples 5(b) and 5(c) show why expressions of the form $\frac{0}{0}$ are said to be indeterminate, as the existence or final value of the original limit cannot be determined without further investigation.

☑ **B.** You've just seen how we can evaluate limits using the limit properties

C. Distinguishing between a Declarative Statement and a Proof

Consider the function $p(x)=x^2-x+41$. Evaluating p for the natural numbers 1 through 7 reveals that all outputs are prime numbers (Table 12.3). Made curious by this discovery, we investigate further and find that values of x from 8 through 14 also generate prime numbers (Table 12.4), as do the inputs 15 through 40. At this point it might

Table 12.3

x	$p(x)$
1	41
2	43
3	47
4	53
5	61
6	71
7	83

Table 12.4

x	$p(x)$
8	97
9	113
10	131
11	151
12	173
13	197
14	223

seem reasonable to declare that p generates a prime number for all natural numbers n. This exercise points out the dangers of making a declarative statement without formal proof, because when $x = 41$, the function returns a value of 1681, which is not a prime number ($41 \cdot 41 = 1681$).

Also, in Section 11.4 we noted

$$1 + 3 + 5 + 7 = 16$$
(first 4 odd numbers)

$$1 + 3 + 5 + 7 + 9 + 11 = 36$$
(first 6 odd numbers)

$$1 + 3 + 5 + 7 + 9 + 11 + 13 + 15 + 17 + 19 + 21 + 23 = 144$$
(first 12 odd numbers)

and it appeared the sum of the first n odd numbers was equal to n^2. While this declaration turns out to be true, no number of finite checks can *prove* the statement is true for all n, and a formal proof had to be rendered using mathematical induction. In exactly the same way, we can view a table of values to "declare" $\lim\limits_{x\to 3}\dfrac{x^2-9}{x-3} = 6$, using values closer and closer to 3, then even closer still, but prior to the development of the limit properties how could we *prove* the limit is 6? It was this type of question that prompted additional sarcasm from George Berkeley. "And what are these fluxions? The velocities of evanescent increments? And what are these same increments? They are neither finite quantities, nor quantities infinitely small, nor yet nothing. May we not then call them the ghosts of departed quantities?" Example 6 demonstrates that in the absence of a formal proof, it appears Mr. Berkeley's skepticism was justified and that a table of values is insufficient "proof."

EXAMPLE 6 ▶ **Evaluating Limits Using a Table**

Evaluate $\lim\limits_{x\to 0}\left(x^2 + \dfrac{\cos x}{1000} + 1\right)$ using the **TABLE** feature of a graphing calculator.

Solution ▶ For the left- and right-hand limits our graphing calculator provides Figures 12.26 and 12.27 respectively, and it appears we can declare that $\lim\limits_{x\to 0} f(x) = 1$.

Figure 12.26

X	Y1
-.6	1.3608
-.5	1.2509
-.4	1.1609
-.3	1.091
-.2	1.041
-.1	1.011
-.01	[redacted]

Y1=1.00109995

Figure 12.27

X	Y1
.6	1.3608
.5	1.2509
.4	1.1609
.3	1.091
.2	1.041
.1	1.011
.01	[redacted]

Y1=1.00109995

However, if we continue the approach using values of x that are even closer to $c = 0$, we find $f(0.001) \approx 1.0010001$, $f(0.0001) \approx 1.00100001$, and it turns out the limit is actually 1.001. Our declarative statement then has no standing and our work falls far short of a proof.

C. You've just seen how we can distinguish between a declarative statement and a proof

Now try Exercises 69 through 72 ▶

12.2 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section, if necessary.

1. The limit of a sum is the _____ of the _____.
2. The limit of a product is the _____ of the limits.
3. The limit of an nth _____ is the _____ root of the limit: $\lim\limits_{x\to c}\sqrt[n]{f(x)} = \sqrt[n]{\lim\limits_{x\to c} f(x)}$, provided _____ if n is even.
4. The limit of a _____ is the quotient of the _____, $\lim\limits_{x\to c}\dfrac{f(x)}{g(x)} = \dfrac{\lim\limits_{x\to c} f(x)}{\lim\limits_{x\to c} g(x)}$, provided _____.
5. Discuss/Explain how applying the limit properties can result in an undefined or indeterminate expression. What should be done in these cases?
6. Discuss/Explain the relationship between limit properties VI and VII, and basic limits 3 and 4. How is basic limit 2 involved here?

▶ DEVELOPING YOUR SKILLS

The following functions will be used for Exercises 7 through 36.

$a(x) = 3 - 2x$ $\quad b(x) = |x - 2|$
$c(x) = 1 - x^2$ $\quad d(x) = 5^x$
$f(x) = \sqrt{x + 7}$ $\quad g(x) = \cos\left(\dfrac{\pi}{2x}\right)$
$h(x) = \sin(x + 3)$ $\quad j(x) = \log[(5x)^2]$
$k(x) = |x^2 - 16|$ $\quad l(x) = \sqrt{x^2 - 10x + 25}$

For Exercises 7 through 16, use the TABLE feature of a graphing calculator to evaluate each limit.

7. $\lim\limits_{x\to -3} a(x)$
8. $\lim\limits_{x\to 2} b(x)$
9. $\lim\limits_{x\to -3} c(x)$
10. $\lim\limits_{x\to 2} d(x)$
11. $\lim\limits_{x\to -3} f(x)$
12. $\lim\limits_{x\to 2} g(x)$
13. $\lim\limits_{x\to -3} h(x)$
14. $\lim\limits_{x\to 2} j(x)$
15. $\lim\limits_{x\to -3} k(x)$
16. $\lim\limits_{x\to 2} l(x)$

For Exercises 17 through 26, use the TABLE feature of a graphing calculator to evaluate each limit. Compare each result with that of the corresponding Exercises in 7 through 16.

17. $\lim\limits_{x\to -3}[a(x) + c(x)]$
18. $\lim\limits_{x\to 2}[d(x) + g(x)]$
19. $\lim\limits_{x\to -3}[f(x) + h(x) + k(x)]$
20. $\lim\limits_{x\to 2}[b(x) + d(x) + j(x)]$
21. $\lim\limits_{x\to -3}[h(x) - c(x)]$
22. $\lim\limits_{x\to 2}[b(x) - g(x)]$
23. $\lim\limits_{x\to -3}[f(x) + k(x) - a(x)]$
24. $\lim\limits_{x\to 2}[j(x) - d(x) + l(x)]$
25. $\lim\limits_{x\to -3}[k(x) + k(x)]$
26. $\lim\limits_{x\to 2}[d(x) + d(x)]$

For Exercises 27 through 36, use a table of values to evaluate each limit. Compare each result with that of the corresponding Exercises in 7 through 16.

27. $\lim\limits_{x\to -3}[c(x)f(x)]$
28. $\lim\limits_{x\to 2}[j(x)d(x)]$
29. $\lim\limits_{x\to -3}\dfrac{k(x)}{f(x)}$
30. $\lim\limits_{x\to 2}\dfrac{d(x)}{g(x)}$
31. $\lim\limits_{x\to -3}[a(x)h(x)k(x)]$
32. $\lim\limits_{x\to 2}[b(x)g(x)l(x)]$
33. $\lim\limits_{x\to -3}[c(x)c(x)]$
34. $\lim\limits_{x\to 2}[d(x)d(x)]$
35. $\lim\limits_{x\to -3}\dfrac{a(x)c(x)}{f(x)}$
36. $\lim\limits_{x\to 2}\dfrac{d(x)}{g(x)j(x)}$

For Exercises 37 through 56, evaluate the limits using the limit properties.

37. $\lim\limits_{x\to -4}(x^3 - 5)$
38. $\lim\limits_{x\to 16}(\sqrt{x} - 16)$
39. $\lim\limits_{x\to -4}(2x^2 - x - 7)$
40. $\lim\limits_{x\to 2}(x^4 - 2x + 5)$

41. $\lim_{x\to 4}(x^2 - 5\sqrt{x} + 3)$

42. $\lim_{x\to -8}\left(\frac{1}{2}x^2 - \sqrt[3]{x} + 3\right)$

43. $\lim_{x\to 2}\dfrac{2x^2 - 5}{x + 3}$

44. $\lim_{x\to -3}\dfrac{x^2 - 2x + 3}{x - 3}$

45. $\lim_{x\to 1}\dfrac{\dfrac{1}{x+1} - x^2}{\dfrac{1}{x} + 2x^2 - x}$

46. $\lim_{x\to 3}\dfrac{\dfrac{1}{x-2} + 3x^2}{x^2 - 6 + \dfrac{1}{x-1}}$

47. $\lim_{x\to 3}(x^2 - 3)^3$

48. $\lim_{x\to 2}(3x^2 - 2x)^2$

49. $\lim_{x\to 10} 5\sqrt[3]{2x + 7}$

50. $\lim_{x\to -2} -2\sqrt[3]{x - 6}$

51. $\lim_{x\to -3}(\sqrt{x + 7} - 7x)$

52. $\lim_{x\to -5}(2x + \sqrt{4 - x})$

53. $\lim_{x\to 2}\dfrac{x^3 - 2x - 10}{2\sqrt[3]{5x^2 + 2x + 3}}$

54. $\lim_{x\to 2}\dfrac{11 - 3x^2}{\sqrt{x^2 + 3x - 1}}$

55. $\lim_{x\to 3}\dfrac{\dfrac{2}{x+1} - 3x}{\sqrt{x - 2} + 1}$

56. $\lim_{x\to -1}\dfrac{\left(\dfrac{x}{2x+1}\right)^2 - 3x}{\sqrt{x^2 + 3} + 1}$

For Exercises 57 through 68, evaluate the limits using limit properties. If a limit does not exist, state why.

57. $\lim_{x\to -2}\dfrac{3x^2 - 11x - 4}{x^2 - 2x - 8}$

58. $\lim_{x\to 1}\dfrac{2x^2 - x - 3}{x^2 - 1}$

59. $\lim_{x\to 7}\dfrac{x^2 - 5x - 14}{x - 7}$

60. $\lim_{x\to -4}\dfrac{x^2 + 7x + 12}{2x + 8}$

61. $\lim_{x\to -2}\dfrac{x^2 + 5x + 6}{x^2 + 4x + 4}$

62. $\lim_{x\to 1}\dfrac{x^2 - 4x + 3}{x^2 - 2x + 1}$

63. $\lim_{x\to -7}\dfrac{\sqrt{x^2 + 14x + 49}}{x^2 + 8x + 7}$

64. $\lim_{x\to -1}\dfrac{2x^2 - x - 3}{\sqrt{x^2 + 2x + 1}}$

65. $\lim_{x\to 0}\dfrac{(x + 3)^2 - 9}{x}$

66. $\lim_{x\to 0}\dfrac{(x - 1)^3 + 1}{x}$

67. $\lim_{x\to 1}\dfrac{x^3 - x^2}{\sqrt{x^2 - 2x + 1}}$

68. $\lim_{x\to 1}\dfrac{x^3|x - 1|}{x - 1}$

For Exercises 69 and 70, (a) complete the table given for each function and state the apparent limit as $x \to 0$, then (b) continue the approach using values even closer to 0 and comment.

69. $f(x) = x^2 + \dfrac{\sin x}{1000x}$

▶ MAINTAINING YOUR SKILLS

73. (3.2) If $p(x) = 2x^2 - x - 3$, in what interval(s) is $p(x) \le 0$?

74. (5.5) Solve the logarithmic equation $\log(x + 2) + \log x = \log 3$.

75. (7.2) Verify the identity: $\sec y - \cos y = \tan y \sin y$

76. (7.7) Use any appropriate method to solve in $[0, 2\pi)$: $\sin 2x = \cos x$.

MID-CHAPTER CHECK

1. Express the following statement using limit notation:

As x decreases without bound, $\frac{6x^2 - 3}{12x^3 - x - 1}$ approaches 0.

Use the **TABLE** feature of a graphing calculator to complete Exercises 2 through 7.

2. Evaluate each limit.

a. $\lim_{h\to 0}\frac{\sin h}{h}$ **b.** $\lim_{h\to 0}\frac{\cos h - 1}{h}$

3. The formula for interest compounded n times per year is $A = P\left(1 + \frac{r}{n}\right)^{nt}$, where P represents the principal deposit, r is the annual interest rate, t is the number of years the funds are on deposit, and n is the number of compoundings per year. If we let $n \to \infty$, this formula can be transformed into the formula for interest compounded continuously: $A = Pe^{rt}$. Verify that \$1000 invested at 3% compounded continuously for 1 yr grows to \$1030.45. Then find the minimum number of compoundings per year needed to yield the same amount with the same \$1000 principal.

4. The function $f(x)$ shown has a pointwise discontinuity. Create a related piecewise-defined function $F(x)$ that is continuous for $x \in \mathbb{R}$.

$$f(x) = \frac{6x^2 - 19x - 7}{2x - 7}$$

5. Given $g(x) = \begin{cases} \dfrac{-x}{2x+5} & x < -5 \\ \cos(x+5) & x \geq -5 \end{cases}$, find the following:

a. $\lim\limits_{x \to -5^-} g(x)$ **b.** $\lim\limits_{x \to -5^+} g(x)$

c. $\lim\limits_{x \to 5} g(x)$

6. Given $h(x) = \cot\left(\dfrac{x^2-4}{x+2}\right)$, find $\lim\limits_{x \to 2} h(x)$.

7. a. Complete the table of values shown.

x	$y = \cos\left(\frac{\pi}{x}\right)$
0.1	
0.01	
0.001	
−0.001	
−0.01	
−0.1	

b. Based on your table, it appears that $\lim\limits_{x \to 0} \cos\left(\dfrac{\pi}{x}\right)$ is approaching what value?

Graph $y = \cos\left(\dfrac{\pi}{x}\right)$ on a graphing calculator, and "Zoom In" a few times. Is your prior observation still valid?

For Exercises 8 through 10, evaluate each limit using the limit properties. If a limit does not exist, state why.

8. $\lim\limits_{x \to 2} \dfrac{4x^2 + x - 5}{x^5 - 3x}$

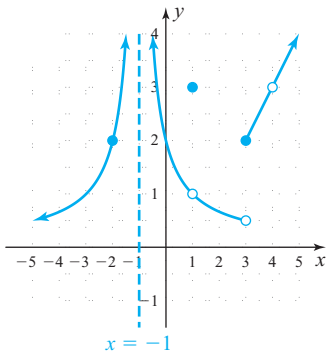
9. $\lim\limits_{x \to -3} \dfrac{2x + 10}{2\sqrt[3]{11 - x^2}}$

10. $\lim\limits_{x \to 2} \dfrac{\sqrt{x^2 - 4x + 4}}{x - 2}$

12.3 Continuity and More on Limits

LEARNING OBJECTIVES

In Section 12.3 you will see how we can:



- ❑ **A.** Determine if a function is continuous at c and find limits by direct substitution
- ❑ **B.** Evaluate limits using algebra and the properties of limits
- ❑ **C.** Evaluate limits at infinity
- ❑ **D.** Use the definition of a limit to evaluate limits graphically

Historically, the careful development of the limit concept also affected the concept of continuity and the two seem to have matured simultaneously. In this section, we'll see how limits help define the continuity of a function more precisely, and once established, how continuity makes finding certain limits an easier task. We'll also see how the algebraic skills developed in previous courses (adding rational expressions, simplifying complex fractions, multiplying by conjugates, etc.) are used to help determine some very important limits.

A. Continuity and Finding Limits by Direct Substitution

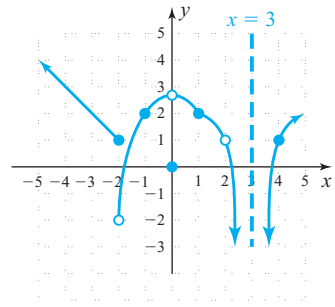
In previous chapters, we stated that a function was **continuous** if you could draw the entire graph without lifting your pencil. We also noted there were several ways that continuity could be interrupted, such as the holes and gaps seen in a study of piecewise-defined functions (Section 2.5), and the vertical asymptotes in some rational and trigonometric graphs. These "interruptions" are called **discontinuities** and can occur with other types of functions as well. The graph of $f(x)$ given in Figure 12.28 shows a vertical asymptote at $x = -1$, which interrupts the continuity of the graph and indicates that f is not defined at -1.

Figure 12.28

This is called an **asymptotic discontinuity.** The graph also shows that continuity is interrupted at $x = 1$ (there is a "hole" in the graph), even though f is still defined there: $f(1) = 3$. This is called a **removable discontinuity,** because the discontinuity can be removed/repaired by redefining the function as $f(x) = 1$ when $x = 1$. The discontinuity at $x = 4$ is also removable, even though the function is not defined at 4. A break in the graph also occurs at $x = 3$, but this time it leaves a gap in the output values, and there is no way to redefine f to "fill the gap." This is called a **jump discontinuity** or a **nonremovable discontinuity.** In fact, of all the points *called out* in Figure 12.28, the function is only continuous at $x = -2$. By comparing the graph at $x = -2$ with the graph of f at other points, we find the following conditions are required for continuity.

Continuity

A function f is continuous at c if



1. f is defined at c **2.** $\lim\limits_{x \to c^-} f(x) = \lim\limits_{x \to c^+} f(x)$ **3.** $\lim\limits_{x \to c} f(x) = f(c)$

In Figure 12.28, the discontinuities at $x = -1$ and $x = 4$ violate condition 1, the discontinuity at $x = 3$ violates condition 2, and the discontinuity at $x = 1$ violates condition 3.

EXAMPLE 1 ▶ **Analyzing the Continuity of a Function Graphically**

WORTHY OF NOTE
The continuity of a function really boils down to condition 3, since if this condition is satisfied, conditions 1 and 2 are satisfied.

The graph of a function f is given. Use the graph to comment on the continuity of the function for all integer values from -2 to 3. If the function is discontinuous at any value, state which of the three conditions are violated.

Solution ▶

$x = -2$: discontinuous, condition 2 is violated

$x = -1$: continuous

$x = 0$: discontinuous, condition 3 is violated

$x = 1$: continuous

$x = 2$: discontinuous, condition 1 is violated

$x = 3$: discontinuous, condition 1 is violated

Now try Exercises 7 through 16 ▶

The fact that condition 3, $\lim\limits_{x \to c} f(x) = f(c)$, is one of the requirements for continuity offers a great advantage when evaluating the limit of many common functions. For example, using properties of limits it can be shown that polynomials are continuous for all real numbers, and rational, root, and trigonometric functions are continuous wherever they are defined. This means as long as c is in the domain of these functions, we can find the limit by **direct substitution** since $\lim\limits_{x \to c} f(x) = f(c)$ can be assumed.

Finding Limits Using Direct Substitution

If f is a polynomial, rational, root, or trigonometric function and c is in the domain of f, then

$$\lim_{x \to c} f(x) = f(c)$$

EXAMPLE 2 ▶ **Finding Limits Using Direct Substitution**

Evaluate the following limits using direct substitution, if possible.

a. $\lim_{x\to -3}(x^3 + 3x - 4)$ **b.** $\lim_{x\to 2}\dfrac{x^4 + 3x^2 - 5}{7 - 4x}$ **c.** $\lim_{x\to 2}\dfrac{x^2 + 3x - 10}{x - 2}$

Solution ▶ **a.** Since $x^3 + 3x - 4$ is a polynomial, the limit can be found by direct substitution:

$$\begin{aligned}\lim_{x\to -3}(x^3 + 3x - 4) &= (-3)^3 + 3(-3) - 4 && \text{substitute } -3 \text{ for } x\\ &= -27 + (-9) - 4 && \text{simplify}\\ &= -40 && \text{result}\end{aligned}$$

See Example 3 of Section 12.2 where this limit was found using limit properties.

b. Since $\lim_{x\to 2}\dfrac{x^4 + 3x^2 - 5}{7 - 4x}$ is a rational function and 2 is in the domain, the limit can be found by direct substitution:

$$\begin{aligned}\lim_{x\to 2}\frac{x^4 + 3x^2 - 5}{7 - 4x} &= \frac{2^4 + 3(2)^2 - 5}{7 - 4(2)} && \text{substitute 2 for } x\\ &= \frac{16 + 12 - 5}{7 - 8} && \text{simplify}\\ &= -23 && \text{result}\end{aligned}$$

See Example 3 of Section 12.2 where this limit was found using limit properties.

c. Since $\lim_{x\to 2}\dfrac{x^2 + 3x - 10}{x - 2}$ is a rational function and 2 is *not* in the domain, the limit cannot be found by direct substitution. This doesn't mean the limit doesn't exist, only that direct substitution cannot be used. Applying the limit properties shows that $\lim_{x\to 2}\dfrac{x^2 + 3x - 10}{x - 2} = 7$ [also see Example 3(a)].

Now try Exercises 17 through 26 ▶

☑ **A.** You've just seen how we can determine if a function is continuous at c and find limits by direct substitution

B. Evaluating Limits Using Algebra and Limit Properties

Recall that for $\lim_{x\to c} f(x) = L$, the difference between x and c is made very small by taking values of x very close to c but not equal to c. In many cases, knowing that $\dfrac{x - c}{x - c} = 1$ (even if $x - c$ is very small), can help evaluate limits where a direct substitution is not initially possible. This is done by using algebra to rewrite the function prior to taking the limit.

EXAMPLE 3 ▶ **Finding Limits Using Algebra and Limit Properties**

Evaluate the following limits.

a. $\lim_{x\to 2}\dfrac{x^2 + 3x - 10}{x - 2}$ **b.** $\lim_{x\to 5}\dfrac{\sqrt{x + 4} - 3}{x - 5}$

Solution ▶

a. Although the function given is rational, $x = 2$ is not in the domain and the limit cannot be found using direct substitution. But noting the numerator is factorable, we can work as follows.

$$\begin{aligned}
\lim_{x\to 2}\frac{x^2+3x-10}{x-2} &= \lim_{x\to 2}\frac{(x+5)(x-2)}{x-2} && \text{factor the numerator}\\
&= \lim_{x\to 2}\frac{(x+5)\cancel{(x-2)}}{\cancel{x-2}} && \text{factors reduce}\\
&= \lim_{x\to 2}(x+5) && \text{result is a polynomial}\\
&= 2+5=7 && \text{evaluate by direct substitution}
\end{aligned}$$

As in Example 2(c), a table of values will support this result.

b. Since $x = 5$ is not in the domain, we again attempt to rewrite the expression in a form that would make direct substitution possible. Note that multiplying the numerator and denominator by $\sqrt{x+4}+3$ (the conjugate of $\sqrt{x+4}-3$) will eliminate the radical in the numerator since $(A-B)(A+B)=A^2-B^2$. This yields

$$\begin{aligned}
\lim_{x\to 5}\frac{\sqrt{x+4}-3}{x-5} &= \lim_{x\to 5}\frac{(\sqrt{x+4}-3)(\sqrt{x+4}+3)}{(x-5)(\sqrt{x+4}+3)} && \text{multiply by } \frac{\sqrt{x+4}+3}{\sqrt{x+4}+3}\\
&= \lim_{x\to 5}\frac{[(x+4)-9]}{(x-5)(\sqrt{x+4}+3)} && (A-B)(A+B)=A^2-B^2\\
&= \lim_{x\to 5}\frac{\cancel{(x-5)}}{\cancel{(x-5)}(\sqrt{x+4}+3)} && \text{simplify numerator}\\
&= \lim_{x\to 5}\frac{1}{\sqrt{x+4}+3} && \text{factors reduce}\\
&= \frac{\lim\limits_{x\to 5}1}{\lim\limits_{x\to 5}(\sqrt{x+4}+3)} && \text{property V}\\
&= \frac{1}{\sqrt{5+4}+3} && \text{evaluate by direct substitution}\\
&= \frac{1}{\sqrt{9}+3}=\frac{1}{6} && \text{result}
\end{aligned}$$

The result can be supported using a table of values.

Now try Exercises 27 through 36 ▶

In Example 4, we need to find the limit as $h \to 0$ rather than $x \to c$, but the concepts are identical $\left(\frac{h}{h} = 1 \text{ as long as } h \text{ is not } 0\right)$. If h is not in the domain, the limit cannot be found by direct substitution, and we again attempt to write the expression in an alternative form.

EXAMPLE 4 ▶ Finding Limits Using Algebra and Limit Properties

Evaluate the following limits.

a. $\lim\limits_{h\to 0}\dfrac{[(x+h)^2+3(x+h)]-(x^2+3x)}{h}$ **b.** $\lim\limits_{h\to 0}\dfrac{\dfrac{1}{x+h}-\dfrac{1}{x}}{h}$

Solution ▶

a. Here we begin by simplifying the numerator.

$$\lim_{h\to 0}\frac{[(x+h)^2+3(x+h)]-(x^2+3x)}{h}$$

$$=\lim_{h\to 0}\frac{x^2+2xh+h^2+3x+3h-x^2-3x}{h}$$ square binomial, distribute 3, distribute -1

$$=\lim_{h\to 0}\frac{2xh+h^2+3h}{h}$$ combine like terms

$$=\lim_{h\to 0}\frac{h(2x+h+3)}{h}$$ factor out h

$$=\lim_{h\to 0}(2x+h+3)$$ factors reduce since $h\neq 0$

$$=2x+3$$ evaluate by direct substitution

b. Here we begin by simplifying the complex fraction, hoping to rewrite the expression in a form that allows a direct substitution.

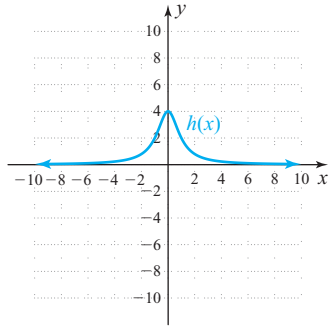
$$\lim_{h\to 0}\frac{\frac{1}{x+h}-\frac{1}{x}}{h}=\lim_{h\to 0}\frac{\frac{x}{x(x+h)}-\frac{(x+h)}{x(x+h)}}{h}$$ LCD for the numerator is $x(x+h)$

$$=\lim_{h\to 0}\frac{\frac{x-(x+h)}{x(x+h)}}{h}$$ combine terms in the numerator

$$=\lim_{h\to 0}\frac{\frac{-h}{x(x+h)}}{h}$$ simplify

$$=\lim_{h\to 0}\frac{-h}{x(x+h)}\cdot\frac{1}{h}$$ invert and multiply

$$=\lim_{h\to 0}\frac{-1}{x(x+h)}$$ factors reduce since $h\neq 0$



$$=\frac{-1}{x^2}$$ evaluate by direct substitution

B. You've just seen how we can evaluate limits using algebra and the properties of limits

Now try Exercises 37 through 44 ▶

C. Evaluating Limits at Infinity

Figure 12.29

The limit of a function as $x\to c$ necessarily has x moving *infinitely close* to a number c from the left or right. In contrast, limits at infinity are concerned with the value of a function as x moves *infinitely away from* an arbitrary number c to the left or right, meaning as $x\to-\infty$ or $x\to\infty$.

The graph of $h(x)=\dfrac{4}{x^2+1}$ is shown in Figure 12.29, and we note as $x\to\infty$, values of $h(x)$ become closer and closer to 0. Similar to our previous work, we could say that values of $h(x)$ can be made arbitrarily close to 0, by taking values of x sufficiently large and positive. This suggests the following definition.

Limits at Positive Infinity

For a function f defined on an interval (c, ∞),

$$\lim_{x \to \infty} f(x) = L$$

means that values of $f(x)$ can be made arbitrarily close to L, by taking values of x sufficiently large and positive.

In the case illustrated in Figure 12.29, we have $\lim_{x \to \infty} \dfrac{4}{x^2 + 1} = 0$.

EXAMPLE 5 ▶ **Evaluating Limits at Infinity**

For $f(x) = \dfrac{3x^2 - x - 12}{2x^2 - 8}$, use the **TABLE** feature of a graphing calculator to evaluate $\lim_{x \to \infty} f(x)$.

Solution ▶ Begin by entering $f(x)$ as Y_1 on the Y= screen of a graphing calcualtor. From our work with rational functions in Chapter 4 (ratio of leading terms), we suspect $\lim_{x \to \infty} f(x) = \dfrac{3}{2}$. This is supported by the **TABLE** shown.

X	Y1
250	1.498
500	1.499
750	1.4993
1000	1.4995
1250	1.4996
1500	1.4997
1750	ERROR

Y1=1.49971428534

Now try Exercises 45 through 52 ▶

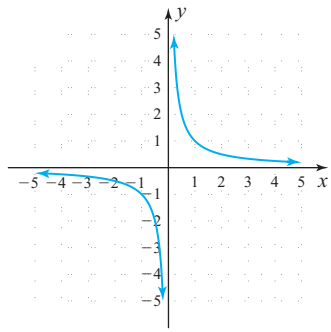
WORTHY OF NOTE

Since ∞ is not a number, the notation $x \to \infty$ should no longer be read, "as x *approaches* infinity," and instead we say, "as x becomes infinitely large," or "as x increases without bound."

The limit of a function as $x \to -\infty$ is likewise defined.

Limits at Negative Infinity

For a function f defined on an interval $(-\infty, c)$



$$\lim_{x \to -\infty} f(x) = L$$

means that values of $f(x)$ can be made arbitrarily close to L, by taking values of x sufficiently large and negative.

EXAMPLE 6 ▶ **Finding Limits at Infinity**

For $f(x) = \dfrac{1}{x}$, evaluate $\lim_{x \to -\infty} f(x)$ and $\lim_{x \to \infty} f(x)$.

Solution ▶ You might recognize this function from our work in Chapter 2, where we observed that as x becomes very large, $\dfrac{1}{x}$ becomes very small and close to zero (see figure). The result was a horizontal asymptote at $y = 0$ (the x-axis). In fact, we can make $f(x)$ as close to 0 as we like, by taking x to be a sufficiently large positive number, or a sufficiently large negative number. In limit notation, we have $\lim_{x \to -\infty} \dfrac{1}{x} = 0$ and $\lim_{x \to \infty} \dfrac{1}{x} = 0$.

Now try Exercises 53 through 60 ▶

From Example 6 we learn two important things. First, horizontal asymptotes can be defined in terms of limits at infinity.

Horizontal Asymptotes

The line $y = L$ is a horizontal asymptote if

$$\lim_{x \to -\infty} f(x) = L \qquad \text{or} \qquad \lim_{x \to \infty} f(x) = L$$

Second, by repeatedly applying limit property VI (the limit properties also hold for limits at infinity), we can state the following result.

Limits of Reciprocal Powers

For any positive integer k,

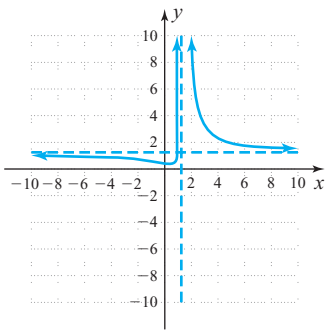
$$\lim_{x \to -\infty} \frac{1}{x^k} = 0 \qquad \text{and} \qquad \lim_{x \to \infty} \frac{1}{x^k} = 0$$

These limits are a great asset to finding limits at infinity. We often need to rewrite an expression and apply these limits of reciprocal powers in order to find the originally desired limit. For rational functions, this involves dividing numerator and denominator by the highest power of x occurring in the denominator.

EXAMPLE 7 ▶ Finding Limits at Infinity for a Rational Function

Evaluate $\lim_{x \to \infty} \dfrac{5x^2 - 6x + 3}{4x^2 - 12x + 9}$.

Solution ▶ Begin by dividing the numerator and denominator by x^2, the highest power of x in the denominator.



$$\lim_{x \to \infty} \frac{5x^2 - 6x + 3}{4x^2 - 12x + 9} = \lim_{x \to \infty} \frac{\dfrac{5x^2}{x^2} - \dfrac{6x}{x^2} + \dfrac{3}{x^2}}{\dfrac{4x^2}{x^2} - \dfrac{12x}{x^2} + \dfrac{9}{x^2}} \qquad \text{divide numerator and denominator by } x^2$$

$$= \lim_{x \to \infty} \frac{5 - \dfrac{6}{x} + \dfrac{3}{x^2}}{4 - \dfrac{12}{x} + \dfrac{9}{x^2}} \qquad \text{simplify}$$

$$= \frac{\lim\limits_{x \to \infty} \left(5 - \dfrac{6}{x} + \dfrac{3}{x^2}\right)}{\lim\limits_{x \to \infty} \left(4 - \dfrac{12}{x} + \dfrac{9}{x^2}\right)} \qquad \text{property V}$$

$$= \frac{\lim\limits_{x \to \infty} 5 - \lim\limits_{x \to \infty} \dfrac{6}{x} + \lim\limits_{x \to \infty} \dfrac{3}{x^2}}{\lim\limits_{x \to \infty} 4 - \lim\limits_{x \to \infty} \dfrac{12}{x} + \lim\limits_{x \to \infty} \dfrac{9}{x^2}} \qquad \text{properties I and II}$$

$$= \frac{5 - 0 + 0}{4 - 0 + 0} = \frac{5}{4} \qquad \lim_{x \to \infty} \frac{k}{x^n} = 0$$

A similar calculation for $x \to -\infty$ shows $\lim_{x \to -\infty} \dfrac{5x^2 - 6x + 3}{4x^2 - 12x + 9}$ is also $\dfrac{5}{4}$. The graph is shown in the figure.

Now try Exercises 61 through 64 ▶

If the function contains a radical term in the numerator or denominator, we attempt to rewrite the expression as a single radical term. We can then apply limit property VII and treat the radicand as a rational function. When doing so, you must particularly note whether you're taking the limit as $x \to -\infty$ or as $x \to \infty$, since this may affect the sign of the final result.

EXAMPLE 8 ▶ Finding Limits at Infinity for a Radical Function

Evaluate each limit:

a. $\lim\limits_{x\to\infty} \dfrac{8x}{\sqrt{4x^2+1}}$ **b.** $\lim\limits_{x\to-\infty} \dfrac{8x}{\sqrt{4x^2+1}}$

Solution ▶

a. Since x is becoming an infinitely large *positive* number, we know $8x$ can be written as $+\sqrt{(8x)^2} = +\sqrt{64x^2}$ (signs added for emphasis). The original expression can then be rewritten as follows.

$$\lim_{x\to\infty} \frac{8x}{\sqrt{4x^2+1}} = \lim_{x\to\infty} \frac{\sqrt{64x^2}}{\sqrt{4x^2+1}} \qquad 8x = \sqrt{64x^2}$$

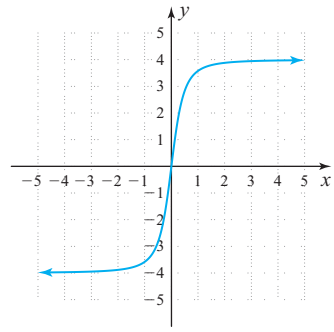
$$= \lim_{x\to\infty} \sqrt{\frac{64x^2}{4x^2+1}} \qquad \text{quotient property of radicals}$$

$$= \sqrt{\lim_{x\to\infty} \left(\frac{64x^2}{4x^2+1}\right)} \qquad \text{property VII}$$

We are now taking the limit of a rational expression, so we next divide the numerator and denominator by x^2.

$$= \sqrt{\lim_{x\to\infty} \left(\frac{\frac{64x^2}{x^2}}{\frac{4x^2}{x^2}+\frac{1}{x^2}}\right)} \qquad \text{divide by } x^2$$

$$= \sqrt{\lim_{x\to\infty} \frac{64}{4+\frac{1}{x^2}}} \qquad \text{simplify}$$



$$= \sqrt{\frac{\lim\limits_{x\to\infty} 64}{\lim\limits_{x\to\infty}\left(4+\frac{1}{x^2}\right)}} \qquad \text{property V}$$

$$= \sqrt{\frac{\lim\limits_{x\to\infty} 64}{\lim\limits_{x\to\infty} 4 + \lim\limits_{x\to\infty} \frac{1}{x^2}}} \qquad \text{property I}$$

$$= \sqrt{\frac{64}{4+0}} \qquad \lim_{x\to\infty} \frac{k}{x^n} = 0$$

$$= \sqrt{16} = 4 \qquad \text{result}$$

b. For part (b), x is becoming an infinitely large *negative* number, so the sign of $\dfrac{8x}{\sqrt{4x^2+1}}$ will be negative for all such values. For this reason $8x$ must be written as $-\sqrt{(8x)^2} = -\sqrt{64x^2}$. This is the only change to be made, and after applying algebra and the limit properties we find $\lim\limits_{x\to-\infty} \dfrac{8x}{\sqrt{4x^2+1}} = -4$. The graph is shown in the figure and shows that this function has two distinct horizontal asymptotes.

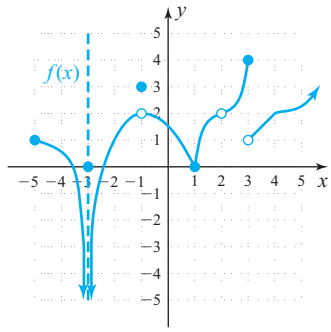
C. You've just seen how we can evaluate limits at infinity

Now try Exercises 65 through 70 ▶

D. Evaluating Limits Graphically

As a complement to the equations and tables we've used to explore the limit concept, we now look at how these concepts appear graphically. This will offer a heightened understanding of important ideas, and an excellent summary of the definitions, properties, and relationships involved. The graphs of two general functions f and g are given (Figures 12.30 and 12.31, respectively) for use in the following examples.

Figure 12.30



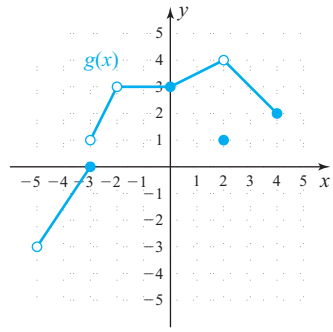


Figure 12.31

EXAMPLE 9 ▶ **Evaluating and Combining Function Values Using Graphs**

Use the graphs of f and g to perform the operations indicated. If any computation is not possible, state why.

a. $f(-1) - g(4)$ **b.** $g(2) + f(4)$ **c.** $f(-3) - f(2)$ **d.** $g(2)\,g(-3)$

Solution ▶

a. $f(-1) - g(4) = 3 - 2 = 1$

b. $g(2) + f(4) = 1 + 2 = 3$

c. $f(-3) - f(2) =$ X
not possible since $f(2)$ is not defined

d. $g(2)\,g(-3) = (1)(0) = 0$

Now try Exercises 71 through 76 ▶

EXAMPLE 10 ▶ **Evaluating One-Sided Limits Graphically**

Use the graphs of f and g to evaluate the one-sided limits necessary to complete each calculation. If any computation is not possible, state why.

a. $\lim\limits_{x\to 1^+} f(x) + \lim\limits_{x\to 4^-} g(x)$

b. $\lim\limits_{x\to 3^+} f(x) - \lim\limits_{x\to -5^+} g(x)$

c. $\lim\limits_{x\to -2^+} g(x) \lim\limits_{x\to -3^+} f(x)$

d. $\lim\limits_{x\to -1^+} f(x) + \lim\limits_{x\to 5^+} g(x)$

Solution ▶

a. $\lim\limits_{x\to 1^+} f(x) + \lim\limits_{x\to 4^-} g(x) = 0 + 2 = 2$

b. $\lim\limits_{x\to 3^+} f(x) - \lim\limits_{x\to -5^+} g(x) = 1 - (-3) = 4$

c. $\lim\limits_{x\to -2^+} g(x) \lim\limits_{x\to -3^+} f(x) =$ X
not possible since
$\lim\limits_{x\to -3^+} f(x) = \left(\begin{matrix}\text{dne}\\ -\infty\end{matrix}\right)$

d. $\lim\limits_{x\to -1^+} f(x) + \lim\limits_{x\to 5^+} g(x) =$ X
not possible since 5 is not in the domain of g

Now try Exercises 77 through 82 ▶

EXAMPLE 11 ▶ **Evaluating Limits Graphically**

Use the graphs of f and g to evaluate the limits necessary to complete each calculation. If any computation is not possible, state why.

a. $\lim\limits_{x\to -2} [f(x) + g(x)]$

b. $\lim\limits_{x\to -1} [3f(x) - g(x)]$

c. $\lim\limits_{x\to 1} \dfrac{g(x)}{f(x)}$

d. $\lim\limits_{x\to 2} [(f(x))^2 + \sqrt{g(x)}]$

Solution ▶

a. $\lim\limits_{x\to -2} [f(x) + g(x)] = \lim\limits_{x\to -2} f(x) + \lim\limits_{x\to -2} g(x)$ property I

$= 1 + 3 = 4$ result

b. $\lim\limits_{x\to -1} [3f(x) - g(x)] = \lim\limits_{x\to -1} 3f(x) - \lim\limits_{x\to -1} g(x)$ property II

$= 3 \lim\limits_{x\to -1} f(x) - \lim\limits_{x\to -1} g(x)$ property IV

$= 3(2) - 3 = 3$ result

c. $\lim\limits_{x\to 1} \dfrac{g(x)}{f(x)} = \dfrac{\lim\limits_{x\to 1} g(x)}{\lim\limits_{x\to 1} f(x)}$ property V (if $\lim\limits_{x\to 1} f(x) \neq 0$)

not possible since $\lim\limits_{x\to 1} f(x) = 0$ limit of the denominator is 0

d. $\lim\limits_{x\to 2} [(f(x))^2 + \sqrt{g(x)}] = \lim\limits_{x\to 2} [f(x)]^2 + \lim\limits_{x\to 2} \sqrt{g(x)}$ property I

$= [\lim\limits_{x\to 2} f(x)]^2 + \sqrt{\lim\limits_{x\to 2} g(x)}$ properties VI and VII

$= (2)^2 + \sqrt{4} = 6$ result

☑ **D.** You've just seen how we can use the definition of a limit to evaluate limits graphically

12.3 EXERCISES

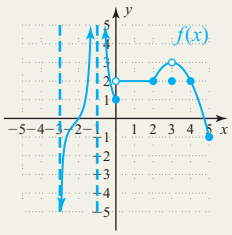
▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section, if necessary.

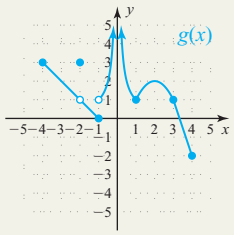
1. There are three types of discontinuities we may encounter. These are (1) _____, (2) _____, and (3) _____ discontinuities.

2. In order for a function $f(x)$ to be continuous at c, it must be _____ at c. Furthermore, $\lim\limits_{x\to c^-} f(x)$ must equal _____ with $\lim\limits_{x\to c} f(x) =$ _____ .

3. If $f(x)$ is continuous at c, we can evaluate $\lim\limits_{x\to c} f(x)$ by _____ _____.



4. The notation $x \to \infty$ is read, "as x becomes _____ _____," or "as x increases without _____."



5. Discuss/Explain the relationship between the horizontal asymptote of a rational function f, and $\lim\limits_{x\to\infty} f(x)$.

6. Discuss/Explain how the three different types of discontinuities appear on the graph of a function.

▶ DEVELOPING YOUR SKILLS

For Exercises 7 through 16, use the given graphs to comment on the continuity of the function at the given x-values. If the function is discontinuous at any value, state which of the three conditions for continuity are violated.

7. $f(x)$ at $x = -1$
8. $f(x)$ at $x = 3$
9. $f(x)$ at $x = 1$
10. $f(x)$ at $x = 2$
11. $f(x)$ at $x = 0$
12. $g(x)$ at $x = -1$
13. $g(x)$ at $x = -3$
14. $g(x)$ at $x = 1$
15. $g(x)$ at $x = -2$
16. $g(x)$ at $x = 0$

Evaluate the following limits using direct substitution, if possible. If not possible, state why.

17. $\lim\limits_{x\to -3} (2x^2 - 5x + 3)$
18. $\lim\limits_{x\to -2} (3x^2 - 5x - 2)$
19. $\lim\limits_{x\to 5} \sqrt{3x - 19}$
20. $\lim\limits_{x\to -6} \sqrt{x^2 + 7x}$
21. $\lim\limits_{x\to 2} \dfrac{x^2}{5x - 2}$
22. $\lim\limits_{x\to 8} \dfrac{2x - 5}{x^2 - 5x}$
23. $\lim\limits_{x\to -1} \dfrac{x + 1}{x^2 - 1}$
24. $\lim\limits_{x\to -2} \dfrac{4 - x^2}{x^2 + 5x + 6}$
25. $\lim\limits_{x\to -5} \sqrt{x^2 - 6x}$
26. $\lim\limits_{x\to 6} \sqrt{3x - 5}$

Evaluate the following limits by rewriting the given expression as needed.

27. $\lim\limits_{x\to -1} \dfrac{x + 1}{x^2 - 1}$
28. $\lim\limits_{x\to -2} \dfrac{4 - x^2}{x^2 + 5x + 6}$
29. $\lim\limits_{x\to 4} \dfrac{x - 4}{\sqrt{x} - 2}$
30. $\lim\limits_{x\to 16} \dfrac{x - 16}{4 - \sqrt{x}}$
31. $\lim\limits_{x\to 3} \dfrac{2x^2 - 3x - 9}{x - 3}$
32. $\lim\limits_{x\to -2} \dfrac{3x^2 + 7x + 2}{x + 2}$
33. $\lim\limits_{x\to -3} \dfrac{\sqrt{x + 7} - 2}{x + 3}$
34. $\lim\limits_{x\to 12} \dfrac{\sqrt{2x + 1} - 5}{x - 12}$
35. $\lim\limits_{x\to -4} \dfrac{x^3 + 8x^2 + 16x}{x^2 + 7x + 12}$
36. $\lim\limits_{x\to 3} \dfrac{2x^3 - 12x^2 + 18x}{x^2 - 7x + 12}$

Evaluate the following limits. Write your answer in simplest form.

37. $\lim\limits_{h\to 0} \dfrac{[2(x + h)^2 - (x + h)] - (2x^2 - x)}{h}$
38. $\lim\limits_{h\to 0} \dfrac{[3(x + h) - (x + h)^2] - (3x - x^2)}{h}$
39. $\lim\limits_{h\to 0} \dfrac{\dfrac{3}{x + h + 2} - \dfrac{3}{x + 2}}{h}$

40. $\lim_{h\to 0} \dfrac{\dfrac{2}{x+h-1} - \dfrac{2}{x-1}}{h}$

41. $\lim_{h\to 0} \dfrac{\sqrt{x+h+2} - \sqrt{x+2}}{h}$

42. $\lim_{h\to 0} \dfrac{\sqrt{x+h-1} - \sqrt{x-1}}{h}$

43. $\lim_{h\to 0} \dfrac{(x+h+2)^3 - (x+2)^3}{h}$

44. $\lim_{h\to 0} \dfrac{(x+h-4)^3 - (x-4)^3}{h}$

Use the TABLE feature of a graphing calculator to evaluate the following limits as x increases without bound.

45. $\lim_{x\to\infty} \dfrac{5x^3+2}{10x^3-2x+1}$

46. $\lim_{x\to\infty} \dfrac{8x-3x^2}{7x^2-x+1}$

47. $\lim_{x\to\infty} \dfrac{6x^2-x+2}{2x^2+1}$

48. $\lim_{x\to\infty} \dfrac{3x-5x^3}{x^3+2x^2-3x+7}$

49. $\lim_{x\to\infty} \dfrac{7x^3}{5x^2+3x}$

50. $\lim_{x\to\infty} \dfrac{x^2+1}{2x-11}$

51. $\lim_{x\to\infty} \dfrac{x^2+6x+9}{2x^3}$

52. $\lim_{x\to\infty} \dfrac{10-3x^2}{10-3x^3}$

Use the TABLE feature of a graphing calculator to evaluate the following limits as x decreases without bound.

53. $\lim_{x\to-\infty} \dfrac{5x^3+2}{10x^3-2x+1}$

54. $\lim_{x\to-\infty} \dfrac{6x^2-x+2}{2x^2+1}$

55. $\lim_{x\to-\infty} \dfrac{x^2+1}{2x-11}$

56. $\lim_{x\to-\infty} \dfrac{7x^3}{5x^2+3x}$

57. $\lim_{x\to-\infty} \dfrac{10-3x^2}{10-3x^3}$

58. $\lim_{x\to-\infty} \dfrac{x^2+6x+9}{2x^3}$

59. Given $\lim_{x\to\infty} \dfrac{1}{x} = 0$, find the smallest positive value of x such that $\dfrac{1}{x} \le 0.001$.

60. Given $\lim_{x\to-\infty} \dfrac{1}{x} = 0$, find the largest negative value of x such that $\dfrac{1}{x} \ge -0.01$.

For Exercises 61 through 64, evaluate the limits by dividing the numerator and denominator by the highest power of x occurring in the denominator.

61. $\lim_{x\to\infty} \dfrac{3x^2-2x+1}{8x^2+5}$

62. $\lim_{x\to\infty} \dfrac{5x^2+11x-3}{12x^2+7x+5}$

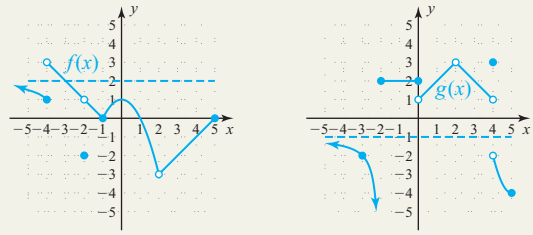
63. $\lim_{x\to-\infty} \dfrac{2x^2-1}{x^3+2x+12}$

64. $\lim_{x\to-\infty} \dfrac{8x^3-27}{x^4-1}$

For Exercises 65 through 70, evaluate each limit.

65. $\lim_{x\to\infty} \dfrac{\sqrt{36x^2-11}}{3x}$

66. $\lim_{x\to-\infty} \dfrac{\sqrt{36x^2-11}}{3x}$



67. $\lim_{x\to\infty} \dfrac{\sqrt{12x^2-6x+1}}{7x}$

68. $\lim_{x\to-\infty} \dfrac{\sqrt{12x^2-6x+1}}{7x}$

69. $\lim_{x\to\infty} \dfrac{\sqrt[3]{216x^3+36x^2-6x+1}}{2x}$

70. $\lim_{x\to-\infty} \dfrac{\sqrt[3]{216x^3+36x^2-6x+1}}{2x}$

The graphs of two functions f and g are given here, for use in Exercises 71 through 88.

For Exercises 71 through 76, use the graphs of f and g to perform the operations indicated. If any computation is not possible, state why.

71. $f(0) + g(-1)$

72. $f(5) - g(-3)$

73. $g(4) - f(2)$

74. $f(-2) + g(2)$

75. $g(0) + f(-4)$

76. $g(5) + f(-1)$

For Exercises 77 through 82, use the graphs of f and g to evaluate the one-sided limits necessary to complete each calculation. If any computation is not possible, state why.

77. $\lim\limits_{x\to -4^-} f(x) - \lim\limits_{x\to 0^+} g(x)$

78. $\lim\limits_{x\to 4^+} g(x) + \lim\limits_{x\to -2^-} f(x)$

79. $\lim\limits_{x\to -4^+} f(x) - \lim\limits_{x\to 0^-} g(x)$

80. $\lim\limits_{x\to 4^-} g(x) + \lim\limits_{x\to -2^+} f(x)$

81. $\lim\limits_{x\to 5^-} f(x) + \lim\limits_{x\to -2^-} g(x)$

82. $\lim\limits_{x\to 2^+} g(x) + \lim\limits_{x\to 6^+} f(x)$

For Exercises 83 through 88, use the graphs of f and g to evaluate the limits necessary to complete each calculation. If any computation is not possible, state why.

83. $\lim\limits_{x\to 0}[f(x) - g(x)]$

84. $\lim\limits_{x\to 2}[g(x) - f(x)]$

85. $\lim\limits_{x\to -3}\left[\dfrac{3f(x)}{g(x)}\right]$

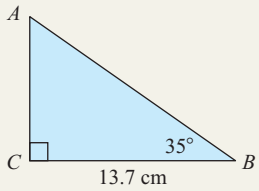
86. $\lim\limits_{x\to -1}\left\{\dfrac{3[g(x)]^2}{f(x)}\right\}$

87. $\lim\limits_{x\to -\infty}[f(x) - \sqrt[3]{g(x)}]$

88. $\lim\limits_{x\to 3}[2g(x)f(x)]$

▶ MAINTAINING YOUR SKILLS

89. **(3.2)** Solve each equation:



a. $3x^2 + 4x - 12 = 0$

b. $\sqrt{3x+1} - \sqrt{2x} = 1$

c. $\dfrac{1}{x+2} + \dfrac{3}{x^2+5x+6} = \dfrac{2}{x+3}$

90. **(7.5)** Find $\cos^{-1}\left[\cos\left(-\dfrac{\pi}{6}\right)\right]$.

91. **(6.6)** Solve the right triangle shown. Round answers to the nearest tenth.

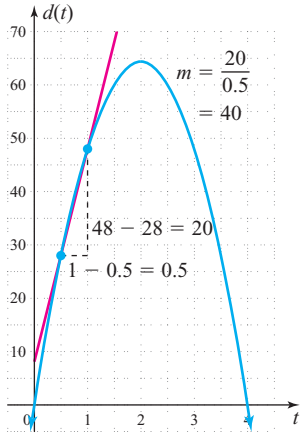
92. **(1.4)** In 2008, a small business purchased a copier for \$4500. By 2011, the value of the copier had decreased to \$3300. Assuming the depreciation is linear, (a) find the rate-of-change $m = \dfrac{\Delta \text{ value}}{\Delta \text{ time}}$ and discuss its meaning in this context. (b) Find the depreciation equation and (c) use the equation to predict the copier's value in 2015. (d) If the copier is traded in for a new model when its value is less than \$700, how long will the company use this copier?

12.4 Applications of Limits: Instantaneous Rates of Change and the Area under a Curve

LEARNING OBJECTIVES

In Section 12.4 you will see how we can:

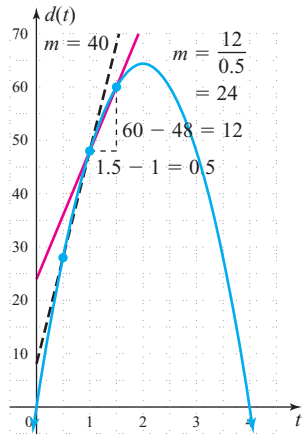
- ❑ **A.** Evaluate the limit of a difference quotient to find instantaneous rates of change
- ❑ **B.** Evaluate the limit of a sum to find the area under a curve



At this point, the concept of rates of change is a familiar theme. From their first introduction in a linear context $\left(\dfrac{\Delta y}{\Delta x} = \dfrac{y_2 - y_1}{x_2 - x_1}\right)$ to investigations of nonlinear functions using the difference quotient, the idea has proven powerful and useful. In Example 11 from Section 3.6, we used the difference quotient to approximate the velocity of a falling wrench with great accuracy. While this study certainly answers Galileo's historic questions regarding the speed of a falling body, business, science, industry, education, and government present us with equally compelling questions that can likewise be answered using the difference quotient.

A. The Limit of a Difference Quotient

In Example 4 of Section 3.4, the height of a soccer ball kicked straight up into the air was modeled by the function $d(t) = -16t^2 + 64t$. Using this function and the rate-of-change formula $\left[\dfrac{\Delta d}{\Delta t} = \dfrac{d(t_2) - d(t_1)}{t_2 - t_1}\right]$, we found that between $t = 0.5$ and $t = 1.0$ sec, the average velocity of the ball was 40 ft/sec. Graphically, this was represented by the slope of the secant line through (0.5, 28) and (1.0, 48). See Figure 12.32 and the related calculation.



For the time interval [1.0, 1.5], the average velocity had slowed to 24 ft/sec (the slope of this secant line is $m = 24$). See Figure 12.33 and the related calculation.

Figure 12.32

$$\frac{\Delta d}{\Delta t} = \frac{d(t_2) - d(t_1)}{t_2 - t_1} = \frac{d(1) - d(0.5)}{1 - 0.5} = \frac{48 - 28}{0.5} = 40$$

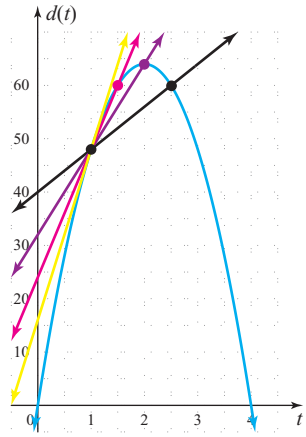


Figure 12.33

$$\frac{\Delta d}{\Delta t} = \frac{d(1.5) - d(1)}{1.5 - 1} = \frac{60 - 48}{0.5} = 24$$

Using smaller and smaller increments of time enables a better and better estimate of the velocity near $t = 1$, but requires a new calculation for each interval. Instead, we consider applying the difference quotient, as it allows for a fixed point t and a second point $(t + h)$ *that becomes arbitrarily close to* t as $h \to 0$: $\dfrac{d(t + h) - d(t)}{h}$. Graphically, this means the two points used for the secant line are becoming arbitrarily close, and in fact, can be made as close as we like by applying the concept of a limit.

Figure 12.34

In Figure 12.34, several secant lines are shown, each with a left endpoint at $t = 1$. Selecting right endpoints that become closer and closer to 1 ($1 + h$ as $h \to 0$), we obtain the sequence of secant lines shown in black ($h = 1.5, m = 8$), then purple ($h = 1, m = 16$), then red ($h = 0.5, m = 24$) (for $h = 0.01$, the difference quotient returns a value of 31.84). As $1 + h$ gets *infinitely close* to 1, the secant line reaches a "limiting position" (the yellow line) as the two points forming the line become infinitely close. The end result is a **tangent line** to the graph of d at $t = 1$ (tangent: touching the curve at only one point in the interval near $t = 1$). As the slope of each secant line gives the average rate of change between two points, in this case the velocity of the ball, the slope of the tangent line gives the **instantaneous velocity** at precisely $t = 1$. As the

graph indicates, the slope of the tangent line is the limit of the slopes of the secant lines and we write,

$$m_{\tan} = \lim_{h\to 0} m_{\sec} = \lim_{h\to 0} \frac{d(t+h) - d(t)}{h}$$

For a general function $f(x)$, we have the following result.

The Slope of a Tangent Line

Given a function $f(x)$ that is smooth and continuous over the interval containing x and $x + h$, the slope of a line drawn tangent to the graph of f at x is given by the function $f'(x)$, where

$$f'(x) = \lim_{h\to 0} \frac{f(x+h) - f(x)}{h}$$

The notation $f'(x)$ is read "f prime of x," and is commonly used to denote the slope of the line drawn tangent to the curve at x.

EXAMPLE 1 ▶ Computing the Limit of a Difference Quotient to Find $d'(t)$

For the function $d(t) = -16t^2 + 64t$ (see page 1204)

a. Find the limit of the difference quotient for d, to obtain a function $d'(t)$ that represents the slope of the line drawn tangent to d at t, and the instantaneous velocity at time t.

b. Use $d'(t)$ to find the velocity at $t = 1$, $t = 2$, and $t = 3.5$.

Solution ▶

a. For $d(t) = -16t^2 + 64t$, $d(t+h) = -16(t+h)^2 + 64(t+h)$. After squaring the binomial and applying the distributive property, we obtain

$$\begin{aligned} d(t+h) &= -16(t^2 + 2th + h^2) + 64t + 64h \\ &= -16t^2 - 32th - 16h^2 + 64t + 64h \end{aligned}$$

To find $d'(t)$, we then have

$$\begin{aligned} \lim_{h\to 0} \frac{d(t+h) - d(t)}{h} &= \lim_{h\to 0} \frac{-16t^2 - 32th - 16h^2 + 64t + 64h - (-16t^2 + 64t)}{h} && \text{apply difference quotient} \\ &= \lim_{h\to 0} \frac{-16t^2 - 32th - 16h^2 + 64t + 64h + 16t^2 - 64t}{h} && \text{distribute } -1 \\ &= \lim_{h\to 0} \frac{-32th - 16h^2 + 64h}{h} && \text{combine like terms} \\ &= \lim_{h\to 0} \frac{h(-32t - 16h + 64)}{h} && \text{factor out } h \\ &= \lim_{h\to 0} (-32t - 16h + 64) && \frac{h}{h} = 1,\ h \neq 0 \\ d'(t) &= -32t + 64 && \text{result} \end{aligned}$$

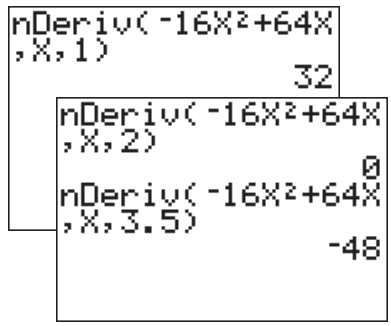
b. For the velocity of the ball at $t = 1$, $t = 2$, and $t = 3.5$, we evaluate $d'(t)$.

$$\begin{aligned} t = 1: \quad d'(1) &= -32(1) + 64 && \text{substitute 1 for } t \\ &= -32 + 64 = 32 && \text{simplify} \end{aligned}$$

At the moment $t = 1$ sec, the velocity is 32 ft/sec.

$$\begin{aligned} t = 2: \quad d'(2) &= -32(2) + 64 && \text{substitute 2 for } t \\ &= -64 + 64 = 0 && \text{simplify} \end{aligned}$$

At the moment $t = 2$ sec, the velocity is 0 ft/sec. This seems reasonable, as we expect the ball will slow as it approaches its maximum height, where it momentarily stops (velocity is 0), then begins its return to the ground.



$$t = 3.5: \quad d'(3.5) = -32(3.5) + 64 \qquad \text{substitute 3.5 for } t$$
$$= -112 + 64 = -48 \qquad \text{simplify}$$

At the moment $t = 3.5$ sec, the velocity is -48 ft/sec. This indicates the ball is *falling back to Earth* (velocity is negative) at a rate of 48 ft/sec.

Now try Exercises 7 through 12 ▶

Most graphing calculators have a built-in feature that can quickly compute the slope of a line tangent to the graph of f at a specific x. Begin by placing the **nDeriv(** command on the home screen with the keystrokes MATH 8. After entering the function, the independent variable x, and the specific x-value (all separated by commas), pressing ENTER calculates and displays the slope of the tangent line at that x-value. The results from Example 1(b) are confirmed in Figure 12.35 using this feature. Note the 2nd ENTER **(ENTRY)** feature (used to recall and edit the previous entry) is very useful for computing the slopes of various tangent lines *of the same function*.

Figure 12.35

In Example 11 of Section 3.6 (page 285), we modeled the distance a wrench had fallen from a skyscraper with the function $d(t) = 16t^2$. Using a very small time interval and the difference quotient, we obtained a close approximation for the velocity of the wrench in various intervals. Using the concept of a limit we can now find the *instantaneous velocity* at any time t, again denoted $d'(t)$.

EXAMPLE 2 ▶ Finding an Instantaneous Rate of Change

For the function $d(t) = 16t^2$,

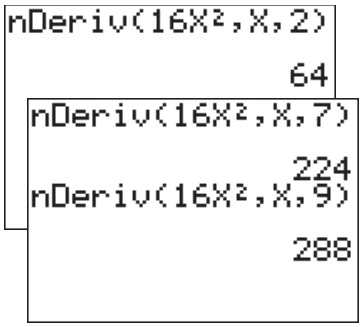
a. Find the limit of the difference quotient for d to obtain a function $d'(t)$ that represents the instantaneous velocity of the falling wrench.

b. Use $d'(t)$ to find the velocity at $t = 2$, $t = 7$, and $t = 9$. Verify your results with a calculator.

Solution ▶

a. In the referenced example we obtained the expression $32t + 16h$ after applying the difference quotient. Using the ideas developed here, we know the velocity of the wrench will be

$$d'(t) = \lim_{h \to 0}(32t + 16h)$$
$$= 32t$$



by direct substitution.

b. For the instantaneous velocity at $t = 2$, $t = 7$, and $t = 9$, we evaluate $d'(t)$.

$$t = 2: \quad d'(2) = 32(2) = 64 \qquad \text{substitute 2 for } t$$

At $t = 2$ sec, the velocity of the wrench is 64 ft/sec.

$$t = 7: \quad d'(7) = 32(7) = 224 \qquad \text{substitute 7 for } t$$

At $t = 7$ sec, the velocity of the wrench is 224 ft/sec.

$$t = 9: \quad d'(9) = 32(9) = 288 \quad \text{substitute 9 for } t$$

At the instant $t = 9$ sec, the velocity of the wrench has increased to 288 ft/sec. In fact, in the absence of air resistance the velocity of the wrench will continue to increase until it hits the ground (with a wham!).

The **nDeriv(** feature of our calculator verifies these velocities (see figure).

Now try Exercises 13 through 16 ▶

Mathematical models of real-world phenomena come in many different forms, and in a calculus course these ideas are applied to a very wide variety of functions. For practice with the algebra required to make these ideas work, **see Exercises 17 through 20.** The following applications demonstrate how these ideas are applied to root and rational function models.

EXAMPLE 3 ▶ Computing a Rate of Change for the Distance to the Horizon

Many new high-rise buildings have external elevators, allowing an unobstructed view of the city as it extends toward the horizon. The distance that Melody can see as the elevator takes her higher is modeled by the function $d(x) = 1.15\sqrt{x}$, where $d(x)$ represents her sight distance in nautical miles, at a height of x feet.

a. Find the limit of the difference quotient for $d(x)$, to obtain a function $d'(x)$ that represents the instantaneous rate of change in the sight distance at x.

b. Find the instantaneous rate of change at heights of 225, 400, and 625 ft.

Solution ▶ **a.** For $d(x) = 1.15\sqrt{x}$, $d(x + h) = 1.15\sqrt{x + h}$. To find $d'(x)$, we have

$$\lim_{h\to 0}\frac{d(x+h)-d(x)}{h} = \lim_{h\to 0}\frac{1.15\sqrt{x+h}-1.15\sqrt{x}}{h} \quad \text{apply difference quotient}$$

$$= 1.15\lim_{h\to 0}\frac{\sqrt{x+h}-\sqrt{x}}{h} \quad \text{factor out the constant}$$

Noting that multiplying the numerator by its conjugate will "free up" the h in the first radicand, we multiply numerator and denominator by $\sqrt{x + h} + \sqrt{x}$.

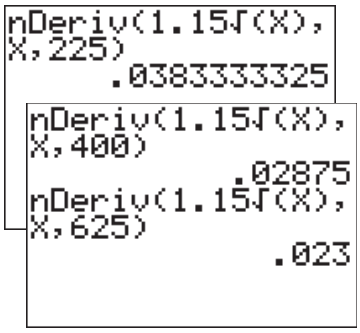
$$= 1.15\lim_{h\to 0}\frac{(\sqrt{x+h}-\sqrt{x})}{h}\frac{(\sqrt{x+h}+\sqrt{x})}{(\sqrt{x+h}+\sqrt{x})}$$

$$= 1.15\lim_{h\to 0}\frac{x+h-x}{h(\sqrt{x+h}+\sqrt{x})} \quad (A-B)(A+B) = A^2 - B^2$$

$$= 1.15\lim_{h\to 0}\frac{\cancel{h}}{\cancel{h}(\sqrt{x+h}+\sqrt{x})} \quad \text{combine like terms}$$

$$= 1.15\lim_{h\to 0}\frac{1}{\sqrt{x+h}+\sqrt{x}} \quad \frac{h}{h} = 1,\ h \neq 0$$

$$= 1.15\left(\frac{1}{\sqrt{x}+\sqrt{x}}\right) \quad \text{apply limit}$$



$$d'(x) = \frac{1.15}{2\sqrt{x}} \quad \text{result}$$

b. To find the instantaneous rate of change at $x = 225$, 400, and 625 ft, we evaluate $d'(x)$.

$$d'(225) = \frac{1.15}{2\sqrt{225}} = \frac{1.15}{2(15)} \quad \text{substitute 225 for } x$$
$$\approx 0.038$$

At $x = 225$ ft, the sight distance is increasing at a rate of about 0.038 mi/ft (about 3.8 nautical miles per 100 ft).

$$d'(400) = \frac{1.15}{2\sqrt{400}} = \frac{1.15}{2(20)} \quad \text{substitute 400 for } x$$
$$\approx 0.029$$

At $x = 400$ ft, the sight distance is increasing at a rate of about 0.029 mi/ft (about 2.9 nautical miles per 100 ft).

$$d'(625) = \frac{1.15}{2\sqrt{625}} = \frac{1.15}{2(25)} \quad \text{substitute 625 for } x$$
$$= 0.023$$

At $x = 625$ ft, the sight distance is increasing at a rate of 0.023 mi/ft (2.3 nautical miles per 100 ft).

These rates of change are verified in the figure.

Now try Exercises 21 through 24 ▶

Note that for square root functions, the algebra involves rationalizing the numerator to "free up" the constant h in hopes that the limit can eventually be found by direct substitution. For rational functions, the difference quotient yields a difference of rational expressions in the numerator, which we then combine for the same reason.

EXAMPLE 4 ▶ Computing Instantaneous Rates of Change for a Cost Function

A county government finds the cost of removing pollutants from a stream can be modeled by the function $C(x) = \frac{2x}{1 - x}$, where $C(x)$ represents the cost in millions of dollars, to remove $x \cdot 100$ percent of the pollutants [$C(x) > 0$, x is a decimal less than 1].

a. Find the limit of the difference quotient for C, to obtain a function $C'(x)$ that represents the instantaneous rate of change in the cost of removing pollutants.

b. Find the rate the cost is increasing at the moment 60%, 70%, and 80% of the pollutants are removed.

c. Use the information from part (b) to *estimate* the rate the cost will be increasing at the moment 90% of the pollutants are removed, then compute the actual rate. Were you surprised?

Solution ▶ **a.** For $C(x) = \dfrac{2x}{1-x}$, $C(x+h) = \dfrac{2(x+h)}{1-(x+h)}$. To find $C'(x)$ we then have

$$\lim_{h\to 0}\frac{C(x+h)-C(x)}{h} = \lim_{h\to 0}\frac{\dfrac{2(x+h)}{1-(x+h)}-\dfrac{2x}{1-x}}{h}$$ apply difference quotient

$$= 2\lim_{h\to 0}\frac{\dfrac{x+h}{1-x-h}-\dfrac{x}{1-x}}{h}$$ factor out 2, distribute -1

$$= 2\lim_{h\to 0}\frac{\dfrac{(x+h)(1-x)-x(1-x-h)}{(1-x-h)(1-x)}}{h}$$ $\frac{A}{B}-\frac{C}{D}=\frac{AD-BC}{BD}$

$$= 2\lim_{h\to 0}\frac{\dfrac{x-x^2+h-xh-x+x^2+xh}{(1-x-h)(1-x)}}{h}$$ F-O-I-L, distribute

$$= 2\lim_{h\to 0}\frac{\dfrac{h}{(1-x-h)(1-x)}}{h}$$ simplify numerator

$$= 2\lim_{h\to 0}\frac{h}{(1-x-h)(1-x)h}$$ invert and multiply

$$= 2\lim_{h\to 0}\frac{1}{(1-x-h)(1-x)}$$ $\frac{h}{h}=1,\ h\neq 0$

$$C'(x) = \frac{2}{(1-x)^2}$$ apply limit, multiply by 2

b. Evaluating $C'(x)$ for $x = 0.6, 0.7, 0.8$ (60%, 70%, and 80%) yields

$$C'(0.6) = \frac{2}{(1-0.6)^2} = \frac{2}{0.16} = 12.5$$ substitute 0.6 for x and simplify

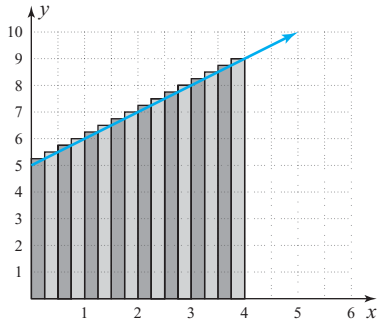
At $x = 0.6$, the cost is increasing at a rate of \$12,500,000 for each additional percentage point of pollution removed.

$$C'(0.7) = \frac{2}{(1-0.7)^2} = \frac{2}{0.09} = 22.\overline{2}$$ substitute 0.7 for x and simplify

At $x = 0.7$, the cost is increasing at a rate of about \$22,222,222 for each additional percentage point.

$$C'(0.8) = \frac{2}{(1-0.8)^2} = \frac{2}{0.04} = 50$$ substitute 0.8 for x and simplify

At $x = 0.8$, the cost is increasing at a rate of \$50,000,000 for each additional percentage point.



c. Evaluating $C(x)$ for $x = 0.9$ shows the cost rises dramatically to a rate of \$200,000,000 per percentage point. Removing anywhere near 100% of the pollutants would become prohibitively expensive.

A. You've just seen how we can evaluate the limit of a difference quotient to find instantaneous rates of change

Now try Exercises 25 through 32 ▶

B. Limits and the Area under a Curve

Figure 12.36

In the *Connections to Calculus* from Chapter 11, the area under the graph of $f(x) = x + 5$ for x in the interval $[0, 4]$ was approximated using the rectangle method with $n = 4$ and $n = 8$ rectangles (see Example 1). While we agreed that using 16 rectangles would give a better estimate (see Figure 12.36), expanding the related summation $\sum LW = \sum_{i=1}^{16} f\left(\frac{1}{4}i\right)\left(\frac{1}{4}\right)$ seemed too tedious and instead we opted to use the properties of summation to write the expression in a form where the sum could be found by substituting $n = 16$ directly. Here we extend this idea to a situation where n rectangles are used, as we can then take the limit of this sum as $n \to \infty$. The key to this extension is a result from Section 12.3, where we noted for any positive integer k, $\lim_{n\to-\infty} \frac{1}{n^k} = 0$ and $\lim_{n\to\infty} \frac{1}{n^k} = 0$ (note the change of variable from x to n, which is more commonly used for summations). The original 4-unit interval would then be divided into n parts, so each rectangle is $\frac{4}{n}$ units wide. The length of each rectangle is still given by $f(x) = x + 5$, but we now evaluate f in increments of $\frac{4}{n}$, giving $\sum LW = \sum_{i=1}^{n} f\left(\frac{4}{n}i\right)\left(\frac{4}{n}\right)$. Since $f\left(\frac{4}{n}i\right) = \frac{4}{n}i + 5$, we can write the sum as $\sum_{i=1}^{n}\left(\frac{4}{n}i + 5\right)\frac{4}{n}$ and proceed as before.

EXAMPLE 5 ▶ Finding the Limit of a Sum

Evaluate the following limit: $\lim_{n\to\infty} \sum_{i=1}^{n}\left(\frac{4}{n}i + 5\right)\frac{4}{n}$.

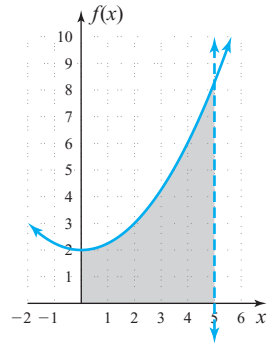
Solution ▶ Begin by applying *summation properties* and formulas to write the expression in a form where the *limit properties* can be applied. Since $\frac{4}{n}$ is a constant, we begin by factoring it out of the summation (summation property II).

$$\begin{aligned}
\frac{4}{n}\sum_{i=1}^{n}\left(\frac{4}{n}i + 5\right) &= \frac{4}{n}\left(\sum_{i=1}^{n}\frac{4}{n}i + \sum_{i=1}^{n}5\right) && \text{summation properties (distribute)}\\
&= \frac{4}{n}\left(\frac{4}{n}\sum_{i=1}^{n} i + \sum_{i=1}^{n}5\right) && \text{factor } \tfrac{4}{n} \text{ from first summation}\\
&= \frac{4}{n}\left[\frac{4}{n}\left(\frac{n^2+n}{2}\right) + 5n\right] && \text{apply summation formulas}\\
&= \frac{16}{n^2}\left(\frac{n^2+n}{2}\right) + 20 && \text{distribute } \tfrac{4}{n}\\
&= \frac{16}{2}\left(\frac{n^2+n}{n^2}\right) + 20 && \text{rewrite denominators (commute)}\\
&= 8\left(\frac{n^2}{n^2} + \frac{n}{n^2}\right) + 20 && \text{decompose rational expression}\\
&= 8\left(1 + \frac{1}{n}\right) + 20 = 28 + \frac{8}{n} && \text{result}
\end{aligned}$$

We can now take the limit of this result and find

$$\lim_{n\to\infty}\left(28 + \frac{8}{n}\right) = 28.$$

This shows



$$\lim_{n\to\infty}\sum_{i=1}^{n}\left(\frac{4}{n}i+5\right)\frac{4}{n}=28,$$

and that the area under the graph of $f(x)=x+5$ between $x=0$ and $x=4$ *is exactly 28 units*^{2}*!*

Now try Exercises 33 through 40 ▶

This result may seem unimpressive, as we could have quickly found the area using simple geometry. But as mentioned earlier, this method is easily applied to areas under a *general function f(x)*. In the *Connections to Calculus* feature from Chapter 3, we noted how the area under a graph could represent the distance covered by a runner. Our work here now takes on added meaning, as the area under a general curve has many other real-world implications in a study of calculus.

EXAMPLE 6 ▶ Using Limits to Find the Area under a Curve

During a training session for the Boston Marathon, Georgiana plans to begin at a leisurely walk of 2 mi/hr and gradually increase her speed over a 5-hr period, finishing up at a clip of over 8 mi/hr. Her speed might then be modeled by the function $f(x)=\frac{1}{4}x^2+2$, where $f(x)$ represents the velocity in miles per hour, and x is the time in hours. The area under the curve in the interval $[0, 5]$ then represents the distance Georgiana has run in these 5 hr.

a. Show that using the rectangle method results in the expression $\frac{5}{n}\sum_{i=1}^{n}\left[\frac{1}{4}\left(\frac{5}{n}i\right)^2+2\right]$.

b. Determine if Georgiana has run a "marathon distance" (about 26.2 mi) in these 5 hr, by applying summation properties and formulas, and taking the limit of this sum as $n\to\infty$.

Solution ▶

a. The area described is shown in the figure. The given interval is 5 units wide, and after dividing it into n parts, each rectangle will have a width of $\frac{5}{n}$. The length of each one is given by $f(x)=\frac{1}{4}x^2+2$, evaluated at each of the $\frac{5}{n}$ subintervals. The total area is then

$$\sum LW=\sum_{i=1}^{n}f\left(\frac{5}{n}i\right)\left(\frac{5}{n}\right)=\frac{5}{n}\sum_{i=1}^{n}f\left(\frac{5}{n}i\right)=\frac{5}{n}\sum_{i=1}^{n}\left[\frac{1}{4}\left(\frac{5}{n}i\right)^2+2\right].$$

b. Proceed as in Example 5.

$$\begin{aligned}
\frac{5}{n}\sum_{i=1}^{n}\left[\frac{1}{4}\left(\frac{5}{n}i\right)^2+2\right] &= \frac{5}{n}\left[\sum_{i=1}^{n}\frac{1}{4}\left(\frac{5}{n}i\right)^2+\sum_{i=1}^{n}2\right] && \text{summation properties (distribute)}\\
&= \frac{5}{n}\left[\sum_{i=1}^{n}\frac{1}{4}\left(\frac{25}{n^2}\right)i^2+\sum_{i=1}^{n}2\right] && \left(\frac{5}{n}i\right)^2=\frac{25}{n^2}i^2\\
&= \frac{5}{n}\left[\sum_{i=1}^{n}\frac{25}{4n^2}i^2+\sum_{i=1}^{n}2\right] && \text{multiply}\\
&= \frac{5}{n}\left[\left(\frac{25}{4n^2}\right)\sum_{i=1}^{n}i^2+\sum_{i=1}^{n}2\right] && \text{factor } \tfrac{25}{n^2} \text{ from first summation}
\end{aligned}$$

$$= \frac{5}{n}\left[\frac{25}{4n^2}\left(\frac{2n^3 + 3n^2 + n}{6}\right) + 2n\right] \quad \text{apply summation formulas}$$

$$= \frac{125}{4n^3}\left(\frac{2n^3 + 3n^2 + n}{6}\right) + 10 \quad \text{distribute } \frac{5}{n}$$

$$= \frac{125}{24}\left(\frac{2n^3 + 3n^2 + n}{n^3}\right) + 10 \quad \text{rewrite denominators (commute)}$$

$$= \frac{125}{24}\left(2 + \frac{3}{n} + \frac{1}{n^2}\right) + 10 \quad \text{decompose rational expression}$$

We can now take the limit of this result, and after applying the needed limit properties we obtain

$$= \frac{125}{24}\lim_{n\to\infty}\left(2 + \frac{3}{n} + \frac{1}{n^2}\right) + \lim_{n\to\infty} 10 \quad \text{apply properties of limits}$$

$$= \left(\frac{125}{24}\right)(2) + 10 = 20.41\overline{6}$$

The area under the graph of $f(x) = \frac{1}{4}x^2 + 2$ between $x = 0$ and $x = 5$ is $20.41\overline{6}$ units^2, which is numerically equivalent to the distance run. Georgiana is still about 5.8 mi short of a marathon.

Now try Exercises 41 through 44 ▶

☑ **B.** You've just seen how we can evaluate the limit of a sum to find the area under a curve

Note: For Learning Objective B, the functions and intervals offered in the Exercise Set were deliberately chosen for their simplicity. In particular, all are polynomials where $f(x) > 0$ in the interval selected. In a calculus course, the same ideas are applied to a greater variety of functions, not all intervals begin at 0, and the function may vary from positive to negative within the interval. Some of these ideas are explored in the *Calculator Exploration and Discovery* for this chapter, but regardless, the general ideas demonstrated here remain consistent.

12.4 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section, if necessary.

1. The slope of a line drawn tangent to the graph of any function $f(x)$ can be found by taking the limit of the _____ quotient for f, as h approaches zero.

2. The instantaneous rate of change of a function $f(x)$ can be found by evaluating the expression _____.

3. In order to obtain a better approximation for the area under a curve, we can use narrower (and thus more) _____ in our computation.

4. As we let the number of approximating rectangles increase without bound, the resulting limit gives a(n) _____ value for the area under the curve.

5. Discuss/Explain the relationship between the difference quotient and the formula for finding the slope of a line given two points.

6. Do some research on geometric shapes other than rectangles that can be used to approximate the area under a curve. Return to the graph on page 1210, and comment on why approximating rectangles consistently give an overestimate of the area.

▶ DEVELOPING YOUR SKILLS

Use the following information to answer Exercises 7 through 12.

Two model rockets are launched at a gathering of the National Association of Rocketry (NAR: www.nar.org). Frank's Apollo II motor burns out at a height of 500 m, at which point the rocket has a velocity of 88.2 meters per second (m/sec). His rocket's height in meters, t sec after engine burnout, is given by $f(t) = 500 + 88.2t - 4.9t^2$. Gwen's Icarus Alpha motor burns out at a height of 600 m, at which point the rocket has a velocity of 78.4 m/sec. Her rocket's height in meters, t sec after burnout, is given by $g(t) = 600 + 78.4t - 4.9t^2$.

7. Find the limit of the difference quotient for f, to obtain a function $f'(t)$ that represents the instantaneous velocity at time t.

8. Find the limit of the difference quotient for g, to obtain a function $g'(t)$ that represents the instantaneous velocity at time t.

9. Use the result from Exercise 7 to find the instantaneous velocity of Frank's rocket at

a. $t = 5$ **b.** $t = 9$ **c.** $t = 13$

Verify your results with a calculator.

10. Use the result from Exercise 8 to find the instantaneous velocity of Gwen's rocket at

a. $t = 2$ **b.** $t = 8$ **c.** $t = 10$

Verify your results with a calculator.

11. Use the result from Exercise 7 to find the maximum height of Frank's rocket. This occurs when $v = 0$.

12. Use the result from Exercise 8 to find the maximum height of Gwen's rocket. This occurs when $v = 0$.

13. To replicate Galileo's famous test as to whether the velocity of a falling body depends on its weight, a science class is dropping bowling balls of different weights from an 11-story building onto the lawn below. The ball's height in meters, t sec after it is released, is modeled by $d(t) = -4.9t^2 + 44.1$. Find the limit of the difference quotient for d, to obtain a function $d'(t)$ that represents the instantaneous velocity of the bowling ball at time t.

14. A rock climber's carabiner falls off her harness 256 ft above the floor of the Grand Canyon. It's height in feet, t sec after it falls, can be modeled by $d(t) = -16t^2 + 256$. Find the limit of the difference quotient for d, to obtain a function $d'(t)$ that represents the instantaneous velocity of the "biner" at time t.

15. Use the results of Exercise 13 to find the instantaneous velocity of the bowling ball at

a. $t = 1$ **b.** $t = 2$ **c.** $t = 3$ (time of impact)

16. Use the results of Exercise 14 to find the instantaneous velocity of the "biner" at

a. $t = 1$ **b.** $t = 3$ **c.** $t = 4$ (time of impact)

Find the limit of the difference quotient for each function $f(x)$ given, to obtain a function $f'(x)$ that represents the instantaneous rate of change at x for each function.

17. $f(x) = \frac{1}{2}x + 5$ **18.** $f(x) = x^2 - 3x$

19. $f(x) = x^3$ **20.** $f(x) = \frac{1}{x}$

21. The population of a small town can be modeled by the function $p(t) = 1.2\sqrt{t} + 40$, where p is measured in thousands and t is the number of years after 2008. Find the limit of the difference quotient for p to obtain a function $p'(t)$ that represents the instantaneous rate of change of population at time t.

22. The number of bacteria in a person's body, after they begin a regimen of antibiotics, can be modeled by the function $b(t) = 6 - \sqrt{t}$, where b is measured in tens of thousands and t is the number of hours after the first dose. Find the limit of the difference quotient for b to obtain a function $b'(t)$ that represents the instantaneous rate of change of number of bacteria at time t.

23. Use the results of Exercise 21 to find the instantaneous rate of change of population of the town in

a. 2009 **b.** 2012 **c.** 2024

24. Use the results of Exercise 22 to find the instantaneous rate of change of number of bacteria after

a. 1 hr **b.** 16 hr **c.** 25 hr

For Exercises 25 through 28, find the limit of the difference quotient of the given function to obtain a function that represents the slope of a line drawn tangent to the curve at x.

25. $f(x) = \frac{2}{x - 1}$ **26.** $g(x) = \frac{3}{x + 2}$

27. $h(x) = \frac{5x}{x + 5}$ **28.** $j(x) = \frac{x}{2(x + 1)}$

Use the results from the corresponding Exercises 25 through 28 for the following exercises.

29. Find the slope of the line drawn tangent to the graph of $f(x)$ at $x = 3$.

30. Find the slope of the line drawn tangent to the graph of $g(x)$ at $x = -1$.

31. Find the slope of the line drawn tangent to the graph of $h(x)$ at $x = 0$.

32. Find the slope of the line drawn tangent to the graph of $j(x)$ at $x = -\frac{1}{2}$.

For Exercises 33 through 36, graph each function over the interval [0, 7]. Then use geometry to find the area of the region below the graph, and above the *x*-axis in the interval [0, 6].

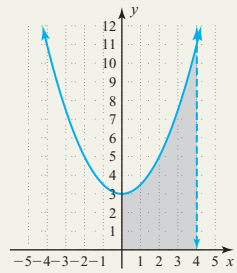
33. $q(x) = \frac{1}{2}x$

34. $r(x) = \frac{1}{3}x$

35. $t(x) = \frac{1}{2}x + 1$

36. $s(x) = \frac{1}{3}x + 2$

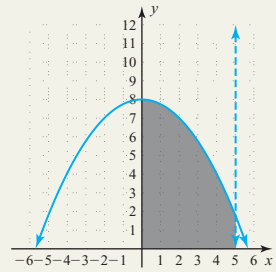
For Exercises 37 through 40, evaluate the following limits and compare your result to the corresponding exercise in 33 through 36.



37. $\lim\limits_{n\to\infty} \sum\limits_{i=1}^{n} \left(\frac{1}{2} \cdot \frac{6}{n} i\right) \frac{6}{n}$

38. $\lim\limits_{n\to\infty} \sum\limits_{i=1}^{n} \left(\frac{1}{3} \cdot \frac{6}{n} i\right) \frac{6}{n}$

39. $\lim\limits_{n\to\infty} \sum\limits_{i=1}^{n} \left(\frac{1}{2} \cdot \frac{6}{n} i + 1\right) \frac{6}{n}$



40. $\lim\limits_{n\to\infty} \sum\limits_{i=1}^{n} \left(\frac{1}{3} \cdot \frac{6}{n} i + 2\right) \frac{6}{n}$

41. For a new machine shop employee, the rate of production for a specialized part is modeled by the function $p(x) = \frac{1}{2}x^2 + 3$ (production increases quickly with experience), where $p(x)$ represents the number of parts completed per day after x days on the job. The area under this curve in the interval $x \in [0, 4]$ then represents the total number of parts produced in the first 4 days. Using the rectangle method results in the expression $\frac{4}{n} \sum\limits_{i=1}^{n} \left[\frac{1}{2}\left(\frac{4}{n} i\right)^2 + 3\right]$. Find the total number of parts produced by applying the summation properties/formulas and taking the limit as $n \to \infty$.

42. Water has been leaking undetected from a reservoir formed by an earthen dam. Due to the accelerating erosion, the rate of water loss can be modeled by the function $g(x) = -\frac{1}{4}x^2 + 8$, $x > 0$, where $g(x)$ represents hundreds of gallons of water lost per hour. The area under the curve in the interval $[0, 5]$ then represents the total water loss in 5 hr. Using the rectangle method results in the expression $\frac{5}{n} \sum\limits_{i=1}^{n} \left[-\frac{1}{4}\left(\frac{5}{n} i\right)^2 + 8\right]$. Find the total amount of water lost by applying summation properties and formulas and taking the limit as $n \to \infty$.

Exercise 42

Find the area under the curve for each function and interval given, using the rectangle method and *n* subintervals of equal width.

43. $f(x) = -\frac{1}{2}x^2 + 4x, x \in [0, 6]$

44. $f(x) = -\frac{1}{2}x^3 + 6x, x \in [0, 3]$

SUMMARY AND CONCEPT REVIEW

SECTION 12.1 An Introduction to Limits Using Tables and Graphs

KEY CONCEPTS

- The concept of a limit involves the incremental approach of a variable x to a fixed constant c (the cause), with a focus on the behavior the function f during this approach (the effect).
- The notation $\lim_{x\to c} f(x) = L$ means values of $f(x)$ can be made arbitrarily close to L by taking values of x sufficiently close to c, but not equal to c. L is called the limit of f as x approaches c.
- Limits can be investigated using a table of values or the graph of a function. Choosing values of x that are closer and closer to c, we observe the resulting values of $f(x)$ to see if it appears a limiting value exists.
- $\lim_{x\to c} f(x)$ may exist even if $f(x)$ is not defined at c, if $f(x)$ is defined at c but $f(c) \neq L$, or if $f(x)$ is defined at c and $f(c) = L$.
- We can also define a left-hand limit and a right-hand limit: $\lim_{x\to c} f(x) = L$ means values of $f(x)$ can be made arbitrarily close to L by taking values of x sufficiently close to c and to the left of c. The right-hand limit is similarly defined.
- A limit can fail to exist in one of three ways.

  (1) the left-hand limit is not equal to the right-hand limit: $\lim_{x\to c} f(x) = \left(\underset{\text{LH}\neq\text{RH}}{\text{dne}}\right)$,

  (2) as $x \to c$, $f(x)$ increases or decreases without bound: $\lim_{x\to c} f(x) = \left(\underset{\pm\infty}{\text{dne}}\right)$, or

  (3) as $x \to c$, there is no fixed number L that $f(x)$ approaches: $\lim_{x\to c} f(x) = \left(\underset{L}{\text{dne}}\right)$.

EXERCISES

1. Estimate the following limits (if they exist) using the tables shown.

a. $\lim_{x\to 2^-} f(x)$ **b.** $\lim_{x\to 2^+} f(x)$ **c.** $\lim_{x\to 2} f(x)$

x	$f(x)$
1.5	−2.5
1.6	−2.6
1.7	−2.7
1.8	−2.8
1.9	−2.9
1.99	−2.99
1.999	−2.999

x	$f(x)$
2.5	5.5
2.4	5.4
2.3	5.3
2.2	5.2
2.1	5.1
2.01	5.01
2.001	5.001

Use the **TABLE** feature of a graphing calculator to evaluate each limit.

2. $\lim_{x\to 5} \dfrac{x^2 - 2x - 15}{x^2 - 6x + 5}$ **3.** $\lim_{x\to \frac{3}{2}} \dfrac{\sin(2x - 3)}{2x - 3}$ **4.** $\lim_{x\to -2} f(x), f(x) = \begin{cases} \dfrac{x-4}{|x|} & x \leq -2 \\ x^2 - 1 & x > -2 \end{cases}$

SECTION 12.2 The Properties of Limits

KEY CONCEPTS

- When evaluating limits using a table, great care must be exercised as results can sometimes be misleading. Using a graph and some common sense will sometimes help.
- Limits possess certain properties that seem plausible using a table of values. These include the sum, difference, product, and quotient properties, as well as the power and root properties. For a review of these properties, see page 1182.
- Once the limit properties have been established, they can be used to evaluate the limit of many different kinds of functions.

- These four basic limits play an important role in the evaluation of general limits.
  (1) $\lim_{x\to c} k = k$ (2) $\lim_{x\to c} x = c$ (3) $\lim_{x\to c} x^k = c^k$ (4) $\lim_{x\to c} \sqrt[k]{x} = \sqrt[k]{c}$, if $c > 0$ when k is even
- If the limit properties lead to an undefined or indeterminate expression, a limit may still exist and other means should be used to investigate.

EXERCISES

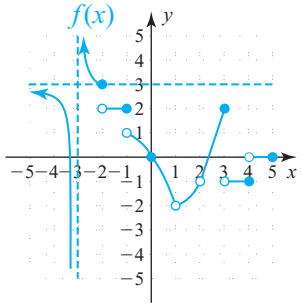
Determine the following limits using limit properties.

5. $\lim_{x\to -3} (2x^3 - 5x + 1)$ **6.** $\lim_{x\to 7} \dfrac{\sqrt{11 - x}}{\sqrt[3]{x^2 - 3x - 1}}$ **7.** $\lim_{x\to 1} \dfrac{\sqrt{x}}{(x^2 - 12x + 9)^5}$ **8.** $\lim_{x\to 1} \dfrac{\sqrt{2 - x} - 1}{1 - x}$

SECTION 12.3 Continuity and More on Limits

KEY CONCEPTS

- Generally, a function is continuous if you can draw the entire graph without lifting your pencil.
- Specifically, a function f is continuous at c if these three conditions are met:
  (1) c is in the domain of f (2) $\lim_{x\to c^-} f(x) = \lim_{x\to c^+} f(x)$ (3) $\lim_{x\to c} f(x) = f(c)$.
- The continuity of a function can be interupted by (1) asymptotic, (2) jump (non-removable), or (3) removable discontinuities.
- If a function is continuous at c, the limit $\lim_{x\to c} f(x)$ can be found by direct substitution.
- Polynomial functions are continuous for $x \in \mathbb{R}$, while rational, root, and trigonometric functions are continuous everywhere they are defined.
- Using algebraic methods, a limit that cannot be evaluated by direct substitution can sometimes be rewritten in a form where a direct substitution becomes possible.
- Limits can also occur as x becomes infinitely large, positively or negatively: $\lim_{x\to \pm\infty} f(x) = L$, provided $f(x)$ can be made arbitrarily close to L, by taking values of x sufficiently large.



EXERCISES

9. Name the x-value(s) where the graph has

a. an asymptotic discontinuity

b. a jump discontinuity

c. a removable discontinuity

Use the graph of f to evaluate the following limits.

10. $\lim_{x\to -\infty} f(x)$ **11.** $\lim_{x\to 3^+} f(x)$ **12.** $\lim_{x\to 3^-} f(x)$

13. $\lim_{x\to -3^-} f(x)$ **14.** $\lim_{x\to 3} f(x)$ **15.** $\lim_{x\to 1} f(x)$

SECTION 12.4 Applications of Limits: Instantaneous Rates of Change and the Area under a Curve

KEY CONCEPTS

- The rate of change of $f(x)$ in the interval $[x_1, x_2]$ can be approximated using the rate-of-change formula:

$$\frac{\Delta f}{\Delta x} = \frac{f(x_2) - f(x_1)}{x_2 - x_1}.$$

- The rate of change of $f(x)$ in the arbitrary interval $[x, x + h]$ can be approximated using the difference quotient:

$$\frac{f(x + h) - f(x)}{h}.$$

- Graphically, the slope of the secant line gives a better and better approximation for the instantaneous rate of change as $h \to 0$, and we define the instantaneous rate of change as the limiting value of this slope:

$$m_{\tan} = \lim_{h\to 0} m_{\sec} = \lim_{h\to 0} \frac{f(x+h) - f(x)}{h}.$$

- The instantaneous rate of change of f at point x is the limit of the difference quotient (if it exists):

$$f'(x) = \lim_{h\to 0} \frac{f(x+h) - f(x)}{h}.$$

- For $f(x) > 0$ in the first quadrant, the area under the graph of f in the interval $[0, b]$ can be found using the rectangle method and n rectangles of equal width. The width of each rectangle will be $\frac{b}{n}$, the height of each is found by evaluating f in increments of $\frac{b}{n}$:

$$A = \lim_{n\to\infty} \sum_{i=1}^{n} LW = \lim_{n\to\infty} \sum_{i=1}^{n} f\left(\frac{b}{n}i\right)\frac{b}{n}.$$

EXERCISES

Find the limit of the difference quotient as $h \to 0$ to determine the instantaneous rate of change for the functions given.

16. $f(x) = x^2 + 5x - 2$ **17.** $g(x) = \sqrt{2x-1}$ **18.** $v(x) = \dfrac{1}{x+3}$

19. Take the limit of a difference quotient to find the slope of the line drawn tangent to $f(x) = -x^2 + 3x$ at $x = 4$.

20. Use the rectangle method to find the area in QI, under the graph of $f(x) = x^2 - 6x + 9$ in the interval $[0, 3]$.

PRACTICE TEST

1. Write the expression in words, as though you were reading it out loud: $\lim_{x\to 5} f(x) = 10$

2. Fill in the blanks: $\lim_{x\to c} f(x) = L$, means that values of _____ can be made arbitrarily close to _____, by taking values of x _____ close to _____.

State true or false and justify your answer.

3. For $f(x) = \dfrac{x^2-1}{x-1}$, $\lim_{x\to 1} f(x)$ cannot exist since $x = 1$ is not in the domain.

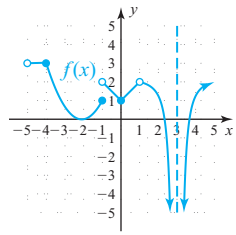
4. For $f(x) = \begin{cases} x+1, & x \geq 1 \\ x-1, & x < 1 \end{cases}$, $\lim_{x\to 1} f(x)$ must exist since $x = 1$ is in the domain.

5. For $g(x) = \sqrt{x-1} + 2$, state which of the following one-sided limits exist. Justify your answer and then find the limit.

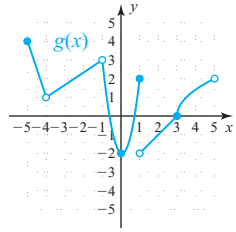
a. $\lim_{x\to 1^-} (\sqrt{x-1} + 2)$

b. $\lim_{x\to 1^+} (\sqrt{x-1} + 2)$

6. Match each expression to its conclusion.



a. $\lim_{x\to 0} \cos\left(\dfrac{1}{x}\right)$ **I.** $\left(\text{dne}_{\infty}\right)$



b. $\lim_{x\to 2} \dfrac{5x}{x^2-4x+4}$ **II.** $\left(\text{dne}_{\not\exists}\right)$

c. $\lim_{x\to 0} \dfrac{\sin x}{x}$ **III.** $\left(\text{dne}_{\text{LH}\neq\text{RH}}\right)$

d. $\lim_{x\to 1} \dfrac{2x^2-2x}{\sqrt{x^2-2x+1}}$ **IV.** 1

Determine the following using the graphs of $f(x)$ and $g(x)$ shown.

7. a. $\lim_{x\to -1^+} f(x)$ **b.** $\lim_{x\to 3^+} f(x)$

8. a. $\lim_{x\to -4} g(x)$ **b.** $\lim_{x\to 3^-} g(x)$

9. a. $f(0) - g(0)$

b. $g(-5)f(-4)$

10. a. $[g(1)]^2$ **b.** $\dfrac{f(-4)}{g(3)}$

11. a. $\lim_{x\to -4} [f(x) + g(x)]$

b. $\lim_{x\to 1^+} f(x)g(x)$

12. a. $\lim_{x\to -5^+} \sqrt{g(x)}$ **b.** $\lim_{x\to -1^+} [g(x)]^2$

13. Evaluate the following limits using the **TABLE** feature of a calculator. If the limit does not exist, state why.

a. $\lim_{x\to 0} \dfrac{\cos x - 1}{x}$ **b.** $\lim_{x\to -1} \dfrac{x^3 + 1}{\sqrt{(x+1)^2}}$

c. $\lim_{x\to 0} \dfrac{\sin x}{2x + \tan x}$ **d.** $\lim_{x\to 0} \dfrac{\sin(3x)}{3x}$

14. Each of the following limits does not exist. State why.

a. $\lim_{x\to 1} \dfrac{|x^2 - 1|}{x - 1}$ **b.** $\lim_{x\to 0} \tan\left(\dfrac{1}{x}\right)$

c. $\lim_{x\to -2^+} \dfrac{x^2 - 1}{x + 2}$ **d.** $\lim_{x\to 3} \sqrt{x - 4}$

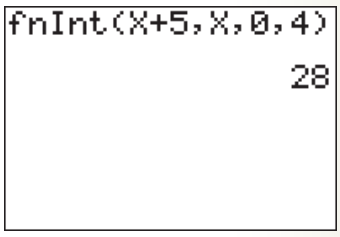
Evaluate each limit.

15. $\lim_{x\to -1} \dfrac{x^3 + 1}{x + 1}$ **16.** $\lim_{x\to -\infty} \dfrac{3x^2 + 5x - 4}{2x^2 - x - 3}$

17. $\lim_{x\to 25} \dfrac{\sqrt{x} - 5}{x - 25}$ **18.** $\lim_{x\to 0} \dfrac{\cos(2x)}{\cos^2 x}$

19. A controlled explosion at a strip mine causes a huge shower of dirt and rock. The height of the debris that was projected vertically upward by the blast can be modeled by the function $d(t) = -16t^2 + 224t$, where $d(t)$ is the height in feet after t sec. (a) Compute the limit of the difference quotient for d to find a function $d'(t)$ that gives the instantaneous velocity of the debris at time t. (b) Find the velocity at $t = 2$, 6, 7, and 11, and explain the significance of each result.

20. In preparation for another sold-out performance by the Danish pianist and comedian Victor Borge (Phonetic Punctuation), stage hands move a large grand piano 15 ft across the main stage and then carefully into position. The force applied can be modeled by the function $f(x) = 225 - x^2$ (the force is much greater as they start than when they finish). Since **Work = Force · Distance,** the area under the curve from 0 to x represents the amount of work done in foot-pounds. Use the rectangle method to (a) find an expression representing the amount of work done in moving the piano the first 6 ft, and (b) find the amount of work done in the interval [0, 6].



CALCULATOR EXPLORATION AND DISCOVERY

Technology and the Area Under a Curve

In Section 12.4, we used approximating rectangles and limit properties to determine the area under a curve. In a calculus course, we will discover a much more efficient method to determine this same area, but for now we can turn to our calculators to verify our work. Most graphing calculators have at least two features that enable us to quickly compute the area under a curve, between two x-values.

In Example 5 from Section 12.4, we used the limit of the sum of these rectangles to determine that the area under the graph of $f(x) = x + 5$ between $x = 0$ and $x = 4$ is 28 units^2. From the home screen of many calculators, the keystrokes MATH 9 call up the **fnInt(** feature, which can be used to calculate these types of areas. To use this feature, we must enter (separated by commas) the function, the variable x, the lower limit of the x-values, and the upper limit of the x-values. The screenshot shown in Figure 12.37 verifies our result from Example 5.

Figure 12.37

While the **fnInt(** command is convenient to use, it ignores the underlying idea of area and reduces these problems to a dry computation. Our calculators have a very nice feature that provides the same information, while highlighting the area connection. Begin by entering the function in the Y= screen, in this case $Y_1 = X + 5$. Setting the x-values of the WINDOW to range from -9.4 to 9.4 and the y-values to range from -1.4 to 11 will create a "friendly" GRAPH of this function, as shown in Figure 12.38. Now for the fun part! The 2nd TRACE **(CALC) 7:∫f(x)dx** feature not only calculates the specified area under the curve, but also uses an animated shading to display the region. After we provide

Figure 12.38

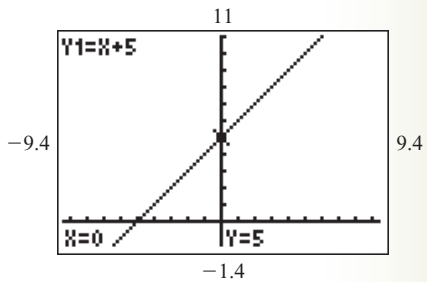


Figure 12.39

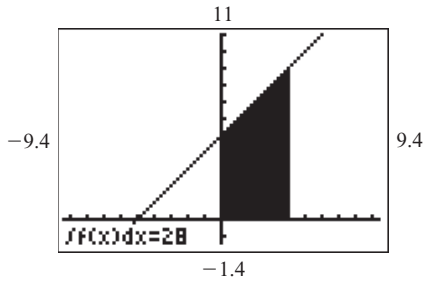

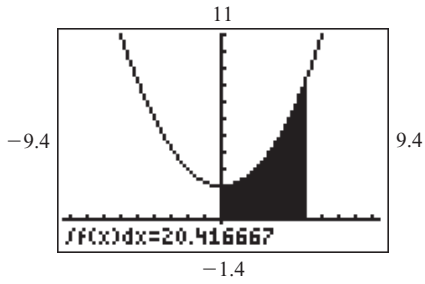

Figure 12.40

the lower and upper x limits with the keystrokes 0 ENTER 4 ENTER (for this example), this feature of our calculator once again confirms the area [which is $\int f(x)dx$ in calculus notation] is 28 units^2. See Figure 12.39.

The graph of the region in Figure 12.39 once again reminds us that we could have found the area of this trapezoid using simple geometry. The usefulness of the approximating rectangles and our calculators becomes apparent when we look to more complex shapes. For instance, in Example 6 of Section 12.4 we used the rectangle technique to determine the area under the graph of $f(x) = \frac{1}{4}x^2 + 2$ in the interval [0, 5] was $20.41\overline{6}$ units^2. After we enter $Y_1 = \frac{1}{4}X^2 + 2$ and graph it in the WINDOW shown in Figure 12.40, our calculator verifies this result.

Exercise 1: Use both the **fnInt(** and 2nd TRACE **(CALC) 7:∫f(x)dx** features to determine the area under the graph of $f(x) = -\frac{1}{2}x^2 + 4x$ over the interval [0, 6]. See Section 12.4, Exercise 43.

Exercise 2: Use both the **fnInt(** and 2nd TRACE **(CALC) 7:∫f(x)dx** features to determine the area under the graph of $f(x) = -\frac{1}{2}x^3 + 6x$ over the interval [0, 3]. See Section 12.4, Exercise 44.

Exercise 3: Use the 2nd TRACE **(CALC) 7:∫f(x)dx** feature to determine the area "under" the graph of $f(x) = \frac{1}{2}x^2 - 4x$ over the interval [0, 6]. Compare your result to Exercise 1 and comment on what you notice.

Exercise 4: Use the 2nd TRACE **(CALC) 7:∫f(x)dx** feature to determine the area "under" the graph of $f(x) = -\frac{1}{2}x^3 + 6x$ over the interval $[-3, 3]$. Comment on what you notice.

CUMULATIVE REVIEW CHAPTERS 1–12

1. Graph the function $f(x) = 2x^2 - 12x + 15$ by completing the square.
2. Solve the system.
$$\begin{cases} x + 3y - 2z = 6 \\ 2x + y + z = 2 \\ -3x + 4y - 2z = 3 \end{cases}$$
3. Write as a sum/difference of logarithmic terms.
$$\ln\left[\frac{x^{\frac{2}{3}}\sqrt{x^2+3}}{(2x+1)^4}\right]$$
4. Standing 134 ft from the St. Louis Arch, the angle of elevation to the top of the arch is 78°. How tall is the arch?
5. Verify that $\left(\frac{8}{17}, -\frac{15}{17}\right)$ is a point on the unit circle, then use it to find the value of $\sin\theta$, $\cos\theta$, and $\tan\theta$.
6. Find the sum of the infinite series
$$\frac{1}{3} + \frac{1}{9} + \frac{1}{27} + \frac{1}{81} + \cdots$$
7. Use the Guidelines for Graphing Rational Functions to graph $v(x) = \frac{x}{x^2 - 9}$.
8. Write $f(x) = x^3 - 2x^2 - 5x + 6$ in completely factored form, then graph the function.

9. Evaluate the following limits:

a. $\lim\limits_{x\to 1^-}\dfrac{|x-1|}{x^2-1}$ and $\lim\limits_{x\to 1^+}\dfrac{|x-1|}{x^2-1}$

b. $\lim\limits_{x\to 1}\dfrac{|x-1|}{x^2-1}$

10. For $z = 2 + 2i$, use De Moivre's theorem to find $z^6 = (2 + 2i)^6$.

11. Solve the equation $2 + \sqrt{3}\tan(\alpha - 1) = 3$. Find all solutions in $[0, 2\pi)$.

12. I am a heavy pencil user. My new pencils are 19 cm long, but after 30 days of heavy use they now average only 9 cm in length. Assuming their length decreases linearly, (a) find a function $L(x)$ that models the length of my pencils after x days of use. (b) Use the model to find the length of a pencil I've been using for 15 days. (c) If one of my pencils is 11 cm long, how many days has it been in use?

13. An airline pilot is having to fight a stiff crosswind to stay on course. If the plane is flying at 250 mph on a heading of 20°, and the wind is from the west at 50 mph, what would be the course and heading of the plane if no course corrections are made?

14. Graph the piecewise-defined function given, then state whether its graph is continuous.

$$f(x) = \begin{cases} (x+2)^2 & x \le 0 \\ x + 2 & x > 0 \end{cases}$$

15. Solve for x: $-3e^{2x-1} = -28.08$.

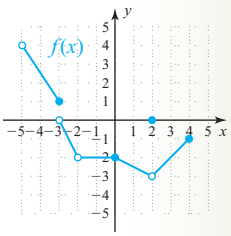
16. Graph the function $y = 2\cos\left(x - \dfrac{\pi}{4}\right)$.

17. Evaluate the limit:

$$\lim_{x\to-\infty}\frac{6x}{\sqrt{4x^2+5}}$$

18. Verify the following is an identity:
$\sin^4 x - \cos^4 x = 2\sin^2 x - 1$

19. Decompose the rational expression $\dfrac{x^2+x+4}{x^2+x-2}$ into a sum of partial fractions.



20. Find all real solutions for

$$3510 = 7000\sin\left(4\theta - \frac{\pi}{6}\right) + 10.$$

21. Find the equation of the ellipse with vertices at $(-4, 1)$ and $(6, 1)$, and foci at $(-3, 1)$ and $(5, 1)$.

22. Graph the hyperbola by completing the square in x and y, then writing the equation in standard form: $x^2 - 4y^2 + 24y + 6x - 43 = 0$.

Determine the following using the graph of $f(x)$ shown:

23. **a.** $\lim\limits_{x\to -3^-} f(x)$

b. $\lim\limits_{x\to -3^+} f(x)$

c. $\lim\limits_{x\to 2} f(x)$

d. $\lim\limits_{x\to 5} f(x)$

24. **a.** $f(-3)f(0)$

b. $f(2) - f(4)$

c. $f(-1) + f(3)$

d. $\dfrac{f(0)}{f(2)}$

25. Hi'ilani has to reset her five-digit PIN number. How many PINs are possible if no repetitions are allowed and two different common vowels must be followed by three different nonzero digits?

Exercises 26 through 30 require the use of a graphing calculator.

26. Solve the system using a graphing calculator. Round your answers to two decimal places.

$$\begin{cases} x + y^2 = 10 \\ 3x^2 + 2y^2 = 30 \end{cases}$$

27. Solve the following system using inverse matrices and your calculator.

$$\begin{cases} w + x + y + z = -2 \\ 2w - x + 3y + z = 9 \\ w - x - y + z = -4 \\ 3w + 2x - 2y + 3z = -19 \end{cases}$$

28. In Cuivre River State Park, there are two dominant squirrel species: gray-tailed and red-tailed. The function $g(t) = \ln|t^5 - 3t^4 + 2t^3 - 5t^2 + t - 3|$ models the population of gray-tailed squirrels from 1990 to 2010, while $r(t) = \ln|-2t^3 + 5t^2 - 3t + 1| + 3$ models the red-tailed population during this same 20-yr period. These two functions give the respective number of squirrels (in hundreds) living in this park during year t, where $t = 0$ corresponds to 1990. Using integer-valued years and the **TABLE** feature of your calculator, determine when these two populations were closest in size. What was the difference in populations that year?

29. Determine the intervals over which the function $f(x) = 4x^3 - 4x^2 - 32x + 17$ is increasing.

30. Find all solutions (if they exist) using a graphing calculator.

$$\sqrt{\frac{x^2}{x+1}} = e^{\frac{x^2}{x+1}}$$

A.1 Algebraic Expressions and the Properties of Real Numbers

LEARNING OBJECTIVES

In Section A.1 you will review how to:

- ❑ **A.** Identify terms, coefficients, and expressions
- ❑ **B.** Create mathematical models
- ❑ **C.** Evaluate algebraic expressions
- ❑ **D.** Identify and use properties of real numbers
- ❑ **E.** Simplify algebraic expressions

To effectively use mathematics as a problem-solving tool, we must develop the ability to translate written or verbal information into a mathematical model. After obtaining a model, many applications require that you work effectively with algebraic terms and expressions. The basic ideas involved are reviewed here.

A. Terms, Coefficients, and Algebraic Expressions

An **algebraic term** is a *collection of factors* that may include numbers, variables, or expressions within parentheses. Here are some examples:

(a) 3 (b) $-6P$ (c) $5xy$ (d) $-8n^2$ (e) n (f) $2(x + 3)$

If a term consists of a single nonvariable number, it is called a **constant** term. In (a), 3 is a constant term. Any term that contains a variable is called a **variable term.** We call the constant factor of a term the **numerical coefficient** or simply the **coefficient.** The coefficients for (a), (b), (c), and (d) are 3, -6, 5, and -8, respectively. In (e), the coefficient of n is 1, since $1 \cdot n = 1n = n$. The term in (f) has two factors as written, 2 and $(x + 3)$. The coefficient is 2.

An **algebraic expression** can be a single term or a sum or difference of terms. To avoid confusion when identifying the coefficient of each term, the expression can be rewritten using algebraic addition if desired: $A - B = A + (-B)$. For instance, $4 - 3x = 4 + (-3x)$ shows the coefficient of x is -3. To identify the coefficient of a rational term, it sometimes helps to **decompose** the term, rewriting it using a unit fraction as in $\frac{n-2}{5} = \frac{1}{5}(n - 2)$ and $\frac{x}{2} = \frac{1}{2}x$.

EXAMPLE 1 ▶ **Identifying Terms and Coefficients**

State the number of terms in each expression as given, then identify the coefficient of each term.

a. $2x - 5y$ **b.** $\frac{x+3}{7} - 2x$ **c.** $-(x - 12)$ **d.** $-2x^2 - x + 5$

Solution ▶ We can begin by rewriting each subtraction using algebraic addition.

Rewritten:	**a.** $2x + (-5y)$	**b.** $\frac{1}{7}(x+3) + (-2x)$	**c.** $-1(x - 12)$	**d.** $-2x^2 + (-1x) + 5$
Number of terms:	two	two	one	three
Coefficient(s):	2 and -5	$\frac{1}{7}$ and -2	-1	-2, -1, and 5

A. You've just seen how we can identify terms, coefficients, and expressions

Now try Exercises 7 through 14 ▶

B. Translating Written or Verbal Information into a Mathematical Model

The key to solving many applied problems is finding an algebraic expression that accurately models relationships described in context. First, we assign a variable to represent an unknown quantity, then build related expressions using words from the English language that suggest mathematical operations. Variables that remind us of what they represent are often used in the modeling process, such as D = RT for Distance equals Rate times Time. These are often called **descriptive variables.** Capital letters are also used due to their widespread appearance in other fields.

EXAMPLE 2 ▶ **Translating English Phrases into Algebraic Expressions**

Assign a variable to the unknown number, then translate each phrase into an algebraic expression.

a. twice a number, increased by five
b. eleven less than eight times the width
c. ten less than triple the payment
d. two hundred fifty dollars more than double the amount

Solution ▶

a. Let n represent the number. Then $2n$ represents twice the number, and $2n + 5$ represents twice the number, increased by five.
b. Let W represent the width. Then $8W$ represents eight times the width, and $8W - 11$ represents 11 less than eight times the width.
c. Let p represent the payment. Then $3p$ represents triple the payment, and $3p - 10$ represents 10 less than triple the payment.
d. Let A represent the amount in dollars. Then $2A$ represents double the amount, and $2A + 250$ represents 250 dollars more than double the amount.

Now try Exercises 15 through 28 ▶

Identifying and translating such phrases *when they occur in context* is an important problem-solving skill. Note how this is done in Example 3.

EXAMPLE 3 ▶ **Creating a Mathematical Model**

The cost for a rental car is $35 plus 15 cents per mile. Express the cost of renting a car in terms of the number of miles driven.

Solution ▶ Let m represent the number of miles driven. Then $0.15m$ represents the cost for each mile and $C = 35 + 0.15m$ represents the total cost for renting the car.

B. You've just seen how we can create mathematical models

Now try Exercises 29 through 40 ▶

C. Evaluating Algebraic Expressions

We often need to **evaluate** expressions to investigate patterns and note relationships.

Evaluating a Mathematical Expression

1. Replace each variable with open parentheses ( ).
2. Substitute the values given for each variable.
3. Simplify using the order of operations.

In this process, it's best to use a **vertical format,** with the original expression written first, the substitutions shown next, followed by the simplified forms and the final result. The numbers substituted or "plugged into" the expression are often called the **input values,** with the result called the **output** value.

EXAMPLE 4 ▶ **Evaluating an Algebraic Expression**

Evaluate the expression $x^3 - 2x^2 + 5$ for $x = -3$.

Solution ▶

For $x = -3$:

$$\begin{aligned} x^3 - 2x^2 + 5 &= (\quad)^3 - 2(\quad)^2 + 5 && \text{replace variables with open parentheses} \\ &= (-3)^3 - 2(-3)^2 + 5 && \text{substitute } -3 \text{ for } x \\ &= -27 - 2(9) + 5 && \text{simplify: } (-3)^3 = -27,\ (-3)^2 = 9 \\ &= -27 - 18 + 5 && \text{simplify: } 2(9) = 18 \\ &= -40 && \text{result} \end{aligned}$$

When the input is -3, the output is -40.

WORTHY OF NOTE

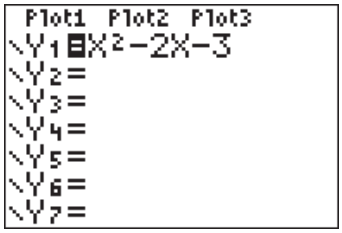
In Example 4, note the importance of the first step in the evaluation process: *replace each variable with open parentheses.* Skipping this step could easily lead to confusion as we try to evaluate the squared term, since $-3^2 = -9$, while $(-3)^2 = 9$. **Also see Exercises 55 and 56.**

Now try Exercises 41 through 60 ▶

If the same expression is evaluated repeatedly, results are often collected and analyzed in a table of values, as shown in Example 5. As a practical matter, the substitutions and simplifications are often done mentally or on scratch paper, with the table showing only the input and output values.

EXAMPLE 5 ▶ **Evaluating an Algebraic Expression**

Evaluate $x^2 - 2x - 3$ to complete the table shown. Which input value(s) of x cause the expression to have an output of 0?



Solution ▶

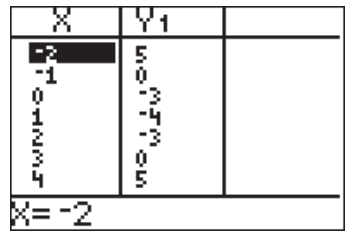
Input x	Output $x^2 - 2x - 3$
-2	$(-2)^2 - 2(-2) - 3 = 5$
-1	0
0	-3
1	-4
2	-3
3	0
4	5

The expression has an output of 0 when $x = -1$ and $x = 3$.

Now try Exercises 61 through 66 ▶

Figure A.1

C. You've just seen how we can evaluate algebraic expressions



Graphing calculators provide an efficient means of evaluating many expressions. After entering the expression on the Y= screen (Figure A.1), we can set up the table using the keystrokes 2nd WINDOW **(TBLSET).** For this exercise, we'll put the table in the "**Indpnt: Auto Ask**" mode, which will have the calculator "automatically" generate the input and output values. In this mode, we can tell the calculator where to start the inputs (we chose **TblStart** $= -2$), and have the calculator produce the input values using any increment desired (we choose Δ**Tbl** $= 1$), as shown in Figure A.2. We access the completed table using 2nd GRAPH **(TABLE)**, and the result for Example 5 is shown in Figure A.3.

For exercises that combine the skills from Examples 3 through 5, **see Exercises 91 to 98.**

Figure A.2

Figure A.3

D. Properties of Real Numbers

While the phrase, "an unknown number times five," is accurately modeled by the expression $n5$ for some number n, in algebra we prefer to have numerical coefficients precede variable factors. When we reorder the *factors* as $5n$, we are using the **commutative property of multiplication.** A reordering of *terms* involves the **commutative property of addition.**

The Commutative Properties

Given that a and b represent real numbers:

ADDITION: $a + b = b + a$	MULTIPLICATION: $a \cdot b = b \cdot a$
Terms can be combined in any order without changing the sum.	Factors can be multiplied in any order without changing the product.

Each property can be extended to include any number of terms or factors. While the commutative property implies a *reordering* or *movement* of terms (to commute implies back-and-forth movement), the **associative property** implies a *regrouping* or reassociation of terms. For example, the sum $(\frac{3}{4} + \frac{3}{5}) + \frac{2}{5}$ is easier to compute if we regroup the addends as $\frac{3}{4} + (\frac{3}{5} + \frac{2}{5})$. This illustrates the **associative property of addition.** Multiplication is also associative.

The Associative Properties

Given that a, b, and c represent real numbers:

ADDITION:	MULTIPLICATION:
$(a + b) + c = a + (b + c)$	$(a \cdot b) \cdot c = a \cdot (b \cdot c)$
Terms can be regrouped.	Factors can be regrouped.

EXAMPLE 6 ▶ **Simplifying Expressions Using Properties of Real Numbers**

Use the commutative and associative properties to simplify each calculation.

a. $\frac{3}{8} - 19 + \frac{5}{8}$ **b.** $[-2.5 \cdot (-1.2)] \cdot 10$

Solution ▶

a. $\frac{3}{8} - 19 + \frac{5}{8} = -19 + \frac{3}{8} + \frac{5}{8}$ commutative property (order changes)

$= -19 + (\frac{3}{8} + \frac{5}{8})$ associative property (grouping changes)

$= -19 + 1$ simplify

$= -18$ result

WORTHY OF NOTE

Is subtraction commutative? Consider a situation involving money. If you had \$100, you could easily buy an item costing \$20: \$100 − \$20 leaves you with \$80. But if you had \$20, could you buy an item costing \$100? Obviously \$100 − \$20 is not the same as \$20 − \$100. Subtraction is *not* commutative. Likewise, 100 ÷ 20 is not the same as 20 ÷ 100, and division is *not* commutative.

b. $[-2.5 \cdot (-1.2)] \cdot 10 = -2.5 \cdot [(-1.2) \cdot 10]$ associative property (grouping changes)

$= -2.5 \cdot (-12)$ simplify

$= 30$ result

Now try Exercises 67 and 68 ▶

For any real number x, $x + 0 = x$ and 0 is called the **additive identity** since the original number was returned or "identified." Similarly, 1 is called the **multiplicative identity** since $1 \cdot x = x$. The identity properties are used extensively in the process of solving equations.

The Additive and Multiplicative Identities

Given that x is a real number,

$x + 0 = x$	$1 \cdot x = x$
Zero is the identity for addition.	One is the identity for multiplication.

For any real number x, there is a real number $-x$ such that $x + (-x) = 0$. The number $-x$ is called the **additive inverse** of x, since their sum results in the additive identity. Similarly, the **multiplicative inverse** of any nonzero number x is $\frac{1}{x}$, since $x \cdot \frac{1}{x} = 1$ (the multiplicative identity). This property can also be stated as $\frac{p}{q} \cdot \frac{q}{p} = 1$ $(p, q \neq 0)$ for any rational number $\frac{p}{q}$. Note that $\frac{p}{q}$ and $\frac{q}{p}$ are **reciprocals.**

The Additive and Multiplicative Inverses

Given that p, q, and x represent real numbers $(p, q \neq 0)$:

$x + (-x) = 0$	$\frac{p}{q} \cdot \frac{q}{p} = 1$
x and $-x$ are additive inverses.	$\frac{p}{q}$ and $\frac{q}{p}$ are multiplicative inverses.

EXAMPLE 7 ▶ **Determining Additive and Multiplicative Inverses**

Replace the box to create a true statement:

a. $\square \cdot \frac{-3}{5}x = 1 \cdot x$ **b.** $x + 4.7 + \square = x$

Solution ▶ **a.** $\square = \frac{5}{-3}$, since $\frac{5}{-3} \cdot \frac{-3}{5} = 1$ **b.** $\square = -4.7$, since $4.7 + (-4.7) = 0$

Now try Exercises 69 and 70 ▶

Note that if no coefficient is indicated, it is assumed to be 1, as in $x = 1x$, $(x^2 + 3x) = 1(x^2 + 3x)$, and $-(x^3 - 5x^2) = -1(x^3 - 5x^2)$.

The **distributive property of multiplication over addition** is widely used in a study of algebra, because it enables us to rewrite a product as an equivalent sum and vice versa.

The Distributive Property of Multiplication over Addition

Given that a, b, and c represent real numbers:

$a(b + c) = ab + ac$	$ab + ac = a(b + c)$
A factor outside a sum can be distributed to each addend in the sum.	A factor common to each addend in a sum can be "undistributed" and written outside a group.

EXAMPLE 8 ▶ **Simplifying Expressions Using the Distributive Property**

Apply the distributive property as appropriate. Simplify if possible.

a. $7(p + 5.2)$ **b.** $-(2.5 - x)$ **c.** $7x^3 - x^3$ **d.** $\frac{5}{2}n + \frac{1}{2}n$

Solution ▶

a. $7(p + 5.2) = 7p + 7(5.2)$
$= 7p + 36.4$

b. $-(2.5 - x) = -1(2.5 - x)$
$= -1(2.5) - (-1)(x)$
$= -2.5 + x$

c. $7x^3 - x^3 = 7x^3 - 1x^3$
$= (7 - 1)x^3$
$= 6x^3$

d. $\frac{5}{2}n + \frac{1}{2}n = \left(\frac{5}{2} + \frac{1}{2}\right)n$
$= \left(\frac{6}{2}\right)n$
$= 3n$

WORTHY OF NOTE
From Example 8b we learn that a negative sign outside a group changes the sign of all terms within the group: $-(2.5 - x) = -2.5 + x$.

Now try Exercises 71 through 78 ▶

D. You've just seen how we can identify and use properties of real numbers

E. Simplifying Algebraic Expressions

Two terms are **like terms** only if they have the *same variable factors* (the coefficient is not used to identify like terms). For instance, $3x^2$ and $-\frac{1}{7}x^2$ are like terms, while $5x^3$ and $5x^2$ are not. We simplify expressions by **combining like terms** using the distributive property, along with the commutative and associative properties. Many times the distributive property is used to eliminate grouping symbols *and* combine like terms within the same expression.

EXAMPLE 9 ▶ **Simplifying an Algebraic Expression**

Simplify the expression completely: $7(2p^2 + 1) - (p^2 + 3)$.

Solution ▶

$7(2p^2 + 1) - 1(p^2 + 3)$	original expression; note coefficient of -1
$= 14p^2 + 7 - 1p^2 - 3$	distributive property
$= (14p^2 - 1p^2) + (7 - 3)$	commutative and associative properties (collect like terms)
$= (14 - 1)p^2 + 4$	distributive property
$= 13p^2 + 4$	result

Now try Exercises 79 through 88 ▶

The steps for simplifying an algebraic expression are summarized here:

To Simplify an Expression

1. Eliminate parentheses by applying the distributive property.
2. Use the commutative and associative properties to group like terms.
3. Use the distributive property to combine like terms.

E. You've just seen how we can simplify algebraic expressions

As you practice with these ideas, many of the steps will become more automatic. At some point, the distributive property, the commutative and associative properties, as well as the use of algebraic addition will all be performed mentally.

A.1 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section, if necessary.

1. A term consisting of a single number is called a(n) _____ term.
2. A term containing a variable is called a(n) _____ term.
3. The constant factor in a variable term is called the _____.
4. When $3 \cdot 14 \cdot \frac{2}{3}$ is written as $3 \cdot \frac{2}{3} \cdot 14$, the _____ property has been used.
5. Discuss/Explain why the additive inverse of -5 is 5, while the multiplicative inverse of -5 is $-\frac{1}{5}$.
6. Discuss/Explain how we can rewrite the sum $3x + 6y$ as a product, and the product $2(x + 7)$ as a sum.

▶ DEVELOPING YOUR SKILLS

Identify the number of terms in each expression and the coefficient of each term.

7. $3x - 5y$
8. $-2a - 3b$
9. $2x + \dfrac{x + 3}{4}$
10. $\dfrac{n - 5}{3} + 7n$
11. $-2x^2 + x - 5$
12. $3n^2 + n - 7$
13. $-(x + 5)$
14. $-(n - 3)$

Translate each phrase into an algebraic expression.

15. seven fewer than a number
16. a number decreased by six
17. the sum of a number and four
18. a number increased by nine
19. the difference between a number and five is squared
20. the sum of a number and two is cubed
21. thirteen less than twice a number
22. five less than double a number
23. a number squared plus the number doubled
24. a number cubed less the number tripled
25. five fewer than two-thirds of a number
26. fourteen more than one-half of a number
27. three times the sum of a number and five, decreased by seven
28. five times the difference of a number and two, increased by six

Create a mathematical model using descriptive variables.

29. The length of the rectangle is three meters less than twice the width.
30. The height of the triangle is six centimeters less than three times the base.
31. The speed of the car was fifteen miles per hour more than the speed of the bus.
32. It took Romulus three minutes more time than Remus to finish the race.
33. **Hovering altitude:** The helicopter was hovering 150 ft above the top of the building. Express the altitude of the helicopter in terms of the building's height.

34. **Stacks on a cruise liner:** The smoke stacks of the luxury liner cleared the bridge by 25 ft as it passed beneath it. Express the height of the stacks in terms of the bridge's height.
35. **Dimensions of a city park:** The length of a rectangular city park is 20 m more than twice its width. Express the length of the park in terms of the width.

36. Dimensions of a parking lot: In order to meet the city code while using the available space, a contractor planned to construct a parking lot with a length that was 50 ft less than three times its width. Express the length of the lot in terms of the width.

37. Cost of milk: In 2010, a gallon of milk cost two and one-half times what it did in 1990. Express the cost of a gallon of milk in 2010 in terms of the 1990 cost.

38. Cost of gas: In 2010, a gallon of gasoline cost two and one-half times what it did in 1990. Express the cost of a gallon of gas in 2010 in terms of the 1990 cost.

39. Pest control: In her pest control business, Judy charges $50 per call plus $12.50 per gallon of insecticide for the control of spiders and certain insects. Express the total charge in terms of the number of gallons of insecticide used.

40. Computer repairs: As his reputation and referral business grew, Keith began to charge $75 per service call plus an hourly rate of $50 for the repair and maintenance of home computers. Express the cost of a service call in terms of the number of hours spent on the call.

Evaluate each algebraic expression given $x = 2$ and $y = -3$.

41. $4x - 2y$ **42.** $5x - 3y$

43. $-2x^2 + 3y^2$ **44.** $-5x^2 + 4y^2$

45. $2y^2 + 5y - 3$ **46.** $3x^2 + 2x - 5$

47. $-2(3y + 1)$ **48.** $-3(2y + 5)$

49. $3x^2y$ **50.** $6xy^2$

51. $(-3x)^2 - 4xy - y^2$ **52.** $(-2x)^2 - 5xy - y^2$

53. $\frac{1}{2}x - \frac{1}{3}y$ **54.** $\frac{2}{3}x - \frac{1}{2}y$

55. $(3x - 2y)^2$ **56.** $(2x - 3y)^2$

57. $\dfrac{-12y + 5}{-3x + 1}$ **58.** $\dfrac{12x + (-3)}{-3y + 1}$

59. $\sqrt{-12y} \cdot 4$ **60.** $7 \cdot \sqrt{-27y}$

Evaluate each expression for integers from -3 to 3 inclusive. Verify results using a graphing calculator. What input(s) give an output of zero?

61. $x^2 - 3x - 4$ **62.** $x^2 - 2x - 3$

63. $-3(1 - x) - 6$ **64.** $5(3 - x) - 10$

65. $x^3 - 6x + 4$ **66.** $x^3 + 5x + 18$

Rewrite each expression using the given property and simplify if possible.

67. Commutative property of addition

a. $-5 + 7$ **b.** $-2 + n$

c. $-4.2 + a + 13.6$ **d.** $7 + x - 7$

68. Associative property of multiplication

a. $2 \cdot (3 \cdot 6)$ **b.** $3 \cdot (4 \cdot b)$

c. $-1.5 \cdot (6 \cdot a)$ **d.** $-6 \cdot (-\frac{5}{6} \cdot x)$

Replace the box so that a true statement results.

69. a. $x + (-3.2) + \square = x$

b. $n - \frac{5}{6} + \square = n$

70. a. $\square \cdot \frac{2}{3}x = 1x$

b. $\square \cdot \dfrac{n}{-3} = 1n$

Apply the distributive property and simplify if possible.

71. $-5(x - 2.6)$

72. $-12(v - 3.2)$

73. $\frac{2}{3}(-\frac{1}{5}p + 9)$

74. $\frac{5}{6}(-\frac{2}{15}q + 24)$

75. $3a + (-5a)$

76. $13m + (-5m)$

77. $\frac{2}{3}x + \frac{3}{4}x$

78. $\frac{5}{12}y - \frac{3}{8}y$

Simplify by removing all grouping symbols (as needed) and combining like terms.

79. $3(a^2 + 3a) - (5a^2 + 7a)$

80. $2(b^2 + 5b) - (6b^2 + 9b)$

81. $x^2 - (3x - 5x^2)$

82. $n^2 - (5n - 4n^2)$

83. $(3a + 2b - 5c) - (a - b - 7c)$

84. $(x - 4y + 8z) - (8x - 5y - 2z)$

85. $\frac{3}{5}(5n - 4) + \frac{5}{8}(n + 16)$

86. $\frac{2}{3}(2x - 9) + \frac{3}{4}(x + 12)$

87. $(3a^2 - 5a + 7) + 2(2a^2 - 4a - 6)$

88. $2(3m^2 + 2m - 7) - (m^2 - 5m + 4)$

▶ WORKING WITH FORMULAS

89. Electrical resistance: $R = \dfrac{kL}{d^2}$

The electrical resistance in a wire depends on the length and diameter of the wire. This resistance can be modeled by the formula shown, where R is the resistance in ohms, L is the length in feet, and d is the diameter of the wire in inches. Find the resistance if $k = 0.000025$, $d = 0.015$ in., and $L = 90$ ft

90. Volume and pressure: $P = \dfrac{k}{V}$

If temperature remains constant, the pressure of a gas held in a closed container is related to the volume of gas by the formula shown, where P is the pressure in pounds per square inch, V is the volume of gas in cubic inches, and k is a constant that depends on given conditions. Find the pressure exerted by the gas if $k = 440{,}310$ and $V = 22{,}580$ in^3.

▶ APPLICATIONS

Translate each key phrase into an algebraic expression, then evaluate as indicated.

91. Cruising speed: A turbo-prop airliner has a cruising speed that is one-half the cruising speed of a 767 jet aircraft. (a) Express the speed of the turbo-prop in terms of the speed of the jet, and (b) determine the speed of the airliner if the cruising speed of the jet is 550 mph.

92. Softball toss: Macklyn can throw a softball two-thirds as far as her father. (a) Express the distance that Macklyn can throw a softball in terms of the distance her father can throw. (b) If her father can throw the ball 210 ft, how far can Macklyn throw the ball?

93. Dimensions of a lawn: The length of a rectangular lawn is 3 ft more than twice its width. (a) Express the length of the lawn in terms of the width. (b) If the width is 52 ft, what is the length?

94. Pitch of a roof: To obtain the proper pitch, the crossbeam for a roof truss must be 2 ft less than three-halves the rafter. (a) Express the length of the crossbeam in terms of the rafter. (b) If the rafter is 18 ft, how long is the crossbeam?

95. Postage costs: In 2009, a first class stamp cost 29¢ more than it did in 1978. Express the cost of a 2009 stamp in terms of the 1978 cost. If a stamp cost 15¢ in 1978, what was the cost in 2009?

96. Minimum wage: In 2009, the federal minimum wage was \$4.95 per hour more than it was in 1976. Express the 2009 wage in terms of the 1976 wage. If the hourly wage in 1976 was \$2.30, what was it in 2009?

97. Repair costs: The TV repair shop charges a flat fee of \$43.50 to come to your house and \$25 per hour for labor. Express the cost of repairing a TV in terms of the time it takes to repair it. If the repair took 1.5 hr, what was the total cost?

98. Repair costs: At the local car dealership, shop charges are \$79.50 to diagnose the problem and \$85 per shop hour for labor. Express the cost of a repair in terms of the labor involved. If a repair takes 3.5 hr, how much will it cost?

▶ EXTENDING THE CONCEPT

99. If C must be a positive odd integer and D must be a negative even integer, then $C^2 + D^2$ must be a:

a. positive odd integer.
b. positive even integer.
c. negative odd integer.
d. negative even integer.
e. cannot be determined.

100. Historically, several attempts have been made to create metric time using factors of 10, but our current system won out. If 1 day was 10 metric hours, 1 metric hour was 10 metric minutes, and 1 metric minute was 10 metric seconds, what time would it really be if a metric clock read 4:3:5? Assume that each new day starts at midnight.

A.2 Exponents, Scientific Notation, and a Review of Polynomials

LEARNING OBJECTIVES

In Section A.2 you will review how to:

- ❑ **A.** Apply properties of exponents
- ❑ **B.** Perform operations in scientific notation
- ❑ **C.** Identify and classify polynomial expressions
- ❑ **D.** Add and subtract polynomials
- ❑ **E.** Compute the product of two polynomials
- ❑ **F.** Compute special products: binomial conjugates and binomial squares

In this section, we review basic exponential properties and operations on polynomials. Although there are five to eight exponential properties (depending on how you count them), all can be traced back to the basic definition involving repeated multiplication.

A. The Properties of Exponents

An exponent is a superscript number or letter occurring to the upper right of a base number, and indicates how many times the base occurs as a factor. For $b \cdot b \cdot b = b^3$, we say b^3 is written in *exponential form*. In some cases, we may refer to b^3 as an **exponential term.**

Exponential Notation

For any positive integer n,

$$b^n = \underbrace{b \cdot b \cdot b \cdot \ldots \cdot b}_{n \text{ times}} \quad \text{and} \quad \underbrace{b \cdot b \cdot b \cdot \ldots \cdot b}_{n \text{ times}} = b^n$$

The Product and Power Properties

There are two properties that follow immediately from this definition. When b^3 is multiplied by b^2, we have an uninterrupted string of five factors: $b^3 \cdot b^2 = (b \cdot b \cdot b) \cdot (b \cdot b)$, which can then be written as b^5. This is an example of the **product property of exponents.**

WORTHY OF NOTE

In this statement of the product property and the exponential properties that follow, it is assumed that for any expression of the form 0^m, $m > 0$ (hence $0^m = 0$).

Product Property of Exponents

For any base b and positive integers m and n:

$$b^m \cdot b^n = b^{m+n}$$

In words, the property says, *to multiply exponential terms with the* **same base,** *keep the common base and add the exponents*. A special application of the product property uses repeated factors of the *same* exponential term, as in $(x^2)^3$. Using the product property, we have $(x^2)(x^2)(x^2) = x^6$. Notice the same result can be found more quickly by multiplying the inner exponent by the outer exponent: $(x^2)^3 = x^{2 \cdot 3} = x^6$. We generalize this idea to state the **power property of exponents.** In words the property says, *to raise an exponential term to a power, keep the same base and multiply the exponents.*

Power Property of Exponents

For any base b and positive integers m and n:

$$(b^m)^n = b^{m \cdot n}$$

EXAMPLE 1 ▶ **Multiplying Terms Using Exponential Properties**

Compute each product.

a. $-4x^3 \cdot \frac{1}{2}x^2$ **b.** $(p^3)^2 \cdot (p^4)^5$

Solution ▶

a.
$$\begin{aligned} -4x^3 \cdot \tfrac{1}{2}x^2 &= (-4 \cdot \tfrac{1}{2})(x^3 \cdot x^2) && \text{commutative and associative properties} \\ &= (-2)(x^{3+2}) && \text{simplify; product property} \\ &= -2x^5 && \text{result} \end{aligned}$$

b.
$$\begin{aligned} (p^3)^2 \cdot (p^4)^5 &= p^{3 \cdot 2} \cdot p^{4 \cdot 5} && \text{power property} \\ &= p^6 \cdot p^{20} && \text{simplify} \\ &= p^{6+20} && \text{product property} \\ &= p^{26} && \text{result} \end{aligned}$$

Now try Exercises 7 through 12 ▶

The power property can easily be extended to include more than one factor within the parentheses. This application of the power property is sometimes called the **product to a power property** and can be extended to include any number of factors. We can also raise a quotient of exponential terms to a power. The result is called the **quotient to a power property.** In words the properties say, to raise a product or quotient of exponential terms to a power, *multiply every exponent inside* the parentheses *by the exponent outside* the parentheses.

Product to a Power Property

For any bases a and b, and positive integers m, n, and p:

$$(a^m b^n)^p = a^{mp} \cdot b^{np}$$

Quotient to a Power Property

For any bases a and $b \neq 0$, and positive integers m, n, and p:

$$\left(\frac{a^m}{b^n}\right)^p = \frac{a^{mp}}{b^{np}}$$

EXAMPLE 2 ▶ **Simplifying Terms Using the Power Properties**

Simplify using the power property (if possible):

a. $(-3a)^2$ **b.** $-3a^2$ **c.** $\left(\dfrac{-5a^3}{2b}\right)^2$

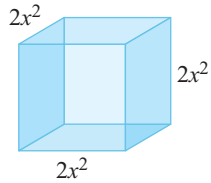
Solution ▶

a. $(-3a)^2 = (-3)^2 \cdot (a^1)^2$
$= 9a^2$

b. $-3a^2$ is in simplified form

c. $\left(\dfrac{-5a^3}{2b}\right)^2 = \dfrac{(-5)^2(a^3)^2}{2^2b^2}$
$= \dfrac{25a^6}{4b^2}$

WORTHY OF NOTE



Regarding Examples 2a and 2b, note the difference between the expressions $(-3a)^2 = (-3 \cdot a)^2$ and $-3a^2 = -3 \cdot a^2$. In the first, the exponent acts on both the negative 3 *and* the a; in the second, the exponent acts on only the a and there is no "product to a power."

Now try Exercises 13 through 24 ▶

Applications of exponents sometimes involve linking one exponential term with another using a substitution. The result is then simplified using exponential properties.

EXAMPLE 3 ▶ **Applying the Power Property after a Substitution**

The formula for the volume of a cube is $V = S^3$, where S is the length of one edge. If the length of each edge is $2x^2$:

a. Find a formula for volume in terms of x.

b. Find the volume if $x = 2$.

Solution ▶

a. $V = S^3$
↓ substitute $2x^2$ for S
$= (2x^2)^3$
$= 8x^6$

b. For $V = 8x^6$,
$V = 8(2)^6$ substitute 2 for x
$= 8 \cdot 64$ or 512 $(2)^6 = 64$
The volume of the cube would be 512 units^3.

Now try Exercises 25 and 26 ▶

The Quotient Property of Exponents

By combining exponential notation and the property $\frac{x}{x} = 1$ for $x \neq 0$, we note a pattern that helps to simplify a *quotient* of exponential terms. For $\frac{x^5}{x^2} = \frac{x \cdot x \cdot x \cdot x \cdot x}{x \cdot x} = x^3$, the exponent of the final result appears to be the *difference between the exponent in the numerator and the exponent in the denominator*. This seems reasonable since the subtraction would indicate a removal of the factors that reduce to 1. Regardless of how many factors are used, we can generalize the idea and state the **quotient property of exponents.** In words the property says, to divide two exponential terms with the same base, *keep the common base and subtract the exponent of the denominator* from *the exponent of the numerator*.

Quotient Property of Exponents

For any base $b \neq 0$ and positive integers m and n:

$$\frac{b^m}{b^n} = b^{m-n}$$

Zero and Negative Numbers as Exponents

If the exponent of the denominator is *greater* than the exponent in the numerator, the quotient property yields a negative exponent: $\frac{x^2}{x^5} = x^{2-5} = x^{-3}$. To help understand what a negative exponent *means,* let's look at the expanded form of the expression: $\frac{x^2}{x^5} = \frac{x \cdot x^1}{x \cdot x \cdot x \cdot x \cdot x} = \frac{1}{x^3}$. A negative exponent can literally be interpreted as "write the factors as a reciprocal." A good way to remember this is

2^{-3} — three factors of 2 written as a reciprocal: $\frac{2^{-3}}{1} = \frac{1}{2^3} = \frac{1}{8}$

Since the result would be similar regardless of the base used, we can generalize this idea and state the **property of negative exponents.**

Property of Negative Exponents

For any base $b \neq 0$ and integer n:

$$\frac{b^{-n}}{1} = \frac{1}{b^n} \qquad \frac{1}{b^{-n}} = \frac{b^n}{1} \qquad \left(\frac{a}{b}\right)^{-n} = \left(\frac{b}{a}\right)^n; a \neq 0$$

WORTHY OF NOTE

The use of zero as an exponent should not strike you as strange or odd; it's simply a way of saying that *no factors of the base remain,* since all terms have been reduced to 1. For $\frac{2^3}{2^3}$, we have $\frac{8}{8} = 1$, or $\frac{\overset{1}{\cancel{2}} \cdot \overset{1}{\cancel{2}} \cdot \overset{1}{\cancel{2}}}{\cancel{2} \cdot \cancel{2} \cdot \cancel{2}} = 1$, or $2^{3-3} = 2^0 = 1$.

Finally, when we consider that $\frac{x^3}{x^3} = 1$ by division, and $\frac{x^3}{x^3} = x^{3-3} = x^0$ using the quotient property, we conclude that $x^0 = 1$ as long as $x \neq 0$. We can also generalize this observation and state the meaning of zero as an exponent. In words the property says, *any nonzero quantity raised to an exponent of zero is equal to 1.*

Zero Exponent Property

For any base $b \neq 0$:

$$b^0 = 1$$

EXAMPLE 4 ▶ **Simplifying Expressions Using Exponential Properties**

Simplify using exponential properties. Answer using positive exponents only.

a. $\left(\dfrac{2a^3}{b^2}\right)^{-2}$ **b.** $(3hk^{-2})^3(6h^{-2}k^{-3})^{-2}$

c. $(3x)^0 + 3x^0 + 3^{-2}$ **d.** $\dfrac{(-2m^2n^3)^5}{(4mn^2)^3}$

Solution ▶

a. $\left(\dfrac{2a^3}{b^2}\right)^{-2} = \left(\dfrac{b^2}{2a^3}\right)^2$ property of negative exponents

$= \dfrac{(b^2)^2}{2^2(a^3)^2}$ power properties

$= \dfrac{b^4}{4a^6}$ result

b. $(3hk^{-2})^3(6h^{-2}k^{-3})^{-2} = 3^3h^3(k^{-2})^3 \cdot 6^{-2}(h^{-2})^{-2}(k^{-3})^{-2}$ power property

$= 3^3h^3k^{-6} \cdot 6^{-2}h^4k^6$ simplify

$= 3^3 \cdot 6^{-2} \cdot h^{3+4} \cdot k^{-6+6}$ product property

$= \dfrac{27h^7k^0}{36}$ simplify $\left(6^{-2} = \dfrac{1}{6^2} = \dfrac{1}{36}\right)$

$= \dfrac{3h^7}{4}$ result ($k^0 = 1$)

c. $(3x)^0 + 3x^0 + 3^{-2} = 1 + 3(1) + \dfrac{1}{3^2}$ zero exponent property; property of negative exponents

$= 4 + \dfrac{1}{9}$ simplify: $(3x)^0 = 1$, $3x^0 = 3 \cdot 1 = 3$

$= 4\dfrac{1}{9} = \dfrac{37}{9}$ result

d. $\dfrac{(-2m^2n^3)^5}{(4mn^2)^3} = \dfrac{(-2)^5(m^2)^5(n^3)^5}{4^3m^3(n^2)^3}$ power property

$= \dfrac{-32m^{10}n^{15}}{64m^3n^6}$ simplify

$= \dfrac{-1m^7n^9}{2}$ quotient property

$= -\dfrac{m^7n^9}{2}$ result

WORTHY OF NOTE

Notice in Example 4(c), we have $(3x)^0 = (3 \cdot x)^0 = 1$, while $3x^0 = 3 \cdot x^0 = 3(1)$. This is another example of operations and grouping symbols working together: $(3x)^0 = 1$ because any *quantity* to the zero power is 1. However, for $3x^0$ there are no grouping symbols, so the exponent 0 acts only on the x and not the 3: $3x^0 = 3 \cdot x^0 = 3(1) = 3$.

Now try Exercises 27 through 66 ▶

Summary of Exponential Properties

For real numbers a and b, and integers m, n, p (excluding 0 raised to a nonpositive power)

Product property:	$b^m \cdot b^n = b^{m+n}$
Power property:	$(b^m)^n = b^{m \cdot n}$
Product to a power:	$(a^m b^n)^p = a^{mp} \cdot b^{np}$
Quotient to a power:	$\left(\frac{a^m}{b^n}\right)^p = \frac{a^{mp}}{b^{np}} (b \neq 0)$
Quotient property:	$\frac{b^m}{b^n} = b^{m-n} (b \neq 0)$
Zero exponents:	$b^0 = 1 (b \neq 0)$
Negative exponents:	$\frac{b^{-n}}{1} = \frac{1}{b^n}, \frac{1}{b^{-n}} = b^n, \left(\frac{a}{b}\right)^{-n} = \left(\frac{b}{a}\right)^n (a, b \neq 0)$

☑ **A.** You've just seen how we can apply properties of exponents

B. Exponents and Scientific Notation

In many technical and scientific applications, we encounter numbers that are either extremely large or very, very small. For example, the mass of the Moon is over 73 quintillion kilograms (73 followed by 18 zeroes), while the constant for universal gravitation contains 10 zeroes before the first nonzero digit. When computing with numbers of this magnitude, scientific notation has a distinct advantage over the common decimal notation (base-10 place values).

WORTHY OF NOTE

Recall that multiplying by 10's (or multiplying by 10^k, $k > 0$) shifts the decimal point to the right k places, making the number larger. Dividing by 10's (or multiplying by 10^{-k}, $k > 0$) shifts the decimal point to the left k places, making the number smaller.

Scientific Notation

A non-zero number written in scientific notation has the form

$$N \times 10^k$$

where $1 \leq |N| < 10$ and k is an integer.

To convert a number from decimal notation into scientific notation, we begin by placing the decimal point to the immediate right of the first nonzero digit (creating a number less than 10 but greater than or equal to 1) and multiplying by 10^k. Then we determine the power of 10 (the value of k) needed to ensure that the two forms are equivalent. When writing large or small numbers in scientific notation, we sometimes round the value of N to two or three decimal places.

EXAMPLE 5 ▶ Converting from Decimal Notation to Scientific Notation

The mass of the Moon is about 73,000,000,000,000,000,000 kg. Write this number in scientific notation.

Solution ▶ Place decimal to the right of first nonzero digit (7) and multiply by 10^k.

$$73{,}000{,}000{,}000{,}000{,}000{,}000 = 7.3 \times 10^k$$

To return the decimal to its original position would require 19 shifts to the *right,* so k must be *positive* 19.

$$73{,}000{,}000{,}000{,}000{,}000{,}000 = 7.3 \times 10^{19}$$

The mass of the Moon is 7.3×10^{19} kg.

Now try Exercises 67 and 68 ▶

Converting a number from scientific notation to decimal notation is simply an application of multiplication or division with powers of 10.

EXAMPLE 6 ▶ **Converting from Scientific Notation to Decimal Notation**

The constant of gravitation is 6.67×10^{-11}. Write this number in common decimal form.

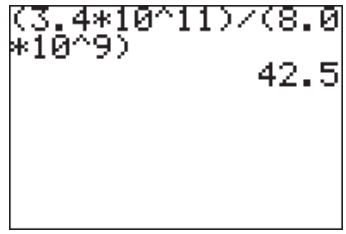
Solution ▶ Since the exponent is *negative* 11, shift the decimal 11 *places to the left,* using placeholder zeroes as needed to return the decimal to its original position:

$$6.67 \times 10^{-11} = 0.000\ 000\ 000\ 066\ 7$$

Now try Exercises 69 and 70 ▶

Computations that involve scientific notation typically use real number properties and the properties of exponents.

EXAMPLE 7 ▶ **Storage Space on a Hard Drive**



A typical 320-gigabyte portable hard drive can hold about 340,000,000,000 bytes of information. A 2-hr DVD movie can take up as much as 8,000,000,000 bytes of storage space. Find the number of movies (to the nearest whole movie) that can be stored on this hard drive.

Solution ▶ Using the ideas from Example 5, the hard drive holds 3.4×10^{11} bytes, while the DVD requires 8.0×10^{9} bytes. Divide to find the number of DVDs the hard drive will hold.

$$\frac{3.4 \times 10^{11}}{8.0 \times 10^{9}} = \frac{3.4}{8.0} \times \frac{10^{11}}{10^{9}} \quad \text{rewrite the expression}$$

$$= 0.425 \times 10^{2} \quad \text{divide; subtract exponents}$$

$$= 42.5 \quad \text{result}$$

The drive will hold approximately 42 DVD movies. A calculator check is shown in the figure.

Now try Exercises 71 and 72 ▶

☑ **B.** You've just seen how we can perform operations in scientific notation

C. Identifying and Classifying Polynomial Expressions

A **monomial** is a term using *only whole number exponents* on variables, with no variables in the denominator. One important characteristic of a monomial is its **degree.** For a monomial in one variable, the degree is the same as the exponent *on the variable*. The degree of a monomial in two or more variables is the sum of exponents occurring on variable factors. A **polynomial** is a monomial or any sum or difference of monomial terms. For instance, $\frac{1}{2}x^2 - 5x + 6$ is a polynomial, while $3n^{-2} + 2n - 7$ is not (the exponent -2 is not a whole number). Identifying polynomials is an important skill because they represent a very different kind of real-world model than nonpolynomials. In addition, there are different **families of polynomials,** with each family having different characteristics. We classify polynomials according to their *degree* and *number of terms*. The **degree of a polynomial** in one variable is the largest exponent occurring on the variable. The degree of a polynomial in more than one variable is the largest sum of exponents in any one term. A polynomial with two terms is called a **binomial** (*bi* means two) and a polynomial with three terms is called a **trinomial** (*tri* means three). There are special names for polynomials with four or more terms, but for these, we simply use the general name *polynomial* (*poly* means many).

EXAMPLE 8 ▶ **Classifying and Describing Polynomials**

For each expression:

a. Classify as a monomial, binomial, trinomial, or polynomial.

b. State the degree of the polynomial.

c. Name the coefficient of each term.

Solution ▶

Expression	Classification	Degree	Coefficients
$5x^2y - 2xy$	binomial	three	$5, -2$
$x^2 - 0.81$	binomial	two	$1, -0.81$
$z^3 - 3z^2 + 9z - 27$	polynomial (four terms)	three	$1, -3, 9, -27$
$\frac{-3}{4}x + 5$	binomial	one	$\frac{-3}{4}, 5$
$2x^2 + x - 3$	trinomial	two	$2, 1, -3$

Now try Exercises 73 through 78 ▶

A polynomial expression is in **standard form** when the terms of the polynomial are written in *descending order of degree,* beginning with the highest-degree term. The coefficient of the highest-degree term is called the **leading coefficient.**

EXAMPLE 9 ▶ **Writing Polynomials in Standard Form**

Write each polynomial in standard form, then identify the leading coefficient.

Solution ▶

Polynomial	Standard Form	Leading Coefficient
$9 - x^2$	$-x^2 + 9$	-1
$5z + 7z^2 + 3z^3 - 27$	$3z^3 + 7z^2 + 5z - 27$	3
$2 + (\frac{-3}{4})x$	$\frac{-3}{4}x + 2$	$\frac{-3}{4}$
$-3 + 2x^2 + x$	$2x^2 + x - 3$	2

Now try Exercises 79 through 84 ▶

☑ **C.** You've just seen how we can identify and classify polynomial expressions

D. Adding and Subtracting Polynomials

Adding polynomials simply involves using the distributive, commutative, and associative properties to combine like terms (at this point, the properties are usually applied mentally). As with real numbers, the subtraction of polynomials involves adding the opposite of the second polynomial using algebraic addition. This can be viewed as distributing -1 to the second polynomial and combining like terms.

EXAMPLE 10 ▶ **Adding and Subtracting Polynomials**

Perform the indicated operations:

$$(0.7n^3 + 4n^2 + 8) + (0.5n^3 - n^2 - 6n) - (3n^2 + 7n - 10).$$

Solution ▶

$$0.7n^3 + 4n^2 + 8 + 0.5n^3 - n^2 - 6n - 3n^2 - 7n + 10$$

eliminate parentheses (distributive property)

$$= 0.7n^3 + 0.5n^3 + 4n^2 - 1n^2 - 3n^2 - 6n - 7n + 8 + 10$$

use properties to collect like terms

$$= 1.2n^3 - 13n + 18$$

combine like terms

Now try Exercises 85 through 90 ▶

Sometimes it's easier to add or subtract polynomials using a vertical format and aligning like terms. Note the use of a placeholder zero in Example 11.

EXAMPLE 11 ▶ **Subtracting Polynomials Using a Vertical Format**

Compute the difference of $x^3 - 5x + 9$ and $x^3 + 3x^2 + 2x - 8$ using a vertical format.

Solution ▶

$$\begin{array}{r} x^3 + 0x^2 - 5x + 9 \\ \underline{-(x^3 + 3x^2 + 2x - 8)} \end{array} \longrightarrow \begin{array}{r} x^3 + 0x^2 - 5x + 9 \\ \underline{-x^3 - 3x^2 - 2x + 8} \\ -3x^2 - 7x + 17 \end{array}$$

The difference is $-3x^2 - 7x + 17$.

☑ **D.** You've just seen how we can add and subtract polynomials

Now try Exercises 91 and 92 ▶

E. The Product of Two Polynomials

Monomial Times Monomial

The simplest case of polynomial multiplication is the product of monomials shown in Example 1a. These were computed using exponential properties and the properties of real numbers.

Monomial Times Polynomial

To compute the product of a monomial and a polynomial, we use the distributive property.

EXAMPLE 12 ▶ **Multiplying a Monomial by a Polynomial**

Find the product: $-2a^2(a^2 - 2a + 1)$.

Solution ▶

$$\begin{aligned} -2a^2(a^2 - 2a + 1) &= -2a^2(a^2) - (-2a^2)(2a^1) + (-2a^2)(1) && \text{distribute} \\ &= -2a^4 + 4a^3 - 2a^2 && \text{simplify} \end{aligned}$$

Now try Exercises 93 and 94 ▶

Binomial Times Polynomial

For products involving binomials, we still use a version of the distributive property—this time to distribute one polynomial to each term of the other polynomial factor. Note the distribution can be performed either from the left or from the right.

EXAMPLE 13 ▶ **Multiplying a Binomial by a Polynomial**

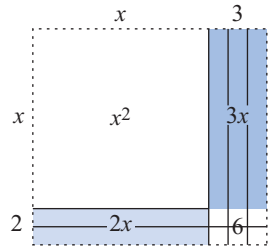
Multiply as indicated:

a. $(2z + 1)(z - 2)$ **b.** $(2v - 3)(4v^2 + 6v + 9)$

Solution ▶

a.
$$\begin{aligned} (2z + 1)(z - 2) &= 2z(z - 2) + 1(z - 2) && \text{distribute to every term in the first binomial} \\ &= 2z^2 - 4z + 1z - 2 && \text{eliminate parentheses (distribute again)} \\ &= 2z^2 - 3z - 2 && \text{simplify} \end{aligned}$$

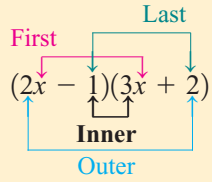
b.
$$\begin{aligned} (2v - 3)(4v^2 + 6v + 9) &= 2v(4v^2 + 6v + 9) - 3(4v^2 + 6v + 9) && \text{distribute} \\ &= 8v^3 + 12v^2 + 18v - 12v^2 - 18v - 27 && \text{simplify} \\ &= 8v^3 - 27 && \text{combine like terms} \end{aligned}$$



Now try Exercises 95 through 100 ▶

The F-O-I-L Method

By observing the product of two binomials in Example 13(a), we note a pattern that can make the process more efficient. The product of two binomials can quickly be computed using the **F**irst, **O**uter, **I**nner, **L**ast **(FOIL)** method, an acronym giving the respective position of each term in a product of binomials in relation to the other terms. We illustrate here using the product $(2x - 1)(3x + 2)$.



WORTHY OF NOTE

Consider the product $(x + 3)(x + 2)$ in the context of *area*. If we view $x + 3$ as the length of a rectangle (an unknown length plus 3 units), and $x + 2$ as its width (the same unknown length plus 2 units), a diagram of the total area would look like the following, with the result $x^2 + 5x + 6$ clearly visible.

$(x + 3)(x + 2) = x^2 + 5x + 6$

The F-O-I-L Method for Multiplying Binomials

$6x^2 + 4x - 3x - 2$
First Outer Inner Last

Combine like terms
$6x^2 + x - 2$

The first term of the result will always be the product of the first terms from each binomial, and the last term of the result is the product of their last terms. We also note that here, the middle term is found by adding the *outermost product* with the *innermost product*. As you practice with the F-O-I-L process, much of the work can be done mentally and you can often compute the entire product without writing anything down except the answer.

EXAMPLE 14 ▶ **Multiplying Binomials Using F-O-I-L**

Compute each product mentally:

a. $(5n - 1)(n + 2)$

b. $(2b + 3)(5b - 6)$

Solution ▶

a. $(5n - 1)(n + 2)$: $5n^2 + 9n - 2$

$10n + (-1n) = 9n$

product of first two terms; sum of outer and inner products; product of last two terms

b. $(2b + 3)(5b - 6)$: $10b^2 + 3b - 18$

$-12b + 15b = 3b$

product of first two terms; sum of outer and inner products; product of last two terms

Now try Exercises 101 through 116 ▶

☑ **E.** You've just seen how we can compute the product of two polynomials

F. Special Polynomial Products

Certain polynomial products are considered "special" for two reasons: (1) the product follows a predictable pattern, and (2) the result can be used to simplify expressions, graph functions, solve equations, and/or develop other skills.

Binomial Conjugates

Expressions like $x + 7$ and $x - 7$ are called **binomial conjugates.** For any given binomial, its conjugate is found by using the same two terms with the opposite sign

between them. Example 15 shows that when we multiply a binomial and its conjugate, the "outers" and "inners" sum to zero and the result is a **difference of two squares.**

EXAMPLE 15 ▶ **Multiplying Binomial Conjugates**

Compute each product mentally:

a. $(x + 7)(x - 7)$ **b.** $(2x - 5y)(2x + 5y)$ **c.** $\left(x + \frac{2}{5}\right)\left(x - \frac{2}{5}\right)$

Solution ▶

a. $(x + 7)(x - 7) = x^2 - 49$ difference of squares $(x)^2 - (7)^2$

$-7x + 7x = 0x$

b. $(2x - 5y)(2x + 5y) = 4x^2 - 25y^2$ difference of squares: $(2x)^2 - (5y)^2$

$10xy + (-10xy) = 0xy$

c. $\left(x + \frac{2}{5}\right)\left(x - \frac{2}{5}\right) = x^2 - \frac{4}{25}$ difference of squares: $x^2 - \left(\frac{2}{5}\right)^2$

$-\frac{2}{5}x + \frac{2}{5}x = 0$

Now try Exercises 117 through 124 ▶

In summary, we have the following.

The Product of a Binomial and Its Conjugate

Given any expression that can be written in the form $A + B$, the conjugate of the expression is $A - B$ and their product is a difference of two squares:

$$(A + B)(A - B) = A^2 - B^2$$

Binomial Squares

Expressions like $(x + 7)^2$ are called **binomial squares** and are useful for solving many equations and sketching a number of basic graphs. Note $(x + 7)^2 = (x + 7)(x + 7) = x^2 + 14x + 49$ using the F-O-I-L process. The expression $x^2 + 14x + 49$ is called a **perfect square trinomial** because it is the result of expanding a binomial square. If we write a binomial square in the more general form $(A + B)^2 = (A + B)(A + B)$ and compute the product, we notice a pattern that helps us write the expanded form more quickly.

$$\begin{aligned} (A + B)^2 &= (A + B)(A + B) && \text{repeated multiplication} \\ &= A^2 + AB + AB + B^2 && \text{F-O-I-L} \\ &= A^2 + 2AB + B^2 && \text{simplify (perfect square trinomial)} \end{aligned}$$

LOOKING AHEAD

Although a binomial square can always be found using repeated factors and F-O-I-L, learning to expand them using the pattern is a valuable skill. Binomial squares occur often in a study of algebra and it helps to find the expanded form quickly.

The first and last terms of the trinomial are squares of the terms A and B. Also, the middle term of the trinomial is *twice the product of these two terms:* $AB + AB = 2AB$. The F-O-I-L process shows us why. Since the outer and inner products are identical, we always end up with two. A similar result holds for $(A - B)^2$ and the process can be summarized for both cases using the $\pm$ symbol.

The Square of a Binomial

Given any expression that can be written in the form $(A \pm B)^2$,

1. $(A + B)^2 = A^2 + 2AB + B^2$
2. $(A - B)^2 = A^2 - 2AB + B^2$

CAUTION ▶ Note the square of a binomial always results in a trinomial (three terms). In particular, $(A + B)^2 \neq A^2 + B^2$.

EXAMPLE 16 ▶ Find each binomial square without using F-O-I-L:

a. $(a + 9)^2$ **b.** $(3x - 5)^2$ **c.** $(3 + \sqrt{x})^2$

Solution ▶

a. $(a + 9)^2 = a^2 + 2(a \cdot 9) + 9^2$ $(A + B)^2 = A^2 + 2AB + B^2$

$= a^2 + 18a + 81$ simplify

b. $(3x - 5)^2 = (3x)^2 - 2(3x \cdot 5) + 5^2$ $(A - B)^2 = A^2 - 2AB + B^2$

$= 9x^2 - 30x + 25$ simplify

c. $(3 + \sqrt{x})^2 = 9 + 2(3 \cdot \sqrt{x}) + (\sqrt{x})^2$ $(A + B)^2 = A^2 + 2AB + B^2$

$= 9 + 6\sqrt{x} + x$ simplify

Now try Exercises 125 through 136 ▶

F. You've just seen how we can compute special products: binomial conjugates and binomial squares

With practice, you will be able to go directly from the binomial square to the resulting trinomial.

A.2 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section, if necessary.

1. The equation $(x^2)^3 = x^6$ is an example of the _____ property of exponents.
2. The equation $(x^3)^{-2} = \dfrac{1}{x^6}$ is an example of the property of _____ exponents.
3. The sum of the "outers" and "inners" for $(2x + 5)^2$ is _____, while the sum of the outers and inners for $(2x + 5)(2x - 5)$ is _____.
4. The expression $2x^2 - 3x - 10$ can be classified as a _____ of degree _____, with a leading coefficient of _____.
5. Discuss/Explain why one of the following expressions can be simplified further, while the other cannot: (a) $-7n^4 + 3n^2$; (b) $-7n^4 \cdot 3n^2$.
6. Discuss/Explain why the degree of $2x^2y^3$ is greater than the degree of $2x^2 + y^3$. Include additional examples for contrast and comparison.

▶ DEVELOPING YOUR SKILLS

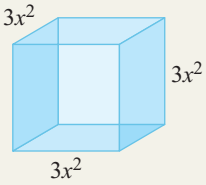
Determine each product using the product and/or power properties.

7. $\dfrac{2}{3}n^2 \cdot 21n^5$
8. $24g^5 \cdot \dfrac{3}{8}g^9$
9. $(-6p^2q)(2p^3q^3)$
10. $(-1.5vy^2)(-8v^4y)$
11. $(a^2)^4 \cdot (a^3)^2 \cdot b^2 \cdot b^5$
12. $d^2 \cdot d^4 \cdot (c^5)^2 \cdot (c^3)^2$

Simplify using the product to a power property.

13. $(6pq^2)^3$ **14.** $(-3p^2q)^2$

15. $(3.2hk^2)^3$ **16.** $(-2.5h^5k)^2$

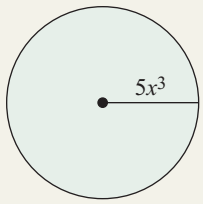


17. $\left(\frac{p}{2q}\right)^2$ **18.** $\left(\frac{b}{3a}\right)^3$

19. $(-0.7c^4)^2(10c^3d^2)^2$ **20.** $(-2.5a^3)^2(3a^2b^2)^3$

21. $(\frac{3}{4}x^3y)^2$ **22.** $(\frac{4}{5}x^3)^2$

23. $(-\frac{3}{8}x)^2(16xy^2)$ **24.** $(\frac{2}{3}m^2n)^2 \cdot (\frac{1}{2}mn^2)$



25. Volume of a cube: The formula for the volume of a cube is $V = S^3$, where S is the length of one edge. If the length of each edge is $3x^2$,

a. Find a formula for volume in terms of the variable x.

b. Find the volume of the cube if $x = 2$.

26. Area of a circle: The formula for the area of a circle is $A = \pi r^2$, where r is the length of the radius. If the radius is given as $5x^3$,

a. Find a formula for area in terms of the variable x.

b. Find the area of the circle if $x = 2$.

Simplify using the quotient property or the property of negative exponents. Write answers using positive exponents only.

27. $\dfrac{-6w^5}{-2w^2}$ **28.** $\dfrac{8z^7}{16z^5}$

29. $\dfrac{-12a^3b^5}{4a^2b^4}$ **30.** $\dfrac{5m^3n^5}{10mn^2}$

31. $(\frac{2}{3})^{-3}$ **32.** $(\frac{5}{6})^{-1}$

33. $\dfrac{2}{h^{-3}}$ **34.** $\dfrac{3}{m^{-2}}$

35. $(-2)^{-3}$ **36.** $(-4)^{-2}$

37. $(\frac{-1}{2})^{-3}$ **38.** $(\frac{-2}{3})^{-2}$

Simplify each expression using the quotient to a power property.

39. $\left(\dfrac{2p^4}{q^3}\right)^2$ **40.** $\left(\dfrac{-5v^4}{7w^3}\right)^2$

41. $\left(\dfrac{0.2x^2}{0.3y^3}\right)^3$ **42.** $\left(\dfrac{-0.5a^3}{0.4b^2}\right)^2$

43. $\left(\dfrac{5m^2n^3}{2r^4}\right)^2$ **44.** $\left(\dfrac{4p^3}{3x^2y}\right)^3$

45. $\left(\dfrac{5p^2q^3r^4}{-2pq^2r^4}\right)^2$ **46.** $\left(\dfrac{9p^3q^2r^3}{12p^5qr^2}\right)^3$

Use properties of exponents to simplify the following. Write the answer using positive exponents only.

47. $\dfrac{9p^6q^4}{-12p^4q^6}$ **48.** $\dfrac{5m^5n^2}{10m^5n}$

49. $\dfrac{20h^{-2}}{12h^5}$ **50.** $\dfrac{5k^3}{20k^{-2}}$

51. $\dfrac{(a^2)^3}{a^4 \cdot a^5}$ **52.** $\dfrac{(5^3)^4}{5^9}$

53. $\left(\dfrac{a^{-3} \cdot b}{c^{-2}}\right)^{-4}$ **54.** $\dfrac{(p^{-4}q^8)^2}{p^5q^{-2}}$

55. $\dfrac{-6(2x^{-3})^2}{10x^{-2}}$ **56.** $\dfrac{18n^{-3}}{-8(3n^{-2})^3}$

57. $\dfrac{14a^{-3}bc^0}{-7(3a^2b^{-2}c)^3}$ **58.** $\dfrac{-3(2x^3y^{-4}z)^2}{18x^{-2}yz^0}$

59. $4^0 + 5^0$ **60.** $(-3)^0 + (-7)^0$

63. $3^0 + 3^{-1} + 3^{-2}$ **64.** $2^{-2} + 2^{-1} + 2^0$

65. $-5x^0 + (-5x)^0$ **66.** $-2n^0 + (-2n)^0$

Convert the following numbers to scientific notation.

67. In mid-2009, the U.S. Census Bureau estimated the world population at nearly 6,770,000,000 people.

68. The mass of a proton is generally given as 0.000 000 000 000 000 000 000 000 001 670 kg.

Convert the following numbers to decimal notation.

69. The smallest microprocessors in common use measure 6.5×10^{-9} m across.

70. In 2009, the estimated net worth of Bill Gates, the founder of Microsoft, was 5.8×10^{10} dollars.

Compute using scientific notation. Show all work.

71. The average distance between the Earth and the planet Jupiter is 465,000,000 mi. How many hours would it take a satellite to reach the planet if it traveled an average speed of 17,500 mi per hour? How many days? Round to the nearest whole.

72. In fiscal terms, a nation's debt-per-capita is the ratio of its total debt to its total population. In the year 2009, the total U.S. debt was estimated at \$11,300,000,000,000, while the population was estimated at 305,000,000. What was the U.S. debt-per-capita ratio for 2009? Round to the nearest whole dollar.

Identify each expression as a polynomial or nonpolynomial (if a nonpolynomial, state why); classify each as a monomial, binomial, trinomial, or none of these; and state the degree of the polynomial.

73. $-35w^3 + 2w^2 + (-12w) + 14$

74. $-2x^3 + \frac{2}{3}x^2 - 12x + 1.2$

75. $5n^{-2} + 4n + \sqrt{17}$

76. $\frac{4}{r^3} + 2.7r^2 + r + 1$

77. $p^3 - \frac{2}{5}$

78. $q^3 + 2q^{-2} - 5q$

Write each polynomial in standard form and name the leading coefficient.

79. $7w + 8.2 - w^3 - 3w^2$

80. $-2k^2 - 12 - k$

81. $c^3 + 6 + 2c^2 - 3c$

82. $-3v^3 + 14 + 2v^2 + (-12v)$

83. $12 - \frac{2}{3}x^2$

84. $8 + 2n^2 + 7n$

Find the indicated sum or difference.

85. $(3p^3 - 4p^2 + 2p - 7) + (p^2 - 2p - 5)$

86. $(5q^2 - 3q + 4) + (-3q^2 + 3q - 4)$

87. $(5.75b^2 + 2.6b - 1.9) + (2.1b^2 - 3.2b)$

88. $(0.4n^2 + 5n - 0.5) + (0.3n^2 - 2n + 0.75)$

89. $(\frac{3}{4}x^2 - 5x + 2) - (\frac{1}{2}x^2 + 3x - 4)$

90. $(\frac{5}{9}n^2 + 4n - \frac{1}{2}) - (\frac{2}{3}n^2 - 2n + \frac{3}{4})$

91. Subtract $q^5 + 2q^4 + q^2 + 2q$ from $q^6 + 2q^5 + q^4 + 2q^3$ using a vertical format.

92. Find $x^4 + 2x^3 + x^2 + 2x$ decreased by $x^4 - 3x^3 + 4x^2 - 3x$ using a vertical format.

Compute each product.

93. $-3x(x^2 - x - 6)$

94. $-2v^2(v^2 + 2v - 15)$

95. $(3r - 5)(r - 2)$

134. $(a + 3)(b - 5)$

135. $(k - 5)(k + 6)(k + 2)$

136. $(a + 6)(a - 1)(a + 5)$

▶ WORKING WITH FORMULAS

137. Medication in the bloodstream: $M = 0.5t^4 + 3t^3 - 97t^2 + 348t$

If 400 mg of a pain medication are taken orally, the number of milligrams in the bloodstream is modeled by the formula shown, where M is the number of milligrams and t is the time in hours, $0 \le t < 5$. Construct a table of values for $t = 1$ through 5, then answer the following.

a. How many milligrams are in the bloodstream after 2 hr? After 3 hr?

b. Based on part a, would you expect the number of milligrams in the bloodstream after 4 hr to be less or more? Why?

c. Approximately how many hours until the medication wears off (the number of milligrams in the bloodstream is 0)?

138. Amount of a mortgage payment: $M = \dfrac{A\left(\frac{r}{12}\right)\left(1+\frac{r}{12}\right)^n}{\left(1+\frac{r}{12}\right)^n - 1}$

The monthly mortgage payment required to pay off (or amortize) a loan is given by the formula shown, where M is the monthly payment, A is the original amount of the loan, r is the annual interest rate, and n is the term of the loan in months. Find the monthly payment (to the nearest cent) required to purchase a $198,000 home, if the interest rate is 6.5% and the home is financed over 30 yr.

▶ APPLICATIONS

139. Attraction between particles: In electrical theory, the force of attraction between two particles P and Q with opposite charges is modeled by $F = \dfrac{kPQ}{d^2}$, where d is the distance between them and k is a constant that depends on certain conditions. This is known as Coulomb's law. Rewrite the formula using a negative exponent.

140. Intensity of light: The intensity of illumination from a light source depends on the distance from the source according to $I = \dfrac{k}{d^2}$, where I is the intensity measured in footcandles, d is the distance from the source in feet, and k is a constant that depends on the conditions. Rewrite the formula using a negative exponent.

141. Rewriting an expression: In advanced mathematics, negative exponents are widely used because they are easier to work with than rational expressions. Rewrite the expression $\dfrac{5}{x^3} + \dfrac{3}{x^2} + \dfrac{2}{x^1} + 4$ using negative exponents.

142. Swimming pool hours: A swimming pool opens at 8 A.M. and closes at 6 P.M. In summertime, the number of people in the pool at any time can be approximated by the formula $S(t) = -t^2 + 10t$, where S is the number of swimmers and t is the number of hours the pool has been open (8 A.M.: $t = 0$, 9 A.M.: $t = 1$, 10 A.M.: $t = 2$, etc.).

a. How many swimmers are in the pool at 6 P.M.? Why?

b. Between what times would you expect the largest number of swimmers?

c. Approximately how many swimmers are in the pool at 3 P.M.?

d. Create a table of values for $t = 1, 2, 3, 4, \ldots$ and check your answer to part b.

143. Maximizing revenue: A sporting goods store finds that if they price their video games at $20, they make 200 sales per day. For each decrease of $1, 20 additional video games are sold. This means the store's revenue can be modeled by the formula $R = (20 - 1x)(200 + 20x)$, where x is the number of $1 decreases. Multiply out the binomials and use a table of values to determine what price will give the most revenue.

144. Maximizing revenue: Due to past experience, a jeweler knows that if they price jade rings at $60, they will sell 120 each day. For each decrease of $2, five additional sales will be made. This means the jeweler's revenue can be modeled by the formula $R = (60 - 2x)(120 + 5x)$, where x is the number of $2 decreases. Multiply out the binomials and use a table of values to determine what price will give the most revenue.

▶ EXTENDING THE CONCEPT

145. If $(3x^2 + kx + 1) - (kx^2 + 5x - 7) + (2x^2 - 4x - k) = -x^2 - 3x + 2$, what is the value of k?

146. If $\left(2x + \dfrac{1}{2x}\right)^2 = 5$, then the expression $4x^2 + \dfrac{1}{4x^2}$ is equal to what number?

A.3 Solving Linear Equations and Inequalities

LEARNING OBJECTIVES

In Section A.3 you will review how to:

- ❑ **A.** Solve linear equations using properties of equality
- ❑ **B.** Recognize equations that are identities or contradictions
- ❑ **C.** Solve linear inequalities
- ❑ **D.** Solve compound inequalities
- ❑ **E.** Solve basic applications of linear equations and inequalities
- ❑ **F.** Solve applications of basic geometry

In a study of algebra, you will encounter many **families of equations,** or groups of equations that share common characteristics. Of interest to us here is the family of **linear equations in one variable,** a study that lays the foundation for understanding more advanced families. This section will also lay the foundation for solving a formula for a specified variable, a practice widely used in science, business, industry, and research.

A. Solving Linear Equations Using Properties of Equality

An **equation** is *a statement that two expressions are equal*. From the expressions $3(x - 1) + x$ and $-x + 7$, we can form the equation

$$3(x - 1) + x = -x + 7,$$

which is a **linear equation in one variable** (the exponent on any variable is a 1). To solve an equation, we attempt to find a specific input or x-value that will make the equation true, meaning the left-hand expression will be equal to the right. Using Table A.1, we find that $3(x - 1) + x = -x + 7$ is a true equation when x is replaced by 2, and is a false equation otherwise. Replacement values that make the equation true are called **solutions** or **roots** of the equation.

Table A.1

x	$3(x - 1) + x$	$-x + 7$
-2	-11	9
-1	-7	8
0	-3	7
1	1	6
2	**5**	**5**
3	9	4
4	13	3

CAUTION ▶ From Appendix A.1, an **algebraic *expression*** is a sum or difference of algebraic terms. Algebraic expressions can be simplified, evaluated or written in an equivalent form, but cannot be "*solved*," since we're not seeking a specific value of the unknown.

Solving equations using a table is too time consuming to be practical. Instead we attempt to write a sequence of **equivalent equations,** each one simpler than the one before, until we reach a point where the solution is obvious. Equivalent equations are those that have the same solution set, and can be obtained by using the distributive property to simplify the expressions on each side of the equation. The additive and multiplicative properties of equality are then used to obtain an equation of the form $x =$ constant.

The Additive Property of Equality	The Multiplicative Property of Equality
If A, B, and C represent algebraic expressions and $A = B$,	If A, B, and C represent algebraic expressions and $A = B$,
then $A + C = B + C$	then $AC = BC$ and $\frac{A}{C} = \frac{B}{C}, (C \neq 0)$

In words, the additive property says that like quantities, numbers, or terms can be added to both sides of an equation. A similar statement can be made for the multiplicative property. These properties are combined into a general guide for solving linear equations, which you've likely encountered in your previous studies. Note that not all steps in the guide are required to solve every equation.

Guide to Solving Linear Equations in One Variable

- Eliminate parentheses using the distributive property, then combine any like terms.
- Use the additive property of equality to write the equation with all variable terms on one side, and all constants on the other. Simplify each side.
- Use the multiplicative property of equality to obtain an equation of the form $x =$ constant.
- For applications, answer in a complete sentence and include any units of measure indicated.

For our first example, we'll use the equation $3(x - 1) + x = -x + 7$ from our initial discussion.

EXAMPLE 1 ▶ **Solving a Linear Equation Using Properties of Equality**

Solve for x: $3(x - 1) + x = -x + 7$.

Solution ▶

$3(x - 1) + x = -x + 7$		original equation
$3x - 3 + x = -x + 7$		distributive property
$4x - 3 = -x + 7$		combine like terms
$5x - 3 = 7$		add x to both sides (additive property of equality)
$5x = 10$		add 3 to both sides (additive property of equality)
$x = 2$		multiply both sides by $\frac{1}{5}$ or divide both sides by 5 (multiplicative property of equality)

As we noted in Table R.1, the solution is $x = 2$.

Now try Exercises 7 through 12 ▶

To check a solution by substitution means we substitute the solution back into the original equation (this is sometimes called **back-substitution**), and verify the left-hand side is equal to the right. For Example 1 we have:

$3(x - 1) + x = -x + 7$		original equation
$3(2 - 1) + 2 = -2 + 7$		substitute 2 for x
$3(1) + 2 = 5$		simplify
$5 = 5$✓		solution checks

If any coefficients in an equation are fractional, multiply both sides by the least common denominator (LCD) to *clear the fractions*. Since any decimal number can be written in fraction form, the same idea can be applied to decimal coefficients.

EXAMPLE 2 ▶ **Solving a Linear Equation with Fractional Coefficients**

Solve for n: $\frac{1}{4}(n + 8) - 2 = \frac{1}{2}(n - 6)$.

Solution ▶

$\frac{1}{4}(n + 8) - 2 = \frac{1}{2}(n - 6)$		original equation
$\frac{1}{4}n + 2 - 2 = \frac{1}{2}n - 3$		distributive property
$\frac{1}{4}n = \frac{1}{2}n - 3$		combine like terms
$4(\frac{1}{4}n) = 4(\frac{1}{2}n - 3)$		multiply both sides by LCD = 4
$n = 2n - 12$		distributive property
$-n = -12$		subtract $2n$
$n = 12$		multiply by -1

Verify the solution is $n = 12$ using back-substitution.

Now try Exercises 13 through 30 ▶

☑ **A.** You've just seen how we can solve linear equations using properties of equality

B. Identities and Contradictions

Example 1 illustrates what is called a **conditional equation,** since the equation is true for $x = 2$, but false for all other values of x. The equation in Example 2 is also conditional. An **identity** is an equation that is *always true,* no matter what value is substituted for the variable. For instance, $2(x + 3) = 2x + 6$ is an identity with a solution set of all real numbers, written as $\{x|x \in \mathbb{R}\}$, or $x \in (-\infty, \infty)$ in interval notation. **Contradictions** are equations that are *never true,* no matter what real number is substituted for the variable. The equations $x - 3 = x + 1$ and $-3 = 1$ are contradictions. To state the solution set for a contradiction, we use the symbol "$\varnothing$" (the null set) or "$\{\ \}$" (the empty set). Recognizing these special equations will prevent some surprise and indecision in later chapters.

EXAMPLE 3 ▶ **Solving Equations (Special Cases)**

Solve each equation and state the solution set.

a. $2(x - 4) + 10x = 8 + 4(3x + 1)$ **b.** $8x - (6 - 10x) = 24 + 6(3x - 5)$

Solution ▶

a. $2(x - 4) + 10x = 8 + 4(3x + 1)$ original equation

$2x - 8 + 10x = 8 + 12x + 4$ distributive property

$12x - 8 = 12x + 12$ combine like terms

$-8 = 12$ subtract $12x$; contradiction

Since -8 is never equal to 12, the original equation is a contradiction. The solution set is empty: $\{\ \}$

b. $8x - (6 - 10x) = 24 + 6(3x - 5)$ original equation

$8x - 6 + 10x = 24 + 18x - 30$ distributive property

$18x - 6 = 18x - 6$ combine like terms

$-6 = -6$ subtract $18x$; identity

The result shows that the original equation is an identity, with an infinite number of solutions: $\{x \mid x \in \mathbb{R}\}$. You may recall this notation is read, "the set of all numbers x, such that x is a real number."

Now try Exercises 31 through 36 ▶

In Example 3(a), our attempt to solve for x ended with all variables being eliminated, leaving an equation that is *always false*—a contradiction (-8 is never equal to 12). There is nothing wrong with the solution process, the result is simply telling us the original equation has *no solution*. In Example 3(b), all variables were again eliminated but the end result was *always true*—an identity (-6 is always equal to -6). Once again we've done nothing wrong mathematically, the result is just telling us that the original equation will be true no matter what value of x we use for an input.

☑ **B.** You've just seen how we can recognize equations that are identities or contradictions

C. Solving Linear Inequalities

A linear *inequality* resembles a linear *equality* in many respects:

	Linear Inequality	Related Linear Equation
(1)	$x < 3$	$x = 3$
(2)	$\frac{3}{8}p - 2 \geq -12$	$\frac{3}{8}p - 2 = -12$

A linear inequality in one variable is one that can be written in the form $ax + b < c$, where a, b, and $c \in \mathbb{R}$ and $a \neq 0$. This definition and the following properties also apply when other inequality symbols are used. Solutions to simple inequalities are easy to spot. For instance, $x = -2$ is a solution to $x < 3$ since $-2 < 3$. For more involved inequalities we use the **additive property of inequality** and the **multiplicative property of**

inequality. Similar to solving equations, we solve inequalities by isolating the variable on one side to obtain a solution form such as *variable* $<$ *number*.

The Additive Property of Inequality

If A, B, and C represent algebraic expressions and $A < B$,

$$\text{then } A + C < B + C$$

Like quantities (numbers or terms) can be added to both sides of an inequality.

While there is little difference between the additive property of *equality* and the additive property of *inequality,* there is an *important difference* between the multiplicative property of *equality* and the multiplicative property of *inequality.* To illustrate, we begin with $-2 < 5$. Multiplying both sides by positive three yields $-6 < 15$, a true inequality. But notice what happens when we **multiply both sides by negative three:**

$$\begin{aligned} -2 &< 5 && \text{original inequality} \\ -2(-3) &< 5(-3) && \text{multiply by negative three} \\ 6 &< -15 && \text{false} \end{aligned}$$

The result is a *false* inequality, because 6 is *to the right* of -15 on the number line. Multiplying (or dividing) an inequality by a negative quantity *reverses the order relationship between two quantities* (we say it changes the *sense* of the inequality). We must compensate for this by reversing the inequality symbol.

$$6 > -15 \quad \text{change direction of symbol to maintain a true statement}$$

For this reason, the multiplicative property of inequality is stated in two parts.

The Multiplicative Property of Inequality

If A, B, and C represent algebraic expressions and $A < B$, then $AC < BC$	If A, B, and C represent algebraic expressions and $A < B$, then $AC > BC$
if C is a *positive quantity* (inequality symbol remains the same).	if C is a *negative quantity* (inequality symbol must be reversed).

EXAMPLE 4 ▶ **Solving an Inequality**

Solve the inequality, then graph the solution set and write it in interval notation: $\frac{-2}{3}x + \frac{1}{2} \le \frac{5}{6}$.

Solution ▶

$$\begin{aligned} \frac{-2}{3}x + \frac{1}{2} &\le \frac{5}{6} && \text{original inequality} \\ 6\left(\frac{-2}{3}x + \frac{1}{2}\right) &\le (6)\frac{5}{6} && \text{clear fractions (multiply by LCD)} \\ -4x + 3 &\le 5 && \text{simplify} \\ -4x &\le 2 && \text{subtract 3} \\ \frac{-4x}{-4} &\ge \frac{2}{-4} && \text{divide by } -4, \textit{ reverse inequality sign} \\ x &\ge -\frac{1}{2} && \text{result} \end{aligned}$$

- Graph:

- Interval notation: $x \in \left[-\frac{1}{2}, \infty\right)$

WORTHY OF NOTE

As an alternative to multiplying or dividing by a negative value, the additive property of inequality can be used to ensure the variable term will be positive. From Example 4, the inequality $-4x \le 2$ can be written as $-2 \le 4x$ by adding $4x$ to both sides and subtracting 2 from both sides. This gives the solution $-\frac{1}{2} \le x$, which is equivalent to $x \ge -\frac{1}{2}$.

Now try Exercises 37 through 46 ▶

To check a linear inequality, you often have an infinite number of choices—any number from the solution set/interval. If a test value from the solution interval results in a true inequality, all numbers in the interval are solutions. For Example 4, using $x = 0$ results in the true statement $\frac{1}{2} \le \frac{5}{6}$ ✓.

Some inequalities have all real numbers as the solution set: $\{x|x \in \mathbb{R}\}$, while other inequalities have no solutions, with the answer given as the empty set: $\{\ \}$.

EXAMPLE 5 ▶ **Solving Inequalities**

Solve the inequality and write the solution in set notation:

a. $7 - (3x + 5) \ge 2(x - 4) - 5x$ **b.** $3(x + 4) - 5 < 2(x - 3) + x$

Solution ▶

a.
$$\begin{aligned} 7 - (3x + 5) &\ge 2(x - 4) - 5x && \text{original inequality} \\ 7 - 3x - 5 &\ge 2x - 8 - 5x && \text{distributive property} \\ -3x + 2 &\ge -3x - 8 && \text{combine like terms} \\ 2 &\ge -8 && \text{add } 3x \end{aligned}$$

Since the resulting statement is always true, the original inequality is true for all real numbers. The solution is all real numbers $\mathbb{R}$.

b.
$$\begin{aligned} 3(x + 4) - 5 &< 2(x - 3) + x && \text{original inequality} \\ 3x + 12 - 5 &< 2x - 6 + x && \text{distribute} \\ 3x + 7 &< 3x - 6 && \text{combine like terms} \\ 7 &< -6 && \text{subtract } 3x \end{aligned}$$

Since the resulting statement is always false, the original inequality is false for all real numbers. The solution is $\{\ \}$.

☑ **C.** You've just seen how we can solve linear inequalities

Now try Exercises 47 through 52 ▶

D. Solving Compound Inequalities

In some applications of inequalities, we must consider more than one solution interval. These are called **compound inequalities,** and these require us to take a close look at the operations of **union** "∪" and **intersection** "∩". The intersection of two sets A and B, written $A \cap B$, is the set of all elements *common to both sets.* The union of two sets A and B, written $A \cup B$, is the set of all elements *that are in either set.* When stating the union of two sets, repetitions are unnecessary.

EXAMPLE 6 ▶ **Finding the Union and Intersection of Two Sets**

For set $A = \{-2, -1, 0, 1, 2, 3\}$ and set $B = \{1, 2, 3, 4, 5\}$, determine $A \cap B$ and $A \cup B$.

Solution ▶

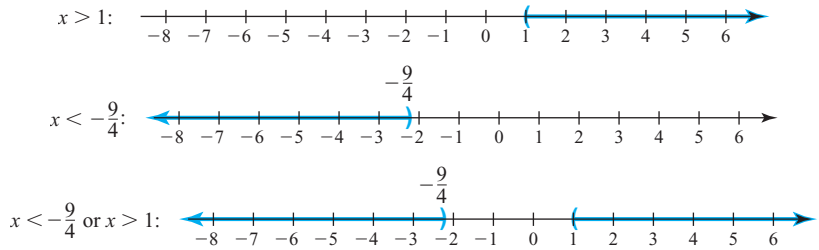
$A \cap B$ is the set of all elements in *both A and B:*
$A \cap B = \{1, 2, 3\}$.
$A \cup B$ is the set of all elements in *either A or B:*
$A \cup B = \{-2, -1, 0, 1, 2, 3, 4, 5\}$.

Now try Exercises 53 through 58 ▶

WORTHY OF NOTE

For the long term, it may help to rephrase the distinction as follows. The intersection is a *selection* of elements that are common to two sets, while the union is a *collection* of the elements from two sets (with no repetitions).

Notice the intersection of two sets is described using the word "and," while the union of two sets is described using the word "or." When compound inequalities are formed using these words, the solution is modeled after the ideas from Example 6. If "and" is used, the solutions must satisfy *both* inequalities. If "or" is used, the solutions can satisfy *either* inequality.



EXAMPLE 7 ▶ **Solving a Compound Inequality**

Solve the compound inequality, then write the solution in interval notation: $-3x - 1 < -4$ **or** $4x + 3 < -6$.

Solution ▶ Begin with the statement as given:

$$\begin{array}{rcrl} -3x - 1 < -4 & \text{or} & 4x + 3 < -6 & \text{original statement} \\ -3x < -3 & \text{or} & 4x < -9 & \text{isolate variable term} \\ x > 1 & \text{or} & x < -\dfrac{9}{4} & \text{solve for } x\text{, reverse first inequality symbol} \end{array}$$

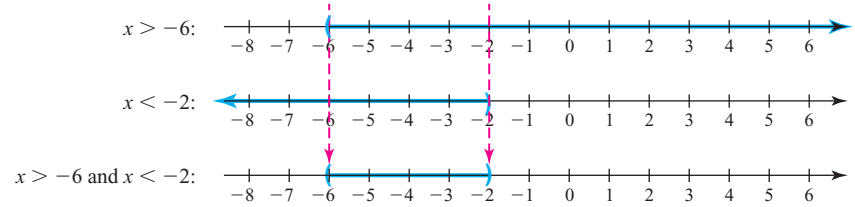
The solution $x > 1$ **or** $x < -\frac{9}{4}$ is better understood by graphing each interval separately, *then selecting both intervals (the union)*.

Interval notation: $x \in \left(-\infty, -\dfrac{9}{4}\right) \cup (1, \infty)$.

WORTHY OF NOTE

The graphs from Example 7 clearly show the solution consists of two disjoint (disconnected) intervals. This is reflected in the "or" statement: $x < -\frac{9}{4}$ or $x > 1$, and in the interval notation. Also, note the solution $x < -\frac{9}{4}$ or $x > 1$ is not equivalent to $-\frac{9}{4} > x > 1$, as there is no single number that is both greater than 1 and less than $-\frac{9}{4}$ at the same time.

Now try Exercises 59 and 60 ▶



EXAMPLE 8 ▶ **Solving a Compound Inequality**

Solve the compound inequality, then write the solution in interval notation: $3x + 5 > -13$ **and** $3x + 5 < -1$.

Solution ▶ Begin with the statement as given:

$$\begin{array}{rcrl} 3x + 5 > -13 & \text{and} & 3x + 5 < -1 & \text{original statement} \\ 3x > -18 & \text{and} & 3x < -6 & \text{subtract five} \\ x > -6 & \text{and} & x < -2 & \text{divide by 3} \end{array}$$

The solution $x > -6$ **and** $x < -2$ can best be understood by graphing each interval separately, then *noting where they intersect*.

Interval notation: $x \in (-6, -2)$.

WORTHY OF NOTE

The inequality $a < b$ (a is less than b) can equivalently be written as $b > a$ (b is greater than a). In Example 8, the solution is read, "$x > -6$ and $x < -2$," but if we rewrite the first inequality as $-6 < x$ (with the "arrowhead" still pointing at -6), we have $-6 < x$ and $x < -2$ and can clearly see that x must be in the single interval between -6 and -2.

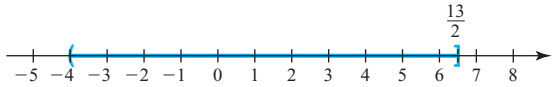
Now try Exercises 61 through 72 ▶

The solution from Example 8 consists of the single interval $(-6, -2)$, indicating the original inequality could actually be *joined* and written as $-6 < x < -2$, called a **joint inequality.** We solve joint inequalities in much the same way as linear inequalities, but must remember they *have three parts (left, middle, and right)*. This means operations must be applied to *all three parts* in each step of the solution process, to obtain a solution form such as *smaller number* $< x <$ *larger number*. The same ideas apply when other inequality symbols are used.

EXAMPLE 9 ▶ **Solving a Joint Inequality**

Solve the joint inequality, then graph the solution set and write it in interval notation: $1 > \dfrac{2x + 5}{-3} \geq -6$.

Solution ▶



$$1 > \frac{2x + 5}{-3} \geq -6 \quad \text{original inequality}$$

$$-3 < 2x + 5 \leq 18 \quad \text{multiply all parts by } -3\text{; reverse the inequality symbols}$$

$$-8 < 2x \leq 13 \quad \text{subtract 5 from all parts}$$

$$-4 < x \leq \frac{13}{2} \quad \text{divide all parts by 2}$$

- Graph:

- Interval notation: $x \in (-4, \frac{13}{2}]$

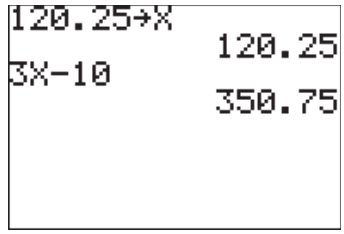
D. You've just seen how we can solve compound inequalities

Now try Exercises 73 through 78 ▶

E. Solving Basic Applications of Linear Equations and Inequalities

Applications of linear equations and inequalities come in many forms. In most cases, you are asked to translate written relationships or information given verbally into an equation using words or phrases that indicate mathematical operations or relationships. Here, we'll practice this skill using ideas that were introduced in Appendix A.1, where we translated English phrases into mathematical expressions. Very soon these skills will be applied in much more significant ways.

EXAMPLE 10 ▶ **Translating Written Information into an Equation**



Translate the following relationships into equations, then solve:

In an effort to lower the outstanding balance on her credit card, Laura paid \$10 less than triple her normal payment. If she sent the credit card company \$350.75, how much was her normal payment? (See Section A.1, Examples 2 and 3.)

Solution ▶ Let p represent her normal payment. Then "triple her normal payment" would be $3p$, and "ten less than triple" would be $3p - 10$. Since "she sent the company \$350.75," we have

$$3p - 10 = 350.75 \quad \text{equation form}$$
$$3p = 360.75 \quad \text{add 10}$$
$$p = 120.25 \quad \text{divide by 3}$$

Laura's normal payment is \$120.25 per month. A calculator check is shown in the figure.

Now try Exercises 83 through 90 ▶

Inequalities are widely used to help gather information, and to make comparisons that will lead to informed decisions.

EXAMPLE 11 ▶ Using an Inequality to Compute Desired Test Scores

Justin earned scores of 78, 72, and 86 on the first three out of four exams. What score must he earn on the fourth exam to have an average of at least 80?

Solution ▶ The current scores are 78, 72, and 86. An average of *at least* 80 means $A \geq 80$. In organized form:

Test 1	Test 2	Test 3	Test 4	Computed Average	Minimum
78	72	86	x	$\frac{78 + 72 + 86 + x}{4}$	80

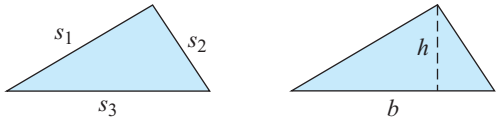
Let x represent Justin's score on the fourth exam, then $\frac{78 + 72 + 86 + x}{4}$ represents his average score.

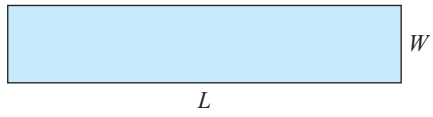
$$\frac{78 + 72 + 86 + x}{4} \geq 80 \quad \text{average must be greater than or equal to 80}$$
$$78 + 72 + 86 + x \geq 320 \quad \text{multiply by 4}$$
$$236 + x \geq 320 \quad \text{simplify}$$
$$x \geq 84 \quad \text{solve for } x \text{ (subtract 236)}$$

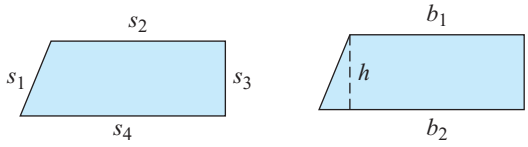
Justin must score at least an 84 on the last exam to earn an 80 average.

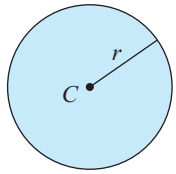
Now try Exercises 91 through 100 ▶

☑ **E.** You've just seen how we can solve applications of linear equations and inequalities









F. Solving Applications of Basic Geometry

As your translation skills grow, your ability to solve a wider range of more significant applications will grow as well. In many cases, the applications will involve some basic geometry and the most often used figures and formulas appear here. For a more complete review of geometry, see *Appendix II Geometry Review with Unit Conversions,* which is posted online at www.mhhe.com/coburn.

Perimeter and Area

Perimeter is a measure of the distance around a two dimensional figure. As this is a linear measure, results are stated in linear units as in centimeters (cm), feet (ft), kilometers (km), miles (mi), and so on. If no unit is specified, simply write the result as x *units*. Area is a measure of the surface of a two dimensional figure, with results stated in square units as in x *units*^{2}. Some of the most common formulas involving perimeter and area are given in Table A.2A.

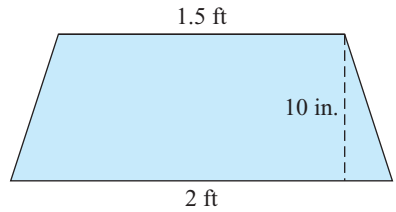


Table A.2A

	Definition and Diagram	Perimeter Formula (linear units or *units*)	Area Formula (square units or *units*^{2})
Triangle	a three-sided polygon 	$P = s_1 + s_2 + s_3$	$A = \frac{1}{2}bh$
Rectangle	a quadrilateral with four right angles and opposite sides parallel 	$P = 2L + 2W$	$A = LW$
Square	a rectangle with four equal sides 	$P = 4S$	$A = S^2$
Trapezoid	a quadrilateral with one pair of parallel sides (called bases b_1 and b_2) 	sum of all sides $P = s_1 + s_2 + s_3 + s_4$	$A = \frac{h}{2}(b_1 + b_2)$
Circle	the set of all points lying in a plane that are an equal distance (called the radius r) from a given point (called the center C). 	$C = 2\pi r$ or $C = \pi d$	$A = \pi r^2$

If an exercise or application uses a formula, begin by *stating the formula first*. Using the formula as a template for the values substituted will help to prevent many careless errors.

EXAMPLE 12A ▶ Computing the Area of a Trapezoidal Window

A basement window is shaped like an isosceles trapezoid (base angles equal, nonparallel sides equal in length), with a height of 10 in. and bases of 1.5 ft and 2 ft. What is the area of the glass in the window?

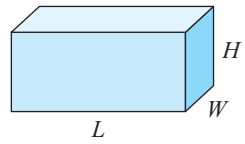
Solution ▶ Before applying the area formula, all measures must use the same unit. In inches, we have 1.5 ft = 18 in. and 2 ft = 24 in.

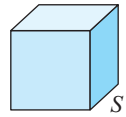
$$A = \frac{h}{2}(b_1 + b_2) \qquad \text{given formula}$$

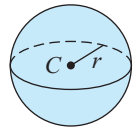
$$A = \frac{10 \text{ in.}}{2}(18 \text{ in.} + 24 \text{ in.}) \qquad \text{substitute 10 for } h, \text{ 18 for } b_1, \text{ and 24 for } b_2$$

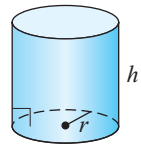
$$A = (5 \text{ in.})(42 \text{ in.}) \qquad \text{simplify}$$

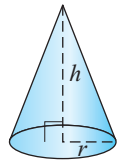
$$A = 210 \text{ in}^2 \qquad \text{result}$$

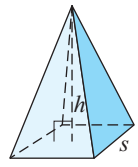








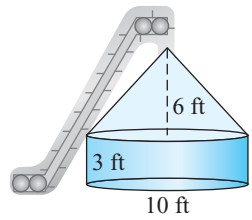




The area of the glass in the window is 210 in^2.

Now try Exercises 101 and 102 ▶

Volume



Volume is a measure of the amount of space occupied by a three dimensional object and is measured in **cubic units.** Some of the more common formulas are given in Table A.2B.

Table A.2B

	Definition and Diagram	Volume Formula (cubic units or *units*^{3})
Rectangular solid	a six-sided, solid figure with opposite faces congruent and adjacent faces meeting at right angles 	$V = LWH$
Cube	a rectangular solid with six congruent, square faces 	$V = S^3$
Sphere	the set of all points in space, an equal distance (called the radius) from a given point (called the center) 	$V = \frac{4}{3}\pi r^3$
Right circular cylinder	union of all line segments connecting two congruent circles in parallel planes, meeting each at a right angle 	$V = \pi r^2 h$
Right circular cone	union of all line segments connecting a given point (vertex) to a given circle (base) and whose altitude meets the center of the base at a right angle 	$V = \frac{1}{3}\pi r^2 h$
Right pyramid	union of all line segments connecting a given point (vertex) to a given square (base) and whose altitude meets the center of the base at a right angle 	$V = \frac{1}{3}s^2 h$

EXAMPLE 12B ▶ Computing the Volume of a Composite Figure

Sand at a cement factory is being dumped from a conveyor belt into a pile shaped like a right circular cone atop a right circular cylinder (see figure). How many cubic feet of sand are there at the moment the cone is 6 ft high with a diameter of 10 ft?

Solution ▶

Total Volume = volume of cylinder + volume of cone — verbal model

$$V = \pi r^2 h_1 + \frac{1}{3}\pi r^2 h_2$$ — formula model (note $h_1 \neq h_2$)

$$= \pi(5)^2(3) + \frac{1}{3}\pi(5)^2(6)$$ — substitute 5 for r, 3 for h_1, and 6 for h_2

$$= 75\pi + 50\pi$$ — simplify

$$= 125\pi$$ — result (exact form)

There are about 392.7 ft^3 of sand in the pile.

☑ **F.** You've just seen how we can solve applications of basic geometry

Now try Exercises 103 and 104 ▶

A.3 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section, if necessary.

1. A(n) _____ is an equation that is always true, regardless of the _____ value while a(n) _____ is an equation that is always false, regardless of the _____ value.
2. For inequalities, the three ways of writing a solution set are _____ notation, a number line graph, and _____ notation.
3. The mathematical sentence $3x + 5 < 7$ is a(n) _____ inequality, while $-2 < 3x + 5 < 7$ is a(n) _____ inequality.
4. The _____ of sets A and B is written $A \cap B$. The _____ of sets A and B is written $A \cup B$.
5. Discuss/Explain the similarities and differences between the properties of equality for equations and those for inequalities.
6. Discuss/Explain the use of the words "and" and "or" in the statement of compound inequalities. Include a few examples to illustrate.

▶ DEVELOPING YOUR SKILLS

Solve each equation. Check your answer by substitution.

7. $4x + 3(x - 2) = 18 - x$
8. $15 - 2x = -4(x + 1) + 9$
9. $21 - (2v + 17) = -7 - 3v$
10. $-12 - 5w = -9 - (6w + 7)$
11. $8 - (3b + 5) = -5 + 2(b + 1)$
12. $2a + 4(a - 1) = 3 - (2a + 1)$

Solve each equation.

13. $\frac{1}{5}(b + 10) - 7 = \frac{1}{3}(b - 9)$
14. $\frac{1}{6}(n - 12) = \frac{1}{4}(n + 8) - 2$
15. $\frac{2}{3}(m + 6) = \frac{-1}{2}$
16. $\frac{4}{5}(n - 10) = \frac{-8}{9}$
17. $\frac{1}{2}x + 5 = \frac{1}{3}x + 7$
18. $-4 + \frac{2}{3}y = \frac{1}{2}y - 5$
19. $\frac{x + 3}{5} + \frac{x}{3} = 7$
20. $\frac{z - 4}{6} - 2 = \frac{z}{2}$

21. $15 = -6 - \frac{3p}{8}$ **22.** $-15 - \frac{2q}{9} = -21$

23. $0.2(24 - 7.5a) - 6.1 = 4.1$

24. $0.4(17 - 4.25b) - 3.15 = 4.16$

25. $6.2v - (2.1v - 5) = 1.1 - 3.7v$

26. $7.9 - 2.6w = 1.5w - (9.1 + 2.1w)$

27. $\frac{n}{2} + \frac{n}{5} = \frac{2}{3}$

28. $\frac{m}{3} - \frac{2}{5} = \frac{m}{4}$

29. $3p - \frac{p}{4} - 5 = \frac{p}{6} - 2p + 6$

30. $\frac{q}{6} + 1 - 3q = 2 - 4q + \frac{q}{8}$

Identify the following equations as an identity, a contradiction, or a conditional equation, then state the solution.

31. $-3(4z + 5) = -15z - 20 + 3z$

32. $5x - 9 - 2 = -5(2 - x) - 1$

33. $8 - 8(3n + 5) = -5 + 6(1 + n)$

34. $2a + 4(a - 1) = 1 + 3(2a + 1)$

35. $-4(4x + 5) = -6 - 2(8x + 7)$

36. $-(5x - 3) + 2x = 11 - 4(x + 2)$

Write the solution set illustrated on each graph in set notation and interval notation.

37.

38.

39.

40.

Solve the inequality and write the solution in set notation. Then graph the solution and write it in interval notation.

41. $5a - 11 \geq 2a - 5$

42. $-8n + 5 > -2n - 12$

43. $2(n + 3) - 4 \leq 5n - 1$

44. $-5(x + 2) - 3 < 3x + 11$

45. $\frac{3x}{8} + \frac{x}{4} < -4$ **46.** $\frac{2y}{5} + \frac{y}{10} < -2$

Solve each inequality and write the solution in set notation.

47. $7 - 2(x + 3) \geq 4x - 6(x - 3)$

48. $-3 - 6(x - 5) \leq 2(7 - 3x) + 1$

49. $4(3x - 5) + 18 < 2(5x + 1) + 2x$

50. $8 - (6 + 5m) > -9m - (3 - 4m)$

51. $-6(p - 1) + 2p \leq -2(2p - 3)$

52. $9(w - 1) - 3w \geq -2(5 - 3w) + 1$

Determine the intersection and union of sets A, B, C, and D as indicated, given $A = \{-3, -2, -1, 0, 1, 2, 3\}$, $B = \{2, 4, 6, 8\}$, $C = \{-4, -2, 0, 2, 4\}$, and $D = \{4, 5, 6, 7\}$.

53. $A \cap B$ and $A \cup B$ **54.** $A \cap C$ and $A \cup C$

55. $A \cap D$ and $A \cup D$ **56.** $B \cap C$ and $B \cup C$

57. $B \cap D$ and $B \cup D$ **58.** $C \cap D$ and $C \cup D$

Express the compound inequalities graphically and in interval notation.

59. $x < -2$ or $x > 1$ **60.** $x < -5$ or $x > 5$

61. $x < 5$ and $x \geq -2$ **62.** $x \geq -4$ and $x < 3$

63. $x \geq 3$ and $x \leq 1$ **64.** $x \geq -5$ and $x \leq -7$

Solve the compound inequalities and graph the solution set.

65. $4(x - 1) \leq 20$ or $x + 6 > 9$

66. $-3(x + 2) > 15$ or $x - 3 \leq -1$

67. $-2x - 7 \leq 3$ and $2x \leq 0$

68. $-3x + 5 \leq 17$ and $5x \leq 0$

69. $\frac{3}{5}x + \frac{1}{2} > \frac{3}{10}$ and $-4x > 1$

70. $\frac{2}{3}x - \frac{5}{6} \leq 0$ and $-3x < -2$

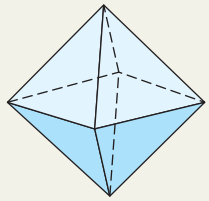
71. $\frac{3x}{8} + \frac{x}{4} < -3$ or $x + 1 > -5$

72. $\frac{2x}{5} + \frac{x}{10} < -2$ or $x - 3 > 2$

73. $-3 \leq 2x + 5 < 7$

74. $2 < 3x - 4 \leq 19$

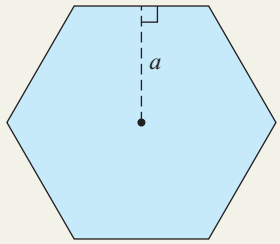
75. $-0.5 \leq 0.3 - x \leq 1.7$



76. $-8.2 < 1.4 - x < -0.9$

77. $-7 < -\frac{3}{4}x - 1 \leq 11$

78. $-21 \leq -\frac{2}{3}x + 9 < 7$



▶ WORKING WITH FORMULAS

79. Euler's Polyhedron Formula: $V + F - E = 2$

Discovered by Leonhard Euler in 1752, this simple but powerful formula states that in any regular polyhedron, the number of vertices V and faces F is always two more than the number of edges E. (a) Verify the formula for a simple cube. (b) Verify the formula for the octahedron shown in the figure. (c) If a dodecahedron has 12 faces and 30 edges, how many vertices does it have?

80. Area of a Regular Polygon: $A = \frac{1}{2}ap$

The area of any regular polygon can be found using the formula shown, where a is the apothem of the polygon (perpendicular distance from center to any edge), and p is the perimeter. (a) Verify the formula using a square with sides of length 6 cm. (b) If the hexagon shown has an area of 259.8 cm^2 with sides 10 cm in length, what is the length a of the apothem?

81. Body mass index: $B = \frac{704W}{H^2}$

The U.S. government publishes a body mass index formula to help people consider the risk of heart disease. An index "B" of 27 or more means that a person is at risk. Here W represents weight in pounds and H represents height in inches. If your height is 5′8″ what range of weights will help ensure you remain safe from the risk of heart disease?

Source: www.surgeongeneral.gov/topics.

82. Lift capacity: $75S + 125B \leq 750$

The capacity in pounds of the lift used by a roofing company to place roofing shingles and buckets of roofing nails on rooftops is modeled by the formula shown, where S represents packs of shingles and B represents buckets of nails. Use the formula to find (a) the largest number of shingle packs that can be lifted, (b) the largest number of nail buckets that can be lifted, and (c) the largest number of shingle packs that can be lifted along with three nail buckets.

▶ APPLICATIONS

Write an equation to model the given information and solve.

83. Celebrity Travel: To avoid paparazzi and overzealous fans, the arrival gates of planes carrying celebrities are often kept secret until the last possible moment. While awaiting the arrival of Angelina Jolie, a large crowd of fans and photographers had gathered at Terminal A, Gate 18. However, the number of fans waiting at Gate 32 was *twice that number increased by 5*. If there were 73 fans at Gate 32, how many were waiting at Gate 18? (See Section A.1, Example 2a.)

84. Famous Architecture: The *Hall of Mirrors* is the central gallery of the Palace of Versailles and is one of the most famous rooms in the world. The length of this hall is *11 m less than 8 times the width*. If the hall is 73 m long, what is its width? (See Section A.1, Example 2b.)

85. Dietary Goals: At the picnic, Mike abandoned his diet and consumed 13 calories more than twice the number of calories he normally allots for lunch. If he consumed 1467 calories, how many calories are normally allotted for lunch?

86. Marathon Training: While training for the Chicago marathon, Christina's longest run of the week was 5 mi less than double the shortest. If the longest run was 11.2 mi, how long was the shortest?

87. Actor's Ages: At the time of this writing, actor Will Smith (*Enemy of the State*, *Seven Pounds,* others), was 1 yr older than two-thirds the age of Samuel Jackson (*The Negotiator, Die Hard III,* others). If Will Smith was 41 at this time, how old was Samuel Jackson?

88. Football versus Fútbol: The area of a regulation field for American football is about 410 square meters (m^2) less than three-fifths of an Olympic-sized soccer field. If an American football field covers 5350 m^2, what is the area of an Olympic soccer field?

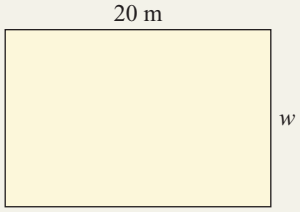
89. Forensic Studies: In forensic studies, skeletal remains are analyzed to determine the height, gender, race, age, and other characteristics of the decedent. For instance, the height of a male individual is approximated as 34 in. more than three and one-third times the length of the radial bone. If a live individual is 74 in. tall, how long is his radial bone?

90. Famous Waterways: The Suez Canal and the Panama Canal are two of the most important waterways in the world, saving ships thousands of miles as they journey from port to destination. The length of the Suez Canal is 39 kilometers (km) less than three times the length of the Panama Canal. If the Egyptian canal is 192 km long, how long is the Central American canal?

Write an inequality to model the given information and solve.

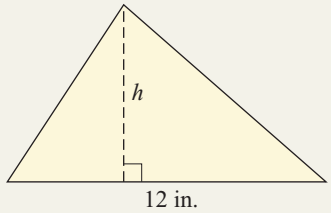
91. Exam scores: Jacques is going to college on an academic scholarship that requires him to maintain at least a 75% average in all of his classes. So far he has scored 82%, 76%, 65%, and 71% on four exams. What scores are possible on his last exam that will enable him to keep his scholarship?

92. Timed trials: In the first three trials of the 100-m butterfly, Johann had times of 50.2, 49.8, and 50.9 sec. How fast must he swim the final timed trial to have an average time of at most 50 sec?



93. Checking account balance: If the average daily balance in a certain checking account drops below \$1000, the bank charges the customer a \$7.50 service fee. The table gives the daily balance for one customer. What must the daily balance be for Friday to avoid a service charge?

Weekday	Balance
Monday	\$1125
Tuesday	\$850
Wednesday	\$625
Thursday	\$400

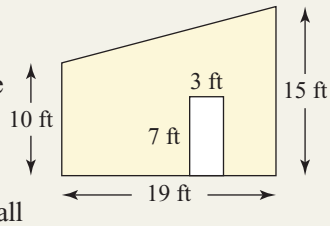


94. Average weight: In the National Football League, many consider an offensive line to be "small" if the average weight of the five down linemen is less than 325 lb. Using the table, what must the weight of the right tackle be so that the line will not be considered small?

Lineman	Weight
Left tackle	318 lb
Left guard	322 lb
Center	326 lb
Right guard	315 lb
Right tackle	?

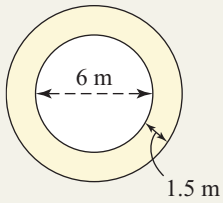
95. Area of a rectangle: Given the rectangle shown, what is the range of values for the width, in order to keep the area less than $150 m^2$?

96. Area of a triangle: Using the triangle shown, find the height that will guarantee an area equal to or greater than 48 in^2.



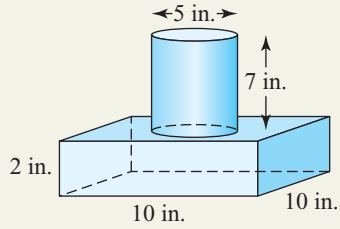
97. Heating and cooling subsidies: As long as the outside temperature is over 45°F and less than 85°F ($45 < F < 85$), the city does not issue heating or cooling subsidies for low-income families. What is the corresponding range of Celsius temperatures C? Recall that $F = \frac{9}{5}C + 32$.

98. U.S. and European shoe sizes: To convert a European male shoe size "E" to an American male shoe size "A," the formula $A = 0.76E - 23$ can be used. Lillian has five sons in the U.S. military, with shoe sizes ranging from size 9 to size 14 ($9 \le A \le 14$). What is the corresponding range of European sizes? Round to the nearest half-size.

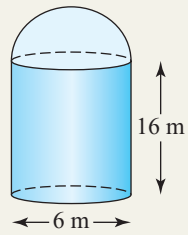


99. Power tool rentals: Sunshine Equipment Co. rents its power tools for a \$20 fee, plus \$4.50/hr. Kealoha's Rentals offers the same tools for an \$11 fee plus \$6.00/hr. How many hours h must a tool be rented to make the cost at Sunshine a better deal?

100. Moving van rentals: Stringer Truck Rentals will rent a moving van for \$15.75/day plus \$0.35 per mile. Bertz Van Rentals will rent the same van for \$25/day plus \$0.30 per mile. How many miles m must the van be driven to make the cost at Bertz a better deal?



101. Cost of drywall: After the studs are up, the wall shown in the figure must be covered in drywall. (a) How many square feet of drywall are needed? (b) If drywall is sold only in 4-ft by 8-ft sheets, approximately how many sheets are required for this job?



102. Paving a walkway: Current plans call for building a circular fountain 6 m in diameter with a circular walkway around it that is 1.5 m wide. (a) What is the approximate area of the walkway? (b) If the concrete for the walkway is to be 6 cm deep, what volume of cement must be used (1 cm = 0.01 m)?

103. Trophy bases: The base of a new trophy has the form of a cylinder sitting atop a rectangular solid. If the base is to be cast in a special aluminum, determine the volume of aluminum to be used.

104. Grain storage: The dimensions of a grain silo are shown in the figure. If the maximum storage capacity of the silo is 95% of the total volume of the silo, how many cubic meters of corn can be stored?

▶ EXTENDING THE CONCEPT

105. Solve for x: $-3(4x^2 + 5x - 2) + 7x = 6(4 - x - 2x^2) - 19$

106. Solve for n: $5\{3 - [4 - 2(5 - 9n)]\} + 15 = -6\{5 + 2[n - 10(9 + n)]\}$

107. Use your local library, the Internet, or another resource to find the highest and lowest point on each of the seven continents. Express the range of altitudes for each continent as a joint inequality. Which continent has the greatest range?

108. The sum of two consecutive even integers is greater than or equal to 12 and less than or equal to 22. List all possible values for the two integers.

Place the correct inequality symbol in the blank to make the statement true.

109. If $m > 0$ and $n < 0$, then mn _____ 0.

110. If $m > n$ and $p > 0$, then mp _____ np.

111. If $m < n$ and $p > 0$, then mp _____ np.

112. If $m \le n$ and $p < 0$, then mp _____ np.

113. If $m > n$, then $-m$ _____ $-n$.

114. If $0 < m < n$, then $\frac{1}{m}$ _____ $\frac{1}{n}$.

115. If $m > 0$ and $n < 0$, then m^2 _____ n.

116. If $m < 0$, then m^3 _____ 0.

A.4 Factoring Polynomials and Solving Polynomial Equations by Factoring

LEARNING OBJECTIVES

In Section A.4 you will review:

- ❑ **A.** Factoring out the greatest common factor
- ❑ **B.** Common binomial factors and factoring by grouping
- ❑ **C.** Factoring quadratic polynomials
- ❑ **D.** Factoring special forms and quadratic forms
- ❑ **E.** Solving Polynomial Equations by Factoring

It is often said that knowing which tool to use is just as important as knowing how to use the tool. In this section, we review the tools needed to factor an expression, an important part of solving polynomial equations. This section will also help us decide which factoring tool is appropriate when many different factorable expressions are presented.

A. The Greatest Common Factor

To **factor** an expression means to *rewrite the expression as an equivalent product*. The distributive property is an example of factoring in action. To factor $2x^2 + 6x$, we might first rewrite each term using the common factor $2x$: $2x^2 + 6x = 2x \cdot x + 2x \cdot 3$, then apply the distributive property to obtain $2x(x + 3)$. We commonly say that we have *factored out 2x*. The **greatest common factor** (or GCF) is the largest factor common to *all* terms in the polynomial.

EXAMPLE 1 ▶ **Factoring Polynomials**

Factor each polynomial:

a. $12x^2 + 18xy - 30y$ **b.** $x^5 + x^2$

Solution ▶

a. 6 is common to all three terms:

$$12x^2 + 18xy - 30y \qquad \text{mentally: } 6 \cdot 2x^2 + 6 \cdot 3xy - 6 \cdot 5y$$
$$= 6(2x^2 + 3xy - 5y)$$

b. x^2 is common to both terms:

$$x^5 + x^2 \qquad \text{mentally: } x^2 \cdot x^3 + x^2 \cdot 1$$
$$= x^2(x^3 + 1)$$

A. You've just seen how we can factor out the greatest common factor

Now try Exercises 7 and 8 ▶

B. Common Binomial Factors and Factoring by Grouping

If the terms of a polynomial have a **common *binomial* factor,** it can also be factored out using the distributive property.

EXAMPLE 2 ▶ **Factoring Out a Common Binomial Factor**

Factor:

a. $(x + 3)x^2 + (x + 3)5$ **b.** $x^2(x - 2) - 3(x - 2)$

Solution ▶

a. $(x + 3)x^2 + (x + 3)5$
$= (x + 3)(x^2 + 5)$

b. $x^2(x - 2) - 3(x - 2)$
$= (x - 2)(x^2 - 3)$

Now try Exercises 9 and 10 ▶

One application of removing a binomial factor involves **factoring by grouping.** At first glance, the expression $x^3 + 2x^2 + 3x + 6$ appears unfactorable. But by grouping the terms (applying the associative property), we can remove a monomial factor from each subgroup, which then reveals a common binomial factor.

$$\underline{x^3 + 2x^2} + \underline{3x + 6} = x^2(x + 2) + 3(x + 2)$$
$$= (x + 2)(x^2 + 3)$$

This grouping of terms must take into account any sign changes and common factors, as seen in Example 3. Also, it will be helpful to note that a general four-term polynomial $A + B + C + D$ is factorable by grouping only if $AD = BC$.

EXAMPLE 3 ▶ **Factoring by Grouping**

Factor $3t^3 + 15t^2 - 6t - 30$.

Solution ▶ Notice that all four terms have a common factor of 3. Begin by factoring it out.

$3t^3 + 15t^2 - 6t - 30$ original polynomial
$= 3(t^3 + 5t^2 - 2t - 10)$ factor out 3
$= 3(\underline{t^3 + 5t^2} - \underline{2t - 10})$ group remaining terms
$= 3[t^2(t + 5) - 2(t + 5)]$ factor common *monomial*
$= 3(t + 5)(t^2 - 2)$ factor common *binomial*

Now try Exercises 11 and 12 ▶

☑ **B.** You've just seen how we can factor common binomial factors and factor by grouping

When asked to factor an expression, first look for common factors. The resulting expression will be easier to work with and help ensure the final answer is written in **completely factored form.** If a four-term polynomial cannot be factored as written, try rearranging the terms to find a combination that enables factoring by grouping.

C. Factoring Quadratic Polynomials

A quadratic polynomial is one that can be written in the form $ax^2 + bx + c$, where $a, b, c \in \mathbb{R}$ and $a \neq 0$. One common form of factoring involves quadratic trinomials such as $x^2 + 7x + 10$ and $2x^2 - 13x + 15$. While we know $(x + 5)(x + 2) = x^2 + 7x + 10$ and $(2x - 3)(x - 5) = 2x^2 - 13x + 15$ using F-O-I-L, how can we factor these trinomials without seeing the original expression in advance? First, it helps to place the trinomials in two families—those with a leading coefficient of 1 and those with a leading coefficient other than 1.

$ax^2 + bx + c$, where $a = 1$

When $a = 1$, the only factor pair for x^2 (other than $1 \cdot x^2$) is $x \cdot x$ and the first term in each binomial will be x: $(x \quad)(x \quad)$. The following observation helps guide us to the complete factorization. Consider the product $(x + b)(x + a)$:

$$(x + b)(x + a) = x^2 + ax + bx + ab \quad \text{F-O-I-L}$$
$$= x^2 + (a + b)x + ab \quad \text{distributive property}$$

Note the last term is the product ab (the *lasts*), while the coefficient of the middle term is $a + b$ (the sum of the *outers* and *inners*). Since the last term of $x^2 - 8x + 7$ is 7 and the coefficient of the middle term is -8, we are seeking two numbers with a product of positive 7 and a sum of negative 8. The numbers are -7 and -1, so the factored form is $(x - 7)(x - 1)$. It is also helpful to note that if the constant term is positive, the binomials will have *like* signs, since only *the product of like signs is positive*. If the constant term is negative, the binomials will have *unlike* signs, since only *the product of unlike signs is negative*. This means we can use the sign of the linear term (the term with degree 1) to guide our choice of factors.

Factoring Trinomials with a Leading Coefficient of 1

If the constant term is positive, the binomials will have *like* signs:

$$(x + \quad)(x + \quad) \text{ or } (x - \quad)(x - \quad),$$

to match the sign of the linear (middle) term.

If the constant term is negative, the binomials will have *unlike* signs:

$$(x + \quad)(x - \quad),$$

with the larger factor placed in the binomial whose sign *matches* the linear (middle) term.

EXAMPLE 4 ▶ **Factoring Trinomials**

Factor these expressions:

a. $-x^2 + 11x - 24$ **b.** $x^2 - 10 - 3x$

Solution ▶

a. First rewrite the trinomial in standard form as $-1(x^2 - 11x + 24)$. For $x^2 - 11x + 24$, the constant term is positive so the binomials will have like signs. Since the linear term is negative,

$$-1(x^2 - 11x + 24) = -1(x - \quad)(x - \quad) \quad \text{like signs, both negative}$$
$$= -1(x - 8)(x - 3) \quad (-8)(-3) = 24;\ -8 + (-3) = -11$$

b. First rewrite the trinomial in standard form as $x^2 - 3x - 10$. The constant term is negative so the binomials will have unlike signs. Since the linear term is negative,

$$x^2 - 3x - 10 = (x + \ )(x - \ )$$
$$= (x + 2)(x - 5)$$

unlike signs, one positive and one negative
$5 > 2$, 5 is placed in the second binomial;
$(2)(-5) = -10$; $2 + (-5) = -3$

Now try Exercises 13 and 14 ▶

Sometimes we encounter **prime polynomials,** or polynomials that cannot be factored. For $x^2 + 9x + 15$, the factor pairs of 15 are $1 \cdot 15$ and $3 \cdot 5$, with neither pair having a sum of $+9$. We conclude that $x^2 + 9x + 15$ is prime.

$ax^2 + bx + c$, where $a \neq 1$

If the leading coefficient is not one, the possible combinations of outers and inners are more numerous. Furthermore, the sum of the outer and inner products will change depending on the position of the possible factors. Note that $(2x + 3)(x + 9) = 2x^2 + 21x + 27$ and $(2x + 9)(x + 3) = 2x^2 + 15x + 27$ result in a different middle term, even though identical numbers were used.

To factor $2x^2 - 13x + 15$, note the constant term is positive so the binomials *must have like signs*. The negative linear term indicates these signs will be negative. We then list possible factors for the first and last terms of each binomial, then sum the outer and inner products.

Possible First and Last Terms for $2x^2$ and 15	Sum of Outers and Inners
1. $(2x - 1)(x - 15)$	$-30x - 1x = -31x$
2. $(2x - 15)(x - 1)$	$-2x - 15x = -17x$
3. $(2x - 3)(x - 5)$	$-10x - 3x = -13x$ ←
4. $(2x - 5)(x - 3)$	$-6x - 5x = -11x$

WORTHY OF NOTE

The number of trials needed to factor a polynomial can also be reduced by noting that the two terms in any binomial cannot share a common factor (all common factors are removed in a preliminary step).

As you can see, only possibility 3 yields a linear term of $-13x$, and the correct factorization is then $(2x - 3)(x - 5)$. With practice, this **trial-and-error** process can be completed very quickly.

If the constant term is negative, the number of possibilities can be reduced by finding a factor pair with a sum *or* difference equal to the *absolute value* of the linear coefficient, as we can then arrange the sign in each binomial to obtain the needed result as shown in Example 5.

EXAMPLE 5 ▶ Factoring a Trinomial Using Trial and Error

Factor $6z^2 - 11z - 35$.

Solution ▶ Note the constant term is negative (binomials will have unlike signs) and $|-11| = 11$. The factors of 35 are $1 \cdot 35$ and $5 \cdot 7$. Two possible first terms are: $(6z \quad)(z \quad)$ and $(3z \quad)(2z \quad)$, and we begin with 5 and 7 as factors of 35.

$(6z \quad)(z \quad)$	Outer and Inner Products		$(3z \quad)(2z \quad)$	Outer and Inner Products	
	Sum	Difference		Sum	Difference
1. $(6z \quad 5)(z \quad 7)$	$42z + 5z$ $47z$	$42z - 5z$ $37z$	3. $(3z \quad 5)(2z \quad 7)$	$21z + 10z$ $31z$	$21z - 10z$ $11z$
2. $(6z \quad 7)(z \quad 5)$	$30z + 7z$ $37z$	$30z - 7z$ $23z$	4. $(3z \quad 7)(2z \quad 5)$	$15z + 14z$ $29z$	$15z - 14z$ $1z$

Since possibility 3 yields a linear term of $11z$, we need not consider other factors of 35 and write the factored form as $6z^2 - 11z - 35 = (3z \quad 5)(2z \quad 7)$. The signs can then be arranged to obtain a middle term of $-11z$: $(3z + 5)(2z - 7)$, $-21z + 10z = -11z$ ✓.

Now try Exercises 15 and 16 ▶

☑ **C.** You've just seen how we can factor quadratic polynomials

D. Factoring Special Forms and Quadratic Forms

Next we consider methods to factor each of the special products we encountered in Appendix A.2.

The Difference of Two Squares

Multiplying and factoring are inverse processes. Since $(x - 7)(x + 7) = x^2 - 49$, we know that $x^2 - 49 = (x - 7)(x + 7)$. In words, *the difference of two squares will factor into a binomial and its conjugate.* To find the terms of the factored form, rewrite each term in the original expression as a square: $(\quad)^2$.

WORTHY OF NOTE

In an attempt to factor a *sum* of two perfect squares, say $v^2 + 49$, let's list all possible binomial factors. These are (1) $(v + 7)(v + 7)$, (2) $(v - 7)(v - 7)$, and (3) $(v + 7)(v - 7)$. Note that (1) and (2) are the binomial squares $(v + 7)^2$ and $(v - 7)^2$, with each product resulting in a "middle" term, whereas (3) is a binomial times its conjugate, resulting in a *difference* of squares: $v^2 - 49$. With all possibilities exhausted, we conclude that *the sum of two squares is prime!*

Factoring the Difference of Two Perfect Squares

Given any expression that can be written in the form $A^2 - B^2$,

$$A^2 - B^2 = (A + B)(A - B)$$

Note that the *sum* of two perfect squares $A^2 + B^2$ *cannot be factored* using real numbers (the expression is prime). As a reminder, always check for a common factor first and be sure to write all results in completely factored form. See Example 6(c).

EXAMPLE 6 ▶ **Factoring the Difference of Two Perfect Squares**

Factor each expression completely.

a. $4w^2 - 81$ **b.** $v^2 + 49$ **c.** $-3n^2 + 48$ **d.** $z^4 - \frac{1}{81}$ **e.** $x^2 - 7$

Solution ▶

a. $4w^2 - 81 = (2w)^2 - 9^2$ write as a difference of squares

$= (2w + 9)(2w - 9)$ $A^2 - B^2 = (A + B)(A - B)$

b. $v^2 + 49$ is prime.

c. $-3n^2 + 48 = -3(n^2 - 16)$ factor out -3

$= -3[n^2 - (4)^2]$ write as a difference of squares

$= -3(n + 4)(n - 4)$ $A^2 - B^2 = (A + B)(A - B)$

d. $z^4 - \frac{1}{81} = (z^2)^2 - (\frac{1}{9})^2$ write as a difference of squares

$= (z^2 + \frac{1}{9})(z^2 - \frac{1}{9})$ $A^2 - B^2 = (A + B)(A - B)$

$= (z^2 + \frac{1}{9})[z^2 - (\frac{1}{3})^2]$ write as a difference of squares ($z^2 + \frac{1}{9}$ is prime)

$= (z^2 + \frac{1}{9})(z + \frac{1}{3})(z - \frac{1}{3})$ result

e. $x^2 - 7 = (x)^2 - (\sqrt{7})^2$ write as a difference of squares

$= (x + \sqrt{7})(x - \sqrt{7})$ $A^2 - B^2 = (A + B)(A - B)$

Now try Exercises 17 and 18 ▶

Perfect Square Trinomials

Since $(x + 7)^2 = x^2 + 14x + 49$, we know that $x^2 + 14x + 49 = (x + 7)^2$. In words, *a perfect square trinomial will factor into a binomial square.* To use this idea effectively, we must learn to *identify* perfect square trinomials. Note that the first and last terms of $x^2 + 14x + 49$ are *the squares* of x and 7, and the middle term is *twice the product of these two terms*: $2(7x) = 14x$. These are the characteristics of a perfect square trinomial.

Factoring Perfect Square Trinomials

Given any expression that can be written in the form $A^2 \pm 2AB + B^2$,

1. $A^2 + 2AB + B^2 = (A + B)^2$
2. $A^2 - 2AB + B^2 = (A - B)^2$

EXAMPLE 7 ▶ **Factoring a Perfect Square Trinomial**

Factor $12m^3 - 12m^2 + 3m$.

Solution ▶

$12m^3 - 12m^2 + 3m$ check for common factors: GCF $= 3m$

$= 3m(4m^2 - 4m + 1)$ factor out $3m$

For the remaining trinomial $4m^2 - 4m + 1$ …

1. Are the first and last terms perfect squares?

$4m^2 = (2m)^2$ and $1 = (1)^2$ ✓ Yes.

2. Is the linear term twice the product of $2m$ and 1?

$2 \cdot 2m \cdot 1 = 4m$ ✓ Yes.

Factor as a binomial square: $4m^2 - 4m + 1 = (2m - 1)^2$

This shows $12m^3 - 12m^2 + 3m = 3m(2m - 1)^2$.

Now try Exercises 19 and 20 ▶

CAUTION ▶ As shown in Example 7, be sure to include the GCF in your final answer. It is a common error to "leave the GCF behind."

In actual practice, these calculations can be performed mentally, making the process much more efficient.

Sum or Difference of Two Perfect Cubes

Recall that the *difference* of two perfect squares is factorable, but the *sum* of two perfect squares is prime. In contrast, *both the sum and difference of two perfect* **cubes** *are factorable*. For either $A^3 + B^3$ or $A^3 - B^3$ we have the following:

1. Each will factor into the product of a binomial and a trinomial: ( )( )
   (binomial) (trinomial)
2. The terms of the binomial are the quantities being cubed: $(A \quad B)(\quad)$
3. The terms of the trinomial are the square of A, the product AB, and the square of B, respectively: $(A \quad B)(A^2 \quad AB \quad B^2)$
4. The binomial takes the same sign as the original expression $(A \pm B)(A^2 \quad AB \quad B^2)$
5. The middle term of the trinomial takes the opposite sign of the original expression (the last term is always positive): $(A \pm B)(A^2 \mp AB + B^2)$

Factoring the Sum or Difference of Two Perfect Cubes: $A^3 \pm B^3$

1. $A^3 + B^3 = (A + B)(A^2 - AB + B^2)$
2. $A^3 - B^3 = (A - B)(A^2 + AB + B^2)$

EXAMPLE 8 ▶ **Factoring the Sum and Difference of Two Perfect Cubes**

Factor completely:

a. $x^3 + 125$ **b.** $-5m^3n + 40n^4$

Solution ▶

a.
$$x^3 + 125 = x^3 + 5^3 \quad \text{write terms as perfect cubes}$$
$$\text{Use } A^3 + B^3 = (A + B)(A^2 - AB + B^2) \quad \text{factoring template}$$
$$x^3 + 5^3 = (x + 5)(x^2 - 5x + 25) \quad A \to x \text{ and } B \to 5$$

b.
$$-5m^3n + 40n^4 = -5n(m^3 - 8n^3) \quad \text{check for common factors (GCF} = -5n\text{)}$$
$$= -5n[m^3 - (2n)^3] \quad \text{write terms as perfect cubes}$$
$$\text{Use } A^3 - B^3 = (A - B)(A^2 + AB + B^2) \quad \text{factoring template}$$
$$m^3 - (2n)^3 = (m - 2n)[m^2 + m(2n) + (2n)^2] \quad A \to m \text{ and } B \to 2n$$
$$= (m - 2n)(m^2 + 2mn + 4n^2) \quad \text{simplify}$$
$$\Rightarrow -5m^3n + 40n^4 = -5n(m - 2n)(m^2 + 2mn + 4n^2). \quad \text{factored form}$$

The results for parts (a) and (b) can be checked using multiplication.

Now try Exercises 21 and 22 ▶

Quadratic Forms and *u*-Substitution

For any quadratic expression $ax^2 + bx + c$ in standard form, the degree of the leading term is twice the degree of the middle term. Generally, a trinomial is in **quadratic form** if it can be written as $a(__)^2 + b(__) + c$, where the parentheses "hold" the same factors. The equation $x^4 - 13x^2 + 36 = 0$ is in quadratic form since $(x^2)^2 - 13(x^2) + 36 = 0$. In many cases, we can factor these expressions using a **placeholder substitution** that transforms them into a more recognizable form. In a study of algebra, the letter "u" often plays this role. If we let u represent x^2, the expression $(x^2)^2 - 13(x^2) + 36$ becomes $u^2 - 13u + 36$, which can be factored into $(u - 9)(u - 4)$. After "unsubstituting" (replace u with x^2), we have $(x^2 - 9)(x^2 - 4) = (x + 3)(x - 3)(x + 2)(x - 2)$.

EXAMPLE 9 ▶ **Factoring a Quadratic Form**

Write in completely factored form: $(x^2 - 2x)^2 - 2(x^2 - 2x) - 3$.

Solution ▶ Expanding the binomials would produce a fourth-degree polynomial that would be very difficult to factor. Instead we note the expression is in *quadratic form*. Letting u represent $x^2 - 2x$ (the variable part of the "middle" term), $(x^2 - 2x)^2 - 2(x^2 - 2x) - 3$ becomes $u^2 - 2u - 3$.

$$u^2 - 2u - 3 = (u - 3)(u + 1) \quad \text{factor}$$

To finish up, write the expression in terms of x, substituting $x^2 - 2x$ for u.

$$= (x^2 - 2x - 3)(x^2 - 2x + 1) \quad \text{substitute } x^2 - 2x \text{ for } u$$

The resulting trinomials can be further factored.

$$= (x - 3)(x + 1)(x - 1)^2 \quad x^2 - 2x + 1 = (x - 1)^2$$

Now try Exercises 23 and 24 ▶

It is well known that information is retained longer and used more effectively when it's placed in an organized form. The "factoring flowchart" provided in Figure A.4 offers a streamlined and systematic approach to factoring and the concepts involved. However, with some practice the process tends to "flow" more naturally than following a chart, with many of the decisions becoming automatic.

☑ **D.** You've just seen how we can factor special forms and quadratic forms

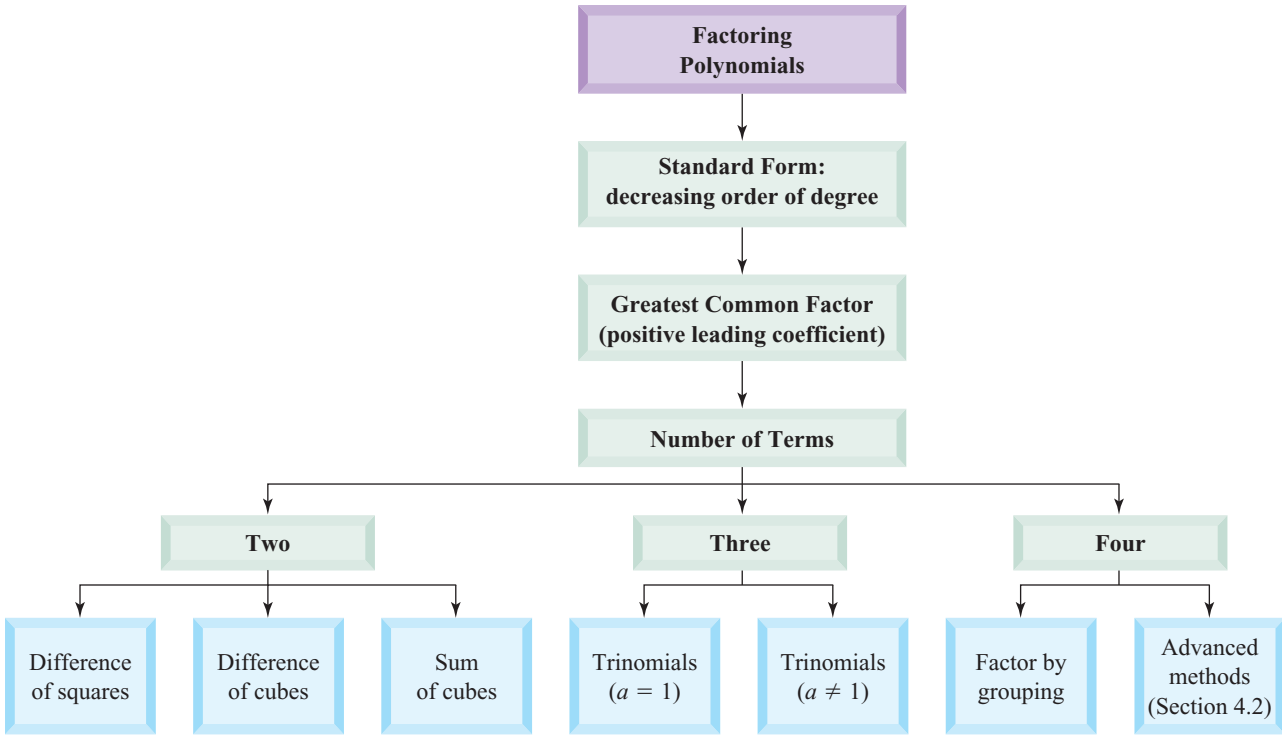


Figure A.4

For additional practice with these ideas, **see Exercises 25 through 52.**

E. Polynomial Equations and the Zero Product Property

The ability to solve linear and quadratic equations is the foundation on which a large percentage of our future studies are built. Both are closely linked to the solution of other equation types, as well as to the graphs of these equations.

In standard form, linear and quadratic equations have a known number of terms, so we commonly represent their coefficients using the early letters of the alphabet, as in $\boldsymbol{a}x^2 + \boldsymbol{b}x + \boldsymbol{c} = 0$. However, these equations belong to the larger family of **polynomial equations.** To write a general polynomial, where the number of terms is unknown, we often represent the coefficients using subscripts on a single variable, such as a_1, a_2, a_3, and so on.

Polynomial Equations

A *polynomial equation of degree n* is one of the form

$$a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x^1 + a_0 = 0$$

where $a_n, a_{n-1}, \ldots, a_1, a_0$ are real numbers and $a_n \neq 0$.

As a prelude to solving polynomial equations of higher degree, we'll first look at quadratic equations and the *zero product property.* As before, a **quadratic equation** is one that can be written in the form $ax^2 + bx + c = 0$, where a, b, and c are real numbers and $a \neq 0$. As written, the equation is in **standard form,** meaning the terms are in decreasing order of degree and the equation is set equal to zero.

Quadratic Equations

A quadratic equation can be written in the form

$$ax^2 + bx + c = 0,$$

with $a, b, c \in \mathbb{R}$, and $a \neq 0$.

Notice that a is the leading coefficient, b is the coefficient of the linear (first degree) term, and c is a constant. All quadratic equations have degree two, but can have one, two, or three terms. The equation $n^2 - 81 = 0$ is a quadratic equation with two terms, where $a = 1$, $b = 0$, and $c = -81$.

EXAMPLE 10 ▶ **Determining Whether an Equation Is Quadratic**

State whether the given equation is quadratic. If yes, identify coefficients a, b, and c.

a. $2x^2 - 18 = 0$ **b.** $z - 12 - 3z^2 = 0$ **c.** $\frac{-3}{4}x + 5 = 0$

d. $z^3 - 2z^2 + 7z = 8$ **e.** $0.8x^2 = 0$

Solution ▶

	Standard Form	Quadratic	Coefficients
a.	$2x^2 - 18 = 0$	yes, deg 2	$a = 2 \quad b = 0 \quad c = -18$
b.	$-3z^2 + z - 12 = 0$	yes, deg 2	$a = -3 \quad b = 1 \quad c = -12$
c.	$\frac{-3}{4}x + 5 = 0$	no, deg 1	(linear equation)
d.	$z^3 - 2z^2 + 7z - 8 = 0$	no, deg 3	(cubic equation)
e.	$0.8x^2 = 0$	yes, deg 2	$a = 0.8 \quad b = 0 \quad c = 0$

WORTHY OF NOTE

The word *quadratic* comes from the Latin word *quadratum,* meaning square. The word historically refers to the "four sidedness" of a square, but mathematically to the *area* of a square. Hence its application to polynomials of the form $ax^2 + bx + c$, where the variable of the leading term is *squared*.

Now try Exercises 53 through 64 ▶

With quadratic and other polynomial equations, we generally cannot isolate the variable on one side using only properties of equality, because the variable is raised to different powers. Instead we attempt to solve the equation by factoring and applying the **zero product property.**

Zero Product Property

If A and B represent real numbers or real-valued expressions

$$\text{and } A \cdot B = 0,$$

$$\text{then } A = 0 \text{ or } B = 0.$$

In words, the property says, *If the product of any two (or more) factors is equal to zero, then at least one of the factors must be equal to zero*. We can use this property to solve higher degree equations after rewriting them in terms of equations with lesser degree. As with linear equations, values that make the original equation true are called *solutions* or *roots* of the equation.

EXAMPLE 11 ▶ **Solving Equations Using the Zero Product Property**

Solve by writing the equations in factored form and applying the zero product property.

a. $3x^2 = 5x$ **b.** $-5x + 2x^2 = 3$ **c.** $4x^2 = 12x - 9$

Solution ▶

a.

$$\begin{aligned} 3x^2 &= 5x && \text{given equation}\\ 3x^2 - 5x &= 0 && \text{standard form}\\ x(3x - 5) &= 0 && \text{factor}\\ x = 0 \quad &\text{or} \quad 3x - 5 = 0 && \text{set factors equal to zero (zero product property)}\\ x = 0 \quad &\text{or} \quad x = \frac{5}{3} && \text{result} \end{aligned}$$

b.

$$\begin{aligned} -5x + 2x^2 &= 3 && \text{given equation}\\ 2x^2 - 5x - 3 &= 0 && \text{standard form}\\ (2x + 1)(x - 3) &= 0 && \text{factor}\\ 2x + 1 = 0 \quad &\text{or} \quad x - 3 = 0 && \text{set factors equal to zero (zero product property)}\\ x = -\frac{1}{2} \quad &\text{or} \quad x = 3 && \text{result} \end{aligned}$$

c.

$$\begin{aligned} 4x^2 &= 12x - 9 && \text{given equation}\\ 4x^2 - 12x + 9 &= 0 && \text{standard form}\\ (2x - 3)(2x - 3) &= 0 && \text{factor}\\ 2x - 3 = 0 \quad &\text{or} \quad 2x - 3 = 0 && \text{set factors equal to zero (zero product property)}\\ x = \frac{3}{2} \quad &\text{or} \quad x = \frac{3}{2} && \text{result} \end{aligned}$$

This equation has only the solution $x = \frac{3}{2}$, which we call a *repeated root*.

Now try Exercises 65 through 88 ▶

CAUTION ▶ Consider the equation $x^2 - 2x - 3 = 12$. While the left-hand side is factorable, the result is $(x - 3)(x + 1) = 12$ and finding a solution becomes a "guessing game" because the equation is not set equal to zero. If you *misapply* the zero factor property and say that $x - 3 = 12$ or $x + 1 = 12$, the "solutions" are $x = 15$ or $x = 11$, which are both incorrect! After subtracting 12 from both sides, $x^2 - 2x - 3 = 12$ becomes $x^2 - 2x - 15 = 0$ giving $(x - 5)(x + 3) = 0$ with solutions $x = 5$ or $x = -3$.

EXAMPLE 12 ▶ **Solving Polynomials by Factoring**

Solve by factoring: $4x^3 - 40x = 6x^2$.

Solution ▶

$$\begin{aligned} 4x^3 - 40x &= 6x^2 && \text{given equation}\\ 4x^3 - 6x^2 - 40x &= 0 && \text{standard form}\\ 2x\,(2x^2 - 3x - 20) &= 0 && \text{common factor is } 2x\\ 2x(2x + 5)(x - 4) &= 0 && \text{factored form}\\ 2x = 0 \quad \text{or} \quad 2x + 5 = 0 \quad &\text{or} \quad x - 4 = 0 && \text{zero product property}\\ x = 0 \quad \text{or} \quad x = \tfrac{-5}{2} \quad &\text{or} \quad x = 4 && \text{result—solve for } x \end{aligned}$$

Substituting these values into the original equation verifies they are solutions.

Now try Exercises 89 through 92 ▶

Example 12 reminds us that in the process of factoring polynomials, there may be a common monomial factor. This factor is also set equal to zero in the solution process (if the monomial is a constant, no solution is generated).

EXAMPLE 13 ▶ **Solving Higher Degree Equations**

Solve each equation by factoring.

a. $x^3 - 4x + 20 = 5x^2$ **b.** $x^4 - 10x^2 + 9 = 0$

Solution ▶

a.

$$x^3 - 4x + 20 = 5x^2 \qquad \text{original equation}$$
$$x^3 - 5x^2 - 4x + 20 = 0 \qquad \text{standard form; factor by grouping}$$
$$x^2(x - 5) - 4(x - 5) = 0 \qquad \text{remove common factors from each group}$$
$$(x - 5)(x^2 - 4) = 0 \qquad \text{factor common binomial}$$
$$(x - 5)(x + 2)(x - 2) = 0 \qquad \text{factored form}$$
$$x - 5 = 0 \text{ or } x + 2 = 0 \text{ or } x - 2 = 0 \qquad \text{zero product property}$$
$$x = 5 \text{ or } x = -2 \text{ or } x = 2 \qquad \text{solve}$$

The solutions are $x = 5$, $x = -2$, and $x = 2$.

b. The equation appears to be in *quadratic form* and we begin by substituting u for x^2 and u^2 for x^4.

$$x^4 - 10x^2 + 9 = 0 \qquad \text{original equation}$$
$$u^2 - 10u + 9 = 0 \qquad \text{substitute } u \text{ for } x^2 \text{ and } u^2 \text{ for } x^4$$
$$(u - 9)(u - 1) = 0 \qquad \text{factored form}$$
$$u - 9 = 0 \text{ or } u - 1 = 0 \qquad \text{zero product property}$$
$$x^2 - 9 = 0 \text{ or } x^2 - 1 = 0 \qquad \text{substitute } x^2 \text{ for } u$$
$$(x + 3)(x - 3) = 0 \text{ or } (x + 1)(x - 1) = 0 \qquad \text{factor}$$
$$x = -3 \text{ or } x = 3 \text{ or } x = -1 \text{ or } x = 1 \qquad \text{zero product property}$$

The solutions are $x = -3$, $x = 3$, $x = -1$, and $x = 1$.

Now try Exercises 93 through 100 ▶

☑ **E. You've just seen how we can solve polynomial equations by factoring**

In Examples 12 and 13, we were able to solve higher degree polynomial equations by "breaking them down" into linear and quadratic forms. This basic idea can be applied to other kinds of equations as well.

A.4 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section, if necessary.

1. To factor an expression means to rewrite the expression as an equivalent _____.
2. If a polynomial will not factor, it is said to be a(n) _____ polynomial.
3. The difference of two perfect squares always factors into the product of a(n) _____ and its _____.
4. The expression $x^2 + 6x + 9$ is said to be a(n) _____ _____ trinomial, since its factored form is a perfect (binomial) square.
5. Discuss/Explain why $4x^2 - 36 = (2x - 6)(2x + 6)$ is not written in completely factored form, then rewrite it so it is factored completely.
6. Discuss/Explain why $a^3 + b^3$ is factorable, but $a^2 + b^2$ is not. Demonstrate by writing $x^3 + 64$ in factored form, and by exhausting all possibilities for $x^2 + 64$ to show it is prime.

▶ DEVELOPING YOUR SKILLS

Factor each expression using the method indicated.

Greatest Common Factor

7. **a.** $-17x^2 + 51$ **b.** $21b^3 - 14b^2 + 56b$
c. $-3a^4 + 9a^2 - 6a^3$

8. **a.** $-13n^2 - 52$ **b.** $9p^2 + 27p^3 - 18p^4$
c. $-6g^5 + 12g^4 - 9g^3$

Common Binomial Factor

9. **a.** $2a(a + 2) + 3(a + 2)$
b. $(b^2 + 3)3b + (b^2 + 3)2$
c. $4m(n + 7) - 11(n + 7)$

10. **a.** $5x(x - 3) - 2(x - 3)$
b. $(v - 5)2v + (v - 5)3$
c. $3p(q^2 + 5) + 7(q^2 + 5)$

Grouping

11. **a.** $9q^3 + 6q^2 + 15q + 10$
b. $h^5 - 12h^4 - 3h + 36$
c. $k^5 - 7k^3 - 5k^2 + 35$

12. **a.** $6h^3 - 9h^2 - 2h + 3$
b. $4k^3 + 6k^2 - 2k - 3$
c. $3x^2 - xy - 6x + 2y$

Trinomial Factoring where $|a| = 1$

13. **a.** $-p^2 + 5p + 14$ **b.** $q^2 - 4q + 12$
c. $n^2 + 20 - 9n$

14. **a.** $-m^2 + 13m - 42$ **b.** $x^2 + 12 + 13x$
c. $v^2 + 10v + 15$

Trinomial Factoring where $a \neq 1$

15. **a.** $3p^2 - 13p - 10$ **b.** $4q^2 + 7q - 15$
c. $10u^2 - 19u - 15$

16. **a.** $6v^2 + v - 35$ **b.** $20x^2 + 53x + 18$
c. $15z^2 - 22z - 48$

Difference of Perfect Squares

17. **a.** $4s^2 - 25$ **b.** $9x^2 - 49$
c. $50x^2 - 72$ **d.** $121h^2 - 144$
e. $b^2 - 5$

18. **a.** $9v^2 - \frac{1}{25}$ **b.** $25w^2 - \frac{1}{49}$
c. $v^4 - 1$ **d.** $16z^4 - 81$
e. $x^2 - 17$

Perfect Square Trinomials

19. **a.** $a^2 - 6a + 9$ **b.** $b^2 + 10b + 25$
c. $4m^2 - 20m + 25$ **d.** $9n^2 - 42n + 49$

20. **a.** $x^2 + 12x + 36$ **b.** $z^2 - 18z + 81$
c. $25p^2 - 60p + 36$ **d.** $16q^2 + 40q + 25$

Sum/Difference of Perfect Cubes

21. **a.** $8p^3 - 27$ **b.** $m^3 + \frac{1}{8}$
c. $g^3 - 0.027$ **d.** $-2t^4 + 54t$

22. **a.** $27q^3 - 125$ **b.** $n^3 + \frac{8}{27}$
c. $b^3 - 0.125$ **d.** $3r^4 - 24r$

***u*-Substitution**

23. **a.** $x^4 - 10x^2 + 9$ **b.** $x^4 + 13x^2 + 36$
c. $x^6 - 7x^3 - 8$

24. **a.** $x^6 - 26x^3 - 27$
b. $3(n + 5)^2 + 2(n + 5) - 21$
c. $2(z + 3)^2 + 3(z + 3) - 54$

25. Completely factor each of the following (recall that "1" is its own perfect square and perfect cube).
a. $n^2 - 1$ **b.** $n^3 - 1$
c. $n^3 + 1$ **d.** $28x^3 - 7x$

26. Carefully factor each of the following trinomials, if possible. Note differences and similarities.
a. $x^2 - x + 6$ **b.** $x^2 + x - 6$
c. $x^2 + x + 6$ **d.** $x^2 - x - 6$
e. $x^2 - 5x + 6$ **f.** $x^2 + 5x - 6$

Factor each expression completely, if possible. Rewrite the expression in standard form (factor out "−1" if needed) and factor out the GCF if one exists. If you believe the expression will not factor, write "prime."

27. $a^2 + 7a + 10$ **28.** $b^2 + 9b + 20$
29. $2x^2 - 24x + 40$ **30.** $10z^2 - 140z + 450$
31. $64 - 9m^2$ **32.** $25 - 16n^2$
33. $-9r + r^2 + 18$ **34.** $28 + s^2 - 11s$
35. $2h^2 + 7h + 6$ **36.** $3k^2 + 10k + 8$
37. $9k^2 - 24k + 16$ **38.** $4p^2 - 20p + 25$
39. $-6x^3 + 39x^2 - 63x$ **40.** $-28z^3 + 16z^2 + 80z$
41. $12m^2 - 40m + 4m^3$ **42.** $-30n - 4n^2 + 2n^3$
43. $a^2 - 7a - 60$ **44.** $b^2 - 9b - 36$
45. $8x^3 - 125$ **46.** $27r^3 + 64$

47. $m^2 + 9m - 24$ **48.** $n^2 - 14n - 36$

49. $x^3 - 5x^2 - 9x + 45$ **50.** $x^3 + 3x^2 - 4x - 12$

51. Match each expression with the description that fits *best.*

____ **a.** prime polynomial
____ **b.** standard trinomial $a = 1$
____ **c.** perfect square trinomial
____ **d.** difference of cubes
____ **e.** binomial square
____ **f.** sum of cubes
____ **g.** binomial conjugates
____ **h.** difference of squares
____ **i.** standard trinomial $a \neq 1$

A. $x^3 + 27$ **B.** $(x + 3)^2$
C. $x^2 - 10x + 25$ **D.** $x^2 - 144$
E. $x^2 - 3x - 10$ **F.** $8s^3 - 125t^3$
G. $2x^2 - x - 3$ **H.** $x^2 + 9$
I. $(x - 7)$ and $(x + 7)$

52. Match each polynomial to its factored form. Two of them are prime.

____ **a.** $4x^2 - 9$
____ **b.** $4x^2 - 28x + 49$
____ **c.** $x^3 - 125$
____ **d.** $8x^3 + 27$
____ **e.** $x^2 - 3x - 10$
____ **f.** $x^2 + 3x + 10$
____ **g.** $2x^2 - x - 3$
____ **h.** $2x^2 + x - 3$
____ **i.** $x^2 + 25$

A. $(x - 5)(x^2 + 5x + 25)$
B. $(2x - 3)(x + 1)$ **C.** $(2x + 3)(2x - 3)$
D. $(2x - 7)^2$ **E.** prime trinomial
F. prime binomial **G.** $(2x + 3)(x - 1)$
H. $(2x + 3)(4x^2 - 6x + 9)$
I. $(x - 5)(x + 2)$

Determine whether each equation is quadratic. If so, identify the coefficients *a*, *b*, and *c*. If not, discuss why.

53. $2x - 15 - x^2 = 0$ **54.** $21 + x^2 - 4x = 0$

55. $\frac{2}{3}x - 7 = 0$ **56.** $12 - 4x = 9$

57. $\frac{1}{4}x^2 = 6x$ **58.** $0.5x = 0.25x^2$

59. $2x^2 + 7 = 0$ **60.** $5 = -4x^2$

61. $-3x^2 + 9x - 5 + 2x^3 = 0$

62. $z^2 - 6z + 9 - z^3 = 0$

63. $(x - 1)^2 + (x - 1) + 4 = 9$

64. $(x + 5)^2 - (x + 5) + 4 = 17$

Solve using the zero factor property. Be sure each equation is in standard form and factor out any common factors before attempting to solve. Check all answers in the original equation.

65. $x^2 - 15 = 2x$ **66.** $z^2 - 10z = -21$

67. $m^2 = 8m - 16$ **68.** $-10n = n^2 + 25$

69. $5p^2 - 10p = 0$ **70.** $6q^2 - 18q = 0$

71. $-14h^2 = 7h$ **72.** $9w = -6w^2$

73. $a^2 - 17 = -8$ **74.** $b^2 + 8 = 12$

75. $g^2 + 18g + 70 = -11$

76. $h^2 + 14h - 2 = -51$

77. $m^3 + 5m^2 - 9m - 45 = 0$

78. $n^3 - 3n^2 - 4n + 12 = 0$

79. $(c - 12)c - 15 = 30$

80. $(d - 10)d + 10 = -6$

81. $9 + (r - 5)r = 33$

82. $7 + (s - 4)s = 28$

83. $(t + 4)(t + 7) = 54$

84. $(g + 17)(g - 2) = 20$

85. $2x^2 - 4x - 30 = 0$

86. $-3z^2 + 12z + 36 = 0$

87. $2w^2 - 5w = 3$

88. $-3v^2 = -v - 2$

89. $22x = x^3 - 9x^2$

90. $x^3 = 13x^2 - 42x$

91. $3x^3 = -7x^2 + 6x$

92. $7x^2 + 15x = 2x^3$

93. $p^3 + 7p^2 - 63 = 9p$

94. $q^3 - 4q + 24 = 6q^2$

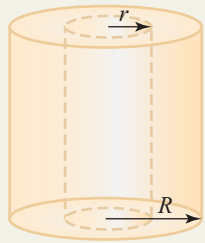
95. $x^3 - 25x = 2x^2 - 50$

96. $3c^2 + c = c^3 + 3$

97. $x^4 - 29x^2 + 100 = 0$

98. $z^4 - 20z^2 + 64 = 0$

99. $(b^2 - 3b)^2 - 14(b^2 - 3b) + 40 = 0$



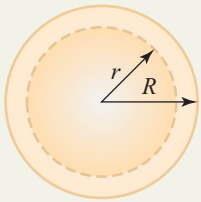
100. $(d^2 - d)^2 - 8(d^2 - d) + 12 = 0$

▶ WORKING WITH FORMULAS

101. Surface area of a cylinder: $2\pi r^2 + 2\pi rh$

The surface area of a cylinder is given by the formula shown, where h is the height of the cylinder and r is the radius. Factor out the GCF and use the result to find the surface area of a cylinder where $r = 35$ cm and $h = 65$ cm. Answer in exact form and in approximate form rounded to the nearest whole number.

102. Volume of a cylindrical shell: $\pi R^2h - \pi r^2h$



The volume of a cylindrical shell (a larger cylinder with a smaller cylinder removed) can be found using the formula shown, where R is the radius of the larger cylinder and r is the radius of the smaller. Factor the expression completely and use the result to find the volume of a shell where $R = 9$ cm, $r = 3$ cm, and $h = 10$ cm. Answer in exact form and in approximate form rounded to the nearest whole number.

▶ APPLICATIONS

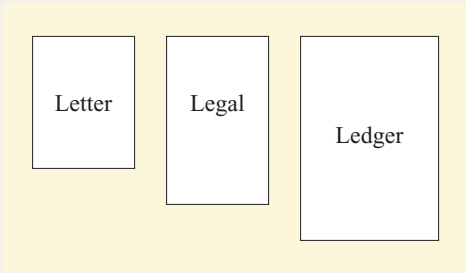
In many cases, factoring an expression can make it easier to evaluate as in the following applications.

103. Conical shells: The volume of a conical shell (like the shell of an ice cream cone) is given by the formula $V = \frac{1}{3}\pi R^2h - \frac{1}{3}\pi r^2h$, where R is the outer radius and r is the inner radius of the cone. Write the formula in completely factored form, then find the volume of a shell when $R = 5.1$ cm, $r = 4.9$ cm, and $h = 9$ cm. Answer in exact form and in approximate form rounded to the nearest tenth.

104. Spherical shells: The volume of a spherical shell (like the outer shell of a cherry cordial) is given by the formula $V = \frac{4}{3}\pi R^3 - \frac{4}{3}\pi r^3$, where R is the outer radius and r is the inner radius of the shell. Write the right-hand side in completely factored form, then find the volume of a shell where $R = 1.8$ cm and $r = 1.5$ cm. Answer in exact form and in approximate form rounded to the nearest tenth.

105. Volume of a box: The volume of a rectangular box x inches in height is given by the relationship $V = x^3 + 8x^2 + 15x$. Factor the right-hand side to determine: (a) The number of inches that the width exceeds the height, (b) the number of inches the length exceeds the height, and (c) the volume given the height is 2 ft.

106. Shipping textbooks: A publisher ships paperback books stacked x copies high in a box. The total number of books shipped per box is given by the relationship $B = x^3 - 13x^2 + 42x$. Factor the right-hand side to determine (a) how many more or fewer books fit the width of the box (than the height), (b) how many more or fewer books fit the length of the box (than the height), and (c) the number of books shipped per box if they are stacked 10 high in the box.



107. Space-Time relationships: Due to the work of Albert Einstein and other physicists who labored on space-time relationships, it is known that the faster an object moves the shorter it appears to become. This phenomenon is modeled by the **Lorentz transformation** $L = L_0\sqrt{1 - \left(\frac{v}{c}\right)^2}$, where L_0 is the length of the object at rest, L is the relative length when the object is moving at velocity v, and c is the speed of light. Factor the radicand and use the result to determine the relative length of a 12-in. ruler if it is shot past a stationary observer at 0.75 times the speed of light ($v = 0.75c$).

108. Tubular fluid flow: As a fluid flows through a tube, it is flowing faster at the center of the tube than at the sides, where the tube exerts a backward drag. **Poiseuille's law** gives the velocity of the flow at any point of the cross section: $v = \frac{G}{4\eta}(R^2 - r^2)$, where R is the inner radius of the tube, r is the distance from the center of the tube to a point in the flow, G represents what is called the pressure gradient, and η is a constant that depends on the viscosity of the fluid. Factor the right-hand side and find v given $R = 0.5$ cm, $r = 0.3$ cm, $G = 15$, and $\eta = 0.25$.

Solve by factoring.

109. Envelope sizes: Large mailing envelopes often come in standard sizes, with 5- by 7-in. and 9- by 12-in. envelopes being the most common. The next larger size envelope has an area of 143 in^2, with a length that is 2 in. longer than the width. What are the dimensions of the larger envelope?

110. Paper sizes: Letter size paper is 8.5 in. by 11 in. Legal size paper is $8\frac{1}{2}$ in. by 14 in. The next larger (common) size of paper has an area of 187 in^2, with a length that is 6 in. longer than the width. What are the dimensions of the Ledger size paper?

▶ EXTENDING THE CONCEPT

111. Factor out a constant that leaves integer coefficients for each term:

a. $\frac{1}{2}x^4 + \frac{1}{8}x^3 - \frac{3}{4}x^2 + 4$

b. $\frac{2}{3}b^5 - \frac{1}{6}b^3 + \frac{4}{9}b^2 - 1$

112. If $x = 2$ is substituted into $2x^3 + hx + 8$, the result is zero. What is the value of h?

113. Factor the expression: $192x^3 - 164x^2 - 270x$.

114. As an alternative to evaluating polynomials by direct substitution, **nested factoring** can be used. The method has the advantage of using only products and sums—no powers. For $P = x^3 + 3x^2 + 1x + 5$, we begin by grouping all variable terms and factoring x: $P = [x^3 + 3x^2 + 1x] + 5 = x[x^2 + 3x + 1] + 5$. Then we group the inner terms with x and factor again: $P = x[x^2 + 3x + 1] + 5 = x[x(x + 3) + 1] + 5$. The expression can now be evaluated using any input and the order of operations. If $x = 2$, we quickly find that $P = 27$. Use this method to evaluate $H = x^3 + 2x^2 + 5x - 9$ for $x = -3$.

Factor each expression completely.

115. $x^4 - 81$

116. $16n^4 - 1$

117. $p^6 - 1$

118. $m^6 - 64$

119. $q^4 - 28q^2 + 75$

120. $a^4 - 18a^2 + 32$

A.5 Rational Expressions and Equations

LEARNING OBJECTIVES

In Section A.5 you will review how to:

- ❑ **A.** Write a rational expression in simplest form
- ❑ **B.** Multiply and divide rational expressions
- ❑ **C.** Add and subtract rational expressions
- ❑ **D.** Simplify compound fractions
- ❑ **E.** Solve rational equations

A rational number is one that can be written as the quotient of two integers. Similarly, a *rational expression* is one that can be written as the quotient of two polynomials. We can apply the skills developed in a study of fractions (how to reduce, add, subtract, multiply, and divide) to **rational expressions,** sometimes called **algebraic fractions.**

A. Writing a Rational Expression in Simplest Form

A rational expression is in **simplest form** when the numerator and denominator have no common factors (other than 1). After factoring the numerator and denominator, we apply the **fundamental property of rational expressions.**

Fundamental Property of Rational Expressions

If P, Q, and R are polynomials, with $Q, R \neq 0$,

$$(1)\ \frac{P \cdot R}{Q \cdot R} = \frac{P}{Q} \quad \text{and} \quad (2)\ \frac{P}{Q} = \frac{P \cdot R}{Q \cdot R}$$

In words, the property says (1) a rational expression can be simplified by canceling common factors in the numerator and denominator, and (2) an equivalent expression can be formed by multiplying numerator and denominator by the same nonzero polynomial.

EXAMPLE 1 ▶ **Simplifying a Rational Expression**

Write the expression in simplest form: $\dfrac{x^2 - 1}{x^2 - 3x + 2}$.

Solution ▶

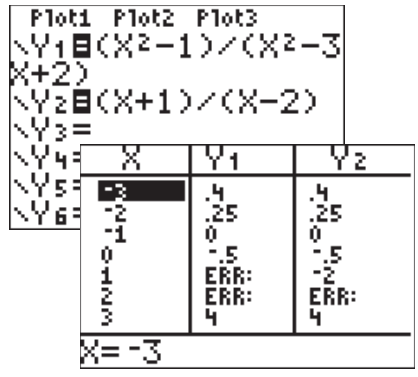
$$\frac{x^2 - 1}{x^2 - 3x + 2} = \frac{(x - 1)(x + 1)}{(x - 1)(x - 2)} \quad \text{factor numerator and denominator}$$

$$= \frac{\overset{1}{\cancel{(x - 1)}}(x + 1)}{\cancel{(x - 1)}(x - 2)} \quad \text{common factors reduce to 1}$$

$$= \frac{x + 1}{x - 2} \quad \text{simplest form}$$

Now try Exercises 7 through 10 ▶

WORTHY OF NOTE



If we view a and b as two points on the number line, we note that they are the same distance apart, regardless of the order they are subtracted. This tells us the numerator and denominator will have the same absolute value but be opposite in sign, giving a value of -1 (check using a few test values).

When simplifying rational expressions, we sometimes encounter expressions of the form $\dfrac{a - b}{b - a}$. If we factor -1 from the numerator, we see that $\dfrac{a - b}{b - a} = \dfrac{-1(\cancel{b - a})}{\cancel{b - a}} = -1$.

CAUTION ▶ When reducing rational numbers or expressions, only common *factors* can be reduced. It is incorrect to reduce (or divide out) individual terms: $\dfrac{-6 + 4\sqrt{3}}{2} \neq -3 + 4\sqrt{3}$, and $\dfrac{x + 1}{x + 2} \neq \dfrac{1}{2}$ (except for $x = 0$)

Note that after simplifying an expression, we are actually saying the resulting (simpler) expression is equivalent to the original expression for all values where both are defined. The first expression is not defined when $x = 1$ or $x = 2$, the second when $x = 2$ (since the denominators would be zero). The calculator screens shown in Figure A.5 help to illustrate this fact, and it appears that we would very much prefer to be working with the simpler expression!

Figure A.5

EXAMPLE 2 ▶ **Simplifying a Rational Expression**

Write the expression in simplest form: $\dfrac{6-2x}{x^2-9}$.

Solution ▶

$$\frac{6-2x}{x^2-9} = \frac{2(3-x)}{(x-3)(x+3)}$$ factor numerator and denominator

$$= \frac{(2)(-1)}{x+3}$$ reduce: $\frac{3-x}{x-3} = -1$

$$= \frac{-2}{x+3}$$ simplest form

A. You've just seen how we can write a rational expression in simplest form

Now try Exercises 11 through 16 ▶

B. Multiplication and Division of Rational Expressions

Operations on rational expressions use the factoring skills reviewed earlier, along with much of what we know about rational numbers.

Multiplying Rational Expressions

Given that P, Q, R, and S are polynomials with $Q, S \neq 0$,

$$\frac{P}{Q} \cdot \frac{R}{S} = \frac{PR}{QS}$$

1. Factor all numerators and denominators completely.
2. Reduce common factors.
3. Multiply numerator × numerator and denominator × denominator.

EXAMPLE 3 ▶ **Multiplying Rational Expressions**

Compute the product: $\dfrac{2a+2}{3a-3a^2} \cdot \dfrac{3a^2-a-2}{9a^2-4}$.

Solution ▶

$$\frac{2a+2}{3a-3a^2} \cdot \frac{3a^2-a-2}{9a^2-4} = \frac{2(a+1)}{3a(1-a)} \cdot \frac{(3a+2)(a-1)}{(3a-2)(3a+2)}$$ factor

$$= \frac{2(a+1)}{3a\cancel{(1-a)}} \cdot \frac{\overset{1}{\cancel{(3a+2)}}\overset{(-1)}{\cancel{(a-1)}}}{(3a-2)\cancel{(3a+2)}}$$ reduce: $\frac{a-1}{1-a} = -1$

$$= \frac{-2(a+1)}{3a(3a-2)}$$ simplest form

Now try Exercises 17 through 20 ▶

To divide fractions, we multiply the first expression by the *reciprocal of the second* (we sometimes say, "invert the divisor and multiply"). The quotient of two rational expressions is computed in the same way.

Dividing Rational Expressions

Given that P, Q, R, and S are polynomials with $Q, R, S \neq 0$,

$$\frac{P}{Q} \div \frac{R}{S} = \frac{P}{Q} \cdot \frac{S}{R} = \frac{PS}{QR}$$

Invert the divisor and multiply.

EXAMPLE 4 ▶ **Dividing Rational Expressions**

Compute the quotient $\dfrac{4m^3 - 12m^2 + 9m}{m^2 - 49} \div \dfrac{10m^2 - 15m}{m^2 + 4m - 21}$.

Solution ▶

$$\frac{4m^3 - 12m^2 + 9m}{m^2 - 49} \div \frac{10m^2 - 15m}{m^2 + 4m - 21}$$

$$= \frac{4m^3 - 12m^2 + 9m}{m^2 - 49} \cdot \frac{m^2 + 4m - 21}{10m^2 - 15m} \quad \text{invert and multiply}$$

$$= \frac{m(4m^2 - 12m + 9)}{(m + 7)(m - 7)} \cdot \frac{(m + 7)(m - 3)}{5m(2m - 3)} \quad \text{factor}$$

$$= \frac{\overset{1}{\cancel{m}}(2m - 3)\cancel{(2m - 3)}}{\cancel{(m + 7)}(m - 7)} \cdot \frac{\overset{1}{\cancel{(m + 7)}}(m - 3)}{5\cancel{m}\cancel{(2m - 3)}} \quad \text{factor and reduce}$$

$$= \frac{(2m - 3)(m - 3)}{5(m - 7)} \quad \text{lowest terms}$$

Note that we sometimes refer to simplest form as *lowest terms*.

Now try Exercises 21 through 42 ▶

CAUTION ▶ For products like $\dfrac{(w + 7)(w - 7)}{(w - 7)(w - 2)} \cdot \dfrac{w - 2}{w + 7}$, it is a common mistake to think that all factors "cancel," leaving an answer of zero. Actually, all factors *reduce to 1,* and the result is a value of 1 for all inputs where the product is defined.

$$\frac{\overset{1}{\cancel{(w + 7)}}\overset{1}{\cancel{(w - 7)}}}{\cancel{(w - 7)}\cancel{(w - 2)}} \cdot \frac{\overset{1}{\cancel{w - 2}}}{\cancel{w + 7}} = 1$$

☑ **B.** You've just seen how we can multiply and divide rational expressions

C. Addition and Subtraction of Rational Expressions

Recall that the addition and subtraction of *fractions* requires finding the lowest common denominator (LCD) and building equivalent fractions. The sum or difference of the numerators is then placed over this denominator. The procedure for the addition and subtraction of *rational expressions* is very much the same. Note that the LCD can also be described as the least common multiple (LCM) of all denominators.

Addition and Subtraction of Rational Expressions

1. Find the LCD of all rational expressions.
2. Build equivalent expressions using the LCD.
3. Add or subtract numerators as indicated.
4. Write the result in lowest terms.

EXAMPLE 5 ▶ **Adding and Subtracting Rational Expressions**

Compute as indicated:

a. $\dfrac{7}{10x} + \dfrac{3}{25x^2}$ **b.** $\dfrac{10x}{x^2 - 9} - \dfrac{5}{x - 3}$

Solution ▶

a. The LCM for $10x$ and $25x^2$ is $50x^2$. find the LCD

$$\frac{7}{10x} + \frac{3}{25x^2} = \frac{7}{10x} \cdot \frac{5x}{5x} + \frac{3}{25x^2} \cdot \frac{2}{2}$$ write equivalent expressions

$$= \frac{35x}{50x^2} + \frac{6}{50x^2}$$ simplify

$$= \frac{35x + 6}{50x^2}$$ add the numerators and write the result over the LCD

The result is in simplest form.

b. The LCM for $x^2 - 9$ and $x - 3$ is $(x - 3)(x + 3)$. find the LCD

$$\frac{10x}{x^2 - 9} - \frac{5}{x - 3} = \frac{10x}{(x - 3)(x + 3)} - \frac{5}{x - 3} \cdot \frac{x + 3}{x + 3}$$ write equivalent expressions

$$= \frac{10x - 5(x + 3)}{(x - 3)(x + 3)}$$ subtract numerators, write the result over the LCD

$$= \frac{10x - 5x - 15}{(x - 3)(x + 3)}$$ distribute

$$= \frac{5x - 15}{(x - 3)(x + 3)}$$ combine like terms

$$= \frac{5\cancel{(x - 3)}^{1}}{\cancel{(x - 3)}(x + 3)} = \frac{5}{x + 3}$$ factor and reduce

Now try Exercises 43 through 48 ▶

EXAMPLE 6 ▶ **Adding and Subtracting Rational Expressions**

Perform the operations indicated:

a. $\dfrac{5}{n + 2} - \dfrac{n - 3}{n^2 - 4}$ **b.** $\dfrac{b^2}{4a^2} - \dfrac{c}{a}$

Solution ▶

a. The LCM for $n + 2$ and $n^2 - 4$ is $(n + 2)(n - 2)$.

$$\frac{5}{n + 2} - \frac{n - 3}{n^2 - 4} = \frac{5}{(n + 2)} \cdot \frac{n - 2}{n - 2} - \frac{n - 3}{(n + 2)(n - 2)}$$ write equivalent expressions

$$= \frac{5(n - 2) - (n - 3)}{(n + 2)(n - 2)}$$ subtract numerators, write the result over the LCD

$$= \frac{5n - 10 - n + 3}{(n + 2)(n - 2)}$$ distribute

$$= \frac{4n - 7}{(n + 2)(n - 2)}$$ result

b. The LCM for a and $4a^2$ is $4a^2$: $\dfrac{b^2}{4a^2} - \dfrac{c}{a} = \dfrac{b^2}{4a^2} - \dfrac{c}{a} \cdot \dfrac{4a}{4a}$ write equivalent expressions

$= \dfrac{b^2}{4a^2} - \dfrac{4ac}{4a^2}$ simplify

$= \dfrac{b^2 - 4ac}{4a^2}$ subtract numerators, write the result over the LCD

Now try Exercises 49 through 64 ▶

CAUTION ▶ When the second term in a subtraction has a binomial numerator as in Example 6a, be sure the subtraction *is applied to both terms*. It is a common error to write $\dfrac{5(n-2)}{(n+2)(n-2)} - \dfrac{n-3}{(n+2)(n-2)} = \dfrac{5n-10-n-3}{(n+2)(n-2)}$ X in which the subtraction is applied to the first term only. This is incorrect!

C. You've just seen how we can add and subtract rational expressions

D. Simplifying Compound Fractions

Rational expressions whose numerator or denominator contain a fraction are called **compound fractions.** The expression $\dfrac{\frac{2}{3m} - \frac{3}{2}}{\frac{3}{4m} - \frac{1}{3m^2}}$ is a compound fraction with a numerator of $\dfrac{2}{3m} - \dfrac{3}{2}$ and a denominator of $\dfrac{3}{4m} - \dfrac{1}{3m^2}$. The two methods commonly used to simplify compound fractions are summarized in the following boxes.

Simplifying Compound Fractions (Method I)

1. Add/subtract fractions in the numerator, writing them as a single expression.
2. Add/subtract fractions in the denominator, also writing them as a single expression.
3. Multiply the numerator by the reciprocal of the denominator and simplify if possible.

Simplifying Compound Fractions (Method II)

1. Find the LCD of all fractions in the numerator and denominator.
2. Multiply the numerator and denominator by this LCD and simplify.
3. Simplify further if possible.

Method II is illustrated in Example 7.

EXAMPLE 7 ▶ **Simplifying a Compound Fraction**

Simplify the compound fraction:

$$\frac{\frac{2}{3m} - \frac{3}{2}}{\frac{3}{4m} - \frac{1}{3m^2}}$$

Solution ▶ The LCD for all fractions is $12m^2$.

$$\frac{\frac{2}{3m}-\frac{3}{2}}{\frac{3}{4m}-\frac{1}{3m^2}} = \frac{\left(\frac{2}{3m}-\frac{3}{2}\right)\left(\frac{12m^2}{1}\right)}{\left(\frac{3}{4m}-\frac{1}{3m^2}\right)\left(\frac{12m^2}{1}\right)}$$

multiply numerator and denominator by $12m^2 = \frac{12m^2}{1}$

$$= \frac{\left(\frac{2}{3m}\right)\left(\frac{12m^2}{1}\right)-\left(\frac{3}{2}\right)\left(\frac{12m^2}{1}\right)}{\left(\frac{3}{4m}\right)\left(\frac{12m^2}{1}\right)-\left(\frac{1}{3m^2}\right)\left(\frac{12m^2}{1}\right)}$$

distribute

$$= \frac{8m-18m^2}{9m-4}$$

simplify

$$= \frac{2m(4-9m)}{9m-4} = -2m$$

factor and write in lowest terms

D. You've just seen how we can simplify compound fractions

Now try Exercises 65 through 74 ▶

E. Solving Rational Equations

In Appendix A.3 we solved linear equations using basic properties of equality. If any equation contained fractional terms, we "cleared the fractions" using the least common denominator (LCD). We can also use this idea to solve **rational equations,** or equations that contain rational *expressions*.

Solving Rational Equations

1. Identify and exclude any values that cause a zero denominator.
2. Multiply both sides by the LCD and simplify (this will eliminate all denominators).
3. Solve the resulting equation.
4. Check all solutions in the original equation.

EXAMPLE 8 ▶ **Solving a Rational Equation**

Solve for m: $\frac{2}{m}-\frac{1}{m-1}=\frac{4}{m^2-m}$.

Solution ▶ Since $m^2-m=m(m-1)$, the LCD is $m(m-1)$, where $m\neq 0$ and $m\neq 1$.

$$m(m-1)\left(\frac{2}{m}-\frac{1}{m-1}\right) = m(m-1)\left[\frac{4}{m(m-1)}\right]$$

multiply by LCD

$$\frac{m(m-1)}{1}\left(\frac{2}{m}\right)-\frac{m(m-1)}{1}\left(\frac{1}{m-1}\right) = \frac{m(m-1)}{1}\left(\frac{4}{m(m-1)}\right)$$

distribute and simplify

$$2(m-1)-m=4$$

denominators are eliminated

$$2m-2-m=4$$

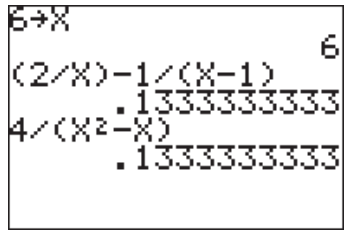
distribute

$$m=6$$

solve for m

Checking by substitution we have:

$$\frac{2}{m} - \frac{1}{m-1} = \frac{4}{m^2 - m} \quad \text{original equation}$$



$$\frac{2}{(6)} - \frac{1}{(6)-1} = \frac{4}{(6)^2 - (6)} \quad \text{substitute 6 for } m$$

$$\frac{1}{3} - \frac{1}{5} = \frac{4}{30} \quad \text{simplify}$$

$$\frac{5}{15} - \frac{3}{15} = \frac{2}{15} \quad \text{common denominator}$$

$$\frac{2}{15} = \frac{2}{15} \checkmark \quad \text{result}$$

A calculator check is shown in the figure.

Now try Exercises 75 through 80 ▶

Multiplying both sides of an equation by a variable sometimes introduces a solution that satisfies the *resulting equation,* but not the original equation—the one we're trying to solve. Such "solutions" are called **extraneous roots** and illustrate the need to check all apparent solutions in the original equation. In the case of rational equations, we are particularly aware that any value that causes a zero denominator is outside the domain and cannot be a solution.

EXAMPLE 9 ▶ Solving a Rational Equation

Solve: $x + \frac{12}{x-3} = 1 + \frac{4x}{x-3}$.

Solution ▶ The LCD is $x - 3$, where $x \neq 3$.

$$(x-3)\left(x + \frac{12}{x-3}\right) = (x-3)\left(1 + \frac{4x}{x-3}\right) \quad \text{multiply both sides by LCD}$$

$$(x-3)x + \left(\frac{\cancel{x-3}}{1}\right)\left(\frac{12}{\cancel{x-3}}\right) = (x-3)(1) + \left(\frac{\cancel{x-3}}{1}\right)\left(\frac{4x}{\cancel{x-3}}\right) \quad \text{distribute and simplify}$$

$$x^2 - 3x + 12 = x - 3 + 4x \quad \text{denominators are eliminated}$$

$$x^2 - 8x + 15 = 0 \quad \text{set equation equal to zero}$$

$$(x-3)(x-5) = 0 \quad \text{factor}$$

$$x = 3 \quad \text{or} \quad x = 5 \quad \text{zero factor property}$$

Checking shows $x = 3$ is an extraneous root, and $x = 5$ is the only valid solution.

☑ **E.** You've just seen how we can solve rational equations

Now try Exercises 81 through 86 ▶

A.5 EXERCISES

▶ CONCEPTS AND VOCABULARY

Fill in each blank with the appropriate word or phrase. Carefully reread the section, if necessary.

1. In simplest form, $(a - b)/(a - b)$ is equal to _____, while $(a - b)/(b - a)$ is equal to _____.
2. A rational expression is in _____ _____ when the numerator and denominator have no common factors, other than _____.
3. As with numeric fractions, algebraic fractions require a _____ _____ for addition and subtraction.
4. Since $x^2 + 9$ is prime, the expression $(x^2 + 9)/(x + 3)$ is already written in _____ _____.

State T or F and discuss/explain your response.

5. $\dfrac{x}{x+3} - \dfrac{x+1}{x+3} = \dfrac{1}{x+3}$

6. $\dfrac{\cancel{(x+3)}\cancel{(x-2)}}{\cancel{(x-2)}\cancel{(x+3)}} = 0$

▶ DEVELOPING YOUR SKILLS

Reduce to lowest terms.

7. **a.** $\dfrac{a-7}{-3a+21}$ **b.** $\dfrac{2x+6}{4x^2-8x}$

8. **a.** $\dfrac{x-4}{-7x+28}$ **b.** $\dfrac{3x-18}{6x^2-12x}$

9. **a.** $\dfrac{x^2-5x-14}{x^2+6x-7}$ **b.** $\dfrac{a^2+3a-28}{a^2-49}$

10. **a.** $\dfrac{r^2+3r-10}{r^2+r-6}$ **b.** $\dfrac{m^2+3m-4}{m^2-4m}$

11. **a.** $\dfrac{x-7}{7-x}$ **b.** $\dfrac{5-x}{x-5}$

12. **a.** $\dfrac{v^2-3v-28}{49-v^2}$ **b.** $\dfrac{u^2-10u+25}{25-u^2}$

36. $\dfrac{x^2 - 0.25}{x^2 + 0.1x - 0.2} \div \dfrac{x^2 - 0.8x + 0.15}{x^2 - 0.16}$

37. $\dfrac{n^2 - \frac{4}{9}}{n^2 - \frac{13}{15}n + \frac{2}{15}} \div \dfrac{n^2 + \frac{4}{3}n + \frac{4}{9}}{n^2 - \frac{1}{25}}$

38. $\dfrac{q^2 - \frac{9}{25}}{q^2 - \frac{1}{10}q - \frac{3}{10}} \div \dfrac{q^2 + \frac{17}{20}q + \frac{3}{20}}{q^2 - \frac{1}{16}}$

39. $\dfrac{3a^3 - 24a^2 - 12a + 96}{a^2 - 11a + 24} \div \dfrac{6a^2 - 24}{3a^3 - 81}$

40. $\dfrac{p^3 + p^2 - 49p - 49}{p^2 + 6p - 7} \div \dfrac{p^2 + p + 1}{p^3 - 1}$

41. $\dfrac{4n^2 - 1}{12n^2 - 5n - 3} \cdot \dfrac{6n^2 + 5n + 1}{2n^2 + n} \cdot \dfrac{12n^2 - 17n + 6}{6n^2 - 7n + 2}$

42. $\left(\dfrac{4x^2 - 25}{x^2 - 11x + 30} \div \dfrac{2x^2 - x - 15}{x^2 - 9x + 18}\right) \cdot \dfrac{4x^2 + 25x - 21}{12x^2 - 5x - 3}$

Compute as indicated. Write answers in lowest terms [recall that $a - b = -1(b - a)$].

43. $\dfrac{3}{8x^2} + \dfrac{5}{2x}$

44. $\dfrac{15}{16y} - \dfrac{7}{2y^2}$

45. $\dfrac{7}{4x^2y^3} - \dfrac{1}{8xy^4}$

46. $\dfrac{3}{6a^3b} + \dfrac{5}{9ab^3}$

47. $\dfrac{4p}{p^2 - 36} - \dfrac{2}{p - 6}$

48. $\dfrac{3q}{q^2 - 49} - \dfrac{3}{2q - 14}$

49. $\dfrac{m}{m^2 - 16} + \dfrac{4}{4 - m}$

50. $\dfrac{2}{4 - p^2} + \dfrac{p}{p - 2}$

51. $\dfrac{2}{m - 7} - 5$

52. $\dfrac{4}{x - 1} - 9$

53. $\dfrac{y + 1}{y^2 + y - 30} - \dfrac{2}{y + 6}$

54. $\dfrac{4n}{n^2 - 5n} - \dfrac{3}{4n - 20}$

55. $\dfrac{1}{a + 4} + \dfrac{a}{a^2 - a - 20}$

56. $\dfrac{2x - 1}{x^2 + 3x - 4} - \dfrac{x - 5}{x^2 + 3x - 4}$

57. $\dfrac{3y - 4}{y^2 + 2y + 1} - \dfrac{2y - 5}{y^2 + 2y + 1}$

58. $\dfrac{-2}{3a + 12} - \dfrac{7}{a^2 + 4a}$

59. $\dfrac{2}{m^2 - 9} + \dfrac{m - 5}{m^2 + 6m + 9}$

60. $\dfrac{m + 2}{m^2 - 25} - \dfrac{m + 6}{m^2 - 10m + 25}$

61. $\dfrac{y + 2}{5y^2 + 11y + 2} + \dfrac{5}{y^2 + y - 6}$

62. $\dfrac{m - 4}{3m^2 - 11m + 6} + \dfrac{m}{2m^2 - m - 15}$

Write each term as a rational expression. Then compute the sum or difference indicated.

63. a. $p^{-2} - 5p^{-1}$ **b.** $x^{-2} + 2x^{-3}$

64. a. $3a^{-1} + (2a)^{-1}$ **b.** $2y^{-1} - (3y)^{-1}$

Simplify each compound fraction. Use either method.

65. $\dfrac{\frac{5}{a}-\frac{1}{4}}{\frac{25}{a^2}-\frac{1}{16}}$

66. $\dfrac{\frac{8}{x^3}-\frac{1}{27}}{\frac{2}{x}-\frac{1}{3}}$

67. $\dfrac{p+\frac{1}{p-2}}{1+\frac{1}{p-2}}$

68. $\dfrac{1+\frac{3}{y-6}}{y+\frac{9}{y-6}}$

69. $\dfrac{\frac{2}{3-x}+\frac{3}{x-3}}{\frac{4}{x}+\frac{5}{x-3}}$

70. $\dfrac{\frac{1}{y-5}-\frac{2}{5-y}}{\frac{3}{y-5}-\frac{2}{y}}$

71. $\dfrac{\frac{2}{y^2-y-20}}{\frac{3}{y+4}-\frac{4}{y-5}}$

72. $\dfrac{\frac{2}{x^2-3x-10}}{\frac{6}{x+2}-\frac{4}{x-5}}$

Rewrite each expression as a compound fraction. Then simplify using either method.

73. a. $\dfrac{1+3m^{-1}}{1-3m^{-1}}$ **b.** $\dfrac{1+2x^{-2}}{1-2x^{-2}}$

74. a. $\dfrac{4-9a^{-2}}{3a^{-2}}$ **b.** $\dfrac{3+2n^{-1}}{5n^{-2}}$

Solve each equation. Identify any extraneous roots.

75. $\dfrac{2}{x}+\dfrac{1}{x+1}=\dfrac{5}{x^2+x}$

76. $\dfrac{3}{m+3}-\dfrac{5}{m^2+3m}=\dfrac{1}{m}$

77. $\dfrac{21}{a+2}=\dfrac{3}{a-1}$

78. $\dfrac{4}{2y-3}=\dfrac{7}{3y-5}$

79. $\dfrac{1}{3y}-\dfrac{1}{4y}=\dfrac{1}{y^2}$

80. $\dfrac{3}{5x}-\dfrac{1}{2x}=\dfrac{1}{x^2}$

81. $x+\dfrac{14}{x-7}=1+\dfrac{2x}{x-7}$

82. $\dfrac{10}{x-5}+x=1+\dfrac{2x}{x-5}$

83. $\dfrac{6}{n+3}+\dfrac{20}{n^2+n-6}=\dfrac{5}{n-2}$

84. $\dfrac{7}{p+2}-\dfrac{1}{p^2+5p+6}=-\dfrac{2}{p+3}$

85. $\dfrac{a}{2a+1}-\dfrac{2a^2+5}{2a^2-5a-3}=\dfrac{3}{a-3}$

86. $\dfrac{-18}{6n^2-n-1}+\dfrac{3n}{2n-1}=\dfrac{4n}{3n+1}$

▶ WORKING WITH FORMULAS

87. Cost to seize illegal drugs: $C=\dfrac{450P}{100-P}$

The cost C, in millions of dollars, for a government to find and seize $P\%$ $(0 \le P < 100)$ of a certain illegal drug is modeled by the rational equation shown. Complete the table (round to the nearest dollar) and answer the following questions.

P	$\frac{450P}{100-P}$
40	
60	
80	
90	
93	
95	
98	
100	

a. What is the cost of seizing 40% of the drugs? Estimate the cost at 85%.

b. Why does cost increase dramatically the closer you get to 100%?

c. Will 100% of the drugs ever be seized?

88. Chemicals in the bloodstream: $C=\dfrac{200H^2}{H^3+40}$

Rational equations are often used to model chemical concentrations in the bloodstream. The percent concentration C of a certain drug H hours after injection into muscle tissue can be modeled by the equation shown $(H \ge 0)$. Complete the table (round to the nearest tenth of a percent) and answer the following questions.

H	$\frac{200H^2}{H^3+40}$
0	
1	
2	
3	
4	
5	
6	
7	

a. What is the percent concentration of the drug 3 hr after injection?

b. Why is the concentration virtually equal at $H=4$ and $H=5$?

c. Why does the concentration begin to decrease?

d. How long will it take for the concentration to become less than 10%?

▶ APPLICATIONS

89. Stock prices: When a hot new stock hits the market, its price will often rise dramatically and then taper off over time. The equation $P = \dfrac{50(7d^2 + 10)}{d^3 + 50}$ models the price of stock XYZ d days after it has "hit the market." (a) Create a table of values showing the price of the stock for the first 10 days (rounded to the nearest dollar) and comment on what you notice. (b) Find the opening price of the stock. (c) Does the stock ever return to its original price?

90. Population growth: The Department of Wildlife introduces 60 elk into a new game reserve. It is projected that the size of the herd will grow according to the equation $N = \dfrac{10(6 + 3t)}{1 + 0.05t}$, where N is the number of elk and t is the time in years. (a) Approximate the population of elk after 14 yr. (b) If recent counts find 225 elk, approximately how many years have passed?

91. Typing speed: The number of words per minute that a beginner can type is approximated by the equation $N = \dfrac{60t - 120}{t}$, where N is the number of words per minute after t weeks, $3 < t < 12$. Use a table to determine how many weeks it takes for a student to be typing an average of forty-five words per minute.

92. Memory retention: A group of students is asked to memorize 50 Russian words that are unfamiliar to them. The number N of these words that the average student remembers D days later is modeled by the equation $N = \dfrac{5D + 35}{D} (D \geq 1)$. How many words are remembered after (a) 1 day? (b) 5 days? (c) 12 days? (d) 35 days? (e) 100 days? According to this model, is there a certain number of words that the average student never forgets? How many?

93. Pollution removal: For a steel mill, the cost C (in millions of dollars) to remove toxins from the resulting sludge is given by $C = \dfrac{22P}{100 - P}$, where P is the percent of the toxins removed. What percent can be removed if the mill spends $88,000,000 on the cleanup? Round to tenths of a percent.

▶ EXTENDING THE CONCEPT

94. One of these expressions is *not* equal to the others. Identify which and explain why.

a. $\dfrac{20n}{10n}$ **b.** $20 \cdot n \div 10 \cdot n$

c. $20n \cdot \dfrac{1}{10n}$ **d.** $\dfrac{20}{10} \cdot \dfrac{n}{n}$

95. The average of A and B is x. The average of C, D, and E is y. The average of A, B, C, D, and E is:

a. $\dfrac{3x + 2y}{5}$ **b.** $\dfrac{2x + 3y}{5}$

c. $\dfrac{2(x + y)}{5}$ **d.** $\dfrac{3(x + y)}{5}$

96. Given the rational numbers $\dfrac{2}{5}$ and $\dfrac{3}{4}$, what is the reciprocal of the sum of their reciprocals? Given that $\dfrac{a}{b}$ and $\dfrac{c}{d}$ are *any* two numbers—what is the reciprocal of the sum of their reciprocals?

A.6 Radicals, Rational Exponents, and Radical Equations

LEARNING OBJECTIVES

In Section A.6 you will review how to:

- ❑ **A.** Simplify radical expressions of the form $\sqrt[n]{a^n}$
- ❑ **B.** Rewrite and simplify radical expressions using rational exponents
- ❑ **C.** Use properties of radicals to simplify radical expressions
- ❑ **D.** Add and subtract radical expressions
- ❑ **E.** Multiply and divide radical expressions; write a radical expression in simplest form
- ❑ **F.** Solve equations and use formulas involving radicals

Square roots and cube roots come from a much larger family called **radical expressions.** Expressions containing radicals can be found in virtually every field of mathematical study, and are an invaluable tool for modeling many real-world phenomena.

A. Simplifying Radical Expressions of the Form $\sqrt[n]{a^n}$

In previous coursework, you likely noted that $\sqrt{a} = b$ only if $b^2 = a$. This definition cannot be applied to expressions like $\sqrt{-16}$, since there is no number b such that $b^2 = -16$. In other words, the expression $\sqrt{a}$ represents a real number only if $a \geq 0$ (for a full review of the real numbers and other sets of numbers, see Appendix I at www.mhhe.com/coburn). Of particular interest to us now is an inverse operation for a^2. In other words, what operation can be applied to a^2 to return a? Consider the following.

EXAMPLE 1 ▶ Evaluating a Radical Expression

Evaluate $\sqrt{a^2}$ for the values given:

a. $a = 3$ **b.** $a = 5$ **c.** $a = -6$

Solution ▶

a. $\sqrt{3^2} = \sqrt{9} = 3$

b. $\sqrt{5^2} = \sqrt{25} = 5$

c. $\sqrt{(-6)^2} = \sqrt{36} = 6$

Now try Exercises 7 and 8 ▶

The pattern seemed to indicate that $\sqrt{a^2} = a$ and that our search for an inverse operation was complete—until Example 1(c), where we found that $\sqrt{(-6)^2} \neq -6$. Using the absolute value concept, we can "repair" this apparent discrepancy and state a general rule for simplifying these expressions: $\sqrt{a^2} = |a|$. For expressions like $\sqrt{49x^2}$ and $\sqrt{y^6}$, the radicands can be rewritten as perfect squares and simplified in the same manner: $\sqrt{49x^2} = \sqrt{(7x)^2} = 7|x|$ and $\sqrt{y^6} = \sqrt{(y^3)^2} = |y^3|$.

The Square Root of a^2: $\sqrt{a^2}$

For any real number a,

$$\sqrt{a^2} = |a|.$$

EXAMPLE 2 ▶ Simplifying Square Root Expressions

Simplify each expression.

a. $\sqrt{169x^2}$ **b.** $\sqrt{x^2 - 10x + 25}$

Solution ▶

a. $\sqrt{169x^2} = |13x| = 13|x|$ since x could be negative

b. $\sqrt{x^2 - 10x + 25} = \sqrt{(x - 5)^2} = |x - 5|$ since $x - 5$ could be negative

Now try Exercises 9 and 10 ▶

CAUTION ▶ In Appendix A.2, we noted that $(A + B)^2 \neq A^2 + B^2$, indicating that you cannot square the individual terms in a sum (the square of a binomial results in a perfect square trinomial). In a similar way, $\sqrt{A^2 + B^2} \neq A + B$, and you cannot take the square root of individual terms. There is a big difference between the expressions $\sqrt{A^2 + B^2}$ and $\sqrt{(A + B)^2} = |A + B|$. Try evaluating each when $A = 3$ and $B = 4$.

To investigate expressions like $\sqrt[3]{x^3}$, note the radicand in both $\sqrt[3]{8}$ and $\sqrt[3]{-64}$ can be written as a perfect cube. From our earlier definition of cube roots we know $\sqrt[3]{8} = \sqrt[3]{(2)^3} = 2$, $\sqrt[3]{-64} = \sqrt[3]{(-4)^3} = -4$, and that every real number has only one real cube root. For this reason, absolute value notation is not used or needed when taking cube roots.

The Cube Root of a^3: $\sqrt[3]{a^3}$

For any real number a,

$$\sqrt[3]{a^3} = a.$$

EXAMPLE 3 ▶ **Simplifying Cube Root Expressions**

Simplify each expression.

a. $\sqrt[3]{-27x^3}$ **b.** $\sqrt[3]{-64n^6}$

Solution ▶

a. $\sqrt[3]{-27x^3} = \sqrt[3]{(-3x)^3} = -3x$

b. $\sqrt[3]{-64n^6} = \sqrt[3]{(-4n^2)^3} = -4n^2$

Now try Exercises 11 and 12 ▶

We can extend these ideas to fourth roots, fifth roots, and so on. For example, the fifth root of a is b only if $b^5 = a$. In symbols, $\sqrt[5]{a} = b$ implies $b^5 = a$. Since an odd number of negative factors is always negative: $(-2)^5 = -32$, and an even number of negative factors is always positive: $(-2)^4 = 16$, we must take the index into account when evaluating expressions like $\sqrt[n]{a^n}$. If n is even and the radicand is unknown, absolute value notation must be used.

WORTHY OF NOTE

Just as $\sqrt[2]{-16}$ is not a real number, $\sqrt[4]{-16}$ and $\sqrt[6]{-16}$ do not represent real numbers. An even number of repeated factors is always positive!

The nth Root of a^n: $\sqrt[n]{a^n}$

For any real number a,

1. $\sqrt[n]{a^n} = |a|$ when n is even.
2. $\sqrt[n]{a^n} = a$ when n is odd.

EXAMPLE 4 ▶ **Simplifying Radical Expressions**

Simplify each expression.

a. $\sqrt[4]{81}$ **b.** $\sqrt[4]{-81}$ **c.** $\sqrt[5]{32}$ **d.** $\sqrt[5]{-32}$

e. $\sqrt[4]{16m^4}$ **f.** $\sqrt[5]{32p^5}$ **g.** $\sqrt[6]{(m + 5)^6}$ **h.** $\sqrt[7]{(x - 2)^7}$

Solution ▶

a. $\sqrt[4]{81} = 3$

b. $\sqrt[4]{-81}$ is not a real number

c. $\sqrt[5]{32} = 2$

d. $\sqrt[5]{-32} = -2$

e. $\sqrt[4]{16m^4} = \sqrt[4]{(2m)^4} = |2m|$ or $2|m|$

f. $\sqrt[5]{32p^5} = \sqrt[5]{(2p)^5} = 2p$

g. $\sqrt[6]{(m + 5)^6} = |m + 5|$

h. $\sqrt[7]{(x - 2)^7} = x - 2$

Now try Exercises 13 and 14 ▶

☑ **A.** You've just seen how we can simplify radical expressions of the form $\sqrt[n]{a^n}$

B. Radical Expressions and Rational Exponents

As an alternative to radical notation, a rational (fractional) exponent can be used, along with the power property of exponents. For $\sqrt[3]{a^3} = a$, notice that an exponent of one-third can replace the cube root notation and produce the same result: $\sqrt[3]{a^3} = (a^3)^{\frac{1}{3}} = a^{\frac{3}{3}} = a$. In the same way, an exponent of one-half can replace the square root notation: $\sqrt{a^2} = (a^2)^{\frac{1}{2}} = a^{\frac{2}{2}} = |a|$. In general, we have the following:

Rational Exponents

If a is a real number and n is an integer greater than 1,

$$\text{then } \sqrt[n]{a} = \sqrt[n]{a^1} = a^{\frac{1}{n}}$$

provided $\sqrt[n]{a}$ represents a real number.

EXAMPLE 5 ▶ **Simplifying Radical Expressions Using Rational Exponents**

Simplify by rewriting each radicand as a perfect nth power and converting to rational exponent notation.

a. $\sqrt[3]{-125}$ **b.** $-\sqrt[4]{16x^{20}}$ **c.** $\sqrt[4]{-81}$ **d.** $\sqrt{\dfrac{8w^3}{27}}$

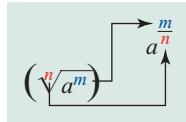
Solution ▶

a. $\sqrt[3]{-125} = \sqrt[3]{(-5)^3}$
$= [(-5)^3]^{\frac{1}{3}}$
$= (-5)^{\frac{3}{3}}$
$= -5$

b. $-\sqrt[4]{16x^{20}} = -\sqrt[4]{(2x^5)^4}$
$= -[(2x^5)^4]^{\frac{1}{4}}$
$= -|2x^5|$
$= -2|x|^5$

c. $\sqrt[4]{-81} = (-81)^{\frac{1}{4}}$
is not a real number

d. $\sqrt{\dfrac{8w^3}{27}} = \sqrt[3]{\left(\dfrac{2w}{3}\right)^3}$
$= \left[\left(\dfrac{2w}{3}\right)^3\right]^{\frac{1}{3}} = \dfrac{2w}{3}$



Now try Exercises 15 and 16 ▶

WORTHY OF NOTE

Any rational number can be decomposed into the product of a unit fraction and an integer: $\dfrac{m}{n} = \dfrac{1}{n} \cdot m$.

When a rational exponent is used, as in $\sqrt[n]{a} = \sqrt[n]{a^1} = a^{\frac{1}{n}}$, the denominator of the exponent represents the index number, while the numerator of the exponent represents the original power on a. *This is true even when the exponent on a is something other than one!* In other words, the radical expression $\sqrt[4]{16^3}$ can be rewritten as $(16^3)^{\frac{1}{4}} = (16^{\frac{3}{1}})^{\frac{1}{4}}$ or $16^{\frac{3}{4}}$. This is further illustrated in Figure A.6 where we see the rational exponent has the form, "power over root." To evaluate this expression without the aid of a calculator, we use the commutative property to rewrite $(16^{\frac{3}{1}})^{\frac{1}{4}}$ as $(16^{\frac{1}{4}})^{\frac{3}{1}}$ and begin with the fourth root of 16: $(16^{\frac{1}{4}})^{\frac{3}{1}} = 2^3 = 8$.

Figure A.6

In general, if m and n have no common factors (other than 1) the expression $a^{\frac{m}{n}}$ can be interpreted in the following two ways.

Rational Exponents

If $\frac{m}{n}$ is a rational number expressed in lowest terms with $n \geq 2$, then

$$(1)\ a^{\frac{m}{n}} = (\sqrt[n]{a})^m \qquad \text{or} \qquad (2)\ a^{\frac{m}{n}} = \sqrt[n]{a^m}$$

(compute $\sqrt[n]{a}$, then take the mth power), (compute a^m, then take the nth root),

provided $\sqrt[n]{a}$ represents a real number.

Expressions with rational exponents are generally easier to evaluate if we compute the root first, then apply the exponent. Computing the root first also helps us determine whether or not an expression represents a real number.

EXAMPLE 6 ▶ **Simplifying Expressions with Rational Exponents**

Simplify each expression, if possible.

a. $-49^{\frac{3}{2}}$ **b.** $(-49)^{\frac{3}{2}}$ **c.** $(-8)^{\frac{2}{3}}$ **d.** $-8^{-\frac{2}{3}}$

Solution ▶

a. $-49^{\frac{3}{2}} = -(49^{\frac{1}{2}})^3$
$= -(\sqrt{49})^3$
$= -(7)^3$ or -343

b. $(-49)^{\frac{3}{2}} = [(-49)^{\frac{1}{2}}]^3$,
$= (\sqrt{-49})^3$
not a real number

c. $(-8)^{\frac{2}{3}} = \left[(-8)^{\frac{1}{3}}\right]^2$
$= (\sqrt[3]{-8})^2$
$= (-2)^2$ or 4

d. $-8^{-\frac{2}{3}} = -(8^{\frac{1}{3}})^{-2}$
$= -(\sqrt[3]{8})^{-2}$
$= -2^{-2}$ or $-\frac{1}{4}$

WORTHY OF NOTE

While the expression $(-8)^{\frac{1}{3}} = \sqrt[3]{-8}$ represents the real number -2, the expression $(-8)^{\frac{2}{6}} = (\sqrt[6]{-8})^2$ is not a real number, even though $\frac{1}{3} = \frac{2}{6}$. Note that the second exponent is not in lowest terms.

Now try Exercises 17 through 22 ▶

B. You've just seen how we can rewrite and simplify radical expressions using rational exponents

C. Using Properties of Radicals to Simplify Radical Expressions

The properties used to simplify radical expressions are closely connected to the properties of exponents. For instance, the product to a power property holds even when n is a rational number. This means $(xy)^{\frac{1}{2}} = x^{\frac{1}{2}}y^{\frac{1}{2}}$ and $(4 \cdot 25)^{\frac{1}{2}} = 4^{\frac{1}{2}} \cdot 25^{\frac{1}{2}}$. When the second statement is expressed in radical form, we have $\sqrt{4 \cdot 25} = \sqrt{4} \cdot \sqrt{25}$, with both forms having a value of 10. This suggests the **product property of radicals,** which can be extended to include cube roots, fourth roots, and so on.

Product Property of Radicals

If $\sqrt[n]{A}$ and $\sqrt[n]{B}$ represent real-valued expressions, then

$$\sqrt[n]{AB} = \sqrt[n]{A} \cdot \sqrt[n]{B} \quad \text{and} \quad \sqrt[n]{A} \cdot \sqrt[n]{B} = \sqrt[n]{AB}.$$

CAUTION ▶ Note that this property applies only to a *product* of two terms, not to a sum or difference. In other words, while $\sqrt{9x^2} = |3x|$, $\sqrt{9 + x^2} \neq |3 + x|$!

One application of the product property is to simplify radical expressions. In general, the expression $\sqrt[n]{a}$ is in simplified form if a has no factors (other than 1) that are perfect nth roots.

EXAMPLE 7 ▶ **Simplifying Radical Expressions**

Write each expression in simplest form using the product property.

a. $\sqrt{18}$ **b.** $5\sqrt[3]{125x^4}$ **c.** $\dfrac{-4 + \sqrt{20}}{2}$ **d.** $1.2\sqrt[3]{16n^4}\,\sqrt[3]{4n^5}$

Solution ▶

a. $\sqrt{18} = \sqrt{9 \cdot 2}$
$= \sqrt{9}\sqrt{2}$
$= 3\sqrt{2}$

b. $5\sqrt[3]{125x^4} = 5 \cdot \sqrt[3]{125 \cdot x^4}$

These steps can be done mentally

$= 5 \cdot \sqrt[3]{125} \cdot \sqrt[3]{x^3} \cdot \sqrt[3]{x^1}$
$= 5 \cdot 5 \cdot x \cdot \sqrt[3]{x}$
$= 25x\sqrt[3]{x}$

WORTHY OF NOTE

For expressions like those in Example 7(c), students must resist the "temptation" to reduce individual terms as in $\frac{-4+\sqrt{20}}{2} \neq -2+\sqrt{20}$. Remember, only *factors* can be reduced.

c. $$\frac{-4+\sqrt{20}}{2} = \frac{-4+\sqrt{4\cdot 5}}{2} = \frac{-4+2\sqrt{5}}{2} = \frac{{}^{1}2(-2+\sqrt{5})}{2} = -2+\sqrt{5}$$

d. $$1.2\sqrt[3]{16n^4}\sqrt[3]{4n^5} = 1.2\sqrt[3]{64\cdot n^9} = 1.2\sqrt[3]{64}\sqrt[3]{n^9} = 1.2\sqrt[3]{64}\sqrt[3]{(n^3)^3} = 1.2(4)n^3 = 4.8n^3$$

Now try Exercises 23 through 26 ▶

When radicals are *combined* using the product property, the result may contain a perfect nth root, which should be simplified. Note that the *index numbers must be the same* in order to use this property.

The **quotient property of radicals** can also be established using exponential properties. The fact that $\frac{\sqrt{100}}{\sqrt{25}} = \sqrt{\frac{100}{25}} = 2$ suggests the following:

Quotient Property of Radicals

If $\sqrt[n]{A}$ and $\sqrt[n]{B}$ represent real-valued expressions with $B \neq 0$, then

$$\sqrt[n]{\frac{A}{B}} = \frac{\sqrt[n]{A}}{\sqrt[n]{B}} \quad \text{and} \quad \frac{\sqrt[n]{A}}{\sqrt[n]{B}} = \sqrt[n]{\frac{A}{B}}.$$

Many times the product and quotient properties must work together to simplify a radical expression, as shown in Example 8A.

EXAMPLE 8A ▶ Simplifying Radical Expressions

Simplify each expression:

a. $\frac{\sqrt{18a^5}}{\sqrt{2a}}$ **b.** $\sqrt[3]{\frac{81}{125x^3}}$

Solution ▶

a. $$\frac{\sqrt{18a^5}}{\sqrt{2a}} = \sqrt{\frac{18a^5}{2a}} = \sqrt{9a^4} = 3a^2$$

b. $$\sqrt[3]{\frac{81}{125x^3}} = \frac{\sqrt[3]{81}}{\sqrt[3]{125x^3}} = \frac{\sqrt[3]{27\cdot 3}}{5x} = \frac{3\sqrt[3]{3}}{5x}$$

Radical expressions can also be simplified using rational exponents.

EXAMPLE 8B ▶ Using Rational Exponents to Simplify Radical Expressions

Simplify using rational exponents:

a. $\sqrt{36p^4q^5}$ **b.** $v\sqrt[3]{v^4}$ **c.** $\sqrt[3]{m}\sqrt{m}$

Solution ▶

a. $$\sqrt{36p^4q^5} = (36p^4q^5)^{\frac{1}{2}} = 36^{\frac{1}{2}}p^{\frac{4}{2}}q^{\frac{5}{2}} = 6p^2q^{(\frac{4}{2}+\frac{1}{2})} = 6p^2q^2q^{\frac{1}{2}} = 6p^2q^2\sqrt{q}$$

b. $$v\sqrt[3]{v^4} = v^1\cdot v^{\frac{4}{3}} = v^{\frac{3}{3}}\cdot v^{\frac{4}{3}} = v^{\frac{7}{3}} = v^{\frac{6}{3}}v^{\frac{1}{3}} = v^2\sqrt[3]{v}$$

c. $$\sqrt[3]{m}\sqrt{m} = m^{\frac{1}{3}}m^{\frac{1}{2}} = m^{\frac{1}{3}+\frac{1}{2}} = m^{\frac{5}{6}} = \sqrt[6]{m^5}$$

C. You've just seen how we can use properties of radicals to simplify radical expressions

Now try Exercises 27 through 30 ▶

D. Addition and Subtraction of Radical Expressions

Since $3x$ and $5x$ are like terms, we know $3x + 5x = 8x$. If $x = \sqrt[3]{7}$, the sum becomes $3\sqrt[3]{7} + 5\sqrt[3]{7} = 8\sqrt[3]{7}$, illustrating how *like* radical expressions can be combined. Like radicals are those that have *the same index and radicand.* In some cases, we can identify like radicals only after radical terms have been simplified.

EXAMPLE 9 ▶ **Adding and Subtracting Radical Expressions**

Simplify and combine (if possible).

a. $\sqrt{45} + 2\sqrt{20}$ **b.** $\sqrt[3]{16x^5} - x\sqrt[3]{54x^2}$

Solution ▶

a. $\sqrt{45} + 2\sqrt{20} = 3\sqrt{5} + 2(2\sqrt{5})$ simplify radicals: $\sqrt{45} = \sqrt{9 \cdot 5}$; $\sqrt{20} = \sqrt{4 \cdot 5}$

$= 3\sqrt{5} + 4\sqrt{5}$ like radicals

$= 7\sqrt{5}$ result

b. $\sqrt[3]{16x^5} - x\sqrt[3]{54x^2} = \sqrt[3]{8 \cdot 2 \cdot x^3 \cdot x^2} - x\sqrt[3]{27 \cdot 2 \cdot x^2}$

$= 2x\sqrt[3]{2x^2} - 3x\sqrt[3]{2x^2}$ simplify radicals

$= -x\sqrt[3]{2x^2}$ result

☑ **D.** You've just seen how we can add and subtract radical expressions

Now try Exercises 31 through 34 ▶

E. Multiplication and Division of Radical Expressions; Radical Expressions in Simplest Form

Multiplying radical expressions is simply an extension of our earlier work. The multiplication can take various forms, from the distributive property to any of the special products reviewed in Appendix A.2. For instance, $(A \pm B)^2 = A^2 \pm 2AB + B^2$, even if A or B is a radical term.

EXAMPLE 10 ▶ **Multiplying Radical Expressions**

Compute each product and simplify.

a. $5\sqrt{3}(\sqrt{6} - 4\sqrt{3})$ **b.** $(2\sqrt{2} + 6\sqrt{3})(3\sqrt{10} + \sqrt{15})$

c. $(x + \sqrt{7})(x - \sqrt{7})$ **d.** $(3 - \sqrt{2})^2$

Solution ▶

a. $5\sqrt{3}(\sqrt{6} - 4\sqrt{3}) = 5\sqrt{18} - 20(\sqrt{3})^2$ distribute

$= 5(3)\sqrt{2} - (20)(3)$ simplify: $\sqrt{18} = 3\sqrt{2}$, $(\sqrt{3})^2 = 3$

$= 15\sqrt{2} - 60$ result

b. $(2\sqrt{2} + 6\sqrt{3})(3\sqrt{10} + \sqrt{15}) = 6\sqrt{20} + 2\sqrt{30} + 18\sqrt{30} + 6\sqrt{45}$ F-O-I-L

$= 12\sqrt{5} + 20\sqrt{30} + 18\sqrt{5}$ extract roots *and* simplify

$= 30\sqrt{5} + 20\sqrt{30}$ result

c. $(x + \sqrt{7})(x - \sqrt{7}) = x^2 - (\sqrt{7})^2$ $(A + B)(A - B) = A^2 - B^2$

$= x^2 - 7$ result

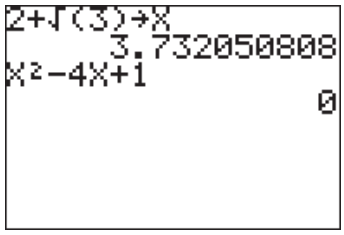
d. $(3 - \sqrt{2})^2 = (3)^2 - 2(3)(\sqrt{2}) + (\sqrt{2})^2$ $(A - B)^2 = A^2 - 2AB + B^2$

$= 9 - 6\sqrt{2} + 2$ simplify each term

$= 11 - 6\sqrt{2}$ result

LOOKING AHEAD

Notice that the answer for Example 10(c) contains no radical terms, since the outer and inner products sum to zero. This result will be used to simplify certain radical expressions in this section and later in Chapter 2.



Now try Exercises 35 through 38 ▶

One application of products and powers of radical expressions is to evaluate certain quadratic expressions, as illustrated in Example 11.

EXAMPLE 11 ▶ **Evaluating a Quadratic Expression**

Show that when $x^2 - 4x + 1$ is evaluated at $x = 2 + \sqrt{3}$, the result is zero.

Solution ▶

$$\begin{aligned} x^2 - 4x + 1 &\quad \text{original expression} \\ (2 + \sqrt{3})^2 - 4(2 + \sqrt{3}) + 1 &\quad \text{substitute } 2 + \sqrt{3} \text{ for } x \\ 4 + 4\sqrt{3} + 3 - 8 - 4\sqrt{3} + 1 &\quad \text{square binomial; distribute} \\ (4 + 3 - 8 + 1) + (4\sqrt{3} - 4\sqrt{3}) &\quad \text{commutative and associative properties} \\ 0 \checkmark \end{aligned}$$

A calculator check is shown in the figure.

Now try Exercises 39 through 42 ▶

When we applied the quotient property in Example 8A, we obtained a denominator free of radicals. Sometimes the denominator is not automatically free of radicals, and the need to write radical expressions in *simplest form* comes into play. This process is called **rationalizing the denominator.**

Radical Expressions in Simplest Form

A radical expression is in simplest form if:

1. The radicand has no perfect nth root factors.
2. The radicand contains no fractions.
3. No radicals occur in a denominator.

As with other types of simplification, the desired form can be achieved in various ways. If the denominator is a single radical term, we multiply the numerator and denominator by the factors required to eliminate the radical in the denominator [see Examples 12(a) and 12(b)]. If the radicand is a rational expression, it is generally easier to build an equivalent fraction *within the radical* having perfect nth root factors in the denominator [see Example 12(c)].

EXAMPLE 12 ▶ **Simplifying Radical Expressions**

Simplify by rationalizing the denominator. Assume $a, x \neq 0$.

a. $\dfrac{2}{5\sqrt{3}}$ **b.** $\dfrac{-7}{\sqrt[3]{x}}$

Solution ▶

a. $\dfrac{2}{5\sqrt{3}} = \dfrac{2}{5\sqrt{3}} \cdot \dfrac{\sqrt{3}}{\sqrt{3}}$ multiply numerator and denominator by $\sqrt{3}$

$= \dfrac{2\sqrt{3}}{5(\sqrt{3})^2} = \dfrac{2\sqrt{3}}{15}$ simplify—denominator is now rational

b. $\dfrac{-7}{\sqrt[3]{x}} = \dfrac{-7(\sqrt[3]{x})(\sqrt[3]{x})}{\sqrt[3]{x}(\sqrt[3]{x})(\sqrt[3]{x})}$ multiply using two additional factors of $\sqrt[3]{x}$

$= \dfrac{-7\sqrt[3]{x^2}}{\sqrt[3]{x^3}}$ product property

$= \dfrac{-7\sqrt[3]{x^2}}{x}$ $\sqrt[3]{x^3} = x$

Now try Exercises 43 and 44 ▶

In some applications, the denominator may be a sum or difference containing a radical term. In this case, the methods from Example 12 are ineffective, and instead we multiply by a conjugate since $(A + B)(A - B) = A^2 - B^2$. If either A or B is a square root, the result will be a denominator free of radicals.

EXAMPLE 13 ▶ **Simplifying Radical Expressions Using a Conjugate**

Simplify the expression by rationalizing the denominator. Write the answer in exact form and approximate form rounded to three decimal places. $\dfrac{2 + \sqrt{3}}{\sqrt{6} - \sqrt{2}}$

Solution ▶

$$\frac{2 + \sqrt{3}}{\sqrt{6} - \sqrt{2}} = \frac{2 + \sqrt{3}}{\sqrt{6} - \sqrt{2}} \cdot \frac{\sqrt{6} + \sqrt{2}}{\sqrt{6} + \sqrt{2}}$$ multiply by the conjugate of the denominator

$$= \frac{2\sqrt{6} + 2\sqrt{2} + \sqrt{18} + \sqrt{6}}{(\sqrt{6})^2 - (\sqrt{2})^2}$$ FOIL

difference of squares

$$= \frac{3\sqrt{6} + 2\sqrt{2} + 3\sqrt{2}}{6 - 2}$$ simplify

$$= \frac{3\sqrt{6} + 5\sqrt{2}}{4}$$ exact form

$$\approx 3.605$$ approximate form

Now try Exercises 45 through 48 ▶

E. You've just seen how we can multiply and divide radical expressions and write a radical expression in simplest form

F. Equations and Formulas Involving Radicals

A **radical equation** is any equation that contains terms with a variable in the radicand. To solve a radical equation, we attempt to isolate a radical term on one side, then apply the appropriate nth power to free up the radicand and solve for the unknown. This is an application of the **power property of equality.**

The Power Property of Equality

If $\sqrt[n]{u}$ and v are real-valued expressions and $\sqrt[n]{u} = v$,

then $(\sqrt[n]{u})^n = v^n$

$u = v^n$

for n an integer, $n \geq 2$.

Raising both sides of an equation to an *even* power can also introduce a false solution (extraneous root). Note that by inspection, the equation $x - 2 = \sqrt{x}$ has only the solution $x = 4$. But the equation $(x - 2)^2 = x$ (obtained by squaring both sides) has both $x = 4$ *and* $x = 1$ as solutions, yet $x = 1$ does not satisfy the original equation. This means we should *check all solutions of an equation where an even power is applied.*

EXAMPLE 14 ▶ **Solving Radical Equations**

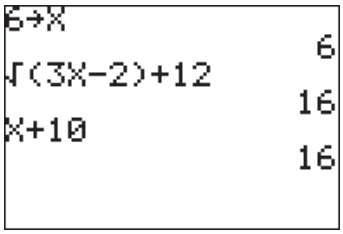
Solve each radical equation:

a. $\sqrt{3x-2}+12=x+10$ **b.** $2\sqrt[3]{x-5}+4=0$

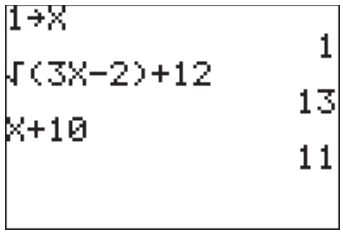
Solution ▶

a.
$$\begin{aligned}
\sqrt{3x-2}+12&=x+10 && \text{original equation}\\
\sqrt{3x-2}&=x-2 && \text{isolate radical term (subtract 12)}\\
(\sqrt{3x-2})^2&=(x-2)^2 && \text{apply power property, power is even}\\
3x-2&=x^2-4x+4 && \text{simplify, square binomial}\\
0&=x^2-7x+6 && \text{set equal to zero}\\
0&=(x-6)(x-1) && \text{factor}\\
x-6=0 \quad &\text{or} \quad x-1=0 && \text{apply zero product property}\\
x=6 \quad &\text{or} \quad x=1 && \text{result, check for extraneous roots}
\end{aligned}$$

Check ▶ $x=6$: $\sqrt{3(6)-2}+12=(6)+10$



$\sqrt{16}+12=16$



$16=16$ ✓

Check ▶ $x=1$: $\sqrt{3(1)-2}+12=(1)+10$

$\sqrt{1}+12=11$

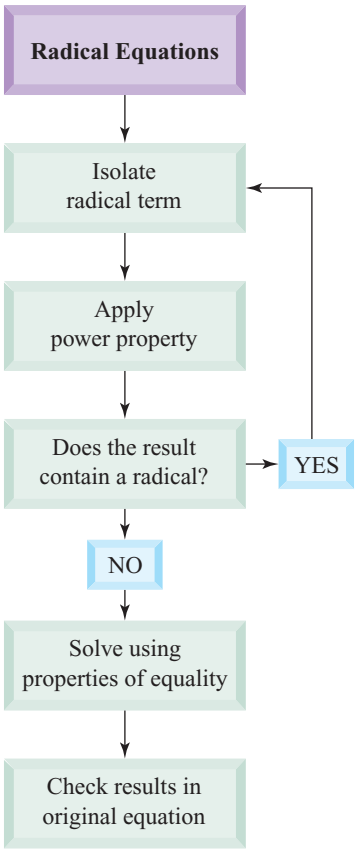
$13=11$ ✗

The only solution is $x=6$; $x=1$ is extraneous. A calculator check is shown in the figures.

b.
$$\begin{aligned}
2\sqrt[3]{x-5}+4&=0 && \text{original equation}\\
\sqrt[3]{x-5}&=-2 && \text{isolate radical term (subtract 4, divide by 2)}\\
(\sqrt[3]{x-5})^3&=(-2)^3 && \text{apply power property, power is odd}\\
x-5&=-8 && \text{simplify: } (\sqrt[3]{x-5})^3=x-5\\
x&=-3 && \text{solve}
\end{aligned}$$

Substituting -3 for x in the original equation verifies it is a solution.

Now try Exercises 49 through 52 ▶



Sometimes squaring both sides of an equation still results in an equation with a radical term, but often there is *one fewer* than before. In this case, we simply repeat the process, as indicated by the flowchart in Figure A.7.

EXAMPLE 15 ▶ **Solving Radical Equations**

Solve the equation: $\sqrt{x+15}-\sqrt{x+3}=2$.

Solution ▶
$$\begin{aligned}
\sqrt{x+15}-\sqrt{x+3}&=2 && \text{original equation}\\
\sqrt{x+15}&=\sqrt{x+3}+2 && \text{isolate one radical}\\
(\sqrt{x+15})^2&=(\sqrt{x+3}+2)^2 && \text{power property}\\
x+15&=(x+3)+4\sqrt{x+3}+4 && (A+B)^2;\ A=\sqrt{x+3},\ B=2\\
x+15&=x+4\sqrt{x+3}+7 && \text{simplify}\\
8&=4\sqrt{x+3} && \text{isolate radical}\\
2&=\sqrt{x+3} && \text{divide by four}\\
4&=x+3 && \text{power property}\\
1&=x && \text{possible solution}
\end{aligned}$$

Figure A.7

Check ▶

$$\begin{aligned}
\sqrt{x+15}-\sqrt{x+3} &= 2 && \text{original equation}\\
\sqrt{(1)+15}-\sqrt{(1)+3} &= 2 && \text{substitute 1 for } x\\
\sqrt{16}-\sqrt{4} &= 2 && \text{simplify}\\
4-2 &= 2 && \text{solution checks}\\
2 &= 2\ \checkmark
\end{aligned}$$

Now try Exercises 53 and 54 ▶

Since rational exponents are so closely related to radicals, the solution process for each is very similar. The goal is still to "undo" the radical (rational exponent) and solve for the unknown.

Power Property of Equality

For real-valued expressions u and v, with positive integers m, n, and $\frac{m}{n}$ in lowest terms:

If m is odd	**If m is even**
and $u^{\frac{m}{n}} = v$,	and $u^{\frac{m}{n}} = v (v > 0)$,
then $(u^{\frac{m}{n}})^{\frac{n}{m}} = v^{\frac{n}{m}}$	then $(u^{\frac{m}{n}})^{\frac{n}{m}} = \pm v^{\frac{n}{m}}$
$u = v^{\frac{n}{m}}$	$u = \pm v^{\frac{n}{m}}$

The power property of equality basically says that if certain conditions are satisfied, both sides of an equation can be raised to any needed power.

EXAMPLE 16 ▶ **Solving Equations with Rational Exponents**

Solve each equation:

a. $3(x+1)^{\frac{3}{4}} - 9 = 15$ **b.** $(x-3)^{\frac{2}{3}} = 4$

Solution ▶

a.
$$\begin{aligned}
3(x+1)^{\frac{3}{4}} - 9 &= 15 && \text{original equation; } \tfrac{m}{n} = \tfrac{3}{4}\\
(x+1)^{\frac{3}{4}} &= 8 && \text{isolate variable term (add 9, divide by 3)}\\
[(x+1)^{\frac{3}{4}}]^{\frac{4}{3}} &= 8^{\frac{4}{3}} && \text{apply power property, note } m \text{ is odd}\\
x+1 &= 16 && \text{simplify } [8^{\frac{4}{3}} = (8^{\frac{1}{3}})^4 = 16]\\
x &= 15 && \text{result}
\end{aligned}$$

Check ▶

$$\begin{aligned}
3(15+1)^{\frac{3}{4}} - 9 &= 15 && \text{substitute 15 for } x \text{ in the original equation}\\
3(16^{\frac{1}{4}})^3 - 9 &= 15 && \text{simplify, rewrite exponent}\\
3(2)^3 - 9 &= 15 && \sqrt[4]{16} = 2\\
3(8) - 9 &= 15 && 2^3 = 8\\
15 &= 15\ \checkmark && \text{solution checks}
\end{aligned}$$

b.
$$\begin{aligned}
(x-3)^{\frac{2}{3}} &= 4 && \text{original equation; } \tfrac{m}{n} = \tfrac{2}{3}\\
[(x-3)^{\frac{2}{3}}]^{\frac{3}{2}} &= \pm 4^{\frac{3}{2}} && \text{apply power property, note } m \text{ is even}\\
x-3 &= \pm 8 && \text{simplify } [4^{\frac{3}{2}} = (4^{\frac{1}{2}})^3 = 8]\\
x &= 3 \pm 8 && \text{result}
\end{aligned}$$

The solutions are $3+8=11$ and $3-8=-5$.
Verify by checking both in the original equation.

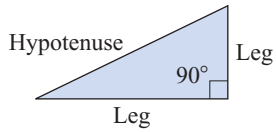
Now try Exercises 55 through 58 ▶

CAUTION ▶ As you continue solving equations with radicals and rational exponents, be careful not to arbitrarily place the "±" sign in front of terms *given* in radical form. The expression $\sqrt{18}$ indicates the positive square root of 18, where $\sqrt{18} = 3\sqrt{2}$. The equation $x^2 = 18$ becomes $x = \pm\sqrt{18}$ after applying the power property, with solutions $x = \pm 3\sqrt{2}$ ($x = -3\sqrt{2}, x = 3\sqrt{2}$), since the square of either number produces 18.

In Appendix A.4, we used a technique called *u-substitution* to factor expressions in quadratic form. The following equations are also in quadratic form since the degree of the leading term is twice the degree of the middle term: $x^{\frac{2}{3}} - 3x^{\frac{1}{3}} - 10 = 0$ and $(x^2 + x)^2 - 8(x^2 + x) + 12 = 0$. The first equation and its solution appear in Example 17.

EXAMPLE 17 ▶ Solving Equations in Quadratic Form

Solve using a *u*-substitution: $x^{\frac{2}{3}} - 3x^{\frac{1}{3}} - 10 = 0$.



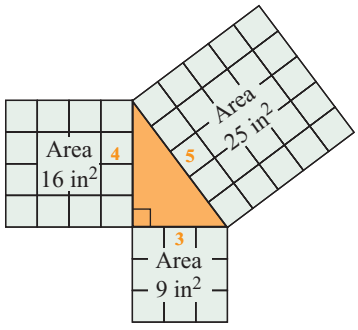
Solution ▶ This equation is in quadratic form since it can be rewritten as: $(x^{\frac{1}{3}})^2 - 3(x^{\frac{1}{3}})^1 - 10 = 0$, where the degree of leading term is twice that of second term. If we let $u = x^{\frac{1}{3}}$, then $u^2 = x^{\frac{2}{3}}$ and the equation becomes $u^2 - 3u^1 - 10 = 0$, which is factorable.

$(u - 5)(u + 2) = 0$			factor
$u = 5$	or	$u = -2$	solution in terms of u
$x^{\frac{1}{3}} = 5$	or	$x^{\frac{1}{3}} = -2$	resubstitute $x^{\frac{1}{3}}$ for u
$(x^{\frac{1}{3}})^3 = 5^3$	or	$(x^{\frac{1}{3}})^3 = (-2)^3$	cube both sides: $\frac{1}{3}(3) = 1$
$x = 125$	or	$x = -8$	solve for x

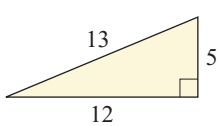
Both solutions check.

Now try Exercises 59 and 60 ▶

Figure A.8



A right triangle is one that has a 90° angle (see Figure A.8). The longest side (opposite the right angle) is called the **hypotenuse,** while the other two sides are simply called "legs." The **Pythagorean theorem** is a formula that says if you add the square of each leg, the result will be equal to the square of the hypotenuse. Furthermore, we note the converse of this theorem is also true.



Pythagorean Theorem

1. For any right triangle with legs a and b and hypotenuse c, $a^2 + b^2 = c^2$
2. For any triangle with sides a, b, and c, if $a^2 + b^2 = c^2$, then the triangle is a right triangle.

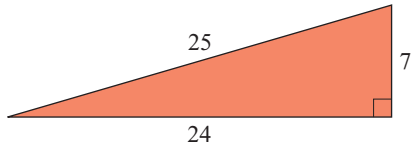


Figure A.9

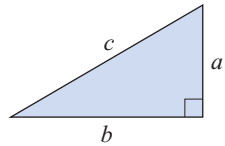
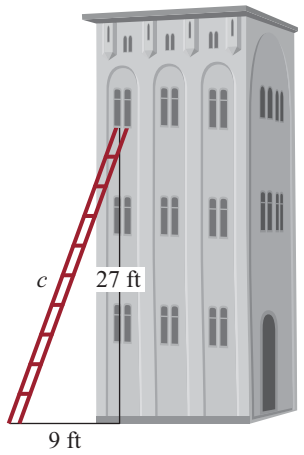


A geometric interpretation of the theorem is given in Figure A.9, which shows $3^2 + 4^2 = 5^2$.

$5^2 + 12^2 = 13^2$
$25 + 144 = 169$ ✓

$7^2 + 24^2 = 25^2$
$49 + 576 = 625$ ✓

$a^2 + b^2 = c^2$
general case



EXAMPLE 18 ▶ **Applying the Pythagorean Theorem**

An extension ladder is placed 9 ft from the base of a building in an effort to reach a third-story window that is 27 ft high. What is the minimum length of the ladder required? Answer in exact form using radicals, and in approximate form by rounding to one decimal place.

Solution ▶ We can assume the building makes a 90° angle with the ground, and use the Pythagorean theorem to find the required length. Let c represent this length.

$c^2 = a^2 + b^2$ Pythagorean theorem
$c^2 = (9)^2 + (27)^2$ substitute 9 for a and 27 for b
$c^2 = 81 + 729$ $9^2 = 81, 27^2 = 729$
$c^2 = 810$ add
$c = \sqrt{810}$ definition of square root; $c > 0$
$c = 9\sqrt{10}$ exact form: $\sqrt{810} = \sqrt{81 \cdot 10} = 9\sqrt{10}$
$c \approx 28.5$ ft approximate form

The ladder must be at least 28.5 ft tall.

☑ **F.** You've just seen how we can solve equations and use formulas involving radicals

b. $(\sqrt{5}-\sqrt{14})(\sqrt{2}+\sqrt{13})$
c. $(2\sqrt{2}+6\sqrt{6})(3\sqrt{10}+\sqrt{7})$

38. **a.** $(5+4\sqrt{10})(1-2\sqrt{10})$
b. $(\sqrt{3}+\sqrt{2})(\sqrt{10}+\sqrt{11})$
c. $(3\sqrt{5}+4\sqrt{2})(\sqrt{15}+\sqrt{6})$

Use a substitution to verify the solutions to the quadratic equation given. Verify results using a calculator.

39. $x^2-4x+1=0$
a. $x=2+\sqrt{3}$ **b.** $x=2-\sqrt{3}$

40. $x^2-10x+18=0$
a. $x=5-\sqrt{7}$ **b.** $x=5+\sqrt{7}$

41. $x^2+2x-9=0$
a. $x=-1+\sqrt{10}$ **b.** $x=-1-\sqrt{10}$

42. $x^2-14x+29=0$
a. $x=7-2\sqrt{5}$ **b.** $x=7+2\sqrt{5}$

Rationalize each expression by building perfect *n*th root factors for each denominator. Assume all variables represent positive quantities.

43. **a.** $\dfrac{3}{\sqrt{12}}$ **b.** $\sqrt{\dfrac{20}{27x^3}}$
c. $\sqrt{\dfrac{27}{50b}}$ **d.** $\sqrt[3]{\dfrac{1}{4p}}$
e. $\dfrac{5}{\sqrt[3]{a}}$

44. **a.** $\dfrac{-4}{\sqrt{20}}$ **b.** $\sqrt{\dfrac{125}{12n^3}}$
c. $\sqrt{\dfrac{5}{12x}}$ **d.** $\sqrt[3]{\dfrac{3}{2m^2}}$
e. $\dfrac{-8}{3\sqrt[3]{5}}$

Simplify the following expressions by rationalizing the denominators. Where possible, state results in exact form and approximate form, rounded to hundredths.

45. **a.** $\dfrac{8}{3+\sqrt{11}}$ **b.** $\dfrac{6}{\sqrt{x}-\sqrt{2}}$

46. **a.** $\dfrac{7}{\sqrt{7}+3}$ **b.** $\dfrac{12}{\sqrt{x}+\sqrt{3}}$

47. **a.** $\dfrac{\sqrt{10}-3}{\sqrt{3}+\sqrt{2}}$ **b.** $\dfrac{7+\sqrt{6}}{3-3\sqrt{2}}$

48. **a.** $\dfrac{1+\sqrt{2}}{\sqrt{6}+\sqrt{14}}$ **b.** $\dfrac{1+\sqrt{6}}{5+2\sqrt{3}}$

Solve each equation and check your solutions by *substitution*. Identify any extraneous roots.

49. **a.** $-3\sqrt{3x-5}=-9$
b. $x=\sqrt{3x+1}+3$

50. **a.** $-2\sqrt{4x-1}=-10$
b. $-5=\sqrt{5x-1}-x$

51. **a.** $2=\sqrt[3]{3m-1}$
b. $2\sqrt[3]{7-3x}-3=-7$
c. $\dfrac{\sqrt[3]{2m+3}}{-5}+2=3$
d. $\sqrt[3]{2x-9}=\sqrt[3]{3x+7}$

52. **a.** $-3=\sqrt[3]{5p+2}$
b. $3\sqrt[3]{3-4x}-7=-4$
c. $\dfrac{\sqrt[3]{6x-7}}{4}-5=-6$
d. $3\sqrt[3]{x+3}=2\sqrt[3]{2x+17}$

53. **a.** $\sqrt{x-9}+\sqrt{x}=9$
b. $x=3+\sqrt{23-x}$
c. $\sqrt{x-2}-\sqrt{2x}=-2$
d. $\sqrt{12x+9}-\sqrt{24x}=-3$

54. **a.** $\sqrt{x+7}-\sqrt{x}=1$
b. $\sqrt{2x+31}+x=2$
c. $\sqrt{3x}=\sqrt{x-3}+3$
d. $\sqrt{3x+4}-\sqrt{7x}=-2$

Write the equation in simplified form, then solve. Check all answers by substitution.

55. **a.** $x^{\frac{3}{5}}+17=9$
b. $-2x^{\frac{3}{4}}+47=-7$

56. **a.** $0.\overline{3}x^{\frac{5}{2}}-39=42$
b. $0.\overline{5}x^{\frac{5}{3}}+92=-43$

57. **a.** $2(x+5)^{\frac{2}{3}}-11=7$
b. $-3(x-2)^{\frac{4}{5}}+29=-19$

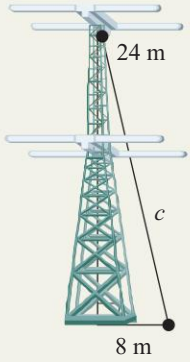
58. **a.** $3x^{\frac{1}{3}}-10=\sqrt[3]{x}$
b. $2\sqrt[5]{x^2}-4=x^{\frac{2}{5}}$

59. $x^{\frac{2}{3}}-2x^{\frac{1}{3}}-15=0$

60. $x^3-9x^{\frac{3}{2}}=-8$

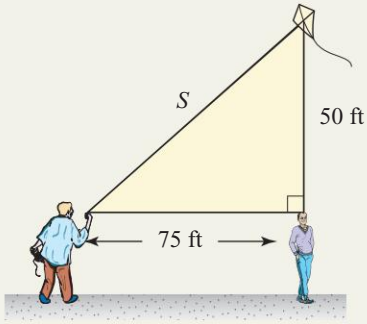
▶ WORKING WITH FORMULAS

61. Fish length to weight relationship: $L = 1.13(W)^{\frac{1}{3}}$



The length to weight relationship of a female Pacific halibut can be approximated by the formula shown, where W is the weight in pounds and L is the length in feet. A fisherman lands a halibut that weighs 400 lb. Approximate the length of the fish (round to two decimal places).

62. Timing a falling object: $t = \dfrac{\sqrt{s}}{4}$



The time it takes an object to fall a certain distance is given by the formula shown, where t is the time in seconds and s is the distance the object has fallen. Approximate the time it takes an object to hit the ground, if it is dropped from the top of a building that is 80 ft in height (round to hundredths).

▶ APPLICATIONS

63. Length of a cable: A radio tower is secured by cables that are anchored in the ground 8 m from its base. If the cables are attached to the tower 24 m above the ground, what is the length of each cable? Answer in (a) exact form using radicals, and (b) approximate form by rounding to one decimal place.

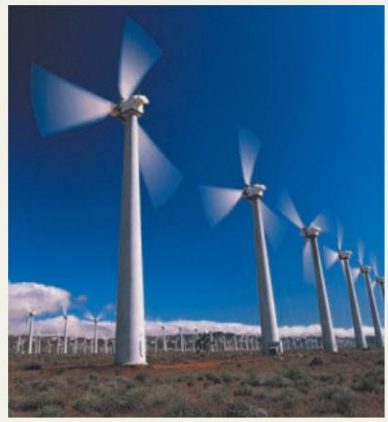
64. Height of a kite: Benjamin Franklin is flying his kite in a storm once again. John Adams has walked to a position directly under the kite and is 75 ft from Ben. If the kite is 50 ft above John Adams' head, how much string S has Ben let out? Answer in (a) exact form using radicals, and (b) approximate form by rounding to one decimal place.

The time T (in days) required for a planet to make one revolution around the sun is modeled by the function $T = 0.407R^{\frac{3}{2}}$, where R is the maximum radius of the planet's orbit (in millions of miles). This is known as *Kepler's third law of planetary motion*. Use the equation given to approximate the number of days required for one complete orbit of each planet, given its maximum orbital radius.

65. a. Earth: 93 million mi

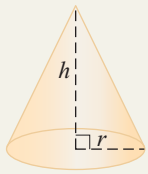
b. Mars: 142 million mi

c. Mercury: 36 million mi



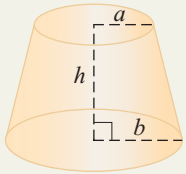
66. a. Venus: 67 million mi

b. Jupiter: 480 million mi



c. Saturn: 890 million mi

67. Accident investigation: After an accident, police officers will try to determine the approximate velocity V that a car was traveling using the formula $V = 2\sqrt{6L}$, where L is the length of the skid marks in feet and V is the velocity in miles per hour. (a) If the skid marks were 54 ft long, how fast was the car traveling? (b) Approximate the speed of the car if the skid marks were 90 ft long.



68. Wind-powered energy: If a wind-powered generator is delivering P units of power, the velocity V of the wind (in miles per hour) can be determined using $V = \sqrt[3]{\dfrac{P}{k}}$, where k is a constant that depends on the size and efficiency of the generator. Rationalize the radical expression and use the new version to find the velocity of the wind if $k = 0.004$ and the generator is putting out 13.5 units of power.

69. Surface area: The lateral surface area (surface area excluding the base) S of a cone is given by the formula $S = \pi r\sqrt{r^2 + h^2}$, where r is the radius of the base and h is the height of the cone. Find the lateral surface area of a cone that has a radius of 6 m and a height of 10 m. Answer in simplest form.

70. Surface area: The lateral surface area S of a frustum (a truncated cone) is given by the formula $S = \pi(a + b)\sqrt{h^2 + (b - a)^2}$, where a is the radius of the upper base, b is the radius of the lower base, and h is the height. Find the surface area of a frustum where $a = 6$ m, $b = 8$ m, and $h = 10$ m. Answer in simplest form.

71. Planetary motion: The time T (in days) for a planet to make one revolution (elliptical orbit) around the sun is modeled by $T = 0.407R^{\frac{3}{2}}$, where R is the maximum radius of the planet's orbit in millions of miles (*Kepler's third law of planetary motion*). Use the equation to approximate the maximum radius of each orbit, given the number of days it takes for one revolution. (See Exercises 65 and 66.)

a. Mercury: 88 days
b. Venus: 225 days
c. Earth: 365 days
d. Mars: 687 days
e. Jupiter: 4333 days
f. Saturn: 10,759 days

72. Wind-powered energy: If a wind-powered generator is delivering P units of power, the velocity V of the wind (in miles per hour) can be determined using $V = \sqrt[3]{\frac{P}{k}}$, where k is a constant that depends on the size and efficiency of the generator. Given $k = 0.004$, approximately how many units of power are being delivered if the wind is blowing at 27 miles per hour? (See Exercise 68.)

▶ EXTENDING THE CONCEPT

The expression $x^2 - 7$ is not factorable using *integer values*. But the expression *can be written* in the form $x^2 - (\sqrt{7})^2$, enabling us to factor it as a "binomial" and its conjugate: $(x + \sqrt{7})(x - \sqrt{7})$. Use this idea to factor the following expressions.

73. a. $x^2 - 5$
b. $n^2 - 19$

74. a. $4v^2 - 11$
b. $9w^2 - 17$

75. The following terms form a pattern that continues until the sixth term is found: $\sqrt{3x} + \sqrt{9x} + \sqrt{27x} + \ldots$ **(a)** Compute the sum of all six terms; **(b)** develop a system (investigate the pattern further) that will enable you to find the sum of 12 such terms *without actually writing out the terms*.

76. Find a quick way to simplify the expression without the aid of a calculator.

$$\left(\left(\left(\left(\left(3^{\frac{5}{6}}\right)^{\frac{3}{2}}\right)^{\frac{4}{5}}\right)^{\frac{3}{4}}\right)^{\frac{2}{5}}\right)^{\frac{10}{3}}$$

77. If $(x^{\frac{1}{2}} + x^{-\frac{1}{2}})^2 = \frac{9}{2}$, find the value of $x^{\frac{1}{2}} + x^{-\frac{1}{2}}$.

78. Rewrite by rationalizing the *numerator:*

$$\frac{\sqrt{x + h} - \sqrt{x}}{h}$$

Determine the values of x for which each expression represents a real number.

79. $\dfrac{\sqrt{x - 1}}{x^2 - 4}$

80. $\dfrac{x^2 - 4}{\sqrt{x - 1}}$

OVERVIEW OF APPENDIX A

Prerequisite Definitions, Properties, Formulas, and Relationships

Notation and Relations

concept	notation	description	example
• Set notation:	{*members*}	braces enclose the members of a set	set of even whole numbers $A = \{0, 2, 4, 6, 8, \ldots\}$
• Is an element of	$\in$	indicates membership in a set	$14 \in A$
• Empty set	$\varnothing$ or $\{\ \}$	a set having no elements	odd numbers in A
• Is a proper subset of	$\subset$	indicates the elements of one set are entirely contained in another	$S = \{0, 6, 12, 18, 24, \ldots\}$ $S \subset A$
• Defining a set	$\{x \mid x \ldots\}$	the set of all x, *such that* x . . .	$S = \{x \mid x = 6n \text{ for } n \in \mathbb{W}\}$

Sets of Numbers

- Natural: $\mathbb{N} = \{1, 2, 3, 4, \ldots\}$
- Whole: $\mathbb{W} = \{0, 1, 2, 3, \ldots\}$
- Integers: $\mathbb{Z} = \{\ldots, -3, -2, -1, 0, 1, 2, 3, \ldots\}$
- Rational: $\mathbb{Q} = \left\{\frac{p}{q}, \text{ where } p, q \in \mathbb{Z}; q \neq 0\right\}$
- Irrational: $\mathbb{H} = \{$numbers with a nonterminating, nonrepeating decimal form$\}$
- Real: $\mathbb{R} = \{$all rational and irrational numbers$\}$

Absolute Value of a Number

- The distance between a number n and zero (always positive)

$$|n| = \begin{cases} n & \text{if } n \geq 0 \\ -n & \text{if } n < 0 \end{cases}$$

Distance between numbers *a* and *b* on the number line

$|a - b|$ or $|b - a|$

For a complete review of these ideas, go to www.mhhe.com/coburn.

A.1 Properties of Real Numbers: For real numbers a, b, and c,

Commutative Property
- Addition: $a + b = b + a$
- Multiplication: $a \cdot b = b \cdot a$

Associative Property
- Addition: $(a + b) + c = a + (b + c)$
- Multiplication: $(a \cdot b) \cdot c = a \cdot (b \cdot c)$

Identities
- Additive: $0 + a = a$
- Multiplicative: $1 \cdot a = a$

Inverses
- Additive: $a + (-a) = 0$
- Multiplicative: $\frac{p}{q} \cdot \frac{q}{p} = 1; p, q \neq 0$

A.2 Properties of Exponents: For real numbers a and b, and integers m, n, and p (excluding 0 raised to a nonpositive power),

- Product property: $b^m \cdot b^n = b^{m+n}$
- Product to a power: $(a^m b^n)^p = a^{mp} \cdot b^{np}$
- Quotient property: $\frac{b^m}{b^n} = b^{m-n}\ (b \neq 0)$
- Negative exponents: $b^{-n} = \frac{1}{b^n}; \left(\frac{a}{b}\right)^{-n} = \left(\frac{b}{a}\right)^n$ $(a, b \neq 0)$
- Power property: $(b^m)^n = b^{mn}$
- Quotient to a power: $\left(\frac{a^m}{b^n}\right)^p = \frac{a^{mp}}{b^{np}}\ (b \neq 0)$
- Zero exponents: $b^0 = 1\ (b \neq 0)$
- Scientific notation: $N \times 10^k; 1 \leq |N| < 10, k \in \mathbb{Z}$

A.2 Polynomials

- A polynomial is a sum or difference of monomial terms
- Polynomials are classified as a monomial, binomial, trinomial, or polynomial, depending on the number of terms
- The degree of a polynomial in one variable is the same as the largest exponent occuring on the variable in any term
- A polynomial expression is in standard form when written with the terms in descending order of degree

A.3 Solving Linear Equations and Inequalities

- **Properties of Equality:**

additive property	**multiplicative property**
If A and B are algebraic expressions, where $A = B$, then $A + C = B + C$.	If A and B are algebraic expressions, where $A = B$, then $A \cdot C = B \cdot C$
[C can be positive or negative]	and $\frac{A}{C} = \frac{B}{C}; C \neq 0$

- A linear equation in one variable is one that can be written in the form $ax + b = c$, where the exponent on the variable is a 1.
- To solve a linear equation, we attempt to isolate the term containing the variable using the additive property, then solve for the variable using the multiplicative property.
- An equation can be an identity (always true), a contradiction (never true) or conditional (true or false depending on the input value[s]).
- If an equation contains fractions, multiplying both sides by the least common denominator of all fractions will "clear the denominators" and reduce the amount of work required to solve.
- Inequalities are solved using properties similar to those used for solving equations. The one exception is when multiplying or dividing by a negative quantity, as the inequality symbol *must then be reversed* to maintain the truth of the resulting statement.
- Solutions to an inequality can be given using a simple inequality, graphed on a number line, stated in set notation, or stated using interval notation.
- Given two sets A and B: A intersect B ($A \cap B$) is the set of elements *shared* by both A **and** B (elements common to both sets). A union B ($A \cup B$) is the set of elements *in either* A **or** B (elements are combined to form a larger set).
- Compound inequalities are formed using the conjunction "and" or the conjunction "or." The result can be either a joint inequality as in $-3 < x \leq 5$, or a disjoint inequality, $x < -2$ or $x > 7$.

A.4 Special Factorizations

- $A^2 - B^2 = (A + B)(A - B)$
- $A^2 \pm 2AB + B^2 = (A \pm B)^2$
- $A^3 - B^3 = (A - B)(A^2 + AB + B^2)$
- $A^3 + B^3 = (A + B)(A^2 - AB + B^2)$
- Certain equations of higher degree can be solved using factoring skills and the zero product property.

A.5 Rational Expressions: For polynomials P, Q, R, and S with no denominator of zero,

- Lowest terms: $\frac{P \cdot R}{Q \cdot R} = \frac{P}{Q}$
- Equivalence: $\frac{P}{Q} = \frac{P \cdot R}{Q \cdot R}$
- Multiplication: $\frac{P}{Q} \cdot \frac{R}{S} = \frac{P \cdot R}{Q \cdot S} = \frac{PR}{QS}$
- Division: $\frac{P}{Q} \div \frac{R}{S} = \frac{P}{Q} \cdot \frac{S}{R} = \frac{PS}{QR}$
- Addition: $\frac{P}{R} + \frac{Q}{R} = \frac{P + Q}{R}$
- Subtraction: $\frac{P}{R} - \frac{Q}{R} = \frac{P - Q}{R}$
- Addition/subtraction with unlike denominators:
  1. Find the LCD of all rational expressions.
  2. Build equivalent expressions using LCD.
  3. Add/subtract numerators as indicated.
  4. Write the result in lowest terms.
- To solve rational equations, first clear denominators using the LCD, noting values that must be excluded.
- Multiplying an equation by a variable quantity sometimes introduces extraneous solutions. Check all results in the original equation.

A.6 Properties of Radicals

- $\sqrt{a}$ is a real number only for $a \geq 0$
- $\sqrt[n]{a} = b$, only if $b^n = a$
- For any real number a, $\sqrt[n]{a^n} = |a|$ when n is even
- If a is a real number and n is an integer greater than 1, then $\sqrt[n]{a} = a^{\frac{1}{n}}$ provided $\sqrt[n]{a}$ represents a real number
- If $\sqrt[n]{A}$ and $\sqrt[n]{B}$ represent real numbers, $\sqrt[n]{AB} = \sqrt[n]{A} \cdot \sqrt[n]{B}$
- $\sqrt{a} = b$, only if $b^2 = a$
- If n is even, $\sqrt[n]{a}$ represents a real number only if $a \geq 0$
- For any real number a, $\sqrt[n]{a^n} = a$ when n is odd
- If $\frac{m}{n}$ is a rational number written in lowest terms with $n \geq 2$, then $a^{\frac{m}{n}} = (\sqrt[n]{a})^m$ and $a^{\frac{m}{n}} = \sqrt[n]{a^m}$ provided $\sqrt[n]{a}$ represents a real number.
- If $\sqrt[n]{A}$ and $\sqrt[n]{B}$ represent real numbers and $B \neq 0$, $\sqrt[n]{\frac{A}{B}} = \frac{\sqrt[n]{A}}{\sqrt[n]{B}}$
- A radical expression is in simplest form when:
  1. the radicand has no factors that are perfect nth roots,
  2. the radicand contains no fractions, and
  3. no radicals occur in a denominator.
- To solve radical equations, isolate the radical on one side, then apply the appropriate "nth power" to free up the radicand. Repeat the process if needed. See flowchart on page 74.
- For equations with a rational exponent $\frac{m}{n}$, isolate the variable term and raise both sides to the $\frac{n}{m}$ power. If m is even, there will be two real solutions.

A.6 Pythagorean Theorem

- For any right triangle with legs a and b and hypotenuse c: $a^2 + b^2 = c^2$.
- For any triangle with sides a, b, and c, if $a^2 + b^2 = c^2$, then the triangle is a right triangle.

PRACTICE TEST

1. State true or false. If false, state why.

a. $(3 + 4)^2 = 25$ **b.** $\frac{7}{0} = 0$

c. $x - 3 = -3 + x$ **d.** $-2(x - 3) = -2x - 3$

2. State the value of each expression.

a. $\sqrt{121}$ **b.** $\sqrt[3]{-125}$

c. $\sqrt{-36}$ **d.** $\sqrt{400}$

3. Evaluate each expression:

a. $\frac{7}{8} - \left(-\frac{1}{4}\right)$ **b.** $-\frac{1}{3} - \frac{5}{6}$

c. $-0.7 + 1.2$ **d.** $1.3 + (-5.9)$

4. Evaluate each expression:

a. $(-4)\left(-2\frac{1}{3}\right)$ **b.** $(-0.6)(-1.5)$

c. $\frac{-2.8}{-0.7}$ **d.** $4.2 \div (-0.6)$

5. Evaluate using a calculator: $2000\left(1 + \frac{0.08}{12}\right)^{12 \cdot 10}$

6. State the value of each expression, if possible.

a. $0 \div 6$ **b.** $6 \div 0$

7. State the number of terms in each expression and identify the coefficient of each.

a. $-2v^2 + 6v + 5$ **b.** $\frac{c + 2}{3} + c$

8. Evaluate each expression given $x = -0.5$ and $y = -2$. Round to hundredths as needed.

a. $2x - 3y^2$ **b.** $\sqrt{2} - x(4 - x^2) + \frac{y}{x}$

9. Translate each phrase into an algebraic expression.

a. Nine less than twice a number is subtracted from the number cubed.

b. Three times the square of half a number is subtracted from twice the number.

10. Create a mathematical model using descriptive variables.

a. The radius of the planet Jupiter is approximately 119 mi less than 11 times the radius of the Earth. Express the radius of Jupiter in terms of the Earth's radius.

b. Last year, Video Venue Inc. earned \$1.2 million more than four times what it earned this year. Express last year's earnings of Video Venue Inc. in terms of this year's earnings.

11. Simplify by combining like terms.

a. $8v^2 + 4v - 7 + v^2 - v$

b. $-4(3b - 2) + 5b$

c. $4x - (x - 2x^2) + x(3 - x)$

12. Factor each expression completely.

a. $9x^2 - 16$ **b.** $4v^3 - 12v^2 + 9v$

c. $x^3 + 5x^2 - 9x - 45$

13. Simplify using the properties of exponents.

a. $\dfrac{5}{b^{-3}}$ **b.** $(-2a^3)^2(a^2b^4)^3$

c. $\left(\dfrac{m^2}{2n}\right)^3$ **d.** $\left(\dfrac{5p^2q^3r^4}{-2pq^2r^4}\right)^2$

14. Simplify using the properties of exponents.

a. $\dfrac{-12a^3b^5}{3a^2b^4}$

b. $(3.2 \times 10^{-17}) \times (2.0 \times 10^{15})$

c. $\left(\dfrac{a^{-3} \cdot b}{c^{-2}}\right)^{-4}$ **d.** $-7x^0 + (-7x)^0$

15. Compute each product.

a. $(3x^2 + 5y)(3x^2 - 5y)$

b. $(2a + 3b)^2$

16. Add or subtract as indicated.

a. $(-5a^3 + 4a^2 - 3) + (7a^4 + 4a^2 - 3a - 15)$

b. $(2x^2 + 4x - 9) - (7x^4 - 2x^2 - x - 9)$

Simplify or compute as indicated.

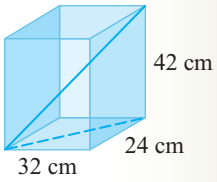
17. **a.** $\dfrac{x - 5}{5 - x}$ **b.** $\dfrac{4 - n^2}{n^2 - 4n + 4}$

c. $\dfrac{x^3 - 27}{x^2 + 3x + 9}$ **d.** $\dfrac{3x^2 - 13x - 10}{9x^2 - 4}$

e. $\dfrac{x^2 - 25}{3x^2 - 11x - 4} \div \dfrac{x^2 + x - 20}{x^2 - 8x + 16}$

f. $\dfrac{m + 3}{m^2 + m - 12} - \dfrac{2}{5(m + 4)}$

18. **a.** $\sqrt{(x + 11)^2}$ **b.** $\sqrt[3]{\dfrac{-8}{27v^3}}$



c. $\left(\dfrac{25}{16}\right)^{\frac{-3}{2}}$ **d.** $\dfrac{-4 + \sqrt{32}}{8}$

e. $7\sqrt{40} - \sqrt{90}$ **f.** $(x + \sqrt{5})(x - \sqrt{5})$

g. $\sqrt{\dfrac{2}{5x}}$ **h.** $\dfrac{8}{\sqrt{6} - \sqrt{2}}$

19. Maximizing revenue: Due to past experience, the manager of a video store knows that if a popular video game is priced at \$30, the store will sell 40 each day. For each decrease of \$0.50, one additional sale will be made. The formula for the store's revenue is then $R = (30 - 0.5x)(40 + x)$, where x represents the number of times the price is decreased. Multiply the binomials and use a table of values to determine (a) the number of 50¢ decreases that will give the most revenue and (b) the maximum amount of revenue.

20. Diagonal of a rectangular prism: Use the Pythagorean theorem to determine the length of the diagonal of the rectangular prism shown in the figure. (*Hint:* First find the diagonal of the base.)

21. Solve each linear equation.

a. $-2b + 7 = -5$ **b.** $3(2n - 6) + 1 = 7$

c. $4m - 5 = 11m + 2$ **d.** $\dfrac{1}{2}x + \dfrac{2}{3} = \dfrac{3}{4}$

e. $-8(3p + 5) - 9 = 6(3 - 4p)$

f. $-\dfrac{g}{6} = 3 - \dfrac{1}{2} - \dfrac{5g}{12}$

22. If one-fourth of the sum of a number and twelve is added to three, the result is sixteen. Find an equation model for this statement, then use it to find the number.

23. Solve each polynomial equation by factoring.

a. $x^3 - 7x^2 = 4x - 28$

b. $-7r^3 + 21r^2 + 28r = 0$

c. $g^4 - 10g^2 + 9 = 0$

24. Solve each rational equation.

a. $\dfrac{3}{5x} + \dfrac{7}{10} = \dfrac{1}{4x}$

b. $\dfrac{3h}{h + 3} - \dfrac{7}{h^2 + 3h} = \dfrac{1}{h}$

c. $\dfrac{n}{n + 2} - \dfrac{3}{n - 4} = \dfrac{4n + 20}{n^2 - 2n - 8}$

25. Solve each radical equation.

a. $\dfrac{\sqrt{x^2 + 7}}{2} + 3 = 5$

b. $3\sqrt{x + 4} = x + 4$

c. $\sqrt{3x + 4} = 2 - \sqrt{x + 2}$

Appendix B

Proof Positive—A Selection of Proofs from Precalculus

The Remainder Theorem

If a polynomial p(x) is divided by $(x - c)$ using synthetic division, the remainder is equal to p(c).

Proof of the Remainder Theorem

From our previous work, any number c used in synthetic division will occur as the factor $(x - c)$ when written as (quotient)(divisor) + remainder: $p(x) = (x - c)q(x) + r$. Here, $q(x)$ represents the quotient polynomial and r is a constant. Evaluating $p(c)$ gives

$$\begin{aligned} p(x) &= (x - c)q(x) + r \\ p(c) &= (c - c)q(c) + r \\ &= 0 \cdot q(c) + r \\ &= r \checkmark \end{aligned}$$

The Factor Theorem

Given a polynomial p(x),
(1) if $p(c) = 0$, then $x - c$ is a factor of p(x), and
(2) if $x - c$ is a factor of p(x), then $p(c) = 0$.

Proof of the Factor Theorem

1. Consider a polynomial p written in the form $p(x) = (x - c)q(x) + r$. From the remainder theorem we know $p(c) = r$, and substituting $p(c)$ for r in the equation shown gives:

   $$p(x) = (x - c)q(x) + p(c)$$

   and $x - c$ is a factor of $p(x)$, if $p(c) = 0$

   $$p(x) = (x - c)q(x) \checkmark$$

2. The steps from part 1 can be reversed, since any factor $(x - c)$ of $p(x)$, can be written in the form $p(x) = (x - c)q(x)$. Evaluating at $x = c$ produces a result of zero:

   $$\begin{aligned} p(c) &= (c - c)q(x) \\ &= 0 \checkmark \end{aligned}$$

Complex Conjugates Theorem

Given p(x) is a polynomial with real number coefficients, complex solutions must occur in conjugate pairs. If $a + bi$, $b \neq 0$ is a solution, then $a - bi$ must also be a solution.

To prove this for polynomials of degree $n > 2$, we let $z_1 = a + bi$ and $z_2 = c + di$ be complex numbers, and let $\bar{z}_1 = a - bi$, and $\bar{z}_2 = c - di$ represent their conjugates, and observe the following properties:

1. The conjugate of a sum is equal to the sum of the conjugates.

sum: $z_1 + z_2$		sum of conjugates: $\bar{z}_1 + \bar{z}_2$
$(a + bi) + (c + di)$		$(a - bi) + (c - di)$
$(a + c) + (b + d)i$	→ conjugate of sum →	$(a + c) - (b + d)i$ ✓

2. The conjugate of a product is equal to the product of the conjugates.

product: $z_1 \cdot z_2$		product of conjugates: $\bar{z}_1 \cdot \bar{z}_2$
$(a + bi) \cdot (c + di)$		$(a - bi) \cdot (c - di)$
$ac + adi + bci + bdi^2$		$ac - adi - cbi + bdi^2$
$(ac - bd) + (ad + bc)i$	→ conjugate of product →	$(ac - bd) - (ad + bc)i$ ✓

Since polynomials involve only sums and products, and the complex conjugate of any real number is the number itself, we have the following:

Proof of the Complex Conjugates Theorem

Given polynomial $p(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x^1 + a_0$, where $a_n, a_{n-1}, \cdots, a_1, a_0$ are real numbers and $z = a + bi$ is a zero of p, we must show that $\bar{z} = a - bi$ is also a zero.

$a_n z^n + a_{n-1}z^{n-1} + \cdots + a_1 z^1 + a_0 = p(z)$		evaluate $p(x)$ at z
$a_n z^n + a_{n-1}z^{n-1} + \cdots + a_1 z^1 + a_0 = 0$		$p(z) = 0$ given
$a_n z^n + a_{n-1}z^{n-1} + \cdots + a_1 z^1 + a_0 = \bar{0}$		conjugate both sides
$\overline{a_n z^n} + \overline{a_{n-1}z^{n-1}} + \cdots + \overline{a_1 z^1} + \overline{a_0} = \bar{0}$		property 1
$\bar{a}_n(\bar{z}^n) + \bar{a}_{n-1}(\bar{z}^{n-1}) + \cdots + \bar{a}_1(\bar{z}^1) + \bar{a}_0 = \bar{0}$		property 2
$a_n(\bar{z}^n) + a_{n-1}(\bar{z}^{n-1}) + \cdots + a_1(\bar{z}^1) + a_0 = 0$		conjugate of a real number is the number
$p(\bar{z}) = 0$	✓	result

An immediate and useful result of this theorem is that any polynomial of odd degree must have at least one real root.

Linear Factorization Theorem

If $p(x)$ is a complex polynomial of degree $n \geq 1$, then p has exactly n linear factors and can be written in the form $p(x) = a_n(x - c_1)(x - c_2) \cdot \ldots \cdot (x - c_n)$, where $a_n \neq 0$ and $c_1, c_2, \ldots, c_n$ are complex numbers. Some factors may have multiplicities greater than 1 ($c_1, c_2, \ldots, c_n$ are not necessarily distinct).

Proof of the Linear Factorization Theorem

Given $p(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$ is a complex polynomial, the Fundamental Theorem of Algebra establishes that $p(x)$ has a least one complex zero, call it c_1. The factor theorem stipulates $(x - c_1)$ must be a factor of P, giving

$$p(x) = (x - c_1)q_1(x)$$

where $q_1(x)$ is a complex polynomial of degree $n - 1$.

Since $q_1(x)$ is a complex polynomial in its own right, it too must also have a complex zero, call it c_2. Then $(x - c_2)$ must be a factor of $q_1(x)$, giving

$$p(x) = (x - c_1)(x - c_2)q_2(x)$$

where $q_2(x)$ is a complex polynomial of degree $n - 2$.

Repeating this rationale n times will cause $p(x)$ to be rewritten in the form

$$p(x) = (x - c_1)(x - c_2) \cdot \cdots \cdot (x - c_n)q_n(x)$$

where $q_n(x)$ has a degree of $n - n = 0$, a nonzero constant typically called a_n.

The result is $p(x) = a_n(x - c_1)(x - c_2) \cdot \cdots \cdot (x - c_n)$, and the proof is complete.

The Product Property of Logarithms

Given M, N, and $b \neq 1$ are positive real numbers,
$\log_b(MN) = \log_b M + \log_b N$.

Proof of the Product Property

For $P = \log_b M$ and $Q = \log_b N$, we have $b^P = M$ and $b^Q = N$ in exponential form. It follows that

$$\begin{aligned}
\log_b(MN) &= \log_b(b^P b^Q) && \text{substitute } b^P \text{ for } M \text{ and } b^Q \text{ for } N \\
&= \log_b(b^{P+Q}) && \text{properties of exponents} \\
&= P + Q && \text{log property 3} \\
&= \log_b M + \log_b N && \text{substitute } \log_b M \text{ for } P \text{ and } \log_b N \text{ for } Q
\end{aligned}$$

The Quotient Property of Logarithms

Given M, N, and $b \neq 1$ are positive real numbers,

$$\log_b\left(\frac{M}{N}\right) = \log_b M - \log_b N.$$

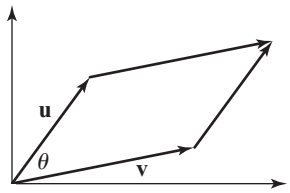
Proof of the Quotient Property

For $P = \log_b M$ and $Q = \log_b N$, we have $b^P = M$ and $b^Q = N$ in exponential form. It follows that

$$\begin{aligned}
\log_b\left(\frac{M}{N}\right) &= \log_b\left(\frac{b^P}{b^Q}\right) && \text{substitute } b^P \text{ for } M \text{ and } b^Q \text{ for } N \\
&= \log_b(b^{P-Q}) && \text{properties of exponents} \\
&= P - Q && \text{log property 3} \\
&= \log_b M - \log_b N && \text{substitute } \log_b M \text{ for } P \text{ and } \log_b N \text{ for } Q
\end{aligned}$$

The Power Property of Logarithms

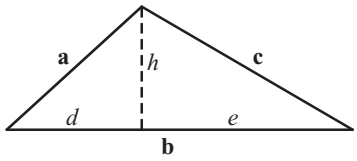
Given M, N, and $b \neq 1$ are positive real numbers and any real number x,
$\log_b M^x = x \log_b M$.



Proof of the Power Property

For $P = \log_b M$, we have $b^P = M$ in exponential form. It follows that

$$\begin{aligned}
\log_b(M)^x &= \log_b(b^P)^x && \text{substitute } b^P \text{ for } M \\
&= \log_b(b^{Px}) && \text{properties of exponents} \\
&= Px && \text{log property 3} \\
&= (\log_b M)x && \text{substitute } \log_b M \text{ for } P \\
&= x \log_b M && \text{rewrite factors}
\end{aligned}$$



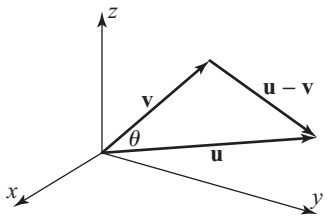
Proof of the Determinant Formula for the Area of a Parallelogram

Since the area of a triangle is $A = \frac{1}{2}ab \sin\theta$, the area of the corresponding parallelogram is twice as large: $A = ab \sin\theta$. In terms of the vectors $\mathbf{u} = \langle a, b\rangle$ and $\mathbf{v} = \langle c, d\rangle$, we have $A = |\mathbf{u}||\mathbf{v}| \sin\theta$, and it follows that

$$\begin{aligned}
\text{Area} &= |\mathbf{u}||\mathbf{v}|\sqrt{1-\cos^2\theta}, && \text{Pythagorean identity}\\
&= |\mathbf{u}||\mathbf{v}|\sqrt{1-\frac{(\mathbf{u}\cdot\mathbf{v})^2}{|\mathbf{u}|^2|\mathbf{v}|^2}} && \text{substitute for } \cos\theta\\
&= |\mathbf{u}||\mathbf{v}|\sqrt{\frac{|\mathbf{u}|^2|\mathbf{v}|^2-(\mathbf{u}\cdot\mathbf{v})^2}{|\mathbf{u}|^2|\mathbf{v}|^2}} && \text{common denominator}\\
&= \sqrt{|\mathbf{u}|^2|\mathbf{v}|^2-(\mathbf{u}\cdot\mathbf{v})^2} && \text{simplify}\\
&= \sqrt{(a^2+b^2)(c^2+d^2)-(ac+bd)^2} && \text{substitute}\\
&= \sqrt{a^2c^2+a^2d^2+b^2c^2+b^2d^2-(a^2c^2+2acbd+b^2d^2)} && \text{expand}\\
&= \sqrt{a^2d^2-2acbd+b^2c^2} && \text{simplify}\\
&= \sqrt{(ad-bc)^2} && \text{factor}\\
&= |ad-bc| && \text{result}
\end{aligned}$$

Proof of Heron's Formula Using Algebra

Note that $\sqrt{a^2-d^2}=h=\sqrt{c^2-e^2}$. It follows that



$$\begin{aligned}
\sqrt{a^2-d^2} &= \sqrt{c^2-e^2}\\
a^2-d^2 &= c^2-e^2\\
a^2-(b-e)^2 &= c^2-e^2\\
a^2-b^2+2be-e^2 &= c^2-e^2\\
a^2-b^2-c^2 &= -2be\\
\frac{b^2+c^2-a^2}{2b} &= e
\end{aligned}$$

This shows:

$$\begin{aligned}
A &= \frac{1}{2}bh\\
&= \frac{1}{2}b\sqrt{c^2-e^2}\\
&= \frac{1}{2}b\sqrt{c^2-\left(\frac{b^2+c^2-a^2}{2b}\right)^2}\\
&= \frac{1}{2}b\sqrt{c^2-\left(\frac{b^4+2b^2c^2-2a^2b^2-2a^2c^2+a^4+c^4}{4b^2}\right)}\\
&= \frac{1}{2}b\sqrt{\frac{4b^2c^2}{4b^2}-\left(\frac{b^4+2b^2c^2-2a^2b^2-2a^2c^2+a^4+c^4}{4b^2}\right)}\\
&= \frac{1}{2}b\sqrt{\frac{4b^2c^2-b^4-2b^2c^2+2a^2b^2+2a^2c^2-a^4-c^4}{4b^2}}\\
&= \frac{1}{4}\sqrt{2a^2b^2+2a^2c^2+2b^2c^2-a^4-b^4-c^4}\\
&= \frac{1}{4}\sqrt{[(a+b)^2-c^2][c^2-(a-b)^2]}\\
&= \frac{1}{4}\sqrt{(a+b+c)(a+b-c)(c+a-b)(c-a+b)}
\end{aligned}$$

From this point, the conclusion of the proof is the same as the trigonometric development found on page 765.

Proof that $\mathbf{u} \cdot \mathbf{v} = \text{comp}_{\mathbf{v}}\, \mathbf{u} \times |\mathbf{v}|$

Consider the vectors in the figure shown, which form a triangle. Applying the Law of Cosines to this triangle yields:

$$|\mathbf{u} - \mathbf{v}|^2 = |\mathbf{u}|^2 + |\mathbf{v}|^2 - 2|\mathbf{u}||\mathbf{v}| \cos\theta$$

Using properties of the dot product (page 680), we can rewrite the left-hand side as follows:

$$\begin{aligned} |\mathbf{u} - \mathbf{v}|^2 &= (\mathbf{u} - \mathbf{v}) \cdot (\mathbf{u} - \mathbf{v}) \\ &= \mathbf{u} \cdot \mathbf{u} - \mathbf{u} \cdot \mathbf{v} - \mathbf{v} \cdot \mathbf{u} + \mathbf{v} \cdot \mathbf{v} \\ &= |\mathbf{u}|^2 - 2\,\mathbf{u} \cdot \mathbf{v} + |\mathbf{v}|^2 \end{aligned}$$

Substituting the last expression for $|\mathbf{u} - \mathbf{v}|^2$ from the Law of Cosines gives

$$\begin{aligned} |\mathbf{u}|^2 - 2\,\mathbf{u} \cdot \mathbf{v} + |\mathbf{v}|^2 &= |\mathbf{u}|^2 + |\mathbf{v}|^2 - 2\,|\mathbf{u}||\mathbf{v}| \cos\theta \\ -2\,\mathbf{u} \cdot \mathbf{v} &= -2\,|\mathbf{u}||\mathbf{v}| \cos\theta \\ \mathbf{u} \cdot \mathbf{v} &= |\mathbf{u}||\mathbf{v}| \cos\theta \\ &= |\mathbf{u}| \cos\theta \times |\mathbf{v}|. \end{aligned}$$

Substituting $\text{comp}_{\mathbf{v}}\, \mathbf{u}$ for $|\mathbf{u}| \cos\theta$ completes the proof:

$$\mathbf{u} \cdot \mathbf{v} = \text{comp}_{\mathbf{v}}\, \mathbf{u} \times |\mathbf{v}|$$

Proof of DeMoivre's Theorem: $(\cos x + i \sin x)^n = \cos(nx) + i \sin(nx)$

For $n > 0$, we proceed using mathematical induction.

1. Show the statement is true for $n = 1$ (base case):

$$\begin{aligned} (\cos x + i \sin x)^1 &= \cos(1x) + i \sin(1x) \\ \cos x + i \sin x &= \cos x + i \sin x \quad \checkmark \end{aligned}$$

2. Assume the statement is true for $n = k$ (induction hypothesis):

$$(\cos x + i \sin x)^k = \cos(kx) + i \sin(kx)$$

3. Show the statement is true for $n = k + 1$:

$$\begin{aligned} (\cos x + i \sin x)^{k+1} &= (\cos x + i \sin x)^k (\cos x + i \sin x)^1 \\ &= [\cos(kx) + i \sin(kx)](\cos x + i \sin x) && \text{induction hypothesis} \\ &= \cos(kx)\cos x - \sin(kx)\sin x + i[\cos(kx)\sin x + \sin(kx)\cos x] \\ &= \cos[(k+1)x] + i \sin[(k+1)x] \quad \checkmark && \text{F-O-I-L; sum/difference identities} \end{aligned}$$

By the principle of mathematical induction, the statement is true for all positive integers. For $n < 0$ (the theorem is obviously true for $n = 0$), consider a positive integer m, where $n = -m$.

$$\begin{aligned} (\cos x + i \sin x)^n &= (\cos x + i \sin x)^{-m} \\ &= \frac{1}{(\cos x + i \sin x)^m} && \text{negative exponent property} \\ &= \frac{1}{\cos(mx) + i \sin(mx)} && \text{DeMoivre's theorem for } n > 0 \\ &= \cos(mx) - i \sin(mx) && \text{multiply numerator and denom by } \cos(mx) - i \sin(mx) \text{ and simplify} \\ &= \cos(-mx) + i \sin(-mx) && \text{even/odd identities} \\ &= \cos(nx) + i \sin(nx) && n = -m \end{aligned}$$

Appendix C

More on Synthetic Division

As the name implies, synthetic division simulates the long division process, but in a condensed and more efficient form. It's based on a few simple observations of long division, as noted in the division $(x^3 - 2x^2 - 13x - 17) \div (x - 5)$ shown in Figure AI.1.

Figure AI.1

$$
\begin{array}{r}
x^2 + 3x + 2 \\
x - 5\overline{)\,x^3 - 2x^2 - 13x - 17} \\
-(x^3 - 5x^2) \\
\hline
3x^2 - 13x \\
-(3x^2 - 15x) \\
\hline
2x - 17 \\
-(2x - 10) \\
\hline
-7 \quad \text{remainder}
\end{array}
$$

Figure AI.2

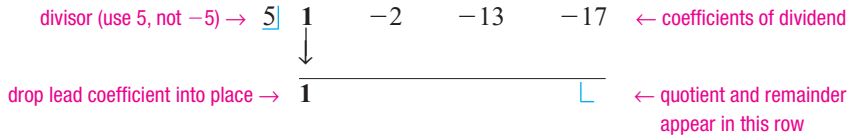
$$
\begin{array}{r}
1 \quad 3 \quad 2 \\
x - 5\overline{)\,1 \quad -2 \quad -13 \quad -17} \\
\underline{\quad 5} \\
3 \\
\underline{\qquad 15} \\
2 \\
\underline{\qquad\quad 10} \\
-7 \quad \text{remainder}
\end{array}
$$

A careful observation reveals a great deal of repetition, as any term in red is a duplicate of the term above it. In addition, since the dividend and divisor must be written in decreasing order of degree, the variable part of each term is unnecessary as we can let the *position of each coefficient* indicate the degree of the term. In other words, we'll agree that

$$1 \quad -2 \quad -13 \quad -17 \quad \text{represents the polynomial} \quad 1x^3 - 2x^2 - 13x - 17.$$

Finally, we know in advance that we'll be subtracting each partial product, so we can "distribute the negative," shown at each stage. Removing the repeated terms and variable factors, then distributing the negative to the remaining terms produces Figure AI.2. The entire process can now be condensed by vertically compressing the rows of the division so that a minimum of space is used (Figure AI.3).

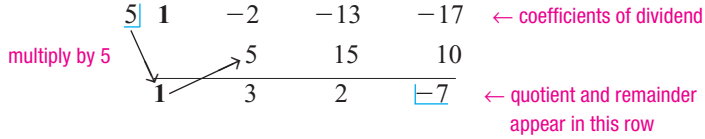
Figure AI.3



$$
\begin{array}{rcccl}
 & 1 & 3 & 2 & \text{quotient} \\
x - 5 & 1 & -2 & -13 & -17 \quad \text{dividend} \\
 & 5 & 15 & 10 & \text{products} \\
\hline
 & 3 & 2 & 7 & \text{sums}
\end{array}
$$

Figure AI.4

$$
\begin{array}{rcccl}
 & 1 & 3 & 2 & \\
x - 5 & 1 & -2 & -13 & -17 \quad \text{dividend} \\
 & \downarrow & 5 & 15 & 10 \quad \text{products} \\
\hline
 & 1 & 3 & 2 & -7 \quad \textbf{remainder} \\
 & \text{quotient} & & &
\end{array}
$$



Further, if we include the lead coefficient in the bottom row (Figure AI.4), the coefficients in the top row (in **blue**) are duplicated and no longer necessary, since the quotient and remainder now appear in the last row. Finally, note all entries in the product row (in **red**) are five times the sum from the prior column. There is a direct connection between this multiplication by 5 and the divisor $x - 5$, and in fact, it is the *zero of the divisor* that is used in synthetic division ($x = 5$ from $x - 5 = 0$). A simple change in format makes this method of division easier to use, and highlights the location of the divisor and remainder (the **blue** brackets in Figure AI.5). Note the process begins by "dropping the lead coefficient into place" (shown in **bold**). The full process of synthetic division is shown in Figure AI.6 for the same exercise.

Figure AI. 5

We then multiply this coefficient by the "divisor," place the result in the next column and add. In a sense, we "multiply in the diagonal direction," and "add in the vertical direction." Continue the process until the division is complete.

Figure AI. 6

The result is $x^2 + 3x + 2 + \dfrac{-7}{x - 5}$, read from the last row.

Appendix D

Reduced Row-Echelon Form and More on Matrices

Reduced Row-Echelon Form

A matrix is in reduced row-echelon form if it satisfies the following conditions:

1. All null rows (zeroes for all entries) occur at the bottom of the matrix.
2. The first non-zero entry of any row must be a 1.
3. For any two consecutive, nonzero rows, the leading 1 in the higher row is to the left of the 1 in the lower row.
4. Every column with a leading 1 has zeroes for all other entries in the column.

Matrices A through D are in reduced row-echelon form.

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 5 \\ 0 & 0 & 0 & 1 & 0 & 3 \\ 0 & 0 & 0 & 0 & 1 & 2 \end{bmatrix} \quad B = \begin{bmatrix} 1 & 0 & 0 & 5 \\ 0 & 1 & 0 & 3 \\ 0 & 0 & 0 & 0 \end{bmatrix} \quad C = \begin{bmatrix} 1 & 0 & 0 & 5 \\ 0 & 1 & 3 & -2 \\ 0 & 0 & 0 & 0 \end{bmatrix} \quad D = \begin{bmatrix} 1 & 0 & 5 & 0 \\ 0 & 1 & 2 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Where *Gaussian elimination* places a matrix in *row-echelon form* (satisfying the first three conditions), *Gauss-Jordan elimination* places a matrix in *reduced row-echelon form*. To obtain this form, continue applying row operations to the matrix until the fourth condition above is also satisfied. For a 3×3 system having a unique solution, the diagonal entries of the coefficient matrix will be 1's, with 0's for all other entries. To illustrate, we'll extend Example 3 from Section 9.2 until reduced row-echelon form is obtained.

EXAMPLE 4B ▶ Solving Systems Using the Augmented Matrix

Solve using Gauss-Jordan elimination: $\begin{cases} 2x + y - 2z = -7 \\ x + y + z = -1 \\ -2y - z = -3 \end{cases}$

$$\begin{cases} 2x + y - 2z = -7 \\ x + y + z = -1 \\ -2y - z = -3 \end{cases} \xrightarrow{R1 \leftrightarrow R2} \begin{cases} x + y + z = -1 \\ 2x + y - 2z = -7 \\ -2y - z = -3 \end{cases} \xrightarrow{\text{matrix form} \rightarrow} \left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 2 & 1 & -2 & -7 \\ 0 & -2 & -1 & -3 \end{array}\right]$$

$$\left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 2 & 1 & -2 & -7 \\ 0 & -2 & -1 & -3 \end{array}\right] \xrightarrow{-2R1 + R2 \rightarrow R2} \left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 0 & -1 & -4 & -5 \\ 0 & -2 & -1 & -3 \end{array}\right] \xrightarrow{-1R2} \left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 0 & 1 & 4 & 5 \\ 0 & -2 & -1 & -3 \end{array}\right]$$

$$\left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 0 & 1 & 4 & 5 \\ 0 & -2 & -1 & -3 \end{array}\right] \xrightarrow{2R2 + R3 \rightarrow R3} \left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 0 & 1 & 4 & 5 \\ 0 & 0 & 7 & 7 \end{array}\right] \xrightarrow{\frac{R3}{7} \rightarrow R3} \left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 0 & 1 & 4 & 5 \\ 0 & 0 & 1 & 1 \end{array}\right]$$

$$\left[\begin{array}{ccc|c} 1 & 1 & 1 & -1 \\ 0 & 1 & 4 & 5 \\ 0 & 0 & 1 & 1 \end{array}\right] \xrightarrow{-R2 + R1 \rightarrow R1} \left[\begin{array}{ccc|c} 1 & 0 & -3 & -6 \\ 0 & 1 & 4 & 5 \\ 0 & 0 & 1 & 1 \end{array}\right] \xrightarrow{\substack{3R3 + R1 \rightarrow R1 \\ -4R3 + R2 \rightarrow R2}} \left[\begin{array}{ccc|c} 1 & 0 & 0 & -3 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{array}\right]$$

The final matrix is in reduced row-echelon form with solution $(-3, 1, 1)$ just as in Section 6.1.

The Determinant of a General Matrix

To compute the determinant of a general square matrix, we introduce the idea of a **cofactor.** For an $n \times n$ matrix A, $A_{ij} = (-1)^{i+j}|M_{ij}|$ is the cofactor of matrix element a_{ij}, where $|M_{ij}|$ represents the determinant of the corresponding minor matrix. Note that $i + j$ is the sum of the row and column of the entry, and if this sum is even, $(-1)^{i+j} = 1$, while if the sum is odd, $(-1)^{i+j} = -1$ (this is how the sign table for a 3×3 determinant was generated). To compute the determinant of an $n \times n$ matrix, multiply each element in any row or column by its cofactor and add. The result is a tier-like process in which the determinant of a larger matrix requires computing the determinant of smaller matrices. In the case of a 4×4 matrix, each of the minor matrices will be size 3×3, whose determinant then requires the computation of other 2×2 determinants. In the following illustration, two of the entries in the first row are zero for convenience. For

$$A = \begin{bmatrix} -2 & 0 & 3 & 0 \\ 1 & 2 & 0 & -2 \\ 3 & -1 & 4 & 1 \\ 0 & -3 & 2 & 1 \end{bmatrix},$$

$$\text{we have: } \det(A) = -2 \cdot (-1)^{1+1} \begin{vmatrix} 2 & 0 & -2 \\ -1 & 4 & 1 \\ -3 & 2 & 1 \end{vmatrix} + (3) \cdot (-1)^{1+3} \begin{vmatrix} 1 & 2 & -2 \\ 3 & -1 & 1 \\ 0 & -3 & 1 \end{vmatrix}$$

Computing the first 3×3 determinant gives -16, the second 3×3 determinant is 14. This gives:

$$\begin{aligned} \det(A) &= -2(-16) + 3(14) \\ &= 74 \end{aligned}$$

Appendix E

The Equation of a Conic

The Equation of an Ellipse

In Section 10.2, the equation $\sqrt{(x+c)^2+y^2}+\sqrt{(x-c)^2+y^2}=2a$ was developed using the distance formula and the definition of an ellipse. To find the standard form of the equation, we treat this result as a radical equation, isolating one of the radicals and squaring both sides.

$$\sqrt{(x+c)^2+y^2}=2a-\sqrt{(x-c)^2+y^2} \qquad \text{isolate one radical}$$

$$(x+c)^2+y^2=4a^2-4a\sqrt{(x-c)^2+y^2}+(x-c)^2+y^2 \qquad \text{square both sides}$$

We continue by simplifying the equation, isolating the remaining radical, and squaring again.

$$x^2+2cx+c^2+y^2=4a^2-4a\sqrt{(x-c)^2+y^2}+x^2-2cx+c^2+y^2$$

$$4cx=4a^2-4a\sqrt{(x-c)^2+y^2} \qquad \text{simplify}$$

$$a\sqrt{(x-c)^2+y^2}=a^2-cx \qquad \text{isolate radical; divide by 4}$$

$$a^2[(x-c)^2+y^2]=a^4-2a^2cx+c^2x^2 \qquad \text{square both sides}$$

$$a^2x^2-2a^2cx+a^2c^2+a^2y^2=a^4-2a^2cx+c^2x^2 \qquad \text{expand and distribute } a^2 \text{ on left}$$

$$a^2x^2-c^2x^2+a^2y^2=a^4-a^2c^2 \qquad \text{add } 2a^2cx \text{ and rewrite equation}$$

$$x^2(a^2-c^2)+a^2y^2=a^2(a^2-c^2) \qquad \text{factor}$$

$$\frac{x^2}{a^2}+\frac{y^2}{a^2-c^2}=1 \qquad \text{divide by } a^2(a^2-c^2)$$

Since $a>c$, we know $a^2>c^2$ and $a^2-c^2>0$. For convenience, we let $b^2=a^2-c^2$ and it also follows that $a^2>b^2$ and $a>b$ (since $c>0$). Substituting b^2 for a^2-c^2 we obtain the standard form of the equation of an ellipse (major axis horizontal, since we stipulated $a>b$): $\dfrac{x^2}{a^2}+\dfrac{y^2}{b^2}=1$. Note once again the x-intercepts are $(\pm a, 0)$, while the y-intercepts are $(0, \pm b)$.

The Equation of a Hyperbola

In Section 10.3, the equation $\sqrt{(x+c)^2+y^2}-\sqrt{(x-c)^2+y^2}=2a$ was developed using the distance formula and the definition of a hyperbola. To find the standard form of this equation, we apply the same procedures as before.

$$\sqrt{(x+c)^2+y^2}=2a+\sqrt{(x-c)^2+y^2} \qquad \text{isolate one radical}$$

$$(x+c)^2+y^2=4a^2+4a\sqrt{(x-c)^2+y^2}+(x-c)^2+y^2 \qquad \text{square both sides}$$

$$x^2+2cx+c^2+y^2=4a^2+4a\sqrt{(x-c)^2+y^2}+x^2-2cx+c^2+y^2 \qquad \text{expand binomials}$$

$$4cx=4a^2+4a\sqrt{(x-c)^2+y^2} \qquad \text{simplify}$$

$$cx-a^2=a\sqrt{(x-c)^2+y^2} \qquad \text{isolate radical; divide by 4}$$

$$c^2x^2-2a^2cx+a^4=a^2[(x-c)^2+y^2] \qquad \text{square both sides}$$

$$c^2x^2-2a^2cx+a^4=a^2x^2-2a^2cx+a^2c^2+a^2y^2 \qquad \text{expand and distribute } a^2 \text{ on the right}$$

$$c^2x^2-a^2x^2-a^2y^2=a^2c^2-a^4 \qquad \text{add } 2a^2cx \text{ and rewrite equation}$$

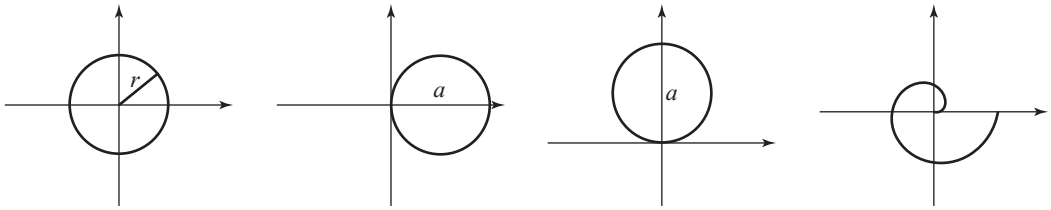
$$x^2(c^2-a^2)-a^2y^2=a^2(c^2-a^2) \qquad \text{factor}$$

$$\frac{x^2}{a^2}-\frac{y^2}{c^2-a^2}=1 \qquad \text{divide by } a^2(c^2-a^2)$$

From the definition of a hyperbola we have $0 < a < c$, showing $c^2 > a^2$ and $c^2 - a^2 > 0$. For convenience, we let $b^2 = c^2 - a^2$ and substitute to obtain the standard form of the equation of a hyperbola (transverse axis horizontal): $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$. Note the x-intercepts are $(0, \pm a)$ and there are no y-intercepts.

The Asymptotes of a Central Hyperbola

From our work in Section 10.3, a central hyperbola with a horizontal axis will have asymptotes at $y = \pm\frac{b}{a}x$. To understand why, recall that for asymptotic behavior we investigate what happens to the relation for large values of x, meaning as $|x| \to \infty$. Starting with $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$, we have



$$\begin{aligned}
b^2x^2 - a^2y^2 &= a^2b^2 && \text{clear denominators}\\
a^2y^2 &= b^2x^2 - a^2b^2 && \text{isolate term with } y\\
a^2y^2 &= b^2x^2\left(1 - \frac{a^2}{x^2}\right) && \text{factor out } b^2x^2 \text{ from right side}\\
y^2 &= \frac{b^2}{a^2}x^2\left(1 - \frac{a^2}{x^2}\right) && \text{divide by } a^2\\
y &= \pm\frac{b}{a}x\sqrt{1 - \frac{a^2}{x^2}} && \text{square root both sides}
\end{aligned}$$

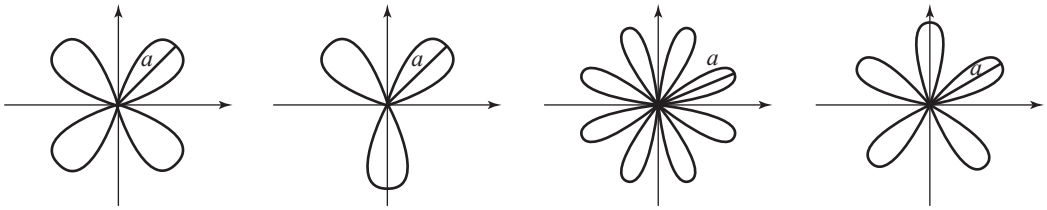
As $|x| \to \infty$, $\frac{a^2}{x^2} \to 0$, and we find that for large values of x, $y \approx \pm\frac{b}{a}x$.

Appendix F

Families of Polar Curves

Circles and Spiral Curves

Circle
$r = \frac{a}{2}$



Circle
$r = a\cos\theta$

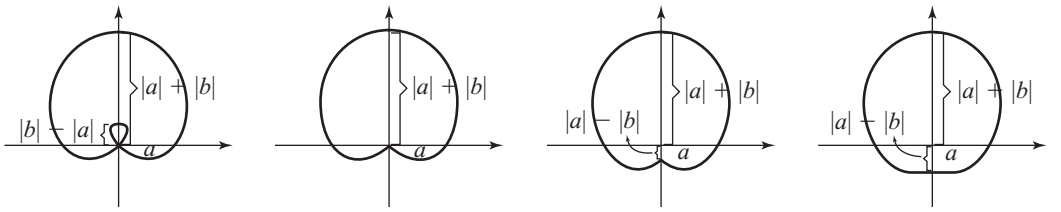
Circle
$r = a\sin\theta$

Spiral
$r = k\theta$

a represents the diameter of the circle

Roses: $r = a\sin(n\theta)$ (illustrated here) and $r = a\cos(n\theta)$

Four-petal rose
$r = a\sin(2\theta)$



Three-petal rose
$r = a\sin(3\theta)$

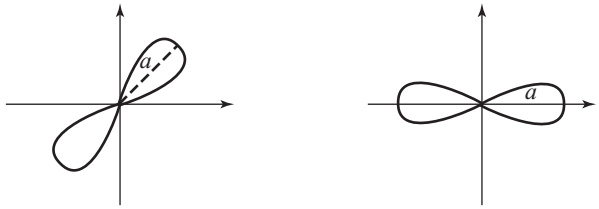
Eight-petal rose
$r = a\sin(4\theta)$

Five-petal rose
$r = a\sin(5\theta)$

If n is odd → there are n petals, if n is even → there are $2n$ petals.
$|a|$ represents the maximum distance from the origin
(the radius of a circumscribed circle)

Limaçons: $r = a + b\sin\theta$ (illustrated here) and $r = a + b\cos\theta$

Limaçon
(inner loop if $|a| < |b|$)
$r = a + b\sin\theta$



Cardioid
(limaçon where $|a| = |b|$)
$r = a + b\sin\theta$

Apple
(limaçon where $|a| > |b|$)
$r = a + b\sin\theta$

Eye-ball
(limaçon where $|a| \geq 2|b|$)
$r = a + b\sin\theta$

$|a| + |b|$ represents the maximum distance from the origin (along the axis of symmetry)

Lemniscates: $r^2 = a^2\sin(2\theta)$ and $r^2 = a^2\cos(2\theta)$

Lemniscate
$r^2 = a^2\sin(2\theta)$

Lemniscate
$r^2 = a^2\cos(2\theta)$

a represents the maximum distance from the origin
(the radius of a circumscribed circle)

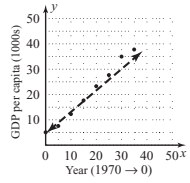
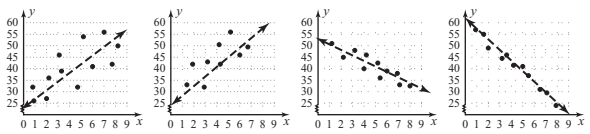
81. 12 lb **83.** 16 lb **85.** Answers will vary. **87.** 69 **89.** $x = -7$
91. a. $(2x + 3)(2x - 3)$ **b.** $(x - 3)(x^2 + 3x + 9)$

Exercises 1.6, pp. 87–93

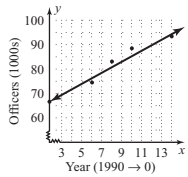


1. scatterplot **3.** linear **5.** Answers will vary.
7. a. **b.** positive

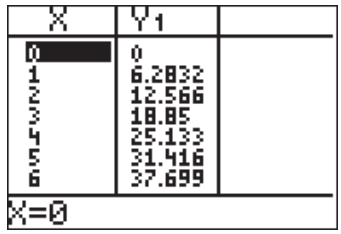


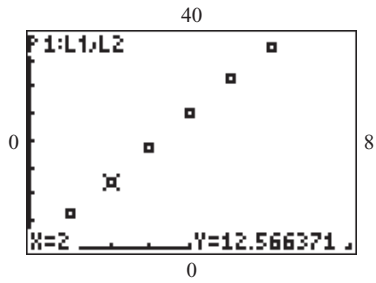
9. a. **b.** linear **c.** positive

11. a. **b.** positive **c.** strong



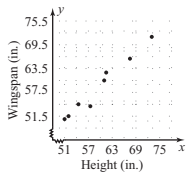
13. a. (A) (D) (C) (B)
b.



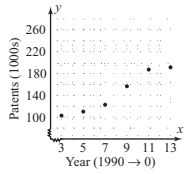


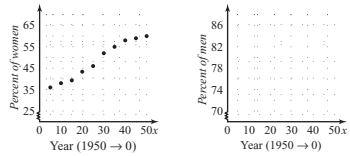
c. positive, **d.** $m \approx 3.8$; **c.** positive, **d.** $m \approx 4.2$; **c.** negative, **d.** $m \approx -2.4$; **c.** negative, **d.** $m \approx -4.6$

15. a. linear **b.** positive **c.** strong **d.** $m \approx 4.2$
17. a. nonlinear **b.** positive **c.** NA **d.** NA
19. a. nonlinear **b.** negative **c.** NA **d.** NA
21. a. **b.** positive **c.** $f(x) = 2.4x + 62.3$, $f(5) = 74.3$(74,300), $f(21) = 112.7$ (112,700)



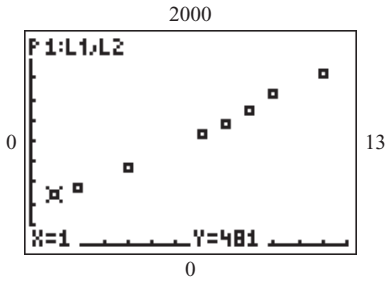
23. Using (5, 7.6) and (20, 23.3): $y \approx 1.05x + 2.37$; GDP in 2010 will be near 44,370
25. a.





b. positive, larger radius ⇒ larger area **c.** perfect correlation
d. $m = 2\pi$
27. a. **b.** linear **c.** positive
d. $y = 0.96x + 1.55$, 63.95 in.

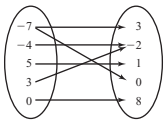
29. a. **b.** linear **c.** positive
d. $y = 9.55x + 70.42$; about 271,000. The number of applications, since the line has a greater slope.



31. a.

b. women: linear **c.** positive; **b. men:** linear **c.** negative
d. yes, |slope| is greater

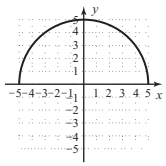
33. a.



a. linear **b.** $y = 108.18x + 330.20$
c. \$1736.54 billion; about \$2601.98 billion
35. a. $r \approx 0.9783$ **b.** $r \approx 0.9783$ **c.** they are almost identical; context, pattern of scatterplot, anticipated growth, etc.
37. No. Except for the endpoints of the domain, one x is mapped to two y's.
39. $r = \dfrac{A - P}{Pt}$

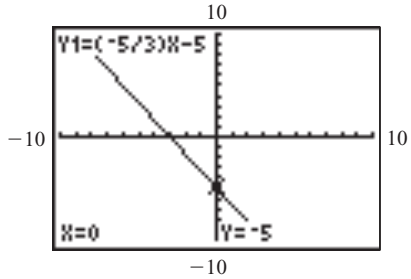
Making Connections, p. 93

1. d **3.** a **5.** b **7.** c **9.** f **11.** d **13.** f **15.** a



Summary and Concept Review, pp. 94–98

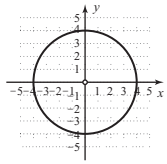
1. $x \in \{-7, -4, 0, 3, 5\}$ $y \in \{-2, 0, 1, 3, 8\}$



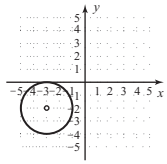
2.

x	y
-5	0
-4	3
-2	$\sqrt{21} \approx 4.58$
0	5
2	$\sqrt{21} \approx 4.58$
4	3
5	0

$x \in [-5, 5]$ $y \in [0, 5]$



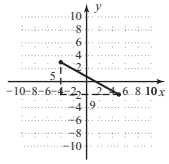
3.



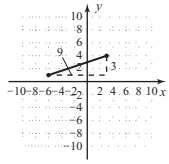
$(0, -5), (-3, 0)$

4. 65 mi **5.** $(\frac{5}{2}, -3)$

6.



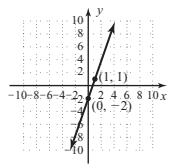
7.



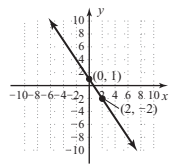
8. $(x + 1.5)^2 + (y - 2)^2 = 6.25$

9. a.

$\frac{-5}{9}$, $(14, -7)$

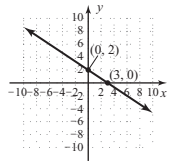


b.

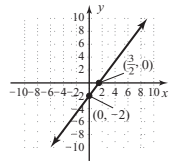


$\frac{1}{3}$, $(0, 3)$

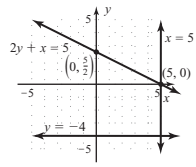
10. a. parallel **b.** perpendicular



11. a.

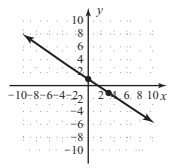


b.

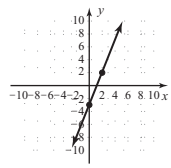


12. a.

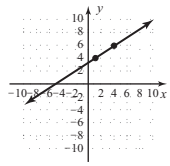
b.



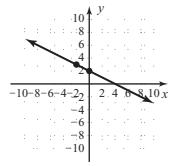
13. a. vertical
b. horizontal
c. neither



14. yes **15.** $m = \frac{2}{3}$, y-intercept $(0, 2)$; when the rodent population increases by 3000, the hawk population increases by 200.
16. a. $x \in [\frac{-5}{4}, \infty)$ **b.** $x \in (-\infty, -2) \cup (-2, 3) \cup (3, \infty)$
17. 14; $\frac{26}{9}$; $18a^2 - 9a$ **18.** It is a function.
19. I. a. $D = \{-1, 0, 1, 2, 3, 4, 5\}$, $R = \{-2, 1, 0, 1, 2, 3, 4\}$ **b.** 1
c. 2 **II. a.** $x \in (-\infty, \infty)$, $y \in (-\infty, \infty)$ **b.** -1 **c.** 3
III. a. $x \in [-3, \infty)$, $y \in [-4, \infty)$ **b.** -1 **c.** -3 or 3
20. a. $y = \frac{-4}{3}x + 4$, $m = \frac{-4}{3}$, y-intercept $(0, 4)$
b. $y = \frac{5}{3}x - 5$, $m = \frac{5}{3}$, y-intercept $(0, -5)$

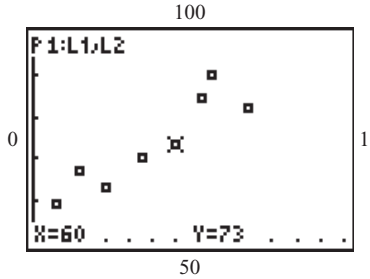


21. a.



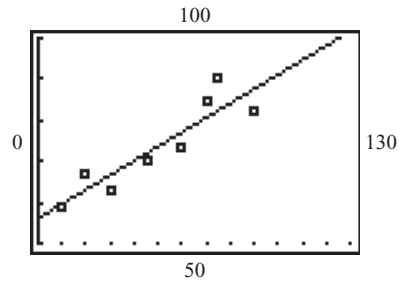
b.

22. a.



b.

23. $y = 5$, $x = -2$; $y = 5$ **24.** $y = \frac{-3}{4}x + \frac{11}{4}$ **25.** $f(x) = \frac{4}{3}x$
26. $m = \frac{2}{5}$, y-intercept $(0, 2)$, $y = \frac{2}{5}x + 2$. When the rabbit population increases by 500, the wolf population increases by 200.
27. a. $(y - 90) = \frac{-15}{2}(x - 2)$ **b.** $(14, 0), (0, 105)$ **c.** $f(x) = \frac{-15}{2}x + 105$
d. $f(20) = -45$, $x = 12$ **28.** $x = -6$ **29.** $x \in (-\infty, \infty)$
30. $x \in (-\infty, -1)$ **31.** $h = \frac{V}{\pi r^2}$ **32.** $L = \frac{P - 2W}{2}$ **33.** $x = \frac{c - b}{a}$
34. $y = \frac{2}{3}x - 2$ **35.** 8 gal **36.** $12 + \frac{9}{8}\pi$ ft$^2 \approx 15.5$ ft^2
37. $\frac{2}{3}$ hr $= 40$ min



38. a.

b. linear **c.** positive

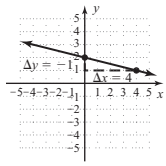
39. a. $f(x) = 0.35x + 56.10$

b.

c. strong

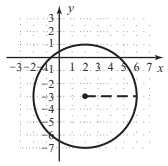
40. $f(120) = 98.1$, over 98%

Practice Test, pp. 99–100



1. a. $x = 27$ **b.** $x = 2$ **c.** $C = \frac{P}{1 + k}$ **d.** $W = \frac{P - 2L}{2}$

2. 30 gal **3.** $S \geq 177$ **4.** about 5.1 sec



5. a and c are nonfunctions, they do not pass the vertical line test

6. neither

7.

8.

$(2, -3)$; $r = 4$

9. $V = \frac{20}{3}t + \frac{20}{3}$, $66\frac{2}{3}$ mph **10.** $y = \frac{-6}{5}x + \frac{2}{5}$

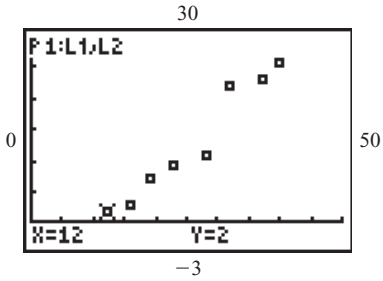
11. a. (7.5, 1.5), **b.** ≈ 61.27 mi **12.** L_1: $x = -3$ L_2: $y = 4$

13. a. $x \in \{-4, -2, 0, 2, 4, 6\}$ $y \in \{-2, -1, 0, 1, 2, 3\}$

b. $x \in [-2, 6]$ $y \in [1, 4]$

14. a. 300 **b.** 30 **c.** $W(h) = \frac{25}{2}h$ **d.** Wages are \$12.50 per hr.

e. $h \in [0, 40]$; $w \in [0, 500]$ **15. a.** $\frac{7}{2}$ **b.** $\frac{-a^2 - 6a - 7}{a^2 + 6a + 9}$



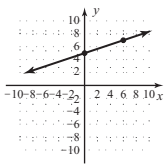
16. a. $\frac{\Delta \text{sales}}{\Delta \text{time}} = \frac{13.5}{1}$

b. sales are increasing at a rate of 13.5 million phones per year

c. 2008: about 15 million sales, 2010: about 42 million sales, 2011: about 55.5 million sales

17. a. $x = -9$ **b.** no solution **18. a.** $x \in [3, \infty)$ **b.** $x \in (-\infty, \infty)$

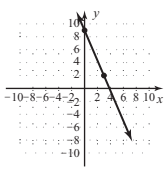
19. a.



b. linear **c.** positive

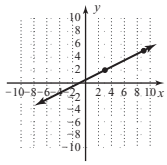
20. a. $f(x) = 0.91x - 10.78$ **b.** $f(50) \approx 35$ **c.** strong: $r \approx 0.974$

Strengthening Core Skills, pp. 100–101



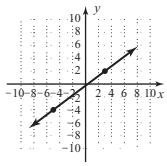
1. a. $\frac{1}{3}$, increasing **b.** $y - 5 = \frac{1}{3}(x - 0)$, $y = \frac{1}{3}x + 5$

c. $(0, 5)$, $(-15, 0)$



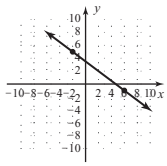
2. a. $\frac{-7}{3}$, decreasing **b.** $y - 9 = \frac{-7}{3}(x - 0)$, $y = \frac{-7}{3}x + 9$

c. $(0, 9)$, $(\frac{27}{7}, 0)$



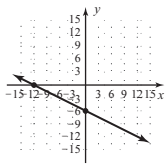
3. a. $\frac{1}{2}$, increasing **b.** $y - 2 = \frac{1}{2}(x - 3)$, $y = \frac{1}{2}x + \frac{1}{2}$

c. $(0, \frac{1}{2})$, $(-1, 0)$



4. a. $\frac{3}{4}$, increasing **b.** $y + 4 = \frac{3}{4}(x + 5)$, $y = \frac{3}{4}x - \frac{1}{4}$

c. $(0, \frac{-1}{4})$, $(\frac{1}{3}, 0)$



5. a. $\frac{-3}{4}$, decreasing **b.** $y - 5 = \frac{-3}{4}(x + 2)$, $y = \frac{-3}{4}x + \frac{7}{2}$

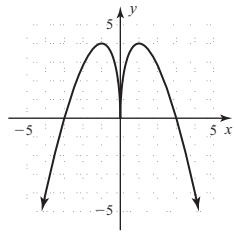
c. $(0, \frac{7}{2})$, $(\frac{14}{3}, 0)$

6. a. $\frac{-1}{2}$, decreasing **b.** $y + 7 = \frac{-1}{2}(x - 2)$, $y = \frac{-1}{2}x - 6$

c. $(0, -6)$, $(-12, 0)$

Connections to Calculus, p. 104

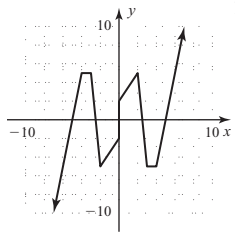
1. $y = -4x - 9$ **3.** $y = -9$ **5.** $y = 44$ **7.** $y = -36x - 1$



9. $y = -\frac{1}{2}x - \frac{5}{2}$ **11.** $y = \frac{1}{2}x + \frac{3}{2}$ **13.** $y = -\frac{3}{4}x + \frac{7}{4}$

CHAPTER 2

Exercises 2.1, pp. 114–119



1. linear, bounce **3.** increasing **5.** Answers will vary.

7.

9. even **11.** even

13.

15. odd **17.** not odd

19. neither **21.** odd **23.** neither **25.** $x \in [-1, 1] \cup [3, \infty)$

27. $x \in (-\infty, -1) \cup (-1, 1) \cup (1, \infty)$ **29.** $x \in [2, \infty)$

31. $x \in (-\infty, 2]$ **33.** $V(x)\uparrow$: $x \in (-3, 1) \cup (4, 6)$;
$V(x)\downarrow$: $x \in (-\infty, -3) \cup (1, 4)$; constant: none

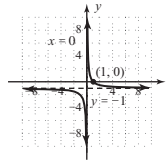
75. $\rho = \frac{2W}{V^2CA}$ **77.** $x \in (-\infty, \frac{5}{2})$

Mid-Chapter Check, pp. 146–147

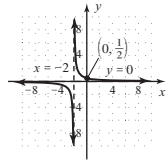
1. neither **2.** max: $y \approx 11.12$ at $x \approx -0.50$, $y \approx 8.55$ at $x \approx 1.47$; min: $y \approx 7.80$ at $x \approx 0.75$
3. increasing on $(-\infty, -0.50) \cup (0.75, 1.47)$, decreasing on $(-0.50, 0.75) \cup (1.47, \infty)$ **4.** $g(x) = \sqrt{x + 4} + 2$
5. a. cubic **b.** up on the left, down on the right; inflection point: (2, 2); x-int: (4, 0); y-int: (0, 5) **c.** $(-\infty, \infty)$; $(-\infty, \infty)$ **d.** $k = 1$
6.

$q(x)$ is a reflection of $p(x)$ across the x-axis, and $r(x)$ is the same as $q(x)$, but compressed by a factor of $\frac{1}{2}$



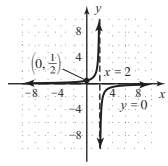
7. a. $\{-4, 14\}$ **b.** $\{\ \}$ **8. a.** $q \in (-8, 0)$ **b.** $\{-6\}$
9. a. $d \in (-\infty, 0] \cup [4, \infty)$ **b.** $y \in \left(-\infty, -\frac{19}{2}\right) \cup \left(\frac{23}{2}, \infty\right)$
c. $k \in (-\infty, \infty)$ **10.** $w \in [8, 26]$; no, yes

Reinforcing Basic Concepts, p. 147

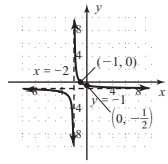


1. $x = -3$ or $x = 7$ **2.** $x \in [-5, 3]$ **3.** $x \in (-\infty, -1] \cup [4, \infty)$

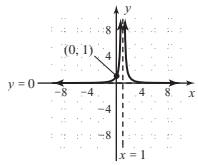
Exercises 2.4, pp. 159–163



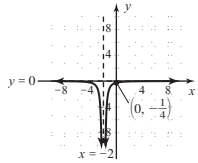
1. as $x \to -\infty, y \to 2$ **3.** vertical, $y = 2$ **5.** Answers will vary.
7. a. as $x \to -\infty, y \to 2$; as $x \to \infty, y \to 2$
b. as $x \to 1^-, y \to -\infty$; as $x \to 1^+, y \to \infty$
9. a. as $x \to -\infty, y \to 1$; as $x \to \infty, y \to 1$
b. $y = 1$
c. as $x \to -2^-, y \to \infty$; as $x \to -2^+, y \to \infty$
11. down 1, $x \in (-\infty, 0) \cup (0, \infty)$, $y \in (-\infty, -1) \cup (-1, \infty)$



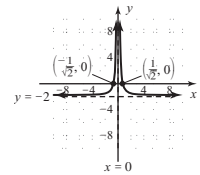
13. left 2, $x \in (-\infty, -2) \cup (-2, \infty)$, $y \in (-\infty, 0) \cup (0, \infty)$



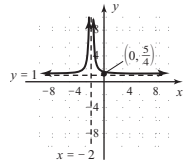
15. right 2, reflected across x-axis, $x \in (-\infty, 2) \cup (2, \infty)$, $y \in (-\infty, 0) \cup (0, \infty)$



17. left 2, down 1, $x \in (-\infty, -2) \cup (-2, \infty)$, $y \in (-\infty, -1) \cup (-1, \infty)$



19. right 1, $x \in (-\infty, 1) \cup (1, \infty)$, $y \in (0, \infty)$



21. left 2, reflected across x-axis, $x \in (-\infty, -2) \cup (-2, \infty)$, $y \in (-\infty, 0)$

23. down 2, $x \in (-\infty, 0) \cup (0, \infty)$, $y \in (-2, \infty)$

25. left 2, up 1, $x \in (-\infty, -2) \cup (-2, \infty)$, $y \in (1, \infty)$

27. reciprocal quadratic, $S(x) = \dfrac{1}{(x+1)^2} - 2$

29. reciprocal function, $Q(x) = \dfrac{1}{x+1} - 2$

31. reciprocal quadratic, $v(x) = \dfrac{1}{(x+2)^2} - 5$ **33.** $\to -2$

35. $\to -\infty$ **37.** $-1, \pm\infty$

39. $g(x)$ increases faster $(3 > 2)$ **a.** $x = 0$ and 1, **b.** $(-\infty, 0) \cup (0, 1)$, **c.** $(1, \infty)$

41. $f(x)$ increases faster $(4 > 2)$ **a.** $x = -1$, 0, and 1, **b.** $(-1, 0) \cup (0, 1)$, **c.** $(-\infty, -1) \cup (1, \infty)$

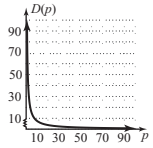
43. $g(x)$ increases faster $\left(\dfrac{4}{5} > \dfrac{2}{3}\right)$ **a.** $x = -1$, 0, and 1, **b.** $(-1, 0) \cup (0, 1)$, **c.** $(-\infty, -1) \cup (1, \infty)$

45. $g(x)$ increases faster $\left(\dfrac{1}{3} > \dfrac{1}{6}\right)$ **a.** $x = 0$ and 1, **b.** $(0, 1)$, **c.** $(1, \infty)$

47. $g(x)$ increases faster $\left(\dfrac{5}{4} > \dfrac{2}{3}\right)$ **a.** $x = 0$ and 1, **b.** $(0, 1)$, **c.** $(1, \infty)$

49. $[0, \infty)$ **51.** $(-\infty, \infty)$ **53.** $(-\infty, \infty)$

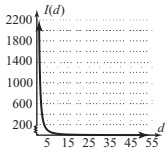
55. defined: b, c, d; undefined: a **57.** defined: a, b, d; undefined: c



59. F is the graph of f shifted left 1 unit and down 2; verified

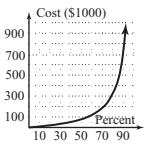
61. P is the graph of p shifted right 2 units and reflected across the x-axis; verified

63. **a.** F becomes very small **b.** $y = \frac{1}{x^2}$ **c.** $m_2 = \frac{d^2F}{km_1}$



65. **a.** It decreases; 75, 25, 15 **b.** It approaches 0.

c. as $p \to 0$, $D \to \infty$

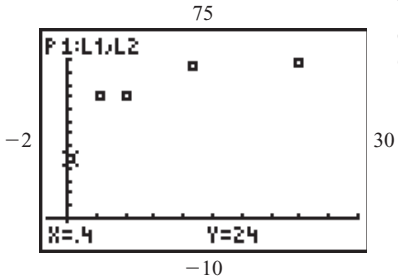


67. a. It decreases; 100, 25, $11.\overline{1}$. **b.** toward the light source

c. as $d \to 0$, $l \to \infty$

69. **a.** \$20,000, \$80,000, \$320,000; cost increases dramatically

b.

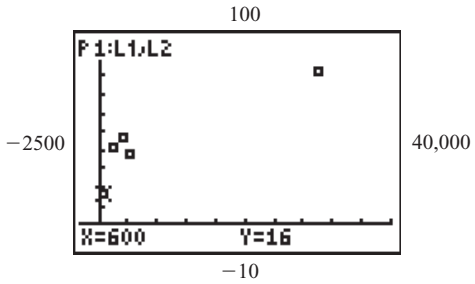


c. as $p \to 100$, $C \to \infty$

71. **a.** 253 ft/sec (about 172 mph) **b.** approx. 791 ft

73. **a.** size 11 **b.** approx. 5 ft, 5 in.

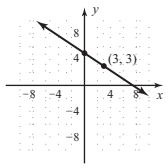
75. **a.**



b. $P = 32.251\, w^{0.246}$

c. about 63 days

d. about 6.9 kg



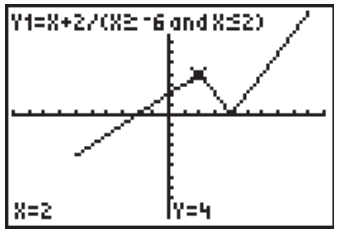
77. **a.**

b. $S = 1.687a^{0.386}$ **c.** about 33 species **d.** about 37,200 mi^2

79. The area is always 1 unit^2; The area is always $\frac{1}{x}$ units^2

81. $y = \frac{-2}{3}x + 5$,

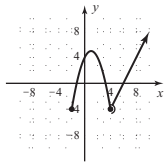
83. $c = \sqrt{\frac{E}{m}}$



Exercises 2.5, pp. 172–176

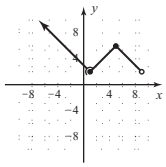
1. continuous **3.** smooth **5.** Each piece must be continuous on the corresponding interval, and the function values at the endpoints of each interval must be equal. Answers will vary.

7. **a.** $f(x) = \begin{cases} x^2 - 6x + 10 & 0 \le x \le 5 \\ \frac{3}{2}x - \frac{5}{2} & 5 < x \le 9 \end{cases}$ **b.** $y \in [1, 11]$

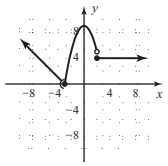


9. -2, 2, $\frac{1}{2}$, 0, 2.999, 5 **11.** 5, 5, 0, -4, 5, 11

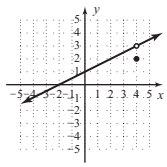
13. D: $x \in [-6, \infty)$; R: $y \in [-4, \infty)$



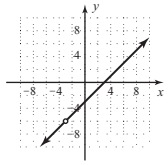
$p(2) = 4$
$p(0) = 2$



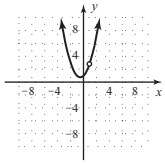
15. D: $x \in [-2, \infty)$; R: $y \in [-4, \infty)$



17. D: $x \in (-\infty, 9)$; R: $y \in [2, \infty)$

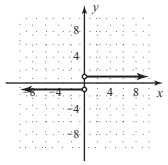


19. D: $x \in (-\infty, \infty)$; R: $y \in [0, \infty)$



21. D: $x \in (-\infty, \infty)$; R: $y \in (-\infty, 3) \cup (3, \infty)$

23. discontinuity at $x = -3$, redefine $f(x) = -6$ at $x = -3$; $c = -6$

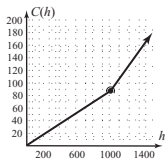


25. discontinuity at $x = 1$, redefine $f(x) = 3$ at $x = 1$; $c = 3$

27. $f(x) = \begin{cases} \frac{1}{2}x - 1 & -4 \le x < 2 \\ 3x - 6 & x \ge 2 \end{cases}$

29. $p(x) = \begin{cases} x^2 + 2x - 3 & x \le 1 \\ x + 1 & x > 1 \end{cases}$

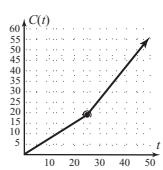
31. Graph is discontinuous at $x = 0$; $f(x) = 1$ for $x > 0$; $f(x) = -1$ for $x < 0$.



33. a. $S(t) = \begin{cases} -t^2 + 6t & 0 \le t \le 5 \\ 5 & t > 5 \end{cases}$ **b.** $S(t) \in [0, 9]$

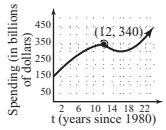
35. a.

Year ($0 \to 1950$)	Percent
5	7.33
15	14.13
25	14.93
35	22.65
45	41.55
55	60.45
65	79.35



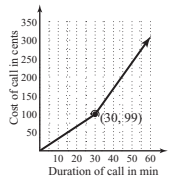
b. Each piece gives a slightly different value due to rounding of coefficients in each model. At $t = 30$, we use the "first" piece: $P(30) = 13.08$.

37. $C(h) = \begin{cases} 0.09h & 0 \le h \le 1000 \\ 0.18h - 90 & h > 1000 \end{cases}$



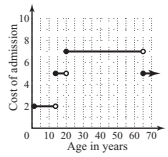
$C(1200) = \$126$

39. $C(t) = \begin{cases} 0.75t & 0 \le t \le 25 \\ 1.5t - 18.75 & t > 25 \end{cases}$



$C(45) = \$48.75$

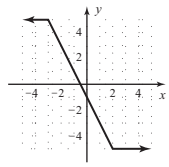
41. $S(t) = \begin{cases} -1.35t^2 + 31.9t + 152 & 0 \le t \le 12 \\ 2.5t^2 - 80.6t + 950 & 12 < t \le 22 \end{cases}$



\$498 billion, \$653 billion, \$931 billion

43. $c(m) = \begin{cases} 3.3m & 0 \le m \le 30 \\ 7m - 111 & m > 30 \end{cases}$

\$2.11



45. $C(a) = \begin{cases} 0 & a < 2 \\ 2 & 2 \le a < 13 \\ 5 & 13 \le a < 20 \\ 7 & 20 \le a < 65 \\ 5 & a \ge 65 \end{cases}$

\$38

47. a. $C(w - 1) = 17\lceil w - 1 \rceil + 88$ **b.** $0 < w \le 13$ **c.** 88¢ **d.** 173¢ **e.** 173¢ **f.** 173¢ **g.** 190¢

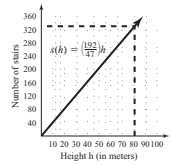
49. yes; $h(x) = \begin{cases} 5 & x \le -3 \\ -2x - 1 & -3 < x < 2 \\ -5 & x \ge 2 \end{cases}$

51. $f(x)$ has a removable discontinuity at $x = -2$; $g(x)$ has a discontinuity at $x = -2$ **53.** $x = -7, x = 4$

55. $y = \frac{4}{3}x - 2$

Exercises 2.6, pp. 183–187

1. constant **3.** directly, height, square **5.** Answers will vary.



7. $d = kr$ **9.** $F = ka$

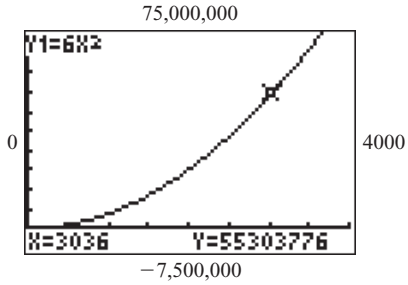
11. $y = 0.025x$

x	y
500	12.5
650	16.25
750	18.75

13. $w = 9.18h$; \$321.30; the hourly wage; $k = \$9.18$/hr

15. a. $k = \frac{192}{47}$, $S = \frac{192}{47}h$ **b.**

c. 330 stairs **d.** $S = 331$; yes



17. $A = kS^2$ **19.** $P = kc^2$

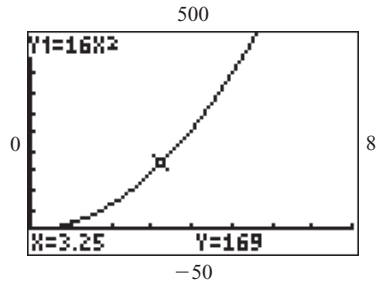
21. $k = 0.112$; $p = 0.112q^2$

q	p
45	226.8
55	338.8
70	548.8

23. a. Area varies directly as a side squared. **b.** $A = ks^2$

c.

d.



X	Y1
0	0

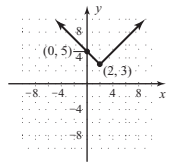
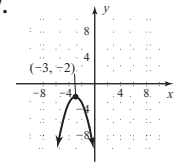
2.



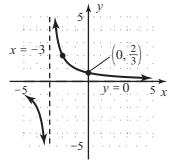
3.



4. max: $y = 8$ at $x = -2$; min: $y = -7$ at $x \approx -5.87$ and $y = -7$ at $x \approx 1.87$

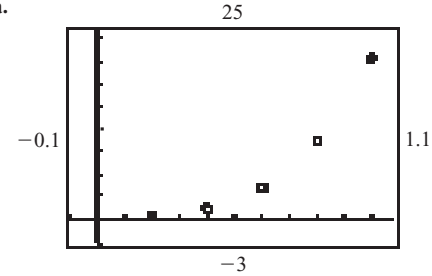
5. I. a. square root **b.** $x \in [-4, \infty)$, $y \in [-3, \infty)$ **c.** $(-2, 0)$, $(0, 1)$
d. up on right **e.** $x \in (-2, \infty)$ **f.** $x \in [-4, -2)$
II. a. cubic **b.** $x \in (-\infty, \infty)$, $y \in (-\infty, \infty)$ **c.** $(2, 0)$, $(0, -1)$
d. down on left, up on right **e.** $x \in (2, \infty)$ **f.** $x \in (-\infty, 2)$
III. a. absolute value **b.** $x \in (-\infty, \infty)$, $y \in (-\infty, 4]$
c. $(-1, 0)$, $(3, 0)$, $(0, 2)$ **d.** down on left, down on right **e.** $x \in (-1, 3)$
f. $x \in (-\infty, -1) \cup (3, \infty)$
IV. a. quadratic **b.** $x \in (-\infty, \infty)$; $y \in [-5.5, \infty)$
c. $(0, 0)$, $(5, 0)$, $(0, 0)$ **d.** up on left, up on right
e. $x \in (-\infty, 0) \cup (5, \infty)$ **f.** $x \in (0, 5)$

6.



7.

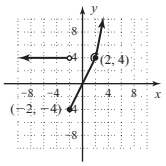
8. $(-\infty, \frac{-20}{3}) \cup (\frac{22}{3}, \infty)$ **9.** $[-4, 0)$ **10.** $x = 0.75$



11.

12. 13.5 sec

13. a. $(-\infty, \infty)$ **b.** $[0, \infty)$ **c.** $[0, \infty)$ **14.** VA: $x = -2$; HA: $y = -1$



15. a.

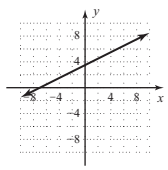
b. $S(t) = 17.27\,t^{2.50}$ **c.** 3.05 mm **d.** 0.95 sec

16. $a = 1, b = 4$ **17.** 1617 KWH/year

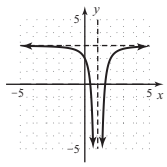
18. a. 4, −4, 6.25 **b.**

19. $M = kd^3\left(\frac{1}{P^2}\right)$, approx. 2.2788×10^8 **20.** 520 lb

Strengthening Core Skills, p. 196

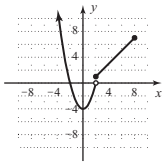


1. $k = \dfrac{1}{6^{\frac{3}{2}}}$ or $\dfrac{1}{\sqrt{6^3}}$



Cumulative Review Chapters 1–2, pp. 197–198

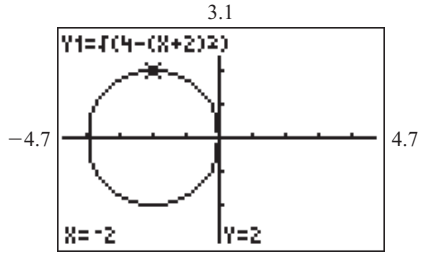
1. $f(-2) = -23, f\left(\dfrac{1}{2}\right) = -\dfrac{7}{4}$ **3.** 29.45 cm **5.** $x = 1$



7. a. $\frac{-1}{3}$ **b.** $\frac{3}{5}$

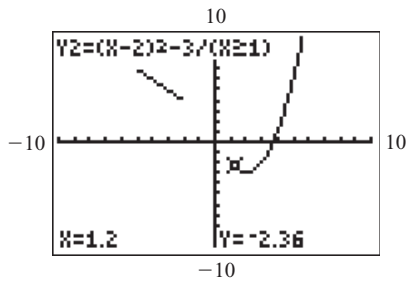
9. $y = \frac{1}{2}x + \frac{7}{2}$ **11.**

13. a. D: $x \in (-\infty, 8]$, R: $y \in [-4, \infty)$ **b.** 5, −3, −3, 1, 2
c. $(-2, 0)$ **d.** $f(x) < 0$: $x \in (-2, 2)$; $f(x) > 0$: $x \in (-\infty, -2) \cup [2, 8]$
e. min: (0, −4), max: (8, 7) **f.** $f(x)\uparrow$: $x \in (0, 8)$; $f(x)\downarrow$: $x \in (-\infty, 0)$



15. a. $\dfrac{x - 7}{(x - 5)(x + 2)}$ **b.** $\dfrac{b^2 - 4ac}{4a^2}$ **17.** $x^2 + 2$

19. center $(-3, 6)$, $r = 3$ **21.** $W = 31$ cm, $L = 47$ cm



23. a. $x = \frac{-4}{3}, \frac{5}{2}$ **b.** $x = -5, -\sqrt{3}, \sqrt{3}$

25. $P = 15 + \sqrt{97}$ units ≈ 24.8 units. No, it is not a right triangle.
$5^2 + (\sqrt{97})^2 \neq 10^2$

27.

29.

Connections to Calculus Exercises, p. 202

1. 4.24 in. **3.** $t = \dfrac{6}{5}$ sec, $t = \dfrac{3}{2}$ sec **5.** If the difference between x and $\dfrac{3}{2}$ is very small, then the difference between $h(x)$ and 6 is very small: if $\left|x - \dfrac{3}{2}\right| < \delta$, then $|h(x) - 6| < \epsilon$. **7.** If the difference between x and 2 is very small, then the difference between $w(x)$ and 14 is very small: if $|x - 2| < \delta$, then $|w(x) - 14| < \epsilon$.

CHAPTER 3

Exercises 3.1, pp. 211–214

1. $3 - 2i$ **3.** $2, 3\sqrt{2}$ **5.** (b) is correct. **7. a.** $12i$ **b.** $7i$
c. $3\sqrt{3}$ **d.** $6\sqrt{2}$ **9. a.** $-3i\sqrt{2}$ **b.** $-5i\sqrt{2}$ **c.** $15i$ **d.** $6i$
11. a. $i\sqrt{19}$ **b.** $i\sqrt{31}$ **c.** $\dfrac{2\sqrt{3}}{5}i$ **d.** $\dfrac{3\sqrt{2}}{8}i$
13. a. $1 + i$ **b.** $2 + i\sqrt{3}$
15. a. $4 + 2i$ **b.** $2 - i\sqrt{2}$
17. a. $5 + 0i$; $a = 5, b = 0$ **b.** $0 + 3i$; $a = 0, b = 3$
19. a. $0 + 18i$; $a = 0, b = 18$ **b.** $0 + \dfrac{\sqrt{2}}{2}i$; $a = 0, b = \dfrac{\sqrt{2}}{2}$
21. a. $4 + 5i\sqrt{2}$; $a = 4, b = 5\sqrt{2}$
b. $-5 + 3i\sqrt{3}$; $a = -5, b = 3\sqrt{3}$
23. a. $\dfrac{7}{4} + \dfrac{7\sqrt{2}}{8}i$; $a = \dfrac{7}{4}, b = \dfrac{7\sqrt{2}}{8}$ **b.** $\dfrac{1}{2} + \dfrac{\sqrt{10}}{2}i$; $a = \dfrac{1}{2}, b = \dfrac{\sqrt{10}}{2}$

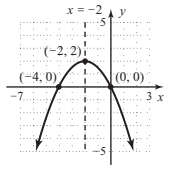
65. $g(x) = -\sqrt[3]{x + 1} - 3$

Mid-Chapter Check, p. 249



1. sum 4, product 13; both yield real numbers **2.** i

3. $(1 + 2i)^2 - 2(1 + 2i) + 5 = 0$
$1 + 4i + 4i^2 - 2 - 4i + 5 = 0$
$1 + (-4) - 2 + 5 = 0$
$0 = 0$✓ Yes.

4. $x = -1$ and 3 **5.** $x = 2 \pm \sqrt{\frac{5}{3}}$ **6.** $x = \frac{7}{4} \pm \frac{\sqrt{17}}{4}$

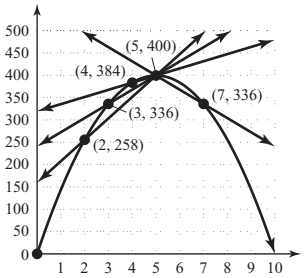
7. $(-\infty, -1] \cup [0.37, \infty)$ **8. a.** about 29.6 in. **b.** about 7.17 ft
c. yes; $3 \times 7.17 > 21.5$

9.

10. $f(x) = \frac{4}{9}(x - 3)^2 - 2$

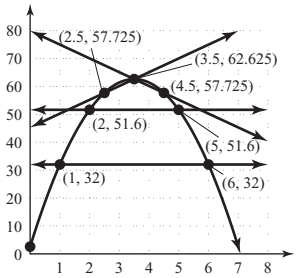
Reinforcing Basic Concepts, pp. 249–250

Exercise 1: $\frac{7}{2} + (-1) = \frac{5}{2} = -\frac{b}{a}$ ✓
$\frac{7}{2} \cdot (-1) = \frac{-7}{2} = \frac{c}{a}$ ✓



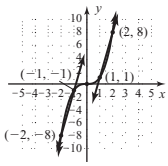
Exercise 2: $\frac{2 + 3\sqrt{2}}{2} + \frac{2 - 3\sqrt{2}}{2} = \frac{4}{2} = \frac{-b}{a}$ ✓
$\frac{2 + 3\sqrt{2}}{2} \cdot \frac{2 - 3\sqrt{2}}{2} = \frac{-14}{4} = \frac{-7}{2} = \frac{c}{a}$ ✓

Exercise 3: $(5 + 2\sqrt{3}i) + (5 - 2\sqrt{3}i) = 10 = \frac{-b}{a}$ ✓
$(5 + 2\sqrt{3}i)(5 - 2\sqrt{3}i) = 25 + 12 = 37 = \frac{c}{a}$ ✓



Exercise 4: $x_1 + x_2 = -\frac{b}{a}$ since radical terms sum to 0, and $2\left(\frac{-b}{2a}\right) = \frac{-b}{a}$;
$x_1 x_2 = \frac{c}{a}$ since $\left(\frac{-b}{2a}\right)^2 - \left(\frac{\sqrt{b^2 - 4ac}}{2a}\right)^2 = \frac{b^2}{4a^2} - \frac{b^2 - 4ac}{4a^2} = \frac{4ac}{4a^2} = \frac{c}{a}$

Exercises 3.4, pp. 257–261



1. quadratic, negative **3.** average, slope, secant line
5. Answers will vary. **7. a.** $y = 1.45x^2 - 2.59x - 4.55$ **b.** 4.1475
c. $x = 6.446$ **9. a.** $y = -0.851x^2 + 3.153x + 64.428$ **b.** 65.037

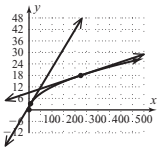
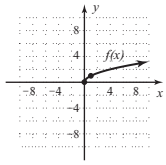
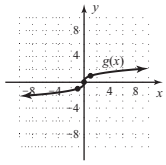
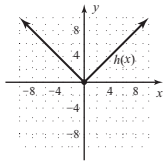
Answers will vary. **59.** $(\frac{1}{2}, \infty)$
61. a. $(-\infty, -1) \cup (2, \infty)$ **b.** $\{\ \}$ **63.** $g(x) = \begin{cases} -|x| & x < 1 \\ \frac{1}{2}(x - 3) & x \geq 1 \end{cases}$







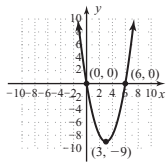


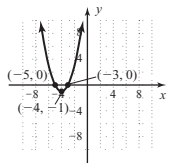
Exercises 3.5, pp. 268–274

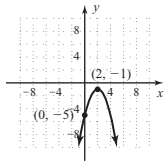
1. $(f + g)(x)$, $A \cap B$ **3.** intersection, $g(x)$ **5.** Answers will vary.
7. a. $x \in \mathbb{R}$ **b.** $f(-2) - g(-2) = 13$
9. a. $h(x) = x^2 - 6x - 3$ **b.** $h(-2) = 13$ **c.** they are identical
11. a. $x \in [3, \infty)$ **b.** $h(x) = \sqrt{x - 3} + 2x^3 - 54$
c. $h(4) = 75$, 2 is not in the domain of h.
13. a. $x \in [-5, 3]$ **b.** $r(x) = \sqrt{x + 5} + \sqrt{3 - x}$
c. $r(2) = \sqrt{7} + 1$, 4 is not in the domain of r.
15. a. $x \in [-4, \infty)$ **b.** $h(x) = \sqrt{x + 4}(2x + 3)$
c. $h(-4) = 0$, $h(21) = 225$
17. a. $x \in [-1, 7]$ **b.** $r(x) = \sqrt{-x^2 + 6x + 7}$
c. 15 is not in the domain of r, $r(3) = 4$
19. a. $x \in (-\infty, -4) \cup (-4, \infty)$ **b.** $h(x) = x - 4, x \neq -4$
21. a. $x \in (-\infty, -4) \cup (-4, \infty)$ **b.** $h(x) = x^2 - 2, x \neq -4$
23. a. $x \in (-\infty, 1) \cup (1, \infty)$ **b.** $h(x) = x^2 - 6x, x \neq 1$
25. a. $x \in (-\infty, 5) \cup (5, \infty)$ **b.** $h(x) = \frac{x + 1}{x - 5}, x \neq 5$
27. a. $x \in (-\infty, -2)$ **b.** $r(x) = \frac{2x - 3}{\sqrt{-2 - x}}$
c. 6 is not in the domain of r, $r(-6) = -\frac{15}{2}$
29. a. $x \in (5, \infty)$ **b.** $r(x) = \frac{x - 5}{\sqrt{x - 5}}$
c. $r(6) = 1$, −6 is not in the domain of r.
31. a. $x \in \left(-\frac{13}{2}, \infty\right)$ **b.** $r(x) = \frac{x^2 - 36}{\sqrt{2x + 13}}$ **c.** $r(6) = 0, r(-6) = 0$
33. a. $h(x) = \frac{2x + 4}{x - 3}$ **b.** $x \in (-\infty, 3) \cup (3, \infty)$ **c.** $x \neq -2, x \neq 0$
35. sum: $3x + 1, x \in (-\infty, \infty)$; difference: $x + 5, x \in (-\infty, \infty)$;
product: $2x^2 - x - 6, x \in (-\infty, \infty)$;
quotient: $\frac{2x + 3}{x - 2}, x \in (-\infty, 2) \cup (2, \infty)$
37. sum: $x^2 + 3x + 5, x \in (-\infty, \infty)$; difference: $x^2 - 3x + 9$,
$x \in (-\infty, \infty)$; product: $3x^3 - 2x^2 + 21x - 14, x \in (-\infty, \infty)$;
quotient: $\frac{x^2 + 7}{3x - 2}, x \in \left(-\infty, \frac{2}{3}\right) \cup \left(\frac{2}{3}, \infty\right)$

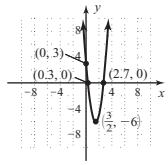
39. sum: $x^2 + 3x - 4, x \in (-\infty, \infty)$; difference: $x^2 + x - 2$, $x \in (-\infty, \infty)$; product: $x^3 + x^2 - 5x + 3, x \in (-\infty, \infty)$; quotient: $x + 3, x \in (-\infty, 1) \cup (1, \infty)$
41. sum: $3x + 1 + \sqrt{x-3}, x \in [3, \infty)$; difference: $3x + 1 - \sqrt{x-3}$, $x \in [3, \infty)$; product: $(3x + 1)\sqrt{x-3}, x \in [3, \infty)$; quotient: $\dfrac{3x+1}{\sqrt{x-3}}, x \in (3, \infty)$
43. sum: $2x^2 + \sqrt{x+1}, x \in [-1, \infty)$; difference: $2x^2 - \sqrt{x+1}$, $x \in [-1, \infty)$; product: $2x^2\sqrt{x+1}, x \in [-1, \infty)$; quotient: $\dfrac{2x^2}{\sqrt{x+1}}, x \in (-1, \infty)$
45. sum: $\dfrac{7x-11}{(x-3)(x+2)}, x \in (-\infty, -2) \cup (-2, 3) \cup (3, \infty)$; difference: $\dfrac{-3x+19}{(x-3)(x+2)}, x \in (-\infty, -2) \cup (-2, 3) \cup (3, \infty)$; product: $\dfrac{10}{(x-3)(x+2)}, x \in (-\infty, -2) \cup (-2, 3) \cup (3, \infty)$; quotient: $\dfrac{2x+4}{5(x-3)}, x \in (-\infty, -2) \cup (-2, 3) \cup (3, \infty)$
47. a. 6000 **b.** 3000 **c.** 8000 **d.** $C(9) - T(9)$; 4000
49. a. \$1 billion **b.** \$5 billion **c.** 2003, 2007, 2010 **d.** $t \in (2000, 2003) \cup (2007, 2010)$ **e.** $t \in (2003, 2007)$ **f.** $R(5) - C(5)$; \$4 billion
51. a. 4 **b.** 0 **c.** 2 **d.** 3 **e.** $-\dfrac{1}{3}$ **f.** 6 **g.** -3 **h.** 1 **i.** 1 **j.** undefined
53. $h(x) = -\frac{2}{3}x + 4$ **55.** $h(x) = 4x - x^2$
57. a. $(-\infty, \infty)$ **b.** $(-\infty, 2) \cup (2, \infty)$ **59. a.** $[-1, \infty)$ **b.** $(-1, \infty)$
61. a. $[-2, 3]$ **b.** $[-2, 3)$ **63. a.** $[-4, \infty)$ **b.** $[-4, \infty)$
65. a. $(-\infty, \infty)$ **b.** $(-\infty, 4) \cup (4, \infty)$ **67. a.** $[-4, 3]$ **b.** $[-4, 3)$
69. a. $V = 400 - 400e^{-0.08t}$ **b.** $f(t) = 400, g(t) = 400e^{-0.08t}$, $V(1) \approx 400 - 369 = 31$ ft/sec, $V(2) \approx 400 - 341 = 59$ ft/sec, $V(20) \approx 400 - 81 = 319$ ft/sec **c.** 400 ft/sec
71. a. $P(x) = 12{,}000x - 108{,}000$ **b.** nine boats must be sold
73. a. $P(n) = 11.45n - 0.1n^2$ **b.** \$123 **c.** \$327 **d.** $C(115) > R(115)$
75. km 115 **77.** Anywhere between km 115 and km 199. Answers will vary. **79. a.** 4 sec **b.** about 494 ft
81. a. 1995 to 1996; 1999 to 2004 **b.** 30; 1995 **c.** 20 seats; 1997 **d.** The total number of seats in the senate (50); the number of additional seats held by the majority
83. 67 a. $x = \frac{2}{3}$, where $Y_1 = Y_2$; **67 b.** $x = -4$, where $Y_1 = 0$; **68 a.** $x = 0$, where $Y_1 = -Y_2$; **68 b.** $x = -1.2$ or 3, the zeroes of Y_1 and Y_2.
85. $x = \dfrac{-148}{9}$ **87. a.** $6x + 5y = -13$ **b.** $d = \sqrt{61}$

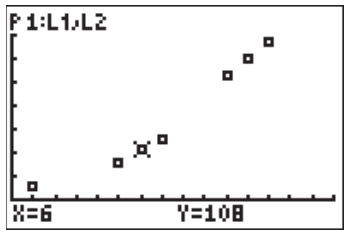
Exercises 3.6, pp. 287–291











1. composition **3.** domain, $g(x)$ **5.** Answers will vary.
7. 0, 0, $4a^2 - 10a - 14$, $a^2 - 9a$
9. a. $h(x) = \sqrt{2x-2}$ **b.** $H(x) = 2\sqrt{x+3} - 5$
c. D of $h(x)$: $x \in [1, \infty)$; D of $H(x)$: $x \in [-3, \infty)$
11. a. $h(x) = \sqrt{3x+1}$ **b.** $H(x) = 3\sqrt{x-3} + 4$
c. D of $h(x)$: $x \in [-\frac{1}{3}, \infty)$; D of $H(x)$: $x \in [3, \infty)$
13. a. $h(x) = x^2 + x - 2$ **b.** $H(x) = x^2 - 3x + 2$
c. D of $h(x)$: $x \in (-\infty, \infty)$; D of $H(x)$: $x \in (-\infty, \infty)$
15. a. $h(x) = x^2 + 7x + 8$ **b.** $H(x) = x^2 + x - 1$
c. D of $h(x)$: $x \in (-\infty, \infty)$; D of $H(x)$: $x \in (-\infty, \infty)$
17. a. $h(x) = |-3x + 1| - 5$ **b.** $H(x) = -3|x| + 16$
c. D of $h(x)$: $x \in (-\infty, \infty)$; D of $H(x)$: $x \in (-\infty, \infty)$
19. $h(-3) = -6, h(\sqrt{2}) \approx 9.071$
$h(\frac{1}{2}) = 2.75, h(5) = 50$
21. $h(-3) = 1, h(\sqrt{2}) \approx 145.91$
$h(\frac{1}{2}) = 64, h(5) =$ ERR;
$x = 5$ is not in the domain of g
23. $h(-3) = 2, h(\sqrt{2}) = 5$
$h(\frac{1}{2}) = 5.5, h(5) =$ ERR;
$g(5)$ is not in the domain of f
25. a. $(f \circ g)(x)$: For $g(x)$ to be defined, $x \neq 0$.
For $f[g(x)] = \dfrac{2g(x)}{g(x)+3}, g(x) \neq -3$ so $x \neq -\dfrac{5}{3}$.
domain: all real numbers except $x = -3$ and $x = -\dfrac{5}{3}$
b. $(g \circ f)(x)$: For $f(x)$ to be defined, $x \neq -3$.
For $g[f(x)] = \dfrac{5}{f(x)}, f(x) \neq 0$ so $x \neq 0$.
domain: all real numbers except $x = -3$ and $x = 0$
c. $(f \circ g)(x) = \dfrac{10}{5+3x}$; $(g \circ f)(x) = \dfrac{5x+15}{2x}$; the domain of a composition cannot always be determined from the composed form
27. a. $(f \circ g)(x)$: For $g(x)$ to be defined, $x \neq 5$.
For $f[g(x)] = \dfrac{4}{g(x)}, g(x) \neq 0$ and $g(x)$ is never zero
domain: $\{x | x \neq 5\}$
b. $(g \circ f)(x)$: For $f(x)$ to be defined, $x \neq 0$.
For $g[f(x)] = \dfrac{1}{f(x)-5}, f(x) \neq 5$ so $x \neq \dfrac{4}{5}$.
domain: all real numbers except $x = 0$ and $x = \dfrac{4}{5}$
c. $(f \circ g)(x) = 4x - 20$; $(g \circ f)(x) = \dfrac{x}{4-5x}$; the domain of a composition cannot always be determined from the composed form
29. a. 41 **b.** 41 **31.** $g(x) = \sqrt{x-2} + 1, f(x) = x^3 - 5$
33. $p(x) = 2(x+4)^2 - 3, q(x) = (2x+7)^2 - 1$
35. a. 2 **b.** 2 **c.** 2 **d.** -1 **e.** -1 **f.** 1 **g.** 3 **h.** ≈ 0.5

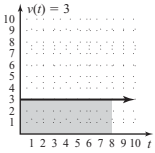
25. $x \in (-\infty, -0.2) \cup (-0.2, 0.2) \cup (0.2, \infty)$

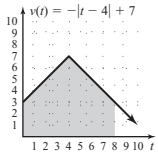
Connections to Calculus Exercises, pp. 305–306



1. a. −3 **b.** as $h \to 0$, −3 remains constant **3. a.** $2x - 3 + h$

b. as $h \to 0$, $2(2) - 3 + h \to 1$ **5. a.** $\frac{-1}{(x + h)x}$

b. as $h \to 0$, $\frac{-1}{(2 + h)(2)} \to \frac{-1}{4}$ **7. a.** $\frac{-2x - h}{2x^2(x + h)^2}$



b. as $h \to 0$, $\frac{-2(2) - h}{2(2)^2 (2 + h)^2} \to \frac{-1}{8}$

9.

$A = 24$, distance = 24 ft

11.

$A = 40$, distance = 40 ft

CHAPTER 4

Exercises 4.1, pp. 316–320

1. synthetic, zero **3.** $P(c)$, remainder **5.** Answers will vary.

7. $x^3 - 5x^2 - 4x + 23 = (x - 2)(x^2 - 3x - 10) + 3$

9. $2x^3 + 5x^2 + 4x + 17 = (x + 3)(2x^2 - x + 7) - 4$

11. $x^3 - 8x^2 + 11x + 20 = (x - 5)(x^2 - 3x - 4) + 0$

13. a. $\frac{2x^2 - 5x - 3}{x - 3} = (2x + 1) + \frac{0}{x - 3}$

b. $2x^2 - 5x - 3 = (x - 3)(2x + 1) + 0$

15. a. $\dfrac{x^3 - 3x^2 - 14x - 8}{x + 2} = (x^2 - 5x - 4) + \dfrac{0}{x + 2}$

b. $x^3 - 3x^2 - 14x - 8 = (x + 2)(x^2 - 5x - 4) + 0$

17. a. $\dfrac{x^3 - 5x^2 - 4x + 23}{x - 2} = (x^2 - 3x - 10) + \dfrac{3}{x - 2}$

b. $x^3 - 5x^2 - 4x + 23 = (x - 2)(x^2 - 3x - 10) + 3$

19. a. $\dfrac{2x^3 - 5x^2 - 11x - 17}{x - 4} = (2x^2 + 3x + 1) + \dfrac{-13}{x - 4}$

b. $2x^3 - 5x^2 - 11x - 17 = (x - 4)(2x^2 + 3x + 1) - 13$

21. $x^3 + 5x^2 + 7 = (x + 1)(x^2 + 4x - 4) + 11$

23. $x^3 - 13x - 12 = (x - 4)(x^2 + 4x + 3) + 0$

25. $3x^3 - 8x + 12 = (x - 1)(3x^2 + 3x - 5) + 7$

27. $n^3 + 27 = (n + 3)(n^2 - 3n + 9) + 0$

29. $x^4 + 3x^3 - 16x - 8 = (x - 2)(x^3 + 5x^2 + 10x + 4) + 0$

31. $\dfrac{2x^3 + 7x^2 - x + 26}{x^2 + 3} = (2x + 7) + \dfrac{-7x + 5}{x^2 + 3}$

33. $\dfrac{x^4 - 5x^2 - 4x + 7}{x^2 - 1} = (x^2 - 4) + \dfrac{-4x + 3}{x^2 - 1}$

35. a. -30 **b.** 12 **37. a.** -2 **b.** -22 **39. a.** -1 **b.** 3

41. a. 31 **b.** 0 **43. a.** -10 **b.** 0 **45. a.** yes **b.** yes

47. a. no **b.** yes **49. a.** yes **b.** yes

51.
$$\begin{array}{r|cccc} -3 & 1 & 2 & -5 & -6 \\ & & -3 & 3 & 6 \\ \hline & 1 & -1 & -2 & 0 \end{array}$$

Summary and Concept Review, pp. 396–400

1. $q(x) = x^2 + 6x + 7$; $r = 8$ **2.** $q(x) = x + 1$; $r = 3x - 4$
3.

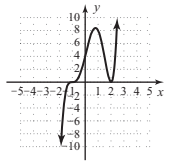
-7	2	13	-6	9	14
		-14	7	-7	-14
	2	-1	1	2	0

Since $r = 0$, -7 is a root and $x + 7$ is a factor.
4. $x^3 - 4x + 5 = (x - 2)(x^2 + 2x) + 5$

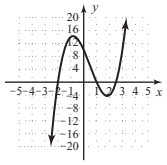
5. $(x + 4)(x + 1)(x - 3)$ **6.** $h(x) = (x - 1)(x - 4)(x^2 + 2x + 2)$

7.
$$\begin{array}{r|rrrr} \frac{1}{2} & 4 & 8 & -3 & -1 \\ & & 2 & 5 & 1 \\ \hline & 4 & 10 & 2 & \underline{|0} \end{array}$$
Since $r = 0, \frac{1}{2}$ is a root and $(x - \frac{1}{2})$ is a factor.

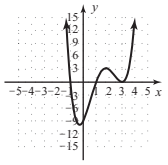
8.
$$\begin{array}{r|rrrr} 3i & 1 & -2 & 9 & -18 \\ & & 3i & -9 - 6i & 18 \\ \hline & 1 & -2 + 3i & -6i & \underline{|0} \end{array}$$
Since $r = 0, 3i$ is a zero



9.
$$\begin{array}{r|rrrr} -7 & 1 & 9 & 13 & -10 \\ & & -7 & -14 & 7 \\ \hline & 1 & 2 & -1 & \underline{|-3} \end{array}$$
$h(-7) = -3$



10. $P(x) = x^3 - x^2 - 5x + 5$ **11.** $C(x) = x^4 - 2x^3 + 5x^2 - 8x + 4$

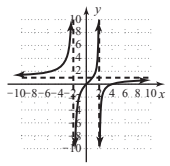


12. a. $C(0) = 350$ customers **b.** more at 2 P.M., 170 **c.** busier at 1 P.M., $760 > 710$ **13.** $\{\pm 1, \pm 10, \pm 2, \pm 5, \pm\frac{1}{2}, \pm\frac{5}{2}, \pm\frac{1}{4}, \pm\frac{5}{4}\}$

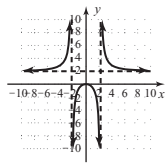
14. $x = -\frac{1}{2}, 2, \frac{5}{2}$ **15.** $P(x) = (2x + 3)(x - 4)(x + 1)$ **16.** only possibilities are $\pm 1, \pm 3$, none give a remainder of zero **17.** [1, 2], [4, 5]; verified **18.** one sign change for $g(x) \to 1$ positive zero; three sign changes for $g(-x) \to 3$ or 1 negative zeroes; 1 positive, 3 negative, 0 complex, or 1 positive, 1 negative, 2 complex; 1 positive, 1 negative, 2 complex, verified

19. degree 5; up/down; $(0, -4)$ **20.** degree 4; up/up; $(0, 8)$

21. 



22. 



23. 

24. a. even **b.** $x = -2$, odd; $x = -1$, even; $x = 1$, odd **c.** deg 6: $P(x) = (x + 2)(x + 1)^2(x - 1)^3$

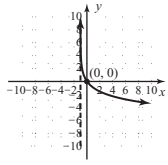
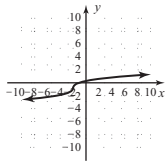
Exercises 5.3, pp. 442–446



1. $\log_b x$, b, b, greater **3.** (1, 0), 0 **5.** 5; answers will vary **7.** $2^3 = 8$
9. $7^{-1} = \frac{1}{7}$ **11.** $9^0 = 1$ **13.** $8^{\frac{1}{3}} = 2$ **15.** $2^1 = 2$ **17.** $7^2 = 49$
19. $10^2 = 100$ **21.** $e^4 \approx 54.598$ **23.** $\log_4 64 = 3$ **25.** $\log_{3^{\frac{1}{9}}} = -2$
27. $0 = \ln 1$ **29.** $\log_{\frac{1}{3}} 27 = -3$ **31.** $\log 1000 = 3$ **33.** $\log_{\frac{1}{100}} = -2$
35. $\log_4 8 = \frac{3}{2}$ **37.** $\log_{4^{\frac{1}{8}}} = \frac{-3}{2}$ **39.** 1 **41.** 2 **43.** 1 **45.** $\dfrac{1}{2}$ **47.** -2
49. -2 **51.** 1.6990 **53.** 0.4700 **55.** 5.4161 **57.** 0.7841
59. shift up 3 **61.** shift right 2, up 3



63. shift left 1 **65.** shift left 1, reflect across x-axis

67. II **69.** VI **71.** V **73.** $x \in (-\infty, -1) \cup (3, \infty)$
75. $x \in (\frac{3}{2}, \infty)$ **77.** $x \in (-3, 3)$ **79.** pH ≈ 4.1; acid
81. a. ≈4.7 **b.** ≈7.9 **83.** about 398 times **85.** about 3.2 times
87. a. ≈2.4 **b.** ≈1.2 **89. a.** 20 dB **b.** 120 dB
91. about 501 times **93.** about 3162 times **95.** 6194 m
97. a. about 5434 m **b.** 4000 m **99. a.** 2225 items **b.** 2732 items
c. \$117,000 **101. a.** about 58.6 cfm **b.** about 1605 ft^2
103. a. 95% **b.** 67% **c.** 39% **105.** ≈4.3; acid **107.** Answers will vary.
a. 0 dB **b.** 90 dB **c.** 15 dB **d.** 120 dB **e.** 100 **f.** 140 dB
109. a. $\frac{-2}{3}$ **b.** $\frac{-3}{2}$ **c.** $\frac{-5}{2}$
111. D: $x \in \mathbb{R}$, R: $y \in \mathbb{R}$

113. $x \in (-\infty, -5)$; $f(x) = (x + 5)(x - 4)^2 = x^3 - 3x^2 - 24x + 80$

Exercises 5.4, pp. 453–456

1. e **3.** extraneous **5.** Answers will vary; Yes, $1.5663025 = 1.5663025$
7. $x \approx 29.964$ **9.** $x \approx 1.778$ **11.** $x \approx 2.200$ **13.** $x \approx 1.260$
15. $x = \ln\frac{65}{4} + 2, x \approx 4.7881$ **17.** $x = \log(78) - 5, x \approx -3.1079$
19. $x = -\frac{\ln 2.32}{0.75}, x \approx -1.1221$ **21.** $x = e^{\frac{8}{3}} - 4, x \approx 10.3919$
23. $x = 5 - 10^{1.25}, x \approx -12.7828$ **25.** $x = \frac{e^{0.4} - 5}{2}, x \approx -1.7541$
27. $\ln(2x^2 - 14x)$ **29.** $\log(x^2 - 1)$ **31.** $\log_3 4$ **33.** $\log\left(\frac{x}{x+1}\right)$
35. $\ln\left(\frac{x-5}{x}\right)$ **37.** $\ln(x-2)$ **39.** $\log_2 42$ **41.** $\log_5(x-2)$
43. $(x+2)\log 8$ **45.** $(2x-1)\ln 5$ **47.** $\frac{1}{2}\log 22$ **49.** $4\log_5 3$
51. $3\log a + \log b$ **53.** $\ln x + \frac{1}{4}\ln y$ **55.** $2\ln x - \ln y$
57. $\frac{1}{2}[\log(x-2) - \log x]$ **59.** $\frac{\ln 60}{\ln 7}$; 2.104076884
61. $\frac{\ln 152}{\ln 5}$; 3.121512475 **63.** $\frac{\log 1.73205}{\log 3}$; 0.499999576
65. $\frac{\log 0.125}{\log 0.5}$; 3
67. $f(x) = \frac{\log(x)}{\log(3)}$; $f(5) \approx 1.4650$; $f(15) \approx 2.4650$; $f(45) \approx 3.4650$; outputs increase by 1; $f(3^3 \cdot 5) \approx 4.4650$
69. $h(x) = \frac{\log(x)}{\log(9)}$; $h(2) \approx 0.3155$; $h(4) \approx 0.6309$; $h(8) \approx 0.9464$; outputs are multiples of 0.3155; $h(2^4) \approx 4(0.3155) \approx 1.2619$
71. verified **73. a.** $N = AX^{-m}$ **b.** ≈ 3500 people **75.** no, pH ≈ 7.32
77. no, pH ≈ 5.9 and the soil must be treated further **79.** 600^{601}
81. zeroes at $x = 3$ and $x = -2$; HA: $y = 1$, VA $x = -1, x = 1$
83. $x = 1$ or $x = -9$

Mid-Chapter Check, p. 456

1. a. $\frac{2}{3} = \log_{27} 9$ **b.** $\frac{5}{4} = \log_{81} 243$ **2. a.** $8^{\frac{5}{3}} = 32$ **b.** $1296^{0.25} = 6$
3. a. $x = 5$ **b.** $b = \frac{5}{4}$ **4. a.** $x = 3$ **b.** $b = 5$ **5. a.** \$71,191.41
b. 6 yr **6.** $F(x) = 4 \cdot 5^{x-3} + 2$ **7.** $f^{-1}(x) = (x-1)^2 + 3$, D: $x \in [1, \infty)$; R: $y \in [3, \infty)$; verified **8. a.** $4 = \log_3 81$, verified
b. $4 \approx \ln 54.598$, verified **9. a.** $27^{\frac{2}{3}} = 9$, verified
b. $e^{1.4} \approx 4.0552$, verified **10.** ≈7.9 times more intense

Reinforcing Basic Concepts, p. 457

Exercise 1. Answers will vary. **Exercise 2. a.** $\log(x^2 + 3x)$
b. $\ln(x^2 - 4)$ **c.** $\log\frac{x}{x+3}$

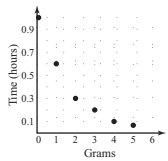
Exercises 5.5, pp. 465–468

1. variable, constant **3.** uniqueness, one, one **5.** False; answers will vary.
7. $x = 32$ **9.** $x = 6.4$ **11.** $x = 20, -5$ is extraneous
13. $x = 2, -\frac{5}{2}$ is extraneous **15.** $x = 0$ **17.** $x = \frac{5}{2}$ **19.** $x = \frac{2}{3}$
21. $x = \frac{3}{2}$ **23.** $x = \frac{-19}{9}$ **25.** $x = \frac{e^2 - 63}{9}$; $x \approx -6.1790$
27. $x = 2$; -9 is extraneous **29.** $x = 3e^3 - \frac{1}{2}$; $x \approx 59.7566$
31. no solution **33.** $x = 2 + \sqrt{3}$; $2 - \sqrt{3}$ is extraneous
35. $x = \frac{\ln 231}{\ln 7}$; $x \approx 2.7968$ **37.** $x = \frac{\ln 128{,}967}{3\ln 5}$; $x \approx 2.4371$
39. $x = \frac{\ln 2}{\ln 3 - \ln 2}$; $x \approx 1.7095$ **41.** $x \approx -4.815, x \approx 102.084$
43. $x \approx 2.013, x \approx 3.608$ **45.** $x \approx 46.210$
47. $t = \frac{\ln\left(\frac{\frac{C}{p} - 1}{a}\right)}{-k}$, $t \approx 55.45$ **49.** about 3.2 cmHg
51. a. 30 fish **b.** about 37 months **53.** about 50.2 min
55. \$15,641 **57. a.** 6 hr **b.** 18.0% **59.** $M_f = 52.76$ tons
61. a. 26 planes **b.** 9 days **63.** $x = 1.609438$
65. a.

$y = 2^{x+1}$	
$x = 2^{y+1}$	
$\ln x = (y+1)\ln 2$	
$\frac{\ln x}{\ln 2} = y + 1$	
$\frac{\ln x}{\ln 2} - 1 = y$	

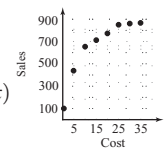
b.

$y = 2\ln(x-3)$	
$x = 2\ln(y-3)$	
$\frac{x}{2} = \ln(y-3)$	
$e^{\frac{x}{2}} = y - 3$	
$y = e^{\frac{x}{2}} + 3$	



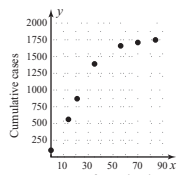
67. a. $y = e^{x\ln 2} = e^{\ln 2^x} = 2^x$;
$y = 2^x \Rightarrow \ln y = x\ln 2$, $e^{\ln y} = e^{x\ln 2} \Rightarrow y = e^{x\ln 2}$
b. $y = b^x$, $\ln y = x\ln b$, $e^{\ln y} = e^{x\ln b}$, $y = e^{xr}$ for $r = \ln b$
69. a. d **b.** e **c.** b **d.** f **e.** a **f.** c
71. a. $x \in [-\frac{3}{2}, \infty), y \in [0, \infty)$ **b.** $x \in (-\infty, \infty), y \in [-3, \infty)$
73. 13.5 tons

Exercises 5.6, pp. 477–482



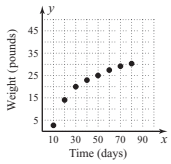
1. Compound **3.** $Q_0 e^{-rt}$ **5.** Answers will vary. **7.** \$4896
9. 250% **11.** \$2152.47 **13.** 5.25 yr **15.** 80% **17.** 4 yr **19.** 16 yr
21. \$7561.33 **23.** about 5 yr **25.** 7.5 yr **27.** no **29. a.** no
b. 9.12% **31.** 7.9 yr **33.** 7.5 yr **35. a.** no **b.** 9.4%
37. a. no **b.** approx 13,609 euros **39.** No; \$234,612.02
41. about 7 yr **43.** 22 yr **45. a.** no **b.** \$298.31
47. a. $t = \frac{A-p}{pr}$ **b.** $p = \frac{A}{1+rt}$ **49. a.** $r = n\left(\sqrt[nt]{\frac{A}{p}} - 1\right)$
b. $t = \frac{\ln\left(\frac{A}{p}\right)}{n\ln\left(1 + \frac{r}{n}\right)}$ **51. a.** $Q_0 = \frac{Q(t)}{e^{rt}}$ **b.** $t = \frac{\ln\left(\frac{Q(t)}{Q_0}\right)}{r}$
53. \$709.74 **55. a.** 5.78% **b.** 91.67 hr **57.** 0.65 g **59.** about 816 yr
61. about 12.4% **63.** \$17,027,502.21 **65.** 7.2%
67. a. $f(x) = x^3, f(x) = x, f(x) = \sqrt{x}, f(x) = \sqrt[3]{x}, f(x) = \frac{1}{x}$
b. $f(x) = |x|, f(x) = x^2, f(x) = \frac{1}{x^2}$ **c.** $f(x) = x, f(x) = x^3, f(x) = \sqrt{x}$, $f(x) = \sqrt[3]{x}$ **d.** $f(x) = \frac{1}{x}, f(x) = \frac{1}{x^2}$
69. $P(x) = x^4 - 4x^3 + 6x^2 - 4x - 15$

Exercises 5.7, pp. 487–495



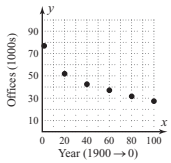
1. scatterplot, context, situation **3.** beyond **5.** (1) clear out old data, (2) enter new data, (3) display the data, (4) calculate the regression equation, (5) display and use the results; Answers will vary.
7. e **9.** a **11.** d **13.** linear **15.** exponential
17. logistic **19.** exponential
21. As time increases, the amount of radioactive material decreases but will never truly reach 0 or become negative. Exponential with $b < 1$ and $k > 0$ is the best choice. $y \approx (1.042)0.5626^x$

23. Sales will increase rapidly, then level off as the market is saturated with ads and advertising becomes less effective, possibly modeled by a logarithmic function. $y \approx 120.4938 + 217.2705\ln(x)$



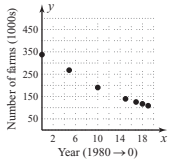
25. a.

b. about 1750 **c.** $y \approx \frac{1719}{1 + 10.2e^{-0.11x}}$ logistic
27. 4.95 **29.** 6.25 **31.** 5.75 **33.** 6.84
35. a. about 19 boards **b.** about 15 days



37. logarithmic, $y \approx -27.4 + 13.5 \ln x$

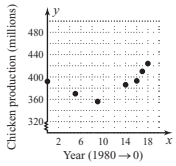
a. 9.2 lb **b.** 29 days **c.** 34.8 lb



39. logarithmic, $y \approx 78.8 - 10.3 \ln x$

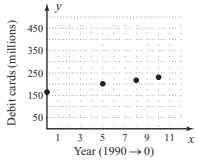
a. 51,000 **b.** 1977 **c.** 29,900

41. exponential, $y \approx 346.79(0.94)^x$



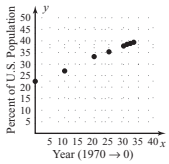
a. 155,100 **b.** 54,200 **c.** 2013

43. quadratic $y \approx 0.576x^2 - 8.879x + 394$



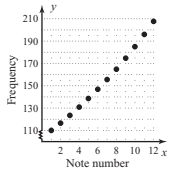
a. 360 million **b.** about 513 million

c. from 1984 to 1990

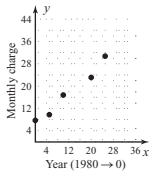


45. linear, $y \approx 6.555x + 165.308$

a. 224.3 million **b.** 329.2 million **c.** 2010

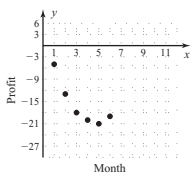


47. linear, $P(t) \approx 0.51t + 22.51$,
2005: 40.4%, 2010: 43.0%, 2015: 45.5%

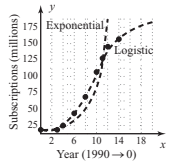


49. exponential, $y \approx 103.83\,(1.0595)^x$

a. 220 **b.** The 22nd note, or F#

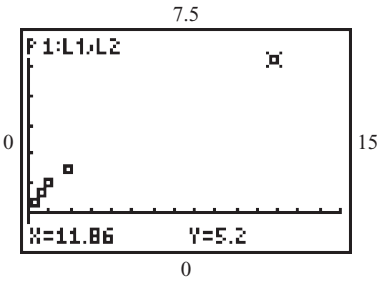


c. frequency doubles, yes

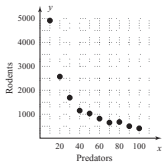


51. exponential, $y \approx 8.02\,(1.0564)^x$
$41.59/mo, $54.72/mo

53. quadratic, $y \approx 1.18x^2 - 10.99x + 4.60$;
month 8

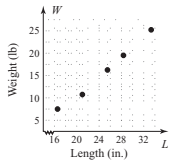


55. logistic, $y \approx \dfrac{222.133}{1 + 32.280e^{-0.336x}}$;



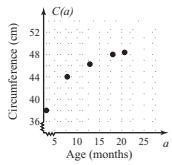
about 55 million, about 184 million, about 214 million; 2014

57.



power regression,
a. $y \approx x^{0.665}$, 9.5 AU;
b. 84.8 yr

59.



a. power regression, $y \approx 58{,}555.89x^{-1.056}$;
b. about 295 rodents **c.** about 17 predators

61. a.

linear, $W \approx 1.24L - 15.83$, 32.5 lb, 35.3 in.

61. b.

logarithmic, $C(a) \approx 37.9694 + 3.4229 \ln (a)$, about 49.3 cm, about 34 mo

63. D: $x \in (-\infty, -2) \cup (-2, 1) \cup (1, 5) \cup (5, \infty)$, $\frac{1}{x+2}$

65. max: $(-0.4, 1.8)$

min: $(-3.5, -3.5)$, $(2.3, -1.4)$

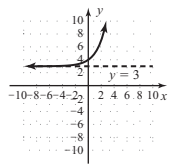
$f(x)\uparrow$: $x \in (-3.5, -0.4) \cup (2.3, \infty)$

$f(x)\downarrow$: $x \in (-\infty, -3.5) \cup (-0.4, 2.3)$

Making Connections, p. 495

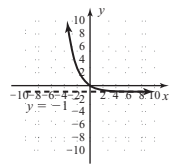
1. a **3.** e **5.** c **7.** e **9.** b **11.** g **13.** c **15.** d

Summary and Concept Review, pp. 496–500



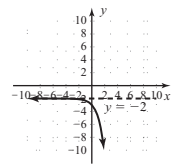
1. no **2.** no **3.** yes **4.** $f^{-1}(x) = \dfrac{x-2}{-3}$ **5.** $f^{-1}(x) = \sqrt{x+2}$

6. $f^{-1}(x) = x^2 + 1; x \geq 0$



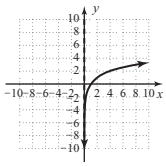
7. $f(x)$: D: $x \in [-4, \infty)$, R: $y \in [0, \infty)$; $f^{-1}(x)$: D: $x \in [0, \infty)$, R: $y \in [-4, \infty)$ **8.** $f(x)$: D: $x \in (-\infty, \infty)$, R: $y \in (-\infty, \infty)$; $f^{-1}(x)$: D: $(-\infty, \infty)$, R: $y \in (-\infty, \infty)$ **9.** $f(x)$: D: $x \in (-\infty, \infty)$, R: $y \in (0, \infty)$; $f^{-1}(x)$: D: $x \in (0, \infty)$, R: $y \in (-\infty, \infty)$

10. a. \$3.05 **b.** $f^{-1}(t) = \frac{t-2}{0.15}$, $f^{-1}(3.05) = 7$ **c.** 12 days

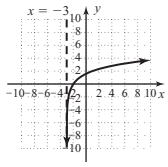


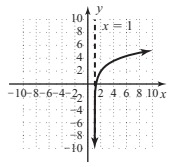
11.

12.



13.





14. 2 **15.** -2 **16.** $\frac{5}{2}$ **17.** 12.1 yr **18.** $3^2 = 9$ **19.** $5^{-3} = \frac{1}{125}$

20. $e^{3.7612} \approx 43$ **21.** $\log_5 25 = 2$ **22.** $\ln 0.7788 \approx -0.25$

23. $\log_3 81 = 4$ **24.** 5 **25.** -1 **26.** $\frac{1}{2}$

27. 

28. 

29. 

30. $x \in (-\frac{3}{2}, \infty)$ **31.** $x \in (-\infty, 0) \cup (6, \infty)$ **32. a.** 4.79 **b.** $10^{7.3} I_0$

33. a. $x = e^{32}$ **b.** $x = 10^{2.38}$ **c.** $x = \ln 9.8$ **d.** $x = \dfrac{1}{2}\log 7$

34. a. $x = \dfrac{\ln 4}{0.5}, x \approx 2.7726$ **b.** $x = \dfrac{\log 19}{0.2}, x \approx 6.3938$

c. $x = \dfrac{10^3}{3}, x \approx 333.3333$ **d.** $x = e^{-2.75}, x \approx 0.0639$

35. a. $\ln 42$ **b.** $\log_9 30$ **c.** $\ln\left(\frac{x+3}{x-1}\right)$ **d.** $\log(x^2 + x)$

36. a. $2\log_5 9$ **b.** $2\log_7 4$ **c.** $(2x - 1)\ln 5$ **d.** $(3x + 2)\ln 10$

37. a. $\ln x + \frac{1}{4}\ln y$ **b.** $\frac{1}{3}\ln p + \ln q$

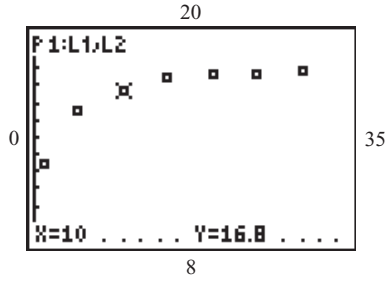
c. $\frac{5}{3}\log x + \frac{4}{3}\log y - \frac{5}{2}\log x - \frac{3}{2}\log y$

d. $\log 4 + \frac{5}{3}\log p + \frac{4}{3}\log q - \frac{3}{2}\log p - \log q$

38. a. $\dfrac{\log 45}{\log 6} \approx 2.215$ **b.** $\dfrac{\log 128}{\log 3} \approx 4.417$ **c.** $\dfrac{\ln 124}{\ln 2} \approx 6.954$

d. $\dfrac{\ln 0.42}{\ln 5} \approx -0.539$ **39.** $x = \frac{\ln 7}{\ln 2}, x \approx 2.8074$

40. $x = \frac{\ln 5}{\ln 3} - 1, 0 \approx x = .4650$ **41.** $\frac{2}{1 + \ln 3}, x \approx 0.9530$

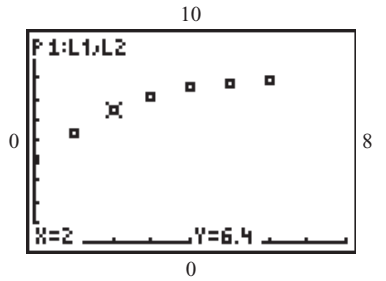


42. $x = e^2 - 1, x \approx 6.3891$ **43.** $x = 5$; -2 is extraneous

44. $x = 4.25$ **45. a.** 17.77% **b.** 23.98 days **46.** 38.6 cmHg

47. 18.5% **48.** Almost, she needs \$42.15 more. **49. a.** no **b.** \$268.93

50. 55.0%



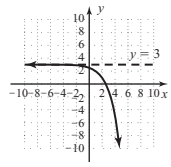
51.

a. logarithmic, $y \approx 12.772 + 1.595 \ln x$ **b.** 16.9 mi/gal

c. the year 2011

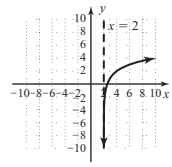
52.

a. logistic, $g(t) = \dfrac{8.0}{1 + 1.0e^{-0.7t}}$ **b.** $\approx$ 6.8 microns



c. $(4 \times 1.96) = 7.84$; 5.56 hr (about 5 hr 34 min)

Practice Test, p. 501

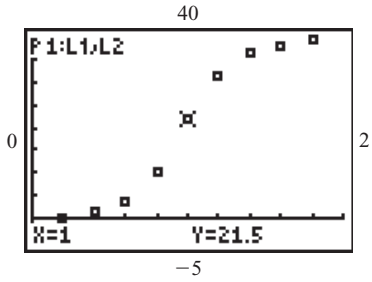


1. $3^4 = 81$ **2.** $\log_{25} 5 = \frac{1}{2}$ **3.** $\frac{5}{2}\log_b x + 3\log_b y - \log_b z$

4. $\log_b \dfrac{m\sqrt{n^3}}{\sqrt{p}}$ **5.** $x = 10$ **6.** $x = \dfrac{-5}{3}$ **7.** 2.68 **8.** -1.24

9.

10.



11. a. 4.19 **b.** -0.81 **12.** f is a parabola (hence not one-to-one), $x \in \mathbb{R}, y \in [-3, \infty)$; vertex is at $(2, -3)$, so restricted domain could be $x \in [2, \infty)$ to create a one-to-one function; $f^{-1}(x) = \sqrt{x + 3} + 2, x \in [-3, \infty), y \in [2, \infty)$.

13. $x = 1 + \frac{\ln 89}{\ln 3}, x \approx 5.0857$ **14.** $x = 1, x = -5$ is extraneous

15. $\approx$5 yr **16. a.** $P = kM^{\alpha}$ **b.** $P \approx 15.3$ lb $(M = 20)$

17. 19.1 months **18. a.** no **b.** \$54.09 **19. a.** 10.2 lb **b.** 34 weeks

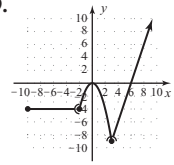
20. logistic; $y = \dfrac{39.1156}{1 + 314.6617e^{-5.9483x}}$; 0.89 sec

Strengthening Core Skills, p. 503

Exercise 1. about 126 times hotter **Exercise 2.** about 4.2 hb

Cumulative Review Chapters 1–5, p. 504

1. $x = 2 \pm 7i$ **3.** $(4 + 5i)^2 - 8(4 + 5i) + 41 = 0$



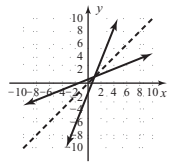
$-9 + 40i - 32 - 40i + 41 = 0 \quad 0 = 0$ ✓

5. $f(g(x)) = x; g(f(x)) = x$; Since $(f \circ g)(x) = (g \circ f)(x)$, they are inverse functions. **7. a.** $T(t) = 455t + 2645$ (1991 $\rightarrow$ year 1)

b. $\dfrac{\Delta T}{\Delta t} = \dfrac{455}{1}$, triple births increase by 455 each year

c. $T(6) = 5375$ sets of triplets, $T(17) = 10{,}380$ sets of triplets

9.



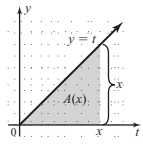
D: $x \in [-10, \infty)$, R: $y \in [-9, \infty)$

$h(x)\uparrow$: $x \in (-2, 0) \cup (3, \infty)$ $h(x)\downarrow$: $x \in (0, 3)$

11. $x = 3, x = 2$ (multiplicity 2); $x = -4$ **13.** $\sqrt{\frac{2V}{\pi a}} = b$

15. a. $f^{-1}(x) = \dfrac{5x - 3}{2}$ **b.**

c. $f^{-1}(f(x)) = x$



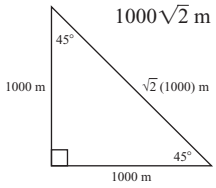
17. $x = 5, x = -6$ is an extraneous root **19. a.** about 88 hp for sport wagon, about 81 hp for minivan **b.** $\approx$3294 rpm **c.** minivan, 208 hp at 5800 rpm **21.** $x \approx 5.064$ **23.** $x \approx 0.649, x \approx -4.967$

25. $x \approx 2.013, x \approx 3.608$

Connections to Calculus Exercises, p. 507

1. $5x + \dfrac{3}{2}\ln x$ **3.** $5\log x - 3\log y - \dfrac{1}{2}\log z$

5. $A(x) = \dfrac{1}{2}x^2$



7. verified (factor out $\frac{1}{2}$, then combine like terms and simplify)

9. $t = \dfrac{1}{2}\ln\left(\dfrac{x + 1}{1 - x}\right)$

CHAPTER 6

Exercises 6.1, pp. 521–526

1. Complementary, 180, less, greater **3.** $r\theta$; $\frac{1}{2}r^2\theta$; radians **5.** Answers will vary. **7. a.** 77.5° **b.** 30.8° **9.** 53° **11.** 42.5° **13.** 67.555° **15.** 285.0025° **17.** 45.7625° **19.** 20° 15′ 00″ **21.** 67° 18′ 25.2″ **23.** 275° 19′ 48″ **25.** 5° 27′ 9″ **27.** No, $19 + 16 < 40$ **29.** 69° **31.** 25° **33.** 62.5 m **35.** $41\sqrt{2}$ ft + 10 ft ≈ 68 ft **37.** −645°, −285°, 435°, 795° **39.** −765°, −405°, 315°, 675° **41.** $s = 980$ m **43.** $\theta = 0.75$ rad **45.** $r \approx 1760$ yd **47.** $s \approx 8.38$ **49.** $r \approx 9.4$ km **51.** $\mathcal{A} = 115.6$ km^2 **53.** $\theta = 0.6$ rad **55.** $r \approx 3$ m **57.** $\theta = 1.5$ rad; $s = 7.5$ cm; $r = 5$ cm; $\mathcal{A} = 18.75$ cm^2 **59.** $\theta = 4.3$ rad; $s = 43$ m; $r = 10$ m; $\mathcal{A} = 215$ m^2 **61.** $\theta = 3$ rad; $\mathcal{A} = 864$ mm^2; $s = 72$ mm; $r = 24$ mm **63.** 2π rad **65.** $\frac{\pi}{4}$ rad **67.** $\frac{7\pi}{6}$ rad **69.** $\frac{-2\pi}{3}$ rad **71.** 0.4712 rad **73.** 3.9776 rad **75.** 60° **77.** 30° **79.** 120° **81.** 720° **83.** 165° **85.** 186.4° **87.** $h \approx 7.06$ cm; $m \approx 3.76$ cm; $n \approx 13.24$ cm **89.** approx. 960.7 mi apart **91. a.** ≈50.3 m^2 **b.** 80° **c.** ≈17 m **93. a.** 1.5π rad/sec **b.** about 15 mi/hr **95. a.** 40π rad/min **b.** $\frac{\pi}{6}$ ft/sec ≈ 0.52 ft/sec **c.** about 11.5 sec **97. a.** 3142 radians per minute **b.** 524 feet per minute **c.** 34 seconds **99. a.** 1000 m **b.** 1000 m **c.** $1000\sqrt{2}$ m ≈ 1414.2 m

57. $y = 2\cot\left(\frac{2\pi}{3}t\right)$ **59.** $\frac{\pi}{8}, \frac{3\pi}{8}$ **61.** about 137.8 ft

63. a. 20π cm $\approx$ 62.8 cm **b.** 80 cm; it is a square.

c.

n	*P*
10	64.984
20	63.354
30	63.063
100	62.853

getting close to 20π

65. a. no; $\approx 35°$ **b.** 1.05 **c.** Angles will be greater than 68.2°; soft rubber on sandstone

67. a. 5.67 units **b.** 86.5° **c.** Yes. Range of $\tan\theta$ is $(-\infty, \infty)$.
d. The closer θ gets to 90°, the longer the line segment gets.

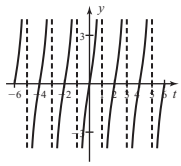
69. $\sin 0.6662394325 = 0.618033989 \approx \frac{-1+\sqrt{5}}{2}$; $\cos x = \tan x$ can be rewritten as $\sin^2 x = 1 - \sin x$, which can in turn be converted to $\sin^2(-x) = 1 + \sin(-x)$, which is the basis of the golden ratio.

71. 21,266,032 km^2

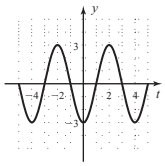
73.

t	*x*	*y*
0	1	0
$\frac{\pi}{4}$	$\frac{\sqrt{2}}{2}$	$\frac{\sqrt{2}}{2}$
$\frac{\pi}{2}$	0	1
π	-1	0
$\frac{3\pi}{4}$	$\frac{-\sqrt{2}}{2}$	$\frac{\sqrt{2}}{2}$
$\frac{3\pi}{2}$	0	-1
2π	1	0

$\tan\left(\frac{\pi}{2}\right)$ is undefined because $\frac{1}{0}$ is und.



Mid-Chapter Check, p. 577



1. a. 36.11°N, 115.08°W **b.** 2495.7 mi. **2.** $\theta = 4.3$; $\mathcal{A} = 860$ cm^2

3. a. $\frac{\sqrt{3}}{3}$ **b.** $\frac{-\sqrt{2}}{2}$ **4. a.** ≈ 1.0353 **b.** ≈ 8.9152

5. $y = \frac{-2}{3}$; $\sin\theta = \frac{-2}{3}$, $\csc\theta = \frac{-3}{2}$, $\cos\theta = \frac{-\sqrt{5}}{3}$, $\sec\theta = \frac{-3\sqrt{5}}{5}$, $\tan\theta = \frac{2\sqrt{5}}{5}$, $\cot\theta = \frac{\sqrt{5}}{2}$ **6.** 221.8°, 3.8713

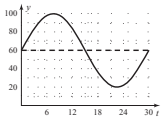
7. asymptotes: $x = -5, -3, -1, 1, 3, 5$; **8.** $|A| = 3$, $P = 4$;

9. a. QIV **b.** $2\pi - 5.94 \approx 0.343$ **c.** $\sin t$, $\tan t$

10. a. $|A| = 6$, $P = \frac{3\pi}{4}$ **b.** $f(t) = -6\cos\left(\frac{8}{3}t\right)$ **c.** $f(\pi) = 3$

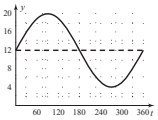
Reinforcing Basic Concepts, pp. 577–578

1. $(-\frac{1}{2}, \frac{\sqrt{3}}{2})$, $\cos t = -\frac{1}{2}$, $\sin t = \frac{\sqrt{3}}{2}$ **2.** $t = \frac{5\pi}{6}$, negative since $x < 0$



3. QIV, negative since $y < 0$ **4.** QI, $\cos t = \frac{1}{2}$, $\sin t = \frac{\sqrt{3}}{2}$, $t = \frac{\pi}{3}$

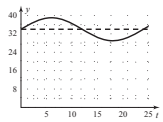
Exercises 6.5, pp. 590–595



1. $y = A\sin(Bt + C) + D$, $y = A\cos(Bt + C) + D$

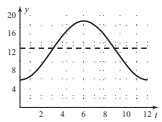
3. $0 \le Bt + C < 2\pi$ **5.** Answers will vary. **7. a.** $|A| = 50$, $P = 24$ **b.** ≈ -25 **c.** [1.6, 10.4] **9. a.** $|A| = 200$, $P = 3$ **b.** -175 **c.** [1.75, 2.75]

11. $y = 40\sin\left(\frac{\pi}{15}t\right) + 60$



13. $y = 8\sin\left(\frac{\pi}{180}t\right) + 12$

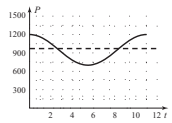
15. a. $y = 5\sin\left(\frac{\pi}{12}t\right) + 34$



b.

c. $\approx$ 1:30 A.M., 10:30 A.M.

17. a. $y = -6.4\cos\left(\frac{\pi}{6}t\right) + 12.4$



b.

c. $\approx$ 134 days

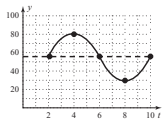
19. a. $P = 11$ yr

b.

c. max = 1200, min = 700 **d.** about 2 yr.

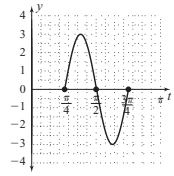
21. $P(t) = 250\cos\left[\frac{2\pi}{11}(t - 2.75)\right] + 950$; $P(t) = 250\sin\left(\frac{2\pi}{11}t\right) + 950$

23. $|A| = 120$; $P = 24$; HS: 6 units right; VS: (none); PI: $6 \le t < 30$



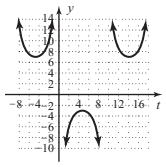
25. $|A| = 1$; $P = 12$; HS: 2 units right; VS: (none); PI: $2 \le t < 14$

27. $|A| = 1$; $P = 8$; HS: $\frac{2}{3}$ unit left; VS: (none); PI: $-\frac{2}{3} \le t < \frac{22}{3}$

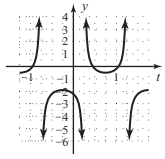


29. $|A| = 24.5$; $P = 20$; HS: 2.5 units right;
VS: 15.5 units up; PI: $2.5 \le t < 22.5$

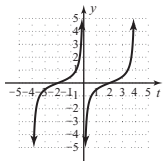
31. $|A| = 28$; $P = 12$; HS: $\frac{5}{2}$ units right; VS: 92 units up; PI: $\frac{5}{2} \le t < \frac{29}{2}$
33. $|A| = 2500$; $P = 8$; HS: $\frac{1}{3}$ unit left; VS: 3150 units up; PI: $-\frac{1}{3} \le t < \frac{23}{3}$
35. $y = 250 \sin\left(\frac{\pi}{12}t\right) + 350$ **37.** $y = 5 \sin\left(\frac{\pi}{50}t + \frac{\pi}{2}\right) + 13$
39. $y = 4 \sin\left(\frac{\pi}{180}t + \frac{\pi}{4}\right) + 7$



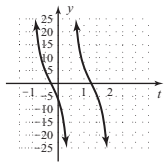
41.



43.

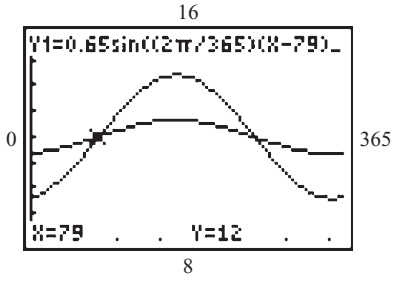


45.



47.

49.



51.

53. $P = \frac{2\pi}{B}$, $B = \frac{2\pi}{P}$; $f = \frac{1}{P}$, $P = \frac{1}{f}$; $B = \frac{2\pi}{1/f} = 2\pi f$.

$A \sin(Bt) = A \sin[(2\pi f)t]$ **55. a.** $P = 4$ sec, $f = \frac{1}{4}$ cycle/sec
b. -4.24 cm, moving away **c.** -4.24 cm, moving toward
d. about 1.76 cm; avg. vel. $= 3.52$ cm/sec; greater, still gaining speed
57. $d(t) = 15 \cos\left(\frac{5\pi}{4}t\right)$ **59.** red $\to D_2$; blue $\to A_2$
61. D_2: $y = \sin[146.84\,(2\pi t)]$; $P \approx 0.0068$ sec;
G_3: $y = \sin[392(2\pi t)]$; $P \approx 0.00255$ sec
63. $y = 5.2 \tan\left(\frac{\pi}{12}x\right)$; $P = 12$; asymptotes at $x = 6 + 12k$, $k \in \mathbb{Z}$;
using (3, 5.2), $|A| = 5.2$; at $x = 2$, model gives $y \approx 3.002$; at $x = -2$, model gives $y \approx -3.002$; answers will vary.
65. Answers will vary; $y = 11.95 \tan\theta$; $P = 180°$; asymptotes at $\theta = 90° + 180°k$; $|A| = 11.95$ from (30°, 6.9 cm); pen is $\approx$ 12 cm long.
67. a. $L(t) = 10 \csc\left(\frac{\pi}{6}t\right)$ **b.** 20 m
69. a. Caracas: $\approx$ 11.4 hr, Tokyo: $\approx$ 9.9 hr
b. (i) Same # of hours on 79th day & 261st day
(ii) Caracas: $\approx$ 81 days, Tokyo: $\approx$ 158 days

71. a. Adds 12 hr. The sinusoidal behavior is actually based on hours more/less than an average of 12 hr of light. **b.** Means 12 hr of light and dark on March 20, day 79 (Solstice). **c.** Additional hours of deviation from average. In the north, the planet is tilted closer toward the Sun or farther from Sun, depending on date. Variations will be greater.
73. Answers will vary. **75.** QIII; $3.7 - \pi \approx 0.5584$
77. sum: -2, difference: $2i\sqrt{5}$, product: 6, quotient: $\frac{-2}{3} - \frac{i\sqrt{5}}{3}$

Exercises 6.6, pp. 604–610

1. $\theta = \tan^{-1}x$ **3.** opposite, hypotenuse **5.** To find the measures of all three angles and all three sides.
7. $\sin\theta = \frac{12}{13}$, $\csc\theta = \frac{13}{12}$, $\sec\theta = \frac{13}{5}$, $\tan\theta = \frac{12}{5}$, $\cot\theta = \frac{5}{12}$
9. $\cos\theta = \frac{13}{85}$, $\sec\theta = \frac{85}{13}$, $\cot\theta = \frac{13}{84}$, $\sin\theta = \frac{84}{85}$, $\csc\theta = \frac{85}{84}$
11. $\sin\theta = \frac{11}{5\sqrt{5}}$, $\tan\theta = \frac{11}{2}$, $\csc\theta = \frac{5\sqrt{5}}{11}$, $\cos\theta = \frac{2}{5\sqrt{5}}$, $\sec\theta = \frac{5\sqrt{5}}{2}$

13.

Angles	Sides
$A = 30°$	$a = 98$ cm
$B = 60°$	$b = 98\sqrt{3}$ cm
$C = 90°$	$c = 196$ cm

15.

Angles	Sides
$A = 45°$	$a = 9.9$ mm
$B = 45°$	$b = 9.9$ mm
$C = 90°$	$c = 9.9\sqrt{2}$ mm

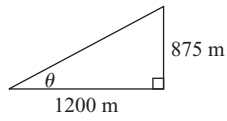
17.

Angles	Sides
$A = 22°$	$a = 14$ m
$B = 68°$	$b \approx 34.65$ m
$C = 90°$	$c \approx 37.37$ m

verified

19.

Angles	Sides
$A = 32°$	$a = 5.6$ mi
$B = 58°$	$b \approx 8.96$ mi
$C = 90°$	$c \approx 10.57$ mi



verified

21.

Angles	Sides
$A = 65°$	$a = 625$ mm
$B = 25°$	$b \approx 291.44$ mm
$C = 90°$	$c \approx 689.61$ mm

verified

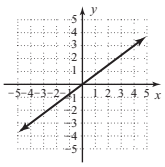
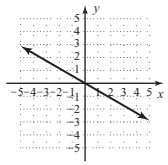
c. 1485 m; 36.1°



87. approx. 450 ft **89. a.** approx. 20.2 cm for each side
b. approx. 35.3° **91.** S 85° W **93. a.** approx. 3055.6 mi
b. approx. 9012.8 mi **c.** approx. 7 hr, 13 min
95. a. local max: $(-5, 2)$, $(2, 3)$; local min: $(-2, -1)$, $(-7, -2)$, $(6, -3)$
b. zeroes: $x = -6, -3, -1, 4$
c. $T(x)\downarrow$: $x \in (-5, -2) \cup (2, 6)$; $T(x)\uparrow$: $x \in (-7, -5) \cup (-2, 2)$
d. $T(x) > 0$: $x \in (-6, -3) \cup (-1, 4)$;
$T(x) < 0$: $x \in (-7, -6) \cup (-3, -1) \cup (4, 6)$
97. $d \approx 53.74$ in. $D \approx 65.82$ in.

Exercises 6.7, pp. 618–621

1. origin, x-axis **3.** positive, clockwise **5.** Answers will vary.



7. slope $= \sqrt{3}$, equation: $y = \sqrt{3}x$,
$\sin 60° = \frac{\sqrt{3}}{2}$, $\cos 60° = \frac{1}{2}$, $\tan 60° = \sqrt{3}$

9.  QI/III;

$(4, 3)$: $\sin\theta = \frac{3}{5}$; $(-4, -3)$: $\sin\theta = -\frac{3}{5}$

$\cos\theta = \frac{4}{5}$ $\cos\theta = -\frac{4}{5}$

$\tan\theta = \frac{3}{4}$ $\tan\theta = \frac{3}{4}$

11.  QII/QIV;

$(-3, \sqrt{3})$: $\sin\theta = \frac{1}{2}$; $(3, -\sqrt{3})$: $\sin\theta = -\frac{1}{2}$

$\cos\theta = -\frac{\sqrt{3}}{2}$ $\cos\theta = \frac{\sqrt{3}}{2}$

$\tan\theta = -\frac{1}{\sqrt{3}}$ $\tan\theta = -\frac{1}{\sqrt{3}}$

13. $\sin\theta = \frac{15}{17}$, $\csc\theta = \frac{17}{15}$, $\cos\theta = \frac{8}{17}$, $\sec\theta = \frac{17}{8}$, $\tan\theta = \frac{15}{8}$, $\cot\theta = \frac{8}{15}$

15. $\sin\theta = \frac{21}{29}$, $\csc\theta = \frac{29}{21}$, $\cos\theta = \frac{-20}{29}$, $\sec\theta = \frac{-29}{20}$, $\tan\theta = \frac{-21}{20}$, $\cot\theta = \frac{-20}{21}$

17. $\sin\theta = \frac{-\sqrt{2}}{2}$, $\csc\theta = -\sqrt{2}$, $\cos\theta = \frac{\sqrt{2}}{2}$, $\sec\theta = \sqrt{2}$, $\tan\theta = -1$, $\cot\theta = -1$

19. $\sin\theta = \frac{1}{2}$, $\csc\theta = 2$, $\cos\theta = \frac{\sqrt{3}}{2}$, $\sec\theta = \frac{2}{\sqrt{3}}$, $\tan\theta = \frac{1}{\sqrt{3}}$, $\cot\theta = \sqrt{3}$

21. $\sin\theta = \frac{4}{\sqrt{17}}$, $\csc\theta = \frac{\sqrt{17}}{4}$, $\cos\theta = \frac{1}{\sqrt{17}}$, $\sec\theta = \sqrt{17}$, $\tan\theta = 4$, $\cot\theta = \frac{1}{4}$

23. $\sin\theta = \frac{-2}{\sqrt{13}}$, $\csc\theta = \frac{-\sqrt{13}}{2}$, $\cos\theta = \frac{-3}{\sqrt{13}}$, $\sec\theta = \frac{-\sqrt{13}}{3}$, $\tan\theta = \frac{2}{3}$, $\cot\theta = \frac{3}{2}$

25. $\sin\theta = \frac{6}{\sqrt{61}}$, $\csc\theta = \frac{\sqrt{61}}{6}$, $\cos\theta = \frac{-5}{\sqrt{61}}$, $\sec\theta = \frac{-\sqrt{61}}{5}$, $\tan\theta = \frac{-6}{5}$, $\cot\theta = \frac{-5}{6}$

27. $\sin\theta = \frac{-2\sqrt{5}}{\sqrt{21}}$, $\csc\theta = -\frac{\sqrt{21}}{2\sqrt{5}}$, $\cos\theta = \frac{1}{\sqrt{21}}$, $\sec\theta = \sqrt{21}$, $\tan\theta = -2\sqrt{5}$, $\cot\theta = \frac{-1}{2\sqrt{5}}$

29. $r = 10$

31. $x = 0$, $y = k$; $k > 0$; $r = k$;
$\sin 90° = \frac{k}{k}$, $\cos 90° = \frac{0}{k}$, $\tan 90° = \frac{k}{0}$,
$\sin 90° = 1$, $\cos 90° = 0$, $\tan 90°$ is undefined
$\csc 90° = 1$, $\sec 90°$ is undefined
$\cot 90° = 0$

33. 60° **35.** 45° **37.** 45° **39.** 68° **41.** 40° **43.** 11.6° **45.** QII

47. QII **49.** $\sin\theta = -\frac{1}{2}$; $\cos\theta = \frac{\sqrt{3}}{2}$; $\tan\theta = -\frac{1}{\sqrt{3}}$

51. $\sin\theta = \frac{-\sqrt{2}}{2}$; $\cos\theta = \frac{\sqrt{2}}{2}$; $\tan\theta = -1$

53. $\sin\theta = \frac{-\sqrt{3}}{2}$; $\cos\theta = \frac{-1}{2}$; $\tan\theta = \sqrt{3}$

55. $\sin\theta = -\frac{1}{2}$; $\cos\theta = \frac{-\sqrt{3}}{2}$; $\tan\theta = \frac{1}{\sqrt{3}}$

57. $x = 4$, $y = -3$, $r = 5$; QIV; $\sin\theta = \frac{-3}{5}$, $\csc\theta = \frac{-5}{3}$, $\cos\theta = \frac{4}{5}$, $\sec\theta = \frac{5}{4}$, $\tan\theta = \frac{-3}{4}$, $\cot\theta = \frac{-4}{3}$

59. $x = -12$, $y = -35$, $r = 37$; QIII; $\sin\theta = \frac{-35}{37}$, $\csc\theta = \frac{-37}{35}$, $\cos\theta = \frac{-12}{37}$, $\sec\theta = \frac{-37}{12}$, $\tan\theta = \frac{35}{12}$, $\cot\theta = \frac{12}{35}$

61. $x = 2\sqrt{2}$, $y = 1$, $r = 3$; QI; $\sin\theta = \frac{1}{3}$, $\csc\theta = 3$, $\cos\theta = \frac{2\sqrt{2}}{3}$, $\sec\theta = \frac{3}{2\sqrt{2}}$, $\tan\theta = \frac{1}{2\sqrt{2}}$, $\cot\theta = 2\sqrt{2}$

63. $x = -\sqrt{15}$, $y = -7$, $r = 8$; QIII; $\sin\theta = \frac{-7}{8}$, $\csc\theta = \frac{-8}{7}$, $\cos\theta = \frac{-\sqrt{15}}{8}$, $\sec\theta = -\frac{8}{\sqrt{15}}$, $\tan\theta = \frac{7}{\sqrt{15}}$, $\cot\theta = \frac{\sqrt{15}}{7}$

81. $\sin\theta = \frac{-1}{2}$, $\cos\theta = \frac{-\sqrt{3}}{2}$, $\tan\theta = \frac{1}{\sqrt{3}}$

83. $\sin\theta = \frac{-1}{2}$, $\cos\theta = \frac{-\sqrt{3}}{2}$, $\tan\theta = \frac{1}{\sqrt{3}}$

85. QIV, neg., -0.0175 **87.** QIV, neg., -1.6643

89. QIV, neg., -1.5890 **91.** QI, pos., 0.0872

93. a. approx. 144.78 units^2 **b.** 53° **c.** The parallelogram is a rectangle whose area is $\mathcal{A} = ab$. **d.** $\mathcal{A} = \frac{ab}{2}\sin\theta$

95. $\theta = 60° + 360°k$ and $\theta = 300° + 360°k$

97. $\theta = 240° + 360°k$ and $\theta = 300° + 360°k$

99. $\theta = 61.1° + 360°k$ and $\theta = 118.9° + 360°k$

101. $\theta = 113.0° + 180°k$ **103.** 1890°; $90° + 360°k$

105. head first; 900° **107.** approx. 701.6° **109.** Answers will vary.

111. a. 12,960° **b.** 125.66 in. **c.** 15,080 in. **d.** 85.68 mph

113. $t = \frac{\ln 0.32}{-0.05} \approx 22.79$ **115.** $y = -\frac{5}{4}x + 2$

Exercises 6.8, pp. 628–633

1. $\sin(Bx + C)$, $A + D$ **3.** critical **5.** Answers will vary.

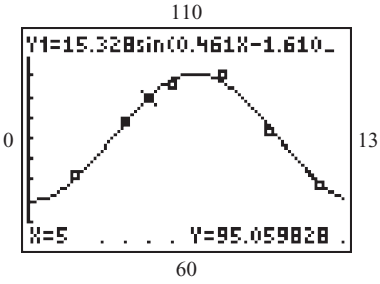
7. $y = 25\sin\left(\frac{\pi}{6}x\right) + 50$ **9.** $y = 2.25\sin\left(\frac{\pi}{12}x + \frac{\pi}{4}\right) + 5.25$

11. $y = 503\sin\left(\frac{\pi}{6}x + \frac{2\pi}{3}\right) + 782$

13. a. $y \approx 49.26\sin(0.213x - 1.104) + 51.43$
b. $y \approx 49\sin(0.203x - 0.963) + 51$ **c.** at day 31 $\approx$ 5.6

15. a. $y \approx 5.88\sin(0.523x - 0.521) + 16.00$
b. $y \approx 6\sin(0.524x - 0.524) + 16$ **c.** at month 9 $\approx$ 0.12

17. a. $D = 2000\cos\left(\frac{\pi}{60}t\right)$ **b.** north, 1258.6 mi



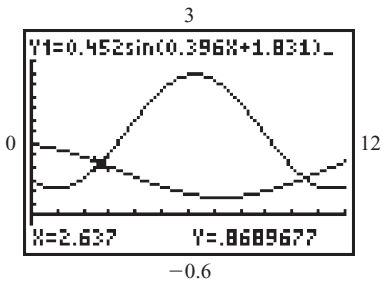
19. a. $T(x) = 19.6\sin\left(\frac{\pi}{6}x + \frac{4\pi}{3}\right) + 84.6$ **b.** about 94.4°F
c. beginning of May ($x \approx 5.1$) to end of August ($x \approx 8.9$)

21. a. $T(t) = 0.4\sin\left(\frac{\pi}{12}t + \frac{13\pi}{12}\right) + 98.6$
b. at 11 A.M. and 11 P.M. **c.** from $t = 1$ to $t = 9$, about 8 hr

23. $P = 12$, $B = \frac{\pi}{12}$, $C = \frac{\pi}{2}$; using (4, 3) gives $A = -3\sqrt{3}$,
so $f(x) = -3\sqrt{3}\tan\left(\frac{\pi}{12}x + \frac{\pi}{2}\right)$ **a.** $f(2.5) \approx 6.77$
b. $f(x) = 16$ for $x \approx 1.20$

25. a. using (18, 10) gives $A \approx 4.14$; $H(d) = 4.14\tan\left(\frac{\pi}{48}d\right)$
b. $\approx$ 12.2 cm **c.** $\approx$ 21.9 mi

27. a. $T(m) \approx 15.328\sin(0.461m - 1.610) + 85.244$



b.

Month	Temp. (°F)
1	71
3	82
5	95
7	101
9	94
11	80

c. max difference is about 1°F in months 6 and 8

29. a. $f(x) \approx 49.659\sin(0.214x - 0.689) + 48.328$ **b.** about 26.8%
c. $g(x) = 49.5\sin\left(\frac{2\pi}{31}x - \frac{7\pi}{62}\right) + 49.5$; values for A, B, and D are very close; some variation in C.

31. a. Reno: $R(t) \approx 0.452\sin(0.396t + 1.831) + 0.750$
b. The graphs intersect at $t \approx 2.6$ and $t \approx 10.5$. Reno gets more rainfall than Cheyenne for about 4 months of the year.

33. $\frac{m - D}{A} = \frac{m - \left(\frac{M + m}{2}\right)}{\frac{M - m}{2}} = \frac{2m - M - m}{M - m} = \frac{m - M}{M - m} = -1$

35. a. $[0, \infty)$ **b.** $(-\infty, \infty)$ **c.** $(-\infty, \infty)$ **37.** $15\pi \approx 47.1$ ft/min

Making Connections, p. 633

1. h **3.** d **5.** e **7.** e **9.** c **11.** b **13.** f **15.** h

Summary and Concept Review, pp. 634–642

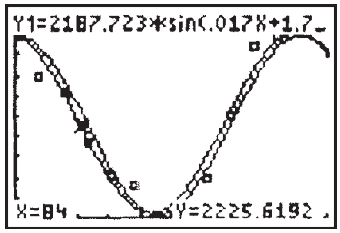
45. approx. 54.5° and 35.5° **46.** $207° + 360°k$; answers will vary.

47. 28°, 19°, 30°

48. a. $\sin\theta = \frac{35}{37}$, $\csc\theta = \frac{37}{35}$, $\cos\theta = \frac{-12}{37}$, $\sec\theta = \frac{-37}{12}$, $\tan\theta = \frac{-35}{12}$, $\cot\theta = \frac{-12}{35}$

b. $\sin\theta = \frac{-3}{\sqrt{13}}$, $\csc\theta = \frac{-\sqrt{13}}{3}$, $\cos\theta = \frac{2}{\sqrt{13}}$, $\sec\theta = \frac{\sqrt{13}}{2}$, $\tan\theta = \frac{-3}{2}$, $\cot\theta = \frac{-2}{3}$

49. a. $x = 4$, $y = -3$, $r = 5$; QIV; $\sin\theta = -\frac{3}{5}$, $\csc\theta = -\frac{5}{3}$, $\cos\theta = \frac{4}{5}$, $\sec\theta = \frac{5}{4}$, $\tan\theta = \frac{-3}{4}$, $\cot\theta = \frac{-4}{3}$

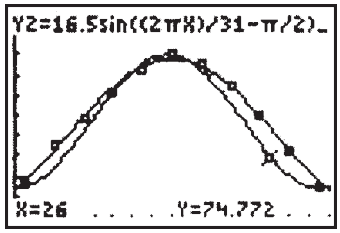


b. $x = 5$, $y = -12$, $r = 13$; QIV; $\sin\theta = \frac{-12}{13}$, $\csc\theta = \frac{-13}{12}$, $\cos\theta = \frac{5}{13}$, $\sec\theta = \frac{13}{5}$, $\tan\theta = \frac{-12}{5}$, $\cot\theta = \frac{-5}{12}$

50. a. $\theta = 135° + 180°k$ **b.** $\theta = 30° + 360°k$ or $\theta = 330° + 360°k$
c. $\theta \approx 76.0° + 180°k$ **d.** $\theta \approx -27.0° + 360°k$ or $\theta = 207.0° + 360°k$

51. a. $y = 2187.723\sin(0.017x + 1.751) + 2307.437$

b. $A = \frac{4450 - 90}{2} = 2180$;
$D = 90 + 2180 = 2270$;
$\frac{2\pi}{B} = 365$, $\frac{2\pi}{365} = B$; $C = \frac{3\pi}{2} - \frac{2\pi}{365}(184) = \frac{359}{730}\pi$
$y = 2180\sin\left(\frac{2\pi}{365}x + \frac{359}{730}\pi\right) + 2270$



c. The largest difference from $0 \le x \le 365$ is about 372 at $x = 85$.

52. a. $y = 19.424\sin(0.145x - 0.748) + 79.581$

b. $A = \frac{100 - 67}{2} = 16.5$;
$D = 67 + 16.5 = 83.5$;
$\frac{2\pi}{B} = 31$,
$\frac{2\pi}{31} = B$
$C = \frac{3\pi}{2} - \frac{2\pi}{31}(31) = -\frac{\pi}{2}$
$y = 16.5\sin\left(\frac{2\pi}{31}x - \frac{\pi}{2}\right) + 83.5$

c. The largest difference is about 7, at $x = 26$.

53. a. $y = 16.800\sin(0.602x - 2.341) + 70.968$

b. $x = 7$ $y = 87.01°$F

c. The model alternates between slightly overpredicting and underpredicting output values, and appears to be a fairly accurate model.

CHAPTER 7

Exercises 7.1, pp. 658–661

1. $\sin\theta$; $\sec\theta$; $\cos\theta$ **3.** $\cos^2\theta$, $\cot^2\theta + 1 = \csc^2\theta$

5. $\frac{1 - \sin^2\theta}{\sin\theta\sec\theta}$; Answers will vary.

7. $1 + \tan^2\theta = 1 + \frac{y^2}{x^2} = \frac{x^2}{x^2} + \frac{y^2}{x^2} = \frac{x^2+y^2}{x^2} = \frac{r^2}{x^2} = \sec^2\theta$

9. $\frac{\sin\theta}{\cos\theta} = \frac{\frac{y}{r}}{\frac{x}{r}} = \frac{y}{x} = \tan\theta$

11. Answers may vary;

$\tan\theta = \frac{\sec\theta}{\csc\theta}; \frac{\sin\theta}{\cos\theta} = \frac{\sec\theta}{\csc\theta}; \frac{1}{\cot\theta} = \frac{\sec\theta}{\csc\theta}; \frac{1}{\cot\theta} = \frac{\sin\theta}{\cos\theta}$

13. Answers may vary:

$1 = \sec^2\theta - \tan^2\theta$; $\tan^2\theta = \sec^2\theta - 1$;

$1 = (\sec\theta + \tan\theta)(\sec\theta - \tan\theta)$; $\tan\theta = \pm\sqrt{\sec^2\theta - 1}$

15. $\sin\theta\cot\theta = \cancel{\sin\theta}\frac{\cos\theta}{\cancel{\sin\theta}} = \cos\theta$

17. $\sec^2\theta\cot^2\theta = \frac{1}{\cancel{\cos^2\theta}}\frac{\cancel{\cos^2\theta}}{\sin^2\theta} = \frac{1}{\sin^2\theta} = \csc^2\theta$

19. $\cos\theta(\sec\theta - \cos\theta) = \cos\theta\sec\theta - \cos^2\theta = 1 - \cos^2\theta = \sin^2\theta$

21. $\sin\theta(\csc\theta - \sin\theta) = \sin\theta\csc\theta - \sin^2\theta = 1 - \sin^2\theta = \cos^2\theta$

23. $\tan\theta(\csc\theta + \cot\theta) = \tan\theta\csc\theta + \tan\theta\cot\theta =$

$\frac{\cancel{\sin\theta}}{\cos\theta}\frac{1}{\cancel{\sin\theta}} + 1 = \frac{1}{\cos\theta} + 1 = \sec\theta + 1$

25. $\tan^2\theta\csc^2\theta - \tan^2\theta = \tan^2\theta(\csc^2\theta - 1) = \tan^2\theta(\cot^2\theta) = 1$

27. $\frac{\sin\theta\cos\theta + \sin\theta}{\cos\theta + \cos^2\theta} = \frac{\sin\theta\,\cancel{(\cos\theta + 1)}}{\cos\theta\,\cancel{(1 + \cos\theta)}} = \frac{\sin\theta}{\cos\theta} = \tan\theta$

29. $\frac{1 + \sin\theta}{\cos\theta + \cos\theta\sin\theta} = \frac{(1)\cancel{(1 + \sin\theta)}}{(\cos\theta)\cancel{(1 + \sin\theta)}} = \frac{1}{\cos\theta} = \sec\theta$

31. $\frac{\sin\theta\tan\theta + \sin\theta}{\tan\theta + \tan^2\theta} = \frac{\sin\theta\cancel{(\tan\theta + 1)}}{\tan\theta\cancel{(1 + \tan\theta)}} =$

$\frac{\sin\theta}{\tan\theta} = \frac{\sin\theta}{\sin\theta/\cos\theta} = \frac{\cancel{\sin\theta}\cos\theta}{\cancel{\sin\theta}} = \cos\theta$

33. $\frac{(\sin\theta + \cos\theta)^2}{\cos\theta} = \frac{\sin^2\theta + 2\sin\theta\cos\theta + \cos^2\theta}{\cos\theta} =$

$\frac{\cos^2\theta + \sin^2\theta + 2\sin\theta\cos\theta}{\cos\theta} = \frac{1 + 2\sin\theta\cos\theta}{\cos\theta} =$

$\frac{1}{\cos\theta} + \frac{2\sin\theta\cos\theta}{\cos\theta} = \sec\theta + 2\sin\theta$

35. $(1 + \sin\theta)(1 - \sin\theta) = 1 - \sin^2\theta = \cos^2\theta$

37. $\frac{(\csc\theta - \cot\theta)(\csc\theta + \cot\theta)}{\tan\theta} = \frac{\csc^2\theta - \cot^2\theta}{\tan\theta} = \frac{1}{\tan\theta} = \cot\theta$

39. $\frac{\cos^2\theta}{\sin\theta} + \frac{\sin\theta}{1} = \frac{\cos^2\theta + \sin^2\theta}{\sin\theta} = \frac{1}{\sin\theta} = \csc\theta$

$= \dfrac{2(1) - 1}{\sec x \csc x}$
$= \dfrac{1}{\sec x \csc x}$
$= \cos x \sin x$

4. $1 + \sec^2 x = \tan^2 x$
$1 + \sec^2 0 = \tan^2 0$
$1 + 1^2 = 0^2$
$1 + 1 = 0$
$2 = 0$ False

5. a. $\dfrac{\sin^3 x + \cos^3 x}{\sin x + \cos x} = \dfrac{\cancel{(\sin x + \cos x)}(\sin^2 x - \sin x \cos x + \cos^2 x)}{\cancel{(\sin x + \cos x)}}$
$= \sin^2 x + \cos^2 x - \sin x \cos x$
$= 1 - \sin x \cos x$

b. $\dfrac{1 + \sec x}{\csc x} - \dfrac{1 + \cos x}{\cot x} = \dfrac{1 + \dfrac{1}{\cos x}}{\dfrac{1}{\sin x}} - \dfrac{1 + \cos x}{\dfrac{\cos x}{\sin x}}$
$= \left(\sin x + \dfrac{\sin x}{\cos x}\right) - \left(\dfrac{\sin x}{\cos x} + \sin x\right)$
$= \sin x + \dfrac{\sin x}{\cos x} - \dfrac{\sin x}{\cos x} - \sin x$
$= 0$

6. a. $\dfrac{\sec^2 x - \tan^2 x}{\sec^2 x} = \dfrac{\sec^2 x}{\sec^2 x} - \dfrac{\tan^2 x}{\sec^2 x}$
$= 1 - \dfrac{\dfrac{\cancel{\sin^2 x}}{\cancel{\cos^2 x}}}{\dfrac{1}{\cancel{\cos^2 x}}}$
$= 1 - \sin^2 x$
$= \cos^2 x$

b. $\dfrac{\cot x - \tan x}{\csc x \sec x} = \dfrac{\cot x}{\csc x \sec x} - \dfrac{\tan x}{\csc x \sec x}$
$= \dfrac{\dfrac{\cos x}{\sin x}}{\dfrac{1}{\sin x} \cdot \dfrac{1}{\cos x}} - \dfrac{\dfrac{\sin x}{\cos x}}{\dfrac{1}{\sin x} \cdot \dfrac{1}{\cos x}}$
$= \dfrac{\cos^2 x \cancel{\sin x}}{\cancel{\sin x}} - \dfrac{\sin^2 x \cancel{\cos x}}{\cancel{\cos x}}$
$= \cos^2 x - \sin^2 x$

7. a. $\dfrac{456}{5785}$ **b.** $-\dfrac{3193}{5785}$ **c.** $\dfrac{456}{5767}$

8. $\sin A = \dfrac{7 + 24\sqrt{3}}{50}$, $\cos A = \dfrac{24 - 7\sqrt{3}}{50}$, $\tan A = \dfrac{7 + 24\sqrt{3}}{24 - 7\sqrt{3}}$

9. $\sin\left(\dfrac{\theta}{2}\right) = \dfrac{4}{\sqrt{17}}$, $\cos\left(\dfrac{\theta}{2}\right) = \dfrac{1}{\sqrt{17}}$

10. $\sin(2\alpha) = \dfrac{336}{625}$, $\cos(2\alpha) = \dfrac{527}{625}$, $\tan(2\alpha) = \dfrac{336}{527}$

Reinforcing Basic Concepts, pp. 693–694

1. $\cos^2 x + \sin^2 x = 1$
$\dfrac{\cos^2 x}{\sin^2 x} + \dfrac{\sin^2 x}{\sin^2 x} = \dfrac{1}{\sin^2 x}$
$\cot^2 x + 1 = \csc^2 x$ ✓
$\cos^2 x + \sin^2 x = 1$
$\dfrac{\cos^2 x}{\cos^2 x} + \dfrac{\sin^2 x}{\cos^2 x} = \dfrac{1}{\cos^2 x}$
$1 + \tan^2 x = \sec^2 x$ ✓

2. $\cos(2\alpha) = \cos(\alpha + \alpha)$
$= \cos\alpha \cos\alpha - \sin\alpha \sin\alpha$
$= \cos^2\alpha - \sin^2\alpha$
$= \cos^2\alpha - (1 - \cos^2\alpha)$
$= 2\cos^2\alpha - 1$
$= \cos^2\alpha - \sin^2\alpha$
$= (1 - \sin^2\alpha) - \sin^2\alpha$
$= 1 - 2\sin^2\alpha$

Exercises 7.5, pp. 705–710

Summary and Concept Review, pp. 733–737

1.
$$\begin{aligned} \sin x(\csc x - \sin x) &= \sin x \csc x - \sin x \sin x \\ &= \sin x \frac{1}{\sin x} - \sin^2 x \\ &= 1 - \sin^2 x \\ &= \cos^2 x \end{aligned}$$

2. $\dfrac{\tan^2 x \csc x + \csc x}{\sec^2 x} = \dfrac{\csc x(\tan^2 x + 1)}{\sec^2 x}$
$= \dfrac{\csc x \sec^2 x}{\sec^2 x}$
$= \csc x$

3. $\dfrac{(\sec x - \tan x)(\sec x + \tan x)}{\csc x} = \dfrac{\sec^2 x - \tan^2 x}{\csc x}$
$= \dfrac{1 + \tan^2 x - \tan^2 x}{\csc x}$
$= \dfrac{1}{\csc x}$
$= \sin x$

4. $\dfrac{\sec^2 x}{\csc x} - \sin x = \dfrac{\sec^2 x - \sin x \csc x}{\csc x}$
$= \dfrac{\sec^2 x - 1}{\csc x}$
$= \dfrac{\tan^2 x}{\csc x}$

5. $\sin\theta = -\dfrac{35}{37}$, $\csc\theta = -\dfrac{37}{35}$, $\cot\theta = \dfrac{12}{35}$, $\tan\theta = \dfrac{35}{12}$, $\sec\theta = -\dfrac{37}{12}$

6. $\sin\theta = -\dfrac{4\sqrt{6}}{25}$, $\csc\theta = -\dfrac{25}{4\sqrt{6}}$, $\cot\theta = -\dfrac{23}{4\sqrt{6}}$, $\tan\theta = -\dfrac{4\sqrt{6}}{23}$, $\cos\theta = \dfrac{23}{25}$

7. $\dfrac{\csc^2 x(1 - \cos^2 x)}{\tan^2 x} = \dfrac{\csc^2 x \sin^2 x}{\tan^2 x}$
$= \dfrac{1}{\tan^2 x}$
$= \cot^2 x$

8. $\dfrac{\cot x}{\sec x} - \dfrac{\csc x}{\tan x} = \cot x \dfrac{1}{\sec x} - \cot x \csc x$
$= \cot x \cos x - \cot x \csc x$
$= \cot x(\cos x - \csc x)$

9. $\dfrac{\sin^4 x - \cos^4 x}{\sin x \cos x} = \dfrac{(\sin^2 x - \cos^2 x)(\sin^2 x + \cos^2 x)}{\sin x \cos x}$
$= \dfrac{(\sin^2 x - \cos^2 x)(1)}{\sin x \cos x}$
$= \dfrac{\sin x \cancel{\sin x}}{\cancel{\sin x} \cos x} - \dfrac{\cancel{\cos x} \cos x}{\sin x \cancel{\cos x}}$
$= \dfrac{\sin x}{\cos x} - \dfrac{\cos x}{\sin x}$
$= \tan x - \cot x$

10. $\dfrac{(\sin x + \cos x)^2}{\sin x \cos x} = \dfrac{\sin^2 x + 2 \sin x \cos x + \cos^2 x}{\sin x \cos x}$
$= \dfrac{\sin^2 x + \cos^2 x}{\sin x \cos x} + \dfrac{2 \sin x \cos x}{\sin x \cos x}$
$= \dfrac{1}{\sin x \cos x} + 2$
$= \csc x \sec x + 2$

11. a. $\cos 75° = \dfrac{\sqrt{6} - \sqrt{2}}{4}$

b. $\tan\left(\dfrac{\pi}{12}\right) = \dfrac{\sqrt{3} - 1}{1 + \sqrt{3}} = \dfrac{(\sqrt{3} - 1)^2}{2} = 2 - \sqrt{3}$

12. a. $\tan 15° = \dfrac{\sqrt{3} - 1}{1 + \sqrt{3}} = \dfrac{(\sqrt{3} - 1)^2}{2} = 2 - \sqrt{3}$

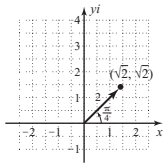
Exercises 8.5, pp. 810–812

1. modulus, argument **3.** multiply, add
5. $2(\cos 240° + i \sin 240°)$, z is in QIII
7. $z_2 = z_1 + z_3$

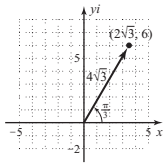
9. $z_2 = z_1 + z_3$



11. QIII; $2\sqrt{2}(\cos 225° + i \sin 225°)$
13. QIII; $10(\cos 210° + i \sin 210°)$
15. $6\left[\cos\left(\frac{3\pi}{4}\right) + i \sin\left(\frac{3\pi}{4}\right)\right]$ **17.** $8\left[\cos\left(\frac{11\pi}{6}\right) + i \sin\left(\frac{11\pi}{6}\right)\right]$
19. $10 \operatorname{cis}\left[\tan^{-1}\left(\frac{6}{8}\right)\right]$; $10 \operatorname{cis} 36.9°$
21. $13 \operatorname{cis}\left[180° + \tan^{-1}\left(\frac{12}{5}\right)\right]$; $13 \operatorname{cis} 247.4°$
23. $18.5 \operatorname{cis}\left[\tan^{-1}\left(\frac{17.5}{6}\right)\right]$; $18.5 \operatorname{cis} 1.2405$
25. $2\sqrt{34} \operatorname{cis}\left[\pi + \tan^{-1}\left(-\frac{5}{3}\right)\right]$; $2\sqrt{34} \operatorname{cis} 2.1112$

27. $r = 2, \theta = \dfrac{\pi}{4}$

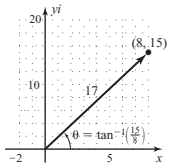
$z = 2\text{ cis}\left(\dfrac{\pi}{4}\right)$



$= \sqrt{2} + i\sqrt{2}$

29. $r = 4\sqrt{3}, \theta = \dfrac{\pi}{3}$

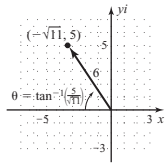
$z = 4\sqrt{3}\text{ cis}\left(\dfrac{\pi}{3}\right)$



$= 2\sqrt{3} + 6i$

31. $r = 17, \theta = \tan^{-1}\left(\dfrac{15}{8}\right)$

$z = 17\text{ cis}\left[\tan^{-1}\left(\dfrac{15}{8}\right)\right]$



$= 17\left(\dfrac{8}{17} + \dfrac{15}{17}i\right) = 8 + 15i$

33. $r = 6, \theta = \pi - \tan^{-1}\left(\dfrac{5}{\sqrt{11}}\right)$

$z = 6\text{ cis}\left[\pi - \tan^{-1}\dfrac{5}{\sqrt{11}}\right]$

$= 6\left(-\dfrac{\sqrt{11}}{6} + \dfrac{5}{6}i\right) = -\sqrt{11} + 5i$

35. $r_1 = 2\sqrt{2}, \quad r_2 = 3\sqrt{2}, \quad \theta_1 = 135°, \quad \theta_2 = 45°;$
$z = z_1z_2 = -12 + 0i \Rightarrow r = 12, \quad \theta = 180°;$
$r_1r_2 = 2\sqrt{2}(3\sqrt{2}) = 12$ ✓
$\theta_1 + \theta_2 = 135° + 45° = 180°$ ✓

37. $r_1 = 2, r_2 = 2, \theta_1 = 30°, \theta_2 = 60°;$
$z = \dfrac{z_1}{z_2} = \dfrac{\sqrt{3}}{2} - \dfrac{1}{2}i \Rightarrow r = 1, \theta = -30°; \dfrac{r_1}{r_2} = \dfrac{2}{2} = 1$ ✓
$\theta_1 - \theta_2 = 30° - 60° = -30°$ ✓

39. $z_1z_2 = -24 + 0i, \dfrac{z_1}{z_2} = -\dfrac{4}{3} + \dfrac{4\sqrt{3}}{3}i$

41. $z_1z_2 = 21\sqrt{3} - 21i, \dfrac{z_1}{z_2} = \dfrac{\sqrt{3}}{7} + \dfrac{1}{7}i$

43. $z_1z_2 = -10.84 + 12.04i, \dfrac{z_1}{z_2} = -1.55 - 4.76i$

45. $z_1z_2 = 0 + 40i, \dfrac{z_1}{z_2} = \dfrac{5\sqrt{3}}{4} + \dfrac{5}{4}i$

47. $z_1z_2 = -10 - 10i\sqrt{3}, \dfrac{z_1}{z_2} = \dfrac{-5}{2} + 0i$

49. $z_1z_2 = -2.93 + 8.51i, \dfrac{z_1}{z_2} = 2.29 + 3.28i$

51. verified; verified, $u^2 + v^2 + w^2 = uv + uw + vw$
$(1 + 4i\sqrt{3}) + (97 + 20i\sqrt{3}) + (-39 + 60i\sqrt{3})$
$= (17 + 12i\sqrt{3}) + (-3 + 16i\sqrt{3}) + (45 + 56i\sqrt{3}),$
$59 + 84i\sqrt{3} = 59 + 84i\sqrt{3}$

53. a. $V(t) = 170\sin(120\pi t)$

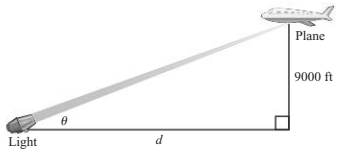
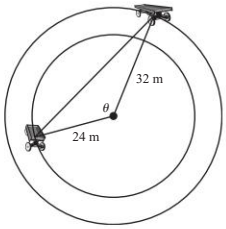
7. $\frac{-4 \pm \sqrt{6}}{5}$ **9.** $\cos 19° \approx 0.94$, $\cos 125° \approx -0.58$
11. a. about \$66,825 **b.** 13, 13, $7\sqrt{2}$; $A = 59.5$ mi^2
13. a. $m = \frac{y_2 - y_1}{x_2 - x_1}$ **b.** $\left(\frac{x_2 + x_1}{2}, \frac{y_2 + y_1}{2}\right)$
c. $x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$ **d.** $d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$
e. $A = Pe^{rt}$
15. $\angle A = 37°$, $a \approx 33$ cm,
$\angle B = 34.4°$, $b = 31$ cm,
$\angle C = 108.6°$, $c = 52$ cm
17. about 422.5 lb
19.



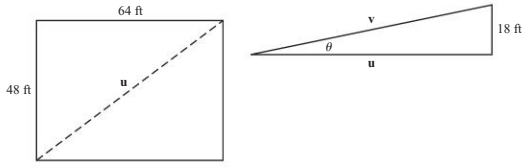
$x \in (-\infty, -1) \cup (2, 3)$

21. $-128 - 128i\sqrt{3}$ **23.** about 3.6 yr **25.** $A = 2$, $B = 1$, $C = \frac{\pi}{4}$
27. $[0, 0.71] \cup \left(\frac{\pi}{2}, 4.37\right] \cup \left(\frac{3\pi}{2}, 2\pi\right)$
29. 0; The vectors are orthogonal.



Connections to Calculus Exercises, pp. 834–835

1.

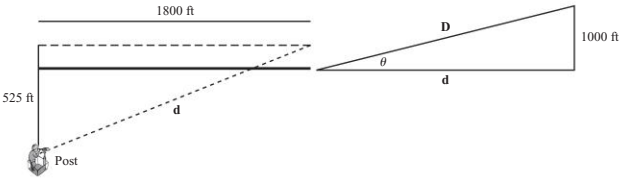


a. $\theta = \tan^{-1}\left(\dfrac{9000}{d}\right)$ **b.** $\theta \approx 35°$

3.

a. $d = \sqrt{24^2 + 32^2 - 2(24)(32)\cos\theta}$ **b.** $d \approx 54.13$ m **c.** about 106.1°

5.



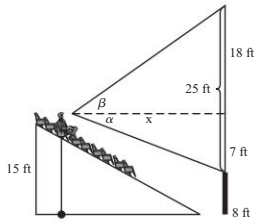
a. $|\mathbf{v}| = \sqrt{48^2 + 64^2 + 18^2} = 82$ ft

b. $\mathbf{u} = \langle 48, 64, 0\rangle$, $\mathbf{v} = \langle 48, 64, 18\rangle$

$$\cos\theta = \frac{\langle 48, 64, 0\rangle \cdot \langle 48, 64, 18\rangle}{(80)(82)}$$

$\theta = \cos^{-1}\left(\dfrac{40}{41}\right) \approx 12.68°$; verified

7.



a. $|\mathbf{D}| = \sqrt{525^2 + 1800^2 + 1000^2} = 2125$ ft

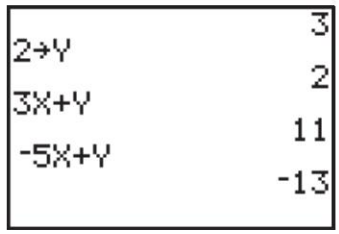
b. $\mathbf{d} = \langle 525, 1800, 0\rangle$, $\mathbf{D} = \langle 525, 1800, 1000\rangle$

$$\cos\theta = \frac{\langle 525, 1800, 0\rangle \cdot \langle 525, 1800, 1000\rangle}{(1875)(2125)}$$

$\theta = \cos^{-1}\left(\dfrac{15}{17}\right) \approx 28.07°$; verified

9.

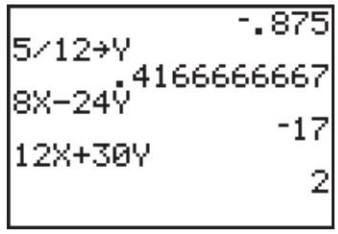
a. $\theta = \alpha + \beta$ **b.** $\theta = \tan^{-1}\left(\dfrac{7}{46}\right) + \tan^{-1}\left(\dfrac{18}{46}\right)$



$= \tan^{-1}\left(\dfrac{7}{x}\right) + \tan^{-1}\left(\dfrac{18}{x}\right) \approx 30.02°$

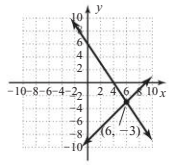
CHAPTER 9

Exercises 9.1, pp. 848–853



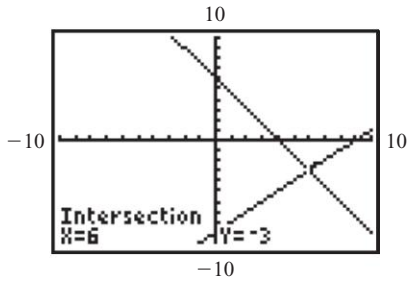
1. inconsistent **3.** consistent, independent **5.** Multiply the first equation by 6 and the second equation by 10. **7.** $y = \frac{7}{4}x - 6, y = \frac{-4}{3}x + 5$ **9.** $y = x + 2$ **11.** $x + 3y = -3$ **13.** $y = x + 2, x + 3y = -3$

15.

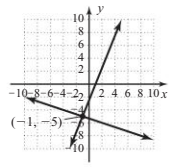


yes

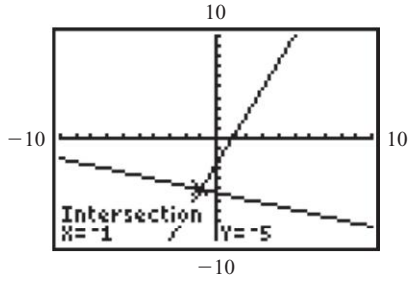
17.



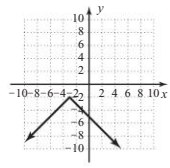
yes



19.



$Y_1 = \dfrac{12 - 3X}{2}$, $Y_2 = X - 9$

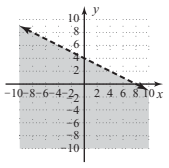


21.

$Y_1 = \dfrac{5 - 5X}{-2}$, $Y_2 = \dfrac{-16 - X}{3}$

23. $(-4, 1)$ **25.** $(3, -5)$ **27.** second equation, y, $(4, -3)$
29. second equation, x, $(10, -1)$ **31.** second equation, x, $(\frac{5}{2}, \frac{7}{4})$
33. $(-2, \frac{5}{2})$ **35.** $(2, -1)$ **37.** $(3, -1)$ **39.** $(-2, -3)$
41. $(\frac{11}{2}, 2)$ **43.** $(-2, 3)$ **45.** $(-3, 4)$ **47.** $(-6, 12)$
49. (2, 8); consistent/independent **51.** $\varnothing$; inconsistent
53. $\{(x, y) | 6x + y = 22\}$; consistent/dependent
55. (4, 1); consistent/independent **57.** $(-3, -4)$; consistent/independent
59. $(\frac{-1}{2}, \frac{4}{3})$; consistent/independent **61.** 1 mph; 4 mph **63.** 2318 adult tickets; 1482 child tickets **65.** premium: \$3.97, regular: \$3.87
67. nursing student \$6500; science major \$3500
69. 150 quarters, 75 dimes **71. a.** 3 mph **b.** 5 mph
73. a. 3.6 ft/sec **b.** 4.4 ft/sec **75. a.** 100 lawns/mo **b.** \$11,500/mo
77. a. 1.6 billion bu, 3 billion bu, yes **b.** 2.7 billion bu, 2.25 billion bu, yes **c.** \$6.65, 2.43 billion bu **79.** about 227 boards at \$410 a piece
81. about 90,000,000 gal at \$3.04/gal **83.** 1776; 1865
85. Tahiti: 402 mi^2, Tonga: 290 mi^2 **87.** $y = 2x + 3$ **89.** \$50,000
91.

93. $x \approx 120.716$



Exercises 9.2, pp. 861–864

1. triple **3.** equivalent, systems **5.** $z = 5$ **7.** Answers will vary.
9. Answers will vary. **11.** yes, no; R2, R3 **13.** (5, 7, 4)
15. $(-2, 4, 3)$ **17.** $(4, 0, -3)$ **19.** (5, 12, 13)
21. no solution, inconsistent
23. $\{(x, y, z) | x \in \mathbb{R}, y = 2 - x, z = 2 - x\}$; $(p, 2 - p, 2 - p)$, other solutions possible
25. $\left\{(x, y, z) \middle| x = -\frac{5}{3}z - \frac{2}{3}, y = -z - 2, z \in \mathbb{R}\right\}$; $\left(-\frac{5}{3}p - \frac{2}{3}, -p - 2, p\right)$, other solutions possible
27. $(p, 2p, p + 1)$ **29.** $(p + 9, p - 4, p)$
31. $\left\{(x, y, z) \middle| x + \frac{1}{2}y - 2z = 6\right\}$ **33.** $(-1, \frac{-3}{2}, 2)$
35. $(-p - 17, -p - 4, p)$ **37.** (12, 6, 4) **39.** $(1, -5, -6)$

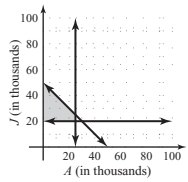
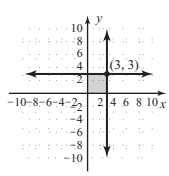
43.



(2, 4)

45.



(3, 2)

47. $\begin{cases} y - x \leq 1 \\ x + y > 3 \end{cases}$ **49.** $\begin{cases} y - x \leq 1 \\ x + y < 3 \\ y \geq 0 \end{cases}$ **51.** (5, 3) **53.** (12, 11)
55. 26 at (2, 2) **57.** 264 at (4, 3) **59.** $5 < H < 10$
61.

$J + A \leq 50{,}000$
$J \geq 20{,}000$
$A \leq 25{,}000$

63. 300 acres of corn; 200 acres of soybeans **65.** 240 sheet metal screws; 480 wood screws **67.** 65 traditionals, 30 Double-T's
69. 3 buses from company X; 4 buses from company Y
71.

a. the region is a square
b. maximum is 35.1 at (3, 3)
c. optimal solutions occur at vertices

73. **a.** $-\frac{3}{5}$ **b.** $\frac{5}{4}$ **c.** $-\frac{3}{4}$ **75.** 324 Ω

Exercises 9.4, pp. 889–891

1. template **3.** repeated linear **5.** Answers will vary

7. $\frac{A}{x+3}+\frac{B}{x-2}$ **9.** $\frac{A}{x-1}+\frac{B}{(x-1)^2}$

11. $\frac{A}{x-1}+\frac{B}{x+2}+\frac{C}{x-3}$ **13.** $\frac{A}{x}+\frac{B}{x-3}+\frac{C}{x+1}$

15. $\frac{A}{x-5}+\frac{B}{(x-5)^2}+\frac{C}{(x-5)^3}$ **17.** $\frac{A}{x}+\frac{B}{x^2}+\frac{C}{x+2}$

19. $\frac{A}{x}+\frac{B}{x^2}+\frac{C}{x-5}+\frac{D}{(x-5)^2}$ **21.** $\frac{A}{x-3}+\frac{Bx+C}{x^2+5x+7}$

23. $\frac{A}{x+1}+\frac{Bx+C}{x^2+2}+\frac{Dx+E}{(x^2+2)^2}$ **25.** $\frac{-4}{2x-5}+\frac{3}{x+3}$

27. $\frac{7}{x}+\frac{2}{x+1}-\frac{1}{x-1}$ **29.** $\frac{-1}{x}+\frac{4}{x+1}+\frac{5}{(x+1)^2}$

31. $\frac{2}{x^2+1}+\frac{3x+1}{x^2+2}$ **33.** $\frac{5}{x+2}+\frac{x-1}{x^2+3}$ **35.** $\frac{1}{x}-\frac{5x+2}{(x^2+1)^2}$

37. $\frac{2}{x}+\frac{1}{x^2}+\frac{x-1}{x^2+x+3}$ **39.** $\frac{3}{2-x}-\frac{4}{4+2x+x^2}$

41. $\frac{5}{x+3}-\frac{2}{(x+3)^2}$ **43.** $\frac{2x+1}{x^2+1}+\frac{3x}{(x^2+1)^2}$

45. $\frac{2}{x-1}+\frac{3}{(x-1)^3}$ **47.** $\frac{\frac{1}{100}}{P}+\frac{\frac{1}{10}}{100-10P}$

49. $\frac{\frac{1}{10}}{P}+\frac{\frac{1}{100}}{10-\frac{1}{10}P}$ **51.** $\frac{49}{50}$ **53.** $\frac{62}{125}$

55. $\frac{4}{\ln x-2}-\frac{4}{\ln x-1}-\frac{3}{(\ln x-1)^2}$

57. Factor out -1 from the denominator:

$$\frac{x+2}{(x-1)(1-x)}=\frac{x+2}{(x-1)(-1)(x-1)}=\frac{-x-2}{(x-1)^2}=\frac{-1}{x-1}-\frac{3}{(x-1)^2}$$

59. $2x-1+\frac{1}{x^2-x+6}$ **61.** Verified

Mid-Chapter Check, p. 891

1. (1, 1); consistent **2.** (5, 3); consistent **3.** 20 oz **4.** no; R2, R3

5. The second equation is a multiple of the first equation. **6.** (1, 2, 3)

7. (1, 2, 3) **8.** $\frac{2}{x+1}-\frac{3}{x-2}+\frac{1}{(x-2)^2}$

9. Mozart = 8 yr; Morphy = 13 yr; Pascal = 16 yr

10. 2 table candles, 9 holiday candles

Reinforcing Basic Concepts, p. 892

Exercise 1: Premium: \$4.17/gal, Regular: \$4.07/gal,

$$\begin{cases}15.3R+35.7P=211.14\\ P=R+0.10\end{cases}$$

Exercise 2: Verified

Exercises 9.5, pp. 901–905

1. square **3.** 2, 3, 1 **5.** Multiply R1 by -2 and add that result to R2. This sum will be the new R2. **7.** 3×2, 5.8 **9.** 4×3, -1

11. $\left[\begin{array}{ccc|c}1&2&-1&1\\1&0&1&3\\2&-1&1&3\end{array}\right]$; diagonal entries 1, 0, 1

13. $\begin{cases}x+4y=5\\ y=\frac{1}{2}\end{cases}\rightarrow(3,\frac{1}{2})$ **15.** $\begin{cases}x+2y-z=0\\ y+2z=2\\ z=3\end{cases}\rightarrow(11,-4,3)$

17. $\begin{cases}x+3y-4z=29\\ y-\frac{3}{2}z=\frac{21}{2}\\ z=3\end{cases}\rightarrow(-4,15,3)$ **19.** $\begin{bmatrix}1&-6&-2\\0&-28&-6\end{bmatrix}$

Exercises 9.8, pp. 942–947

1. $a_{11}a_{22} - a_{21}a_{12}$ **3.** constant **5.** Answers will vary.

7. $D = \begin{vmatrix} 2 & 5 \\ -3 & 4 \end{vmatrix}$; $D_x = \begin{vmatrix} 7 & 5 \\ 1 & 4 \end{vmatrix}$; $D_y = \begin{vmatrix} 2 & 7 \\ -3 & 1 \end{vmatrix}$ **9.** $(-5, 9)$

11. $\left(\frac{-26}{3}, \frac{25}{3}\right)$ **13.** not possible

15. a. $D = \begin{vmatrix} 4 & -1 & 2 \\ -3 & 2 & -1 \\ 1 & -5 & 3 \end{vmatrix}$ $D_x = \begin{vmatrix} -5 & -1 & 2 \\ 8 & 2 & -1 \\ -3 & -5 & 3 \end{vmatrix}$

$D_y = \begin{vmatrix} 4 & -5 & 2 \\ -3 & 8 & -1 \\ 1 & -3 & 3 \end{vmatrix}$ $D_z = \begin{vmatrix} 4 & -1 & -5 \\ -3 & 2 & 8 \\ 1 & -5 & -3 \end{vmatrix}$,

b. $|D| = 22$, solutions possible

c. $|D| = 0$, Cramer's rule cannot be used: coefficients $R_1 + R_2 = R_3$

17. $(1, 2, 1)$ **19.** $\left(\frac{3}{4}, \frac{5}{3}, \frac{-1}{3}\right)$ **21.** $(0, -1, 2, -3)$

23. $320 + 32\pi \approx 420.5\text{ in}^2$ **25.** 8 cm^2 **27.** 27 ft^2 **29.** 19 m^3

31. 96 in^3 **33.** yes **35.** no **37.** yes; yes; yes

39. $\frac{1}{x} - \frac{\frac{1}{2}}{x+1} - \frac{\frac{3}{4}}{(x+1)^2} + \frac{\frac{1}{2}}{x-1} - \frac{\frac{1}{4}}{(x-1)^2}$

41. $\frac{3}{x+1} - \frac{2}{x-3} + \frac{1}{(x-3)^3}$ **43.** 214.5 ft^2 of skin, 231.0 ft^2 of wood veneer, 516 tension rods, and 498 ft of hoop **45.** 955 ft^2 of skin, 1021.5 ft^2 of wood veneer, 2180 tension rods, and 2129.5 ft of hoop **47.** 5 Silver, 9 Gold, and 2 Platinum

49. one bundle of first class = 9.25 measures of grain;
one bundle of second class = 4.25 measures of grain;
one bundle of third class = 2.75 measures of grain

51. Answers will vary. **53.** Answers will vary. **55.** Answers will vary.

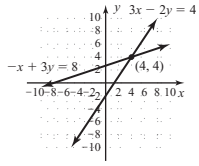
63. Answers will vary. **65.** Answers will vary. **67.** Answers will vary.

69. \$15,000 at 6%, \$25,000 at 8% **71.** apples: 29¢/lb; kiwi: 39¢/lb; pears: 19¢/lb **73.** 10 lb of \$1.90, 8 lb of \$2.25, 6 lb of \$3.50

75. Answers will vary. **77.** $x^2 + y^2 - 4x - 6y - 12 = 0$

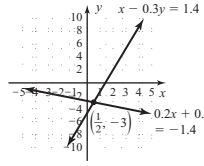
79.



81. $\angle B \approx 76.3°$, $\angle C \approx 54.7°$, side $c = 9.4$ in.

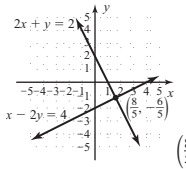
Making Connections, p. 947

1. h **3.** d **5.** a **7.** f **9.** b **11.** f **13.** h **15.** c



Summary and Concept Review, pp. 948–953

1.



(4, 4)

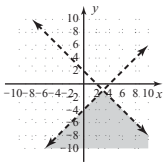
2.

$(\frac{1}{2}, -3)$

3.

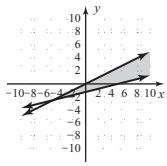
$\left(\frac{8}{5}, \frac{-6}{5}\right)$

4. no solution; inconsistent



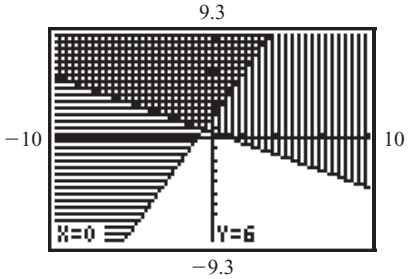
5. $(5, -1)$; consistent **6.** $(7, 2)$; consistent **7.** $(3, -1)$; consistent

8. $\left(\frac{11}{4}, \frac{-1}{6}\right)$; consistent **9.** Willis Tower is 1450 ft; Hancock Building is 1127 ft. **10.** \$1.20 **11.** $(0, 3, 2)$ **12.** $(1, 1, 1)$

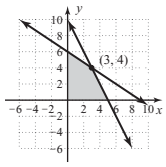


13. no solution, inconsistent **14.** 72 nickels, 85 dimes, 60 quarters

15. $y = -x^2 + 10x - 9$



16.



17.

18.

19. 

Maximum of 270 occurs at both (0, 6) and (3, 4)

20. 50 cows, 425 chickens **21.** $\frac{4}{x-3}+\frac{2}{x+5}$ **22.** $\frac{7}{x-3}+\frac{2}{2x+1}$

23. $\frac{1}{x+4}+\frac{2}{x^2+1}$ **24.** $\frac{-3}{x-5}+\frac{x+2}{x^2+3}$ **25.** $\frac{-3}{x+3}+\frac{x+1}{x^2-3x+9}$

26. $\frac{5}{x-1}+\frac{x-2}{x^2+x+1}$ **27.** $\frac{5}{(x-2)^2}-\frac{1}{x-2}+\frac{3}{x+3}$

28. $\frac{1}{(x-1)^2}-\frac{3}{x-1}+\frac{2}{x+5}$ **29.** $\frac{2}{x^2+3}-\frac{x+5}{(x^2+3)^2}$

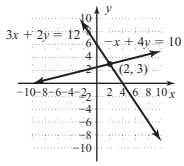
30. $(-2, -4)$ **31.** $(1, 6, 9)$ **32.** $(-2, 7, 1, 8)$

33. $\begin{bmatrix}-7.25 & 5.25\\ 0.875 & -2.875\end{bmatrix}$ **34.** $\begin{bmatrix}-6.75 & 6.75\\ 1.125 & -1.125\end{bmatrix}$ **35.** not possible

36. $\begin{bmatrix}-2 & -6\\ -1 & -7\end{bmatrix}$ **37.** $\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}$ **38.** $\begin{bmatrix}1 & 0 & 4\\ 5.5 & -1 & -1\\ 10 & -2.9 & 7\end{bmatrix}$

39. $\begin{bmatrix}3 & -6 & -4\\ -4.5 & 3 & -1\\ -2 & 3.1 & 3\end{bmatrix}$ **40.** not possible **41.** $\begin{bmatrix}-8 & 12 & 0\\ -2 & -4 & 4\\ -16 & -0.4 & -20\end{bmatrix}$

42. $\begin{bmatrix}15.5 & 6.4 & 17\\ 9 & -17 & 2\\ 18.5 & -20.8 & 13\end{bmatrix}$ **43.** D **44.** It's an identity matrix.



45. It's the inverse of B. **46.** E **47.** It's an identity matrix.

48. It's the inverse of F. **49.** matrix multiplication is not generally commutative **50.** $(-8, -6)$ **51.** $(2, 0, -3)$

52. $\left(\frac{-19}{35}, \frac{25}{14}\right)$ **53.** $(1, -1, 2)$ **54.** $\left(\frac{-37}{19}, \frac{36}{19}, \frac{31}{19}\right)$ **55.** $\frac{91}{2}$ units^2

56. $\frac{5}{x-2}+\frac{2x-1}{x^2+3}$ **57.** 92,250 gal gasoline, 595,000 lb corn, 227,500 oz yeast, and 134,750 gal water **58.** 287,250 gal gasoline, 2,035,000 lb corn, 777,500 oz yeast, and 460,750 gal water **59.** PIE ARE SQUARE

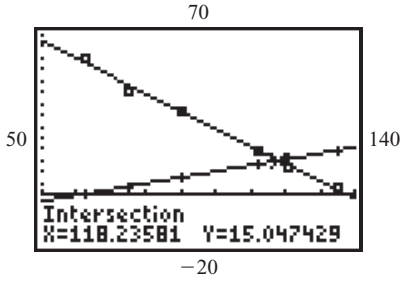
Practice Test, pp. 953–954

1. 

$(2, 3)$ **2.** $\left(\frac{2}{5}, \frac{-4}{5}\right)$ **3.** $(-3, 2)$ **4.** $(2, -1, 4)$

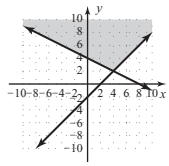
5. a. $\begin{bmatrix}-6 & -5\\ 8 & 9\end{bmatrix}$ **b.** $\begin{bmatrix}1.2 & 1.2\\ -1.2 & -2\end{bmatrix}$ **c.** $\begin{bmatrix}-3 & 1\\ 3 & -5\end{bmatrix}$

d. $\begin{bmatrix}-2 & -1\\ 2.5 & 1.5\end{bmatrix}$ **e.** -2



6. a. $\begin{bmatrix}0 & -0.1 & 0\\ 0.5 & -0.6 & 0\\ -0.2 & -0.8 & -0.9\end{bmatrix}$ **b.** $\begin{bmatrix}-0.3 & -0.06 & -0.12\\ 0.06 & -0.06 & 0\\ -0.18 & -0.24 & -0.48\end{bmatrix}$

c. $\begin{bmatrix}0.31 & -0.13 & 0.08\\ -0.01 & -0.05 & -0.02\\ 0.39 & -0.52 & -0.02\end{bmatrix}$ **d.** $\begin{bmatrix}\frac{40}{17} & 0 & \frac{-10}{17}\\ \frac{40}{17} & 10 & \frac{-10}{17}\\ \frac{-35}{17} & -5 & \frac{30}{17}\end{bmatrix}$ **e.** 0.034



7. $\left(2, 1, \frac{-1}{3}\right)$ **8.** $(3, -2, 3)$ **9.** $\left(\frac{97}{34}, \frac{-18}{17}\right)$ **10.** $(1, 6, 9)$

11. 21.59 cm by 35.56 cm **12.** Tahiti 402 mi^2; Tonga 290 mi^2

13. \$15,000 at 7%; \$8000 at 5%; \$7000 at 9%

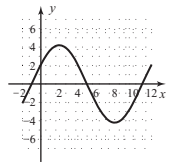
14. a.

b. equilibrium is achieved when approx 150,000 plugs are sold at a price near \$1.18 **15.** $h(t) = -16t^2 + 144$ **16.** 144 ft, 3 sec

17. 

18. maximum 250 at (5, 0)

19. 30 plain; 20 deluxe **20.** $\frac{1}{x-3}+\frac{3x+2}{x^2+3x+9}$



Strengthening Core Skills, pp. 955–956

Exercise 1: $(1, -4, 1)$

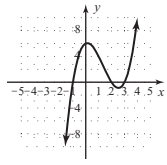
Cumulative Review Chapters 1–9, pp. 956–957

1. a. $x = \frac{2}{3}$ **b.** $x = 0, 7$ **c.** $x = 5, \pm i\sqrt{2}$ **d.** $x = -1, 0, 4$

3. $R = \pm\frac{1}{\pi}\sqrt{A + (\pi r)^2}$

5. 

7. a. $(a + bi) + (a - bi) = 2a$



b. $(a + bi)(a - bi) = a^2 - (bi)^2 = a^2 + b^2$

9. $x = 12 \pm \frac{\sqrt{15}}{3}$ **11.** $\sin\theta = \frac{\sqrt{13}}{4}$, $\cos\theta = \frac{\sqrt{3}}{4}$, $\tan\theta = \frac{\sqrt{39}}{3}$

13. a. $m = \frac{y_2 - y_1}{x_2 - x_1}$ **b.** $\left(\frac{x_2 + x_1}{2}, \frac{y_2 + y_1}{2}\right)$ **c.** $x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$

d. $d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$ **e.** $A = Pe^{rt}$ **15.** $\langle -3, -18\rangle$

17. a. $\frac{\sqrt{121 + x^2}}{11}$ **b.** $\frac{x}{\sqrt{9 + x^2}}$

19. 

$x \in (-\infty, -1) \cup (2, 3)$

21. $-128 - 128i\sqrt{3}$ **23.** about 3.6 yr

25. $A = 2$, $B = 1$, $C = \frac{\pi}{4}$

27. $q(x) = \pi^2$, $r(x) = \pi x - \pi^3$, crosses at $x = \pi^2$ (≈ 9.87)

29. $y = -4$ at $x = 2$

Connections to Calculus Exercises, p. 960

1. a. $\frac{k}{(x+a)(x+b)} = \frac{A}{x+a} + \frac{B}{x+b}$; $(A + B)x + (Ab + Ba) = k$

b. $B = -A \Rightarrow Ab + (-Aa) = k$; $A(b - a) = k$

c. $A = \frac{k}{b-a}$; $\frac{16}{(x+3)(x-5)} = \frac{-2}{x+3} + \frac{2}{x-5}$

3. $\dfrac{-1}{x+3}+\dfrac{1}{x-3}$ **5.** $\dfrac{2}{x+7}+\dfrac{-2}{x-4}$

7. $\dfrac{-1}{x+8}+\dfrac{2}{x+5}$ **9.** 114 units^2 **11.** 36 units^2

13. 240 units^3; $V = LWH = (5)(6)(8) = 240$ units^3

CHAPTER 10

Exercises 10.1, pp. 966–968

1. geometry, algebra **3.** perpendicular **5.** point, intersecting

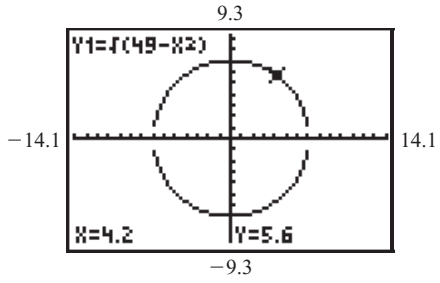
7. $(-2, -2)$; verified **9.** $(2, -2)$; verified **11.** $(\frac{13}{2}, -9)$; verified

13. $(x+2)^2+(y+2)^2=5^2$ **15.** $(x-2)^2+(y+2)^2=5^2$

17. $\left(x-\dfrac{13}{2}\right)^2+(y+9)^2=\left(\dfrac{25}{2}\right)^2$ **19.** $d = 13$; B, C, E, G

21. Verified, $d=\dfrac{8\sqrt{5}}{5}$ **23.** B, C, E **25.** Verified **27.** $y=-\dfrac{1}{16}x^2$

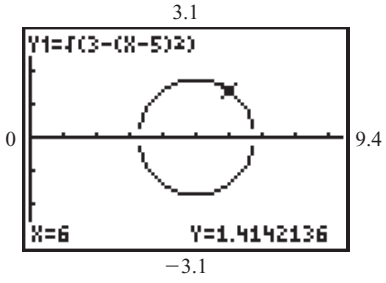
29. $4x^2+3y^2=48$ **31.** Verified, verified **33.** $3x^2-y^2=3$



35. Verified **37.** $=\dfrac{\cos^2 x-\sin^2 x+\sin^2 x}{\sin^2 x}=\dfrac{\cos^2 x}{\sin^2 x}=\cot^2 x$

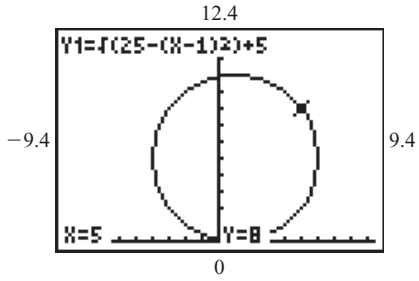
39. a. $x = 2\ln 9, x \approx 4.39$ **b.** $x=\dfrac{5}{2}\ln 54, x \approx 9.97$

Exercises 10.2, pp. 979–983



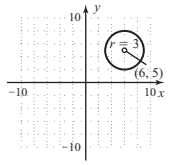
1. $c^2 = |a^2 - b^2|$ **3.** $2a, 2b$ **5.** Answers will vary.

7. $x^2+y^2=49$



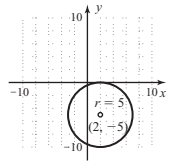
$(4.2, 5.6), (4.2, -5.6)$

9. $(x-5)^2+y^2=3$

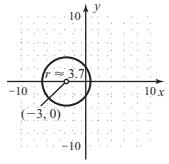


$(6, \sqrt{2}), (6, -\sqrt{2})$

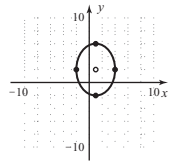
11. $(x-1)^2+(y-5)^2=25$



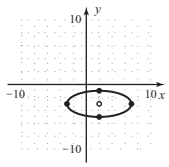
$(5, 8), (5, 2)$



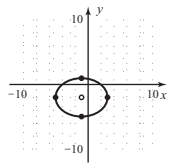
13. $(x-6)^2+(y-5)^2=9$
center: $(6, 5)$, $r = 3$



15. $(x-2)^2+(y+5)^2=25$
center: $(2, -5)$, $r = 5$

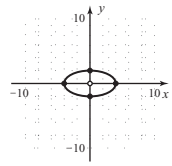


17. $(x+3)^2+y^2=14$
center: $(-3, 0)$, $r=\sqrt{14}$

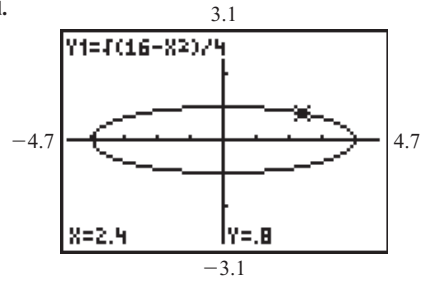


19.

21.

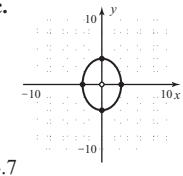


23.

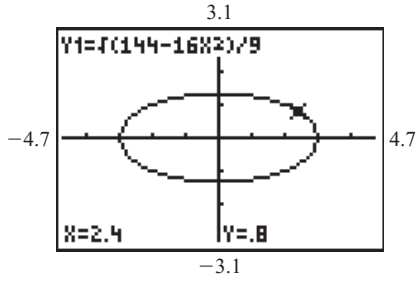


25. a. $\dfrac{x^2}{16}+\dfrac{y^2}{4}=1$, $(0, 0)$, $a = 4$, $b = 2$

b. $(-4, 0), (4, 0), (0, -2), (0, 2)$ **c.**



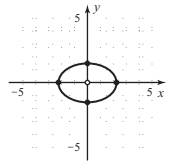
d.



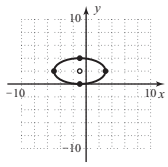
$(2.4, 0.8), (2.4, -0.8), (-2.4, 0.8), (-2.4, -0.8)$

27. a. $\dfrac{x^2}{9}+\dfrac{y^2}{16}=1$, $(0, 0)$, $a = 3$, $b = 4$

b. $(0, -4), (0, 4), (-3, 0), (3, 0)$ **c.**

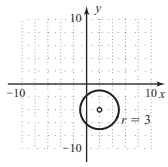


d.

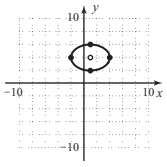


$(2.4, 0.8), (2.4, -0.8), (-2.4, 0.8), (-2.4, -0.8)$

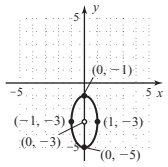
29. a. $\dfrac{x^2}{5}+\dfrac{y^2}{2}=1$, $(0, 0)$, $a=\sqrt{5}$, $b=\sqrt{2}$



b. $(-\sqrt{5}, 0), (\sqrt{5}, 0), (0, -\sqrt{2}), (0, \sqrt{2})$ **c.**

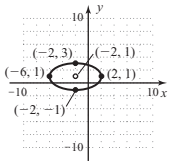


31. ellipse

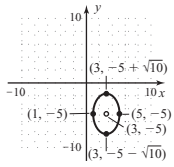


33. circle

35. ellipse

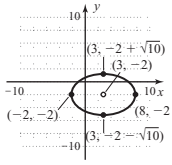


37. $x^2 + \dfrac{(y+3)^2}{4} = 1$



D: $x \in [-1, 1]$, R: $y \in [-5, -1]$

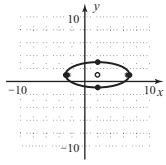
39. $\dfrac{(x+2)^2}{16} + \dfrac{(y-1)^2}{4} = 1$



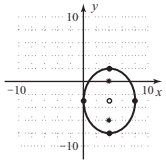
D: $x \in [-6, 2]$, R: $y \in [-1, 3]$

41. $\dfrac{(x-3)^2}{4} + \dfrac{(y+5)^2}{10} = 1$

D: $x \in [1, 5]$,
R: $y \in [-5 - \sqrt{10}, -5 + \sqrt{10}]$

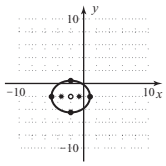


43. $\dfrac{(x-3)^2}{25} + \dfrac{(y+2)^2}{10} = 1$

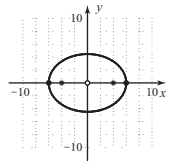


D: $x \in [-2, 8]$,
R: $y \in [-2 - \sqrt{10}, -2 + \sqrt{10}]$

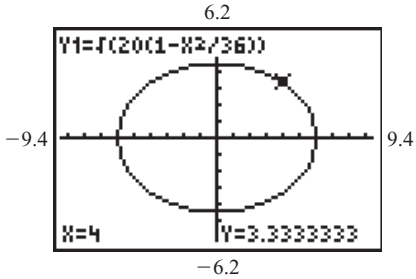
45. $k = 20$ **47.** $k = 20$



49. a. (2, 1) **b.** (−3, 1) and (7, 1) **c.** $(2 - \sqrt{21}, 1)$ and $(2 + \sqrt{21}, 1)$ **d.** (2, 3) and (2, −1) **e.**

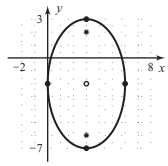


51. a. (4, −3) **b.** (4, 2) and (4, −8) **c.** (4, 0) and (4, −6) **d.** (0, −3) and (8, −3) **e.**

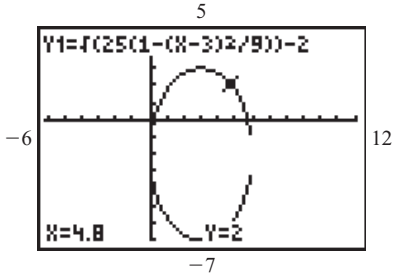


53. a. (−2, −2) **b.** (−5, −2) and (1, −2)
c. $(-2 + \sqrt{3}, -2)$ and $(-2 - \sqrt{3}, -2)$ **d.** $(-2, -2 + \sqrt{6})$ and $(-2, -2 - \sqrt{6})$ **e.**

55. $\dfrac{x^2}{36} + \dfrac{y^2}{20} = 1$ **a.**



b.



c. $L = 6.\overline{6}$ **d.** verified

57. $\dfrac{(x-3)^2}{9} + \dfrac{(y+2)^2}{25} = 1$ **a.**

b.

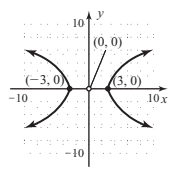
c. $L = 3.6$ **d.** verified

59. $\dfrac{x^2}{16} + \dfrac{y^2}{9} = 1$, $(\pm\sqrt{7}, 0)$

61. $\dfrac{(x+3)^2}{4} + \dfrac{(y+1)^2}{16} = 1$, $(-3, -1 \pm 2\sqrt{3})$

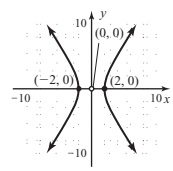
63. $A = 12\pi$ units^2 **65.** $\sqrt{7} \approx 2.65$ ft, 2.25 ft

67. 8.9 ft, 17.9 ft **69.** $\dfrac{x^2}{15^2} + \dfrac{y^2}{8^2} = 1$; 6.4 ft **71.** $\dfrac{x^2}{6.25} + \dfrac{y^2}{2.25} = 1$



73. $\dfrac{x^2}{36^2} + \dfrac{y^2}{(35.25)^2} = 1$ **75.** $a \approx 142$ million miles, $b \approx 141$ million miles, orbit time ≈ 686 days **77.** about 66,697 mph **79.** 90,000 π yd^2
81. a. 45 ft **b.** 106 ft **c.** 25 ft **83.** ellipse, since squared terms are positive and $A \neq B$; $6(x+3)^2 + 3(y-4)^2 = 0$, the constant term becomes zero; the graph is the single point $(-3, 4)$

85. $\dfrac{\log 20}{\log 3} \approx 2.73$ **87.** $z = 64$



Exercises 10.3, pp. 993–997

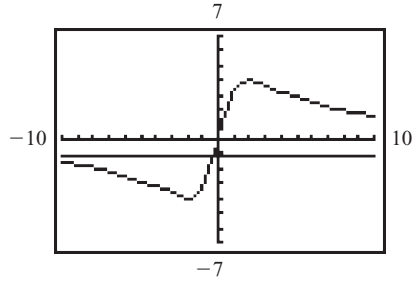
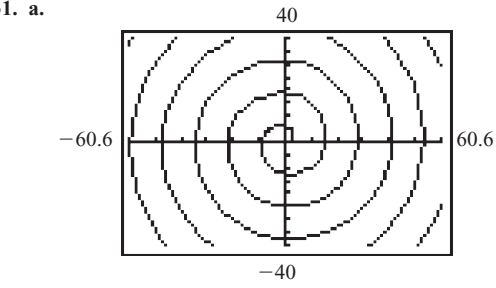
23. $x = t, y = \tan^2(t - 2) + 1, t \neq \pi k + \dfrac{\pi}{2} + 2, k \in \mathbb{Z}; x = t + 2, y = \sec^2 t, t \neq \left(k + \dfrac{1}{2}\right)\pi, k \in \mathbb{Z}; x = \tan^{-1} t + 2, y = t^2 + 1$



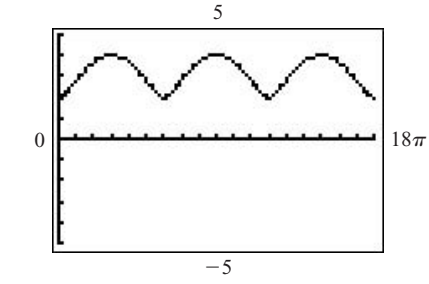
25. verified

27. a.



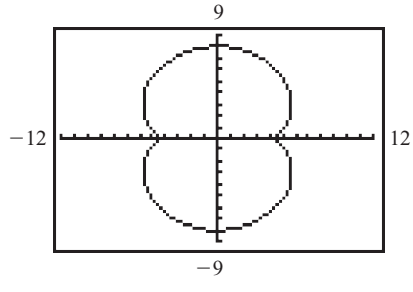
b. x-intercepts: $t = 0, x = 10$, $y = 0$ and $t = \pi, x = -6, y = 0$; y-intercepts: $t \approx 1.757, x = 0, y \approx 6.5$ and $t \approx 4.527, x = 0, y \approx -6.5$; minimum x-value is -8.1; maximum x-value is 10; minimum y-value is -9.5; maximum y-value is 9.5

29. a.



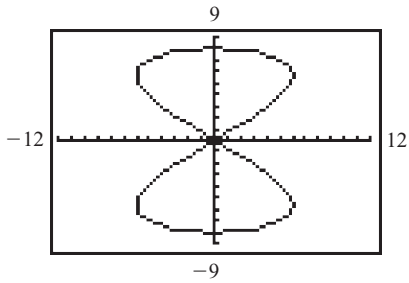
b. x-intercepts none, y-intercepts none; no minimum or maximum x-values; minimum y-value is -4 and maximum y-value is 4

31. a.



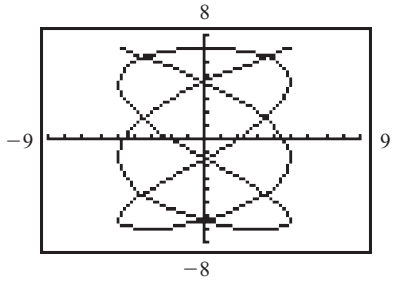
b. x-intercepts: $t = 0, x = 2, y = 0$ and $t \approx 4.493, x \approx -9.2, y = 0$; infinitely many others; y-intercepts: $t \approx 2.798, x = 0, y \approx 5.9$ and $t \approx 6.121, x = 0, y \approx -12.4$; infinitely many others; no minimum or maximum values for x or y

33. a.



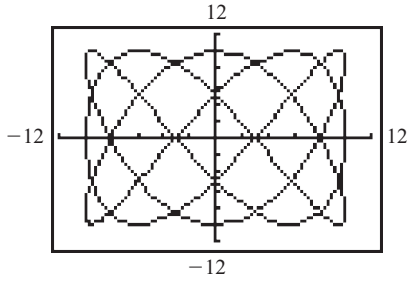
b. no x-intercepts; y-intercept is $t = 0, x = 0, y = 2$; no minimum or maximum x-values; minimum y-value is 2; maximum y-value is 4

35. a.



b. x-intercepts: $t = 0, x = 4, y = 0$ and $t = \pi, x = -4, y = 0$; y-intercepts: $t = \frac{\pi}{2}, x = 0, y = 8$ and $t = \frac{3\pi}{2}, x = 0, y = -8$; minimum and maximum x-values are approx. ± 5.657; minimum and maximum y-values are ± 8

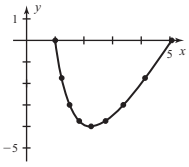
37.



width 12 and height 16; including the endpoint $t = 2\pi$, the graph crosses itself two times from 0 to 2π.

39.

width 10 and height 14; including the endpoint $t = 2\pi$, the graph crosses itself nine times from 0 to 2π.



41.

width 20 and height 20; including the endpoint $t = 4\pi$, the graph crosses itself 23 times from 0 to 4π.

43. The maximum value (as the graph swells to a peak) is at $(x, y) = \left(a, \frac{b}{2}\right)$. The minimum value (as the graph dips to the valley) is at $(x, y) = \left(-a, \frac{-b}{2}\right)$.

45. a. The curve is approaching $y = 2$ as t approaches $\frac{3\pi}{2}$, but $\cot\left(\frac{3\pi}{2}\right)$ is undefined, and the trig form seems to indicate a hole at $t = \frac{3\pi}{2}, x = 0, y = 2$. The algebraic form does not have this problem and shows a maximum defined at $t = 0, x = 0, y = 2$.
b. As $|t| \to \infty, y(t) \to 0$ **c.** The maximum value occurs at $(0, 2k)$.
47. a. Yes **b.** Yes **c.** ≈ 0.82 ft **49.** No, the kick is short.
51. The electron is moving left and downward.
53. 3 orbits; about 2.1 orbits **55.** $\left(t, \frac{6t}{17} - \frac{6}{17}, \frac{13t}{17} + \frac{21}{17}\right)$
57. Inconsistent, no solutions
59. $x = 1.22475^t$
$y = 0.25t^2 - 2t$
The parametric equations fit the data very well.

61. $x = 2\cos t - 3, y = \cos(2t)$; no, the range of $\cos(2t)$ is $[-1, 1]$
63. Taller (The Eiffel Tower is about 1063 ft tall) **65.** $\theta \approx 55°$

129. $40{,}000 + 1750x$ vs. $40{,}000(1.04)^x$; 6 yr

131. **a.** For an arithmetic sequence, the difference $d = a_k - a_{k-1}$ must be constant. For $a_k = a_1 r^{k-1}$ and $a_{k-1} = a_1 r^{k-2}$, we have
$d = \log(a_1 r^{k-1}) - \log(a_1 r^{k-2})$
$= \log(a_1) + \log(r^{k-1}) - [\log(a_1) + \log(r^{k-2})]$
$= \log(a_1) + (k-1)\log(r) - \log(a_1) - (k-2)\log(r)$
$= \log(r)[(k-1) - (k-2)]$
$= \log(r)$✓

b. For a geometric sequence, the ratio $r = \frac{a_k}{a_{k-1}}$ must be constant.
For $a_k = a_1 + (k-1)d$ and $a_{k-1} = a_1 + (k-2)d$ we have
$r = \frac{10^{a_1+(k-1)d}}{10^{a_1+(k-2)d}}$
$= \frac{10^{a_1}10^{(k-1)d}}{10^{a_1}10^{(k-2)d}}$
$= \frac{10^{(k-1)d}}{10^{(k-2)d}}$
$= 10^{(k-1)d-(k-2)d}$
$= 10^{d[(k-1)-(k-2)]}$
$= 10^d$✓

133. $\frac{3}{\sqrt{58}}\mathbf{i} - \frac{7}{\sqrt{58}}\mathbf{j}$ **135.** ≈ 942 ft per min, ≈ 10.7 mph

Exercises 11.4, pp. 1117–1118

1. finite, universally **3.** induction, hypothesis **5.** Answers will vary.
7. $a_n = 10n - 6$
$a_4 = 10(4) - 6 = 40 - 6 = 34$;

$S_4 = 2^4 - 1 = 16 - 1 = 15$;
$S_5 = 2^5 - 1 = 32 - 1 = 31$;
$S_k = 2^k - 1$;
$S_{k+1} = 2^{k+1} - 1$
19. $a_n = 10n - 6$; $S_n = n(5n-1)$
$S_4 = 4(5(4) - 1) = 4(20 - 1) = 4(19) = 76$;
$a_5 = 10(5) - 6 = 50 - 6 = 44$;
$S_5 = 5(5(5) - 1) = 5(25 - 1) = 5(24) = 120$;
$S_4 + a_5 = S_5$

$76 + 44 = 120$
$120 = 120$
Verified

21. $a_n = n$; $S_n = \dfrac{n(n+1)}{2}$
$S_4 = \dfrac{4(4+1)}{2} = \dfrac{4(5)}{2} = 10$;
$a_5 = 5$;
$S_5 = \dfrac{5(5+1)}{2} = \dfrac{5(6)}{2} = 15$;
$S_4 + a_5 = S_5$
$10 + 5 = 15$
$15 = 15$
Verified

23. $a_n = 2^{n-1}$; $S_n = 2^n - 1$
$S_4 = 2^4 - 1 = 16 - 1 = 15$;
$a_5 = 2^{5-1} = 2^4 = 16$;
$S_5 = 2^5 - 1 = 32 - 1 = 31$;
$S_4 + a_5 = S_5$
$15 + 16 = 31$
$31 = 31$
Verified

25. a. $a_n = n^3$; $S_n = (1 + 2 + 3 + 4 + \cdots + n)^2$
$S_1 = 1^2 = 1^3$
$S_5 = (1 + 2 + 3 + 4 + 5)^2$
$= 15^2$
$= 225$
$1 + 8 + 27 + 64 + 125 = 225$
$S_9 = (1 + 2 + \cdots + 9)^2$
$= 45^2$
$= 2025$
$1 + 8 + \cdots + 729 = 2025$

b. $\left[\dfrac{n(n+1)}{2}\right]^2 = \dfrac{n^2(n+1)^2}{4}$

27. 1. Show S_n is true for $n = 1$.
$S_1 = 1(1+1) = 1(2) = 2$
Verified
2. Assume S_k is true: $2 + 4 + 6 + 8 + 10 + \cdots + 2k = k(k+1)$
and use it to show the truth of S_{k+1} follows. That is:
$2 + 4 + 6 + \cdots + 2k + 2(k+1) = (k+1)(k+1+1)$
$S_k + a_{k+1} = S_{k+1}$
Working with the left hand side:
$2 + 4 + 6 + \cdots + 2k + 2(k+1)$
$= k(k+1) + 2(k+1)$
$= (k+1)(k+2)$
$= S_{k+1}$
Since the truth of S_{k+1} follows from S_k, the formula is true for all n.

29. 1. Show S_n is true for $n = 1$.
$S_1 = \dfrac{5(1)(1+1)}{2} = \dfrac{5(2)}{2} = 5$
Verified
2. Assume S_k is true:
$5 + 10 + 15 + \cdots + 5k = \dfrac{5k(k+1)}{2}$
and use it to show the truth of S_{k+1} follows. That is:
$5 + 10 + 15 + \cdots + 5k + 5(k+1) = \dfrac{5(k+1)(k+1+1)}{2}$
$S_k + a_{k+1} = S_{k+1}$
Working with the left hand side:
$5 + 10 + 15 + \cdots + 5k + 5(k+1)$
$= \dfrac{5k(k+1)}{2} + 5(k+1)$
$= \dfrac{5k(k+1) + 10(k+1)}{2}$
$= \dfrac{(k+1)(5k+10)}{2}$
$= \dfrac{5(k+1)(k+2)}{2}$
$= S_{k+1}$
Since the truth of S_{k+1} follows from S_k, the formula is true for all n.

31. 1. Show S_n is true for $n = 1$.
$S_1 = 1(2(1) + 3) = 5$
Verified
2. Assume S_k is true:
$5 + 9 + 13 + 17 + \cdots + (4k+1) = k(2k+3)$
and use it to show the truth of S_{k+1} follows. That is:
$5 + 9 + 13 + 17 + \cdots + (4k+1) + [4(k+1)+1]$
$= (k+1)(2(k+1)+3)$
$S_k + a_{k+1} = S_{k+1}$
Working with the left hand side:
$5 + 9 + 13 + 17 + \cdots + (4k+1) + [4(k+1)+1]$
$= k(2k+3) + 4k + 5$
$= 2k^2 + 3k + 4k + 5$
$= 2k^2 + 7k + 5$
$= (k+1)(2k+5)$
$= S_{k+1}$
Since the truth of S_{k+1} follows from S_k, the formula is true for all n.

33. 1. Show S_n is true for $n = 1$.
$S_1 = \dfrac{3(3^1 - 1)}{2} = \dfrac{3(3-1)}{2} = \dfrac{3(2)}{2} = 3$
Verified
2. Assume S_k is true:
$3 + 9 + 27 + \cdots + 3^k = \dfrac{3(3^k - 1)}{2}$
and use it to show the truth of S_{k+1} follows. That is:
$3 + 9 + 27 + \cdots + 3^k + 3^{k+1} = \dfrac{3(3^{k+1} - 1)}{2}$
$S_k + a_{k+1} = S_{k+1}$
Working with the left hand side:
$3 + 9 + 27 + \cdots + 3^k + 3^{k+1}$
$= \dfrac{3(3^k - 1)}{2} + 3^{k+1}$
$= \dfrac{3(3^k - 1) + 2(3^{k+1})}{2}$
$= \dfrac{3^{k+1} - 3 + 2(3^{k+1})}{2}$
$= \dfrac{3(3^{k+1}) - 3}{2}$
$= \dfrac{3(3^{k+1} - 1)}{2}$
$= S_{k+1}$
Since the truth of S_{k+1} follows from S_k, the formula is true for all n.

35. 1. Show S_n is true for $n = 1$.
$S_1 = 2^{1+1} - 2 = 2^2 - 2 = 4 - 2 = 2$
Verified
2. Assume S_k is true:
$2 + 4 + 8 + \cdots + 2^k = 2^{k+1} - 2$
and use it to show the truth of S_{k+1} follows. That is:
$2 + 4 + 8 + \cdots + 2^k + 2^{k+1} = 2^{k+2} - 2$
$S_k + a_{k+1} = S_{k+1}$
Working with the left hand side:
$2 + 4 + 8 + \cdots + 2^k + 2^{k+1}$
$= 2^{k+1} - 2 + 2^{k+1}$
$= 2(2^{k+1}) - 2$
$= 2^{k+2} - 2$
$= S_{k+1}$
Since the truth of S_{k+1} follows from S_k, the formula is true for all n.

37. 1. Show S_n is true for $n = 1$.

$S_1 = \dfrac{1}{2(1)+1} = \dfrac{1}{2+1} = \dfrac{1}{3}$

Verified

2. Assume S_k is true:

$\dfrac{1}{3} + \dfrac{1}{15} + \dfrac{1}{35} + \cdots + \dfrac{1}{(2k-1)(2k+1)} = \dfrac{k}{2k+1}$

and use it to show the truth of S_{k+1} follows. That is:

$\dfrac{1}{3} + \dfrac{1}{15} + \dfrac{1}{35} + \cdots + \dfrac{1}{(2k-1)(2k+1)} + \dfrac{1}{(2(k+1)-1)(2(k+1)+1)} = \dfrac{k+1}{2(k+1)+1}$

$S_k + a_{k+1} = S_{k+1}$

Working with the left hand side:

$\dfrac{1}{3} + \dfrac{1}{15} + \dfrac{1}{35} + \cdots + \dfrac{1}{(2k-1)(2k+1)} + \dfrac{1}{(2k+1)(2k+3)}$

$= \dfrac{k}{2k+1} + \dfrac{1}{(2k+1)(2k+3)}$

$= \dfrac{k(2k+3)+1}{(2k+1)(2k+3)}$

$= \dfrac{2k^2+3k+1}{(2k+1)(2k+3)}$

$= \dfrac{(2k+1)(k+1)}{(2k+1)(2k+3)}$

$= \dfrac{k+1}{2k+3}$

$= S_{k+1}$

Since the truth of S_{k+1} follows from S_k, the formula is true for all n.

39. 1. Show P_n is true for $n = 1$.

P_1:

$3^1 \geq 2(1) + 1$

$3 \geq 2 + 1$

$3 \geq 3$

Verified

2. Assume P_k: $3^k \geq 2k + 1$ is true and use it to show the truth of P_{k+1} follows. That is: $3^{k+1} \geq 2(k+1) + 1$.

Working with the left hand side:

$3^{k+1} = 3(3^k)$

$\geq 3(2k+1)$

$\geq 6k + 3$

Since k is a positive integer,

$6k + 3 \geq 2k + 3$

Showing P_{k+1}: $3^{k+1} \geq 2k + 3$

Since the truth of P_{k+1} follows from P_k, the statement is true for all n.

41. 1. Show P_n is true for $n = 1$.

P_1:

$3 \cdot 4^{1-1} \leq 4^1 - 1$

$3 \cdot 4^0 \leq 4 - 1$

$3 \cdot 1 \leq 3$

$3 \leq 3$

Verified

2. Assume P_k: $3 \cdot 4^{k-1} \leq 4^k - 1$ is true and use it to show the truth of P_{k+1} follows. That is: $3 \cdot 4^{k+1-1} \leq 4^{k+1} - 1$.

Working with the left hand side:

$3 \cdot 4^k = 3 \cdot 4(4^{k-1})$

$= 4 \cdot 3(4^{k-1})$

$\leq 4(4^k - 1)$

$\leq 4^{k+1} - 4$

Since k is a positive integer, $4^{k+1} - 4 \leq 4^{k+1} - 1$

Showing P_{k+1}: $3 \cdot 4^k \leq 4^{k+1} - 1$

Since the truth of P_{k+1} follows from P_k, the statement is true for all n.

43. $n^2 - 7n$ is divisible by 2

1. Show P_n is true for $n = 1$.

P_n: $n^2 - 7n = 2m$

P_1:

$(1)^2 - 7(1) = 2m$

$1 - 7 = 2m$

$-6 = 2m$ Verified

2. Assume P_k: $k^2 - 7k = 2m$ for $m \in \mathbb{Z}$ and use it to show the truth of P_{k+1} follows. That is: $(k+1)^2 - 7(k+1) = 2p$ for $p \in \mathbb{Z}$.

Working with the left hand side:

$(k+1)^2 - 7(k+1)$

$= k^2 + 2k + 1 - 7k - 7$

$= k^2 - 7k + 2k - 6$

$= 2m + 2k - 6$

$= 2(m + k - 3)$

is divisible by 2.

Since the truth of P_{k+1} follows from P_k, the statement is true for all n.

45. $n^3 + 3n^2 + 2n$ is divisible by 3

1. Show P_n is true for $n = 1$. P_n: $n^3 + 3n^2 + 2n = 3m$

P_1:

$(1)^3 + 3(1)^2 + 2(1) = 3m$

$1 + 3 + 2 = 3m$

$6 = 3m$

$2 = m$

Verified

2. Assume P_k: $k^3 + 3k^2 + 2k = 3m$ for $m \in \mathbb{Z}$ and use it to show the truth of P_{k+1} follows.

That is: $(k+1)^3 + 3(k+1)^2 + 2(k+1) = 3p$ for $p \in \mathbb{Z}$.

Working with the left hand side:

$(k+1)^3 + 3(k+1)^2 + 2(k+1)$

$= k^3 + 3k^2 + 3k + 1 + 3(k^2 + 2k + 1) + 2k + 2$

$= k^3 + 3k^2 + 2k + 3(k^2 + 2k + 1) + 3k + 3$

$= k^3 + 3k^2 + 2k + 3(k^2 + 2k + 1) + 3(k + 1)$

$= 3m + 3(k^2 + 2k + 1) + 3(k + 1)$ is divisible by 3.

Since the truth of P_{k+1} follows from P_k, the statement is true for all n.

47. $6^n - 1$ is divisible by 5

1. Show P_n is true for $n = 1$. P_n: $6^n - 1 = 5m$

P_1:

$6^1 - 1 = 5m$

$6 - 1 = 5m$

$5 = 5m$

$1 = m$

Verified

2. Assume P_k: $6^k - 1 = 5m$ or $6^k = 5m + 1$ for $m \in \mathbb{Z}$ and use it to show the truth of P_{k+1} follows.

That is: $6^{k+1} - 1 = 5p$ for $p \in \mathbb{Z}$.

Working with the left hand side:

$6^k - 1$

$= 6(6^k) - 1$

$= 6(5m + 1) - 1$

$= 30m + 6 - 1$

$= 30m + 5$

$= 5(6m + 1)$

is divisible by 5.

Since the truth of P_{k+1} follows from P_k, the statement is true for all n.

35. (1) Show S_n is true for $n = 1$: $S_1 = \frac{1(1+1)}{2} = 1$✓

(2) Assume S_k is true: $1 + 2 + 3 + \cdots + k = \frac{k(k+1)}{2}$

Use it to show the truth of S_{k+1}:

$$1 + 2 + 3 + \cdots + k + (k+1) = \frac{(k+1)(k+1+1)}{2}$$

left hand side: $1 + 2 + 3 + \cdots + k + (k+1)$

$$= \frac{k(k+1)}{2} + (k+1) = \frac{k(k+1) + 2(k+1)}{2}$$
$$= \frac{(k+1)(k+2)}{2}$$

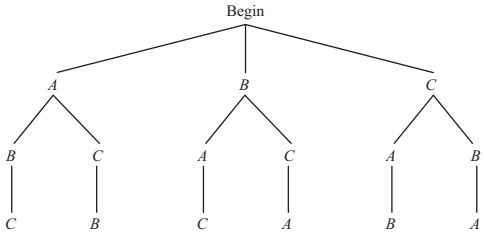
36. (1) Show S_n is true for $n = 1$: $S_1 = \frac{1(1+1)[2(1)+1]}{6} = 1$✓

(2) Assume S_k is true: $1 + 4 + 9 + \cdots + k^2 = \frac{k(k+1)(2k+1)}{6}$

Use it to show the truth of S_{k+1}:

$$1 + 4 + 9 + \cdots + k^2 + (k+1)^2 = \frac{(k+1)(k+1+1)[2(k+1)+1]}{6}$$

left hand side: $1 + 4 + 9 + \cdots + k^2 + (k+1)^2$



$$= \frac{k(k+1)(2k+1)}{6} + \frac{6(k+1)^2}{6} = \frac{(k+1)[(2k^2+k+6k+6]}{6}$$
$$= \frac{(k+1)(2k^2+7k+6)}{6} = \frac{(k+1)(k+2)(2k+3)}{6}$$

37. (1) Show P_n is true for $n = 1$: P_1: $4^1 \geq 3(1) + 1$✓
(2) Assume P_k is true: $4^k \geq 3k + 1$
Use it to show the truth of P_{k+1}:
$4^{k+1} \geq 3(k+1) + 1 = 3k + 4$
left hand side: $4^{k+1} = 4(4^k)$
$\geq 4(3k+1) = 12k + 4$
Since k is a positive integer, $12k + 4 \geq 3k + 4$ showing $4^{k+1} \geq 3k + 4$

38. (1) Show P_n is true for $n = 1$: P_1: $6 \cdot 7^{1-1} \le 7^1 - 1$✓
(2) Assume P_k is true: $6 \cdot 7^{k-1} \le 7^k - 1$
Use it to show the truth of P_{k+1}:
$6 \cdot 7^k \le 7^{k+1} - 1$
left hand side: $6 \cdot 7^k = 7 \cdot 6 \cdot 7^{k-1}$
$\le 7 \cdot 7^k - 1$
$\le 7^{k+1} - 7$
Since k is a positive integer, $7^{k+1} - 7 \le 7^{k+1} - 1$.

39. (1) Show P_n is true for $n = 1$: P_1: $3^1 - 1 = 2$ or $2(1)$✓
(2) Assume P_k is true: $3^k - 1 = 2p$ or $3^k = 2p + 1$ for $p \in \mathbb{Z}$
Use it to show the truth of P_{k+1}:
$3^{k+1} - 1 = 2q$ for $q \in \mathbb{Z}$
left hand side: $3^{k+1} - 1 = 3 \cdot 3^k - 1$
$= 3 \cdot (2p + 1) - 1$
$= 3 \cdot 2p + 3 - 1$
$= 3 \cdot 2p + 2$
$= 2(3p + 1)$
$= 2q$ is divisible by 2

7. \$6756.57 **8.** \$22,185.27
9. $a_k = 5k - 3, a_{k+1} = 5(k + 1) - 3$,

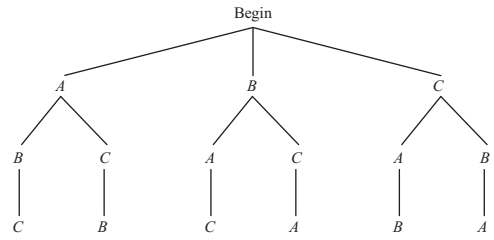
$S_k = \dfrac{5k^2 - k}{2}, S_{k+1} = \dfrac{5(k+1)^2 - (k+1)}{2}$;

For $n = 1$: $S_1 = \dfrac{5(1)^2 - 1}{2} = 2$✓

Assume: $S_k = \dfrac{5k^2 - k}{2}$ is true,

Prove: $\dfrac{5k^2 - k}{2} + 5(k+1) - 3 = \dfrac{5(k+1)^2 - (k+1)}{2}$

$\dfrac{5k^2 - k}{2} + \dfrac{10(k+1) - 6}{2} = \dfrac{(k+1)[5(k+1) - 1]}{2}$



$\dfrac{5k^2 + 9k + 4}{2} = \dfrac{(k+1)(5k+4)}{2}$

$\dfrac{(5k+4)(k+1)}{2} = \dfrac{(5k+4)(k+1)}{2}$✓

10. For $n = 1$: $2 \cdot 3^{1-1} \le 3^1 - 1$
$2(1) \le 2$✓
Assume: $2 \cdot 3^{k-1} \le 3^k - 1$
Prove: $2 \cdot 3^{(k+1)-1} \le 3^{k+1} - 1$

$2 \cdot 3^{(k+1)-1} = 2 \cdot 3^{(k-1)+1}$
$= 2 \cdot 3^{(k-1)} \cdot 3$
$\le (3^k - 1) \cdot 3$
$(3^k - 1) \cdot 3 = 3^{k+1} - 3 \le 3^{k+1} - 1$✓

Connections to Calculus Exercises, p. 1167

1. a. 

$$\sum LW = \sum_{i=1}^{4} f(i)(1) = 1\sum_{i=1}^{4} f(i)$$

$$1\sum_{i=1}^{4} f(i) = 1[f(1) + f(2) + f(3) + f(4)]$$
$$= 5 + 4 + 3 + 2$$
$$= 14 \text{ units}^2$$

b. $\displaystyle\sum LW = \sum_{i=1}^{8} f\left(\frac{1}{2}i\right)\left(\frac{1}{2}\right) = \frac{1}{2}\sum_{i=1}^{8} f\left(\frac{1}{2}i\right)$

$$\frac{1}{2}\sum_{i=1}^{8} f\left(\frac{1}{2}i\right) = \frac{1}{2}\left[f\left(\frac{1}{2}\right) + f(1) + f\left(\frac{3}{2}\right) + f(2) + f\left(\frac{5}{2}\right) + f(3) + f\left(\frac{7}{2}\right) + f(4)\right]$$
$$= \frac{1}{2}\left[\frac{11}{2} + 5 + \frac{9}{2} + 4 + \frac{7}{2} + 3 + \frac{5}{2} + 2\right]$$
$$= \frac{1}{2}[30] = 15 \text{ units}^2$$

True area is 16 units^2, more rectangles $\rightarrow$ better estimate.

3. a. Since the interval [0, 4] is 4 units wide and we're using 32 subintervals of equal length, the width of each interval (the width of each rectangle) will be $\frac{4}{32} = \frac{1}{8}$. The length of each rectangle is determined by a point of the graph of $f(x) = -x + 6$, so the length of the first rectangle is $f(\frac{1}{8})$, the second length is $f(\frac{2}{8})$, the third is $f(\frac{3}{8})$, and so on up to the 32nd rectangle. Since $A = LW$, we multiply each length $f(\frac{1}{8}i)$ by width $\frac{1}{8}$ and sum the areas of all such rectangles. Using i for a counter, this can be written as $A = \displaystyle\sum_{i=1}^{32} LW = \sum_{i=1}^{32} f\left(\frac{1}{8}i\right)\left(\frac{1}{8}\right)$. Since all lengths are multiplied by $\frac{1}{8}$ (the counter i does not affect the constant $\frac{1}{8}$), we can factor out this term and evaluate $f(x) = -x + 6$ at $x = \frac{1}{8}i$. The result is $\frac{1}{8}\displaystyle\sum_{i=1}^{32}\left(-\frac{1}{8}i + 6\right)$.

b.
$$\frac{1}{8}\sum_{i=1}^{32}\left(-\frac{1}{8}i + 6\right) = \frac{1}{8}\left[\sum_{i=1}^{32}\left(-\frac{1}{8}i\right) + \sum_{i=1}^{32} 6\right]$$
$$= \frac{1}{8}\left[-\frac{1}{8}\sum_{i=1}^{32} i + \sum_{i=1}^{32} 6\right]$$
$$= \frac{1}{8}\left[-\frac{1}{8}\left(\frac{32^2 + 32}{2}\right) + 6(32)\right]$$
$$= -\frac{1}{64}\left(\frac{1056}{2}\right) + 24$$
$$= -8.25 + 24 = 15.75$$

For $n = 32$ the approximate area under the graph is 15.75 units^2, even closer to the known area of 16 units^2.

CHAPTER 12

Exercises 12.1, pp. 1177–1180

1. infinity **3.** left-hand; right-hand; greater **5.** Answers will vary.

7. $\lim_{n\to\infty} V_n = \frac{4}{3}\pi r^3$ **9.** $\lim_{t\to-\infty} e^{f(t)} = 0$ **11.** $\lim_{x\to\infty} \cos\left(\frac{1}{x}\right) = 1$

13. 500 sides **15.** 425 sides **17.** $\lim_{t\to 5} s_t = 5r$

19. $\lim_{x\to a} \tan^{-1}[g(x)] = \frac{\pi}{3}$ **21.** $\lim_{x\to -3} \dfrac{x + 3}{x^2 - 9} = -\dfrac{1}{6}$

23. As x approaches π, $p(x)$ approaches -2: $\lim_{x\to\pi} p(x) = -2$

25. As x approaches 2, $v(x)$ approaches $\frac{1}{4}$: $\lim_{x\to 2} v(x) = \frac{1}{4}$

27. As x approaches 0, $s(x)$ approaches 0: $\lim_{x\to 0} s(x) = 0$

29. $R(x) = \begin{cases} \dfrac{2x^2 - 7x + 6}{\sin(x - 2)} & x \neq 2 \\ 1 & x = 2 \end{cases}$

31. As x approaches 2, $f(x)$ approaches $\frac{1}{2}$: $\lim_{x\to 2} f(x) = \frac{1}{2}$

33. As x approaches 1, $g(x)$ approaches 4: $\lim_{x\to 1} g(x) = 4$

35. As x approaches 1, $f(x)$ approaches 0: $\lim_{x\to 1} f(x) = 0$

37. 27 **39.** 24 **41.** 1

&= \frac{6}{n}\left[-\frac{1}{2}\sum_{i=1}^{n}\left(\frac{6}{n}i\right)^2 + 4\sum_{i=1}^{n}\left(\frac{6}{n}i\right)\right] && \text{distribute summation} \\
&= \frac{6}{n}\left[-\frac{1}{2}\sum_{i=1}^{n}\frac{36}{n^2}i^2 + 4\sum_{i=1}^{n}\frac{6}{n}i\right] && \text{simplify} \\
&= \frac{6}{n}\left[-\frac{36}{2n^2}\sum_{i=1}^{n}i^2 + \frac{24}{n}\sum_{i=1}^{n}i\right] && \text{factor } \frac{36}{n^2} \text{ and } \frac{6}{n} \\
&= \frac{6}{n}\left[-\frac{18}{n^2}\left(\frac{2n^3+3n^2+n}{6}\right) + \frac{24}{n}\left(\frac{n^2+n}{2}\right)\right] && \text{summation formulas} \\
&= -\frac{108}{n^3}\left(\frac{2n^3+3n^2+n}{6}\right) + \frac{144}{n^2}\left(\frac{n^2+n}{2}\right) && \text{distribute } \frac{6}{n} \\
&= -\frac{108}{6}\left(\frac{2n^3+3n^2+n}{n^3}\right) + \frac{144}{2}\left(\frac{n^2+n}{n^2}\right) && \text{rewrite denominators} \\
&= -18\left(2 + \frac{3}{n} + \frac{1}{n^2}\right) + 72\left(1 + \frac{1}{n}\right) && \text{decompose rational expression}
\end{aligned}$$

As $n \to \infty$, $\frac{3}{n}, \frac{1}{n^2}, \frac{1}{n} \to 0$, and the area is $-(18)(2) + 72 = 36$ units^2.

45. $x \approx 29.87$ **47.** $x = 5, \pm i\sqrt{3}$

Making Connections, p. 1215

1. d **3.** e **5.** g **7.** f **9.** b **11.** c **13.** a **15.** e

Summary and Concept Review, pp. 1216–1218

1. a. -3 **b.** 5 **c.** $\left(\underset{\text{LH}\neq\text{RH}}{\text{dne}}\right)$ **2.** 2 **3.** 1 **4.** $\left(\underset{\text{LH}\neq\text{RH}}{\text{dne}}\right)$

5. -38 **6.** $\frac{2}{3}$ **7.** $-\frac{1}{32}$ **8.** $\frac{1}{2}$ **9. a.** $x = -3$ **b.** $x = -2, -1, 3, 4$

c. $x = 1, 2$ **10.** 3 **11.** -1 **12.** 2 **13.** $\left(\underset{-\infty}{\text{dne}}\right)$ **14.** $\left(\underset{\text{LH}\neq\text{RH}}{\text{dne}}\right)$

15. -2 **16.** $f'(x) = 2x + 5$ **17.** $g'(x) = \dfrac{1}{\sqrt{2x-1}}$

18. $v'(x) = \dfrac{-1}{(x+3)^2}$ **19.** at $x = 4$, $m_{\tan} = -5$ **20.** 9 units^2

Practice Test, pp. 1218–1219

1. The limit of $f(x)$ as x approaches 5 is 10.

2. $f(x)$; L; sufficiently; c

3. False, a limit can exist even if c is not in the domain.

4. False, a limit can fail to exist even if a function is defined at c.

5. As the domain of g is $x \geq 1$, the limit in **b.** exists and the limit in **a.** does not. $\lim\limits_{x\to 1^+}(\sqrt{x-1}+2) = 2$.

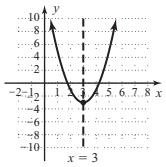
6. a. II **b.** I **c.** IV **d.** III **7. a.** 2 **b.** $\left(\underset{-\infty}{\text{dne}}\right)$ **8. a.** 1 **b.** 0

9. a. 3 **b.** 12 **10. a.** 4 **b.** undefined, $g(3) = 0$ **11. a.** 4 **b.** -4

12. a. 2 **b.** 9 **13. a.** 0 **b.** $\left(\underset{\text{LH}\neq\text{RH}}{\text{dne}}\right)$ **c.** $\frac{1}{3}$ **d.** 1

14. a. $\left(\underset{\text{LH}\neq\text{RH}}{\text{dne}}\right)$ **b.** $\left(\underset{\not\in}{\text{dne}}\right)$ **c.** $\left(\underset{-\infty}{\text{dne}}\right)$ **d.** 3 is not in the domain

15. 3 **16.** $\frac{3}{2}$ **17.** $\frac{1}{10}$ **18.** 1

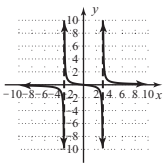


19. a. $d'(t) = -32t + 224$ **b.** $d'(2) = 160$, the debris is rising at a velocity of 160 ft/sec; $d'(6) = 32$, the upward velocity of the debris has slowed to 32 ft/sec; $d'(7) = 0$, the debris has reached its maximum height (velocity is 0 ft/sec); $d'(11) = -128$, the velocity of the debris is now in the downward direction ($v < 0$) at 128 ft/sec.

20. a. $\lim\limits_{n\to\infty}\sum\limits_{i=1}^{n} LW = \lim\limits_{n\to\infty}\sum\limits_{i=1}^{n} f\left(\frac{6}{n}i\right)\frac{6}{n} = \lim\limits_{n\to\infty}\frac{6}{n}\sum\limits_{i=1}^{n}\left[225 - \left(\frac{6}{n}i\right)^2\right]$

b. 1278 ft-lb

Cumulative Review Chapters 1–12, pp. 1220–1221



1.

3. $\frac{2}{3}\ln x + \frac{1}{2}\ln(x^2+3) - 4\ln(2x+1)$

5. $\sin\theta = -\frac{15}{17}, \cos\theta = \frac{8}{17}, \tan\theta = -\frac{15}{8}$

7.

9. a. $-\frac{1}{2}, \frac{1}{2}$ **b.** $\left(\underset{\text{LH}\neq\text{RH}}{\text{dne}}\right)$ **11.** $\alpha = \frac{\pi}{6} + 1, \frac{7\pi}{6} + 1$

13. The plane would be on a heading of 16.7°, traveling 297.5 mph.

15. $x = \dfrac{\ln 9.36 + 1}{2}, x \approx 1.618$ **17.** -3

19. $1 + \dfrac{-2}{x+2} + \dfrac{2}{x-1}$ **21.** $\dfrac{(x-1)^2}{25} + \dfrac{(y-1)^2}{9} = 1$

23. a. 1 **b.** 0 **c.** -3 **d.** 5 not in domain, limit does not exit

25. $(5)(4)(9)(8)(7) = 10{,}080$ PINs **27.** $(w, x, y, z) = (1, -2, 3, -4)$

29. $\left(-\infty, \dfrac{-4}{3}\right) \cup (2, \infty)$

Exercises A.6, pp. A-75–A-79

1. even **3.** $(16^{\frac{1}{4}})^3$ **5.** Answers will vary. **7.** **a.** $|9|=9$ **b.** $|-10|=10$
9. **a.** $7|p|$ **b.** $|x-3|$ **c.** $9m^2$ **d.** $|x-3|$ **11.** **a.** 4 **b.** $-6x$ **c.** $6z^4$
d. $\frac{v}{-2}$ **13.** **a.** 2 **b.** not a real number **c.** $3x^2$ **d.** $-3x$ **e.** $k-3$
f. $|h+2|$ **15.** **a.** -5 **b.** $-3|n^3|$ **c.** not a real number **d.** $\frac{7|v^5|}{6}$
17. **a.** 4 **b.** $\frac{64}{125}$ **c.** $\frac{125}{8}$ **d.** $\frac{9p^4}{4q^2}$ **19.** **a.** -1728
b. not a real number **c.** $\frac{1}{9}$ **d.** $\frac{-256}{81x^4}$ **21.** **a.** $\frac{32n^{10}}{p^2}$ **b.** $\frac{1}{2y^{\frac{1}{4}}}$
23. **a.** $3m\sqrt{2}$ **b.** $10pq^2\sqrt[3]{q}$ **c.** $\frac{3}{2}mn\sqrt[3]{n^2}$ **d.** $4pq^3\sqrt{2p}$
e. $-3+\sqrt{7}$ **f.** $\frac{9}{2}-\sqrt{2}$ **25.** **a.** $15a^2$ **b.** $-4b\sqrt{b}$ **c.** $\frac{x^4\sqrt{y}}{3}$
d. $3u^2v\sqrt[3]{v}$ **27.** **a.** $2m^2$ **b.** $3n$ **c.** $\frac{3\sqrt{5}}{4x}$ **d.** $\frac{18\sqrt[3]{3}}{z^3}$
29. **a.** $2x^2y^3$ **b.** $x^2\sqrt[4]{x}$ **c.** $\sqrt[12]{b}$ **d.** $\frac{1}{\sqrt[6]{6}}=\frac{\sqrt[6]{6^5}}{6}$ **e.** $b^{\frac{3}{4}}$
31. **a.** $9\sqrt{2}$ **b.** $14\sqrt{3}$ **c.** $16\sqrt{2m}$ **d.** $-5\sqrt{7p}$
33. **a.** $-x\sqrt[3]{2x}$ **b.** $2-\sqrt{3x}+3\sqrt{5}$
c. $6x\sqrt{2x}+5\sqrt{2}-\sqrt{7x}+3\sqrt{3}$ **35.** **a.** 98 **b.** $\sqrt{15}+\sqrt{21}$
c. n^2-5 **d.** $39-12\sqrt{3}$
37. **a.** -19 **b.** $\sqrt{10}+\sqrt{65}-2\sqrt{7}-\sqrt{182}$
c. $12\sqrt{5}+2\sqrt{14}+36\sqrt{15}+6\sqrt{42}$
39. Verified **41.** Verified **43.** **a.** $\frac{\sqrt{3}}{2}$ **b.** $\frac{2\sqrt{15x}}{9x^2}$ **c.** $\frac{3\sqrt{6b}}{10b}$
d. $\frac{\sqrt[3]{2p^2}}{2p}$ **e.** $\frac{5\sqrt[3]{a^2}}{a}$ **45.** **a.** $-12+4\sqrt{11}$; 1.27 **b.** $\frac{6\sqrt{x}+6\sqrt{2}}{x-2}$
47. **a.** $\sqrt{30}-2\sqrt{5}-3\sqrt{3}+3\sqrt{2}$; 0.05
b. $\frac{7+7\sqrt{2}+\sqrt{6}+2\sqrt{3}}{-3}$; -7.60 **49.** **a.** $x=\frac{14}{3}$
b. $x=8, x=1$ is extraneous **51.** **a.** $m=3$ **b.** $x=5$ **c.** $m=-64$
d. $x=-16$ **53.** **a.** $x=25$ **b.** $x=7$; $x=-2$ is extraneous
c. $x=2, x=18$ **d.** $x=6$; $x=0$ is extraneous **55.** **a.** $x=-32$
b. $x=81$ **57.** **a.** $x=-32, x=22$ **b.** $x=-30, x=34$
59. $x=-27, x=125$ **61.** 8.33 ft **63.** **a.** $8\sqrt{10}\,m$ **b.** about 25.3 m
65. **a.** 365.02 days **b.** 688.69 days **c.** 87.91 days **67.** **a.** 36 mph
b. 46.5 mph **69.** $12\pi\sqrt{34}\approx 219.82\text{ m}^2$ **71.** **a.** 36 million mi
b. 67 million mi **c.** 93 million mi **d.** 142 million mi **e.** 484 million mi
f. 887 million mi **73.** **a.** $(x+\sqrt{5})(x-\sqrt{5})$ **b.** $(n+\sqrt{19})(n-\sqrt{19})$
75. **a.** $13\sqrt{3x}+39\sqrt{x}$ **b.** Answers will vary. **77.** $\frac{3\sqrt{2}}{2}$
79. $x\in[1,2)\cup(2,\infty)$

Practice Test, pp. A-82–A-83

1. **a.** False; parentheses first **b.** False; undefined **c.** True
d. False; $-2x+6$ **2.** **a.** 11 **b.** -5 **c.** not a real number **d.** 20
3. **a.** $\frac{9}{8}$ **b.** $\frac{-7}{6}$ **c.** 0.5 **d.** -4.6 **4.** **a.** $\frac{28}{3}$ **b.** 0.9 **c.** 4 **d.** -7
5. ≈ 4439.28 **6.** **a.** 0 **b.** undefined **7.** **a.** 3; -2, 6, 5
b. 2; $\frac{1}{3}$, 1 **8.** **a.** -13 **b.** ≈ 7.29 **9.** **a.** $x^3-(2x-9)$
b. $2n-3\left(\frac{n}{2}\right)^2$ **10.** **a.** Let r represent Earth's radius. Then $11r-119$ represents Jupiter's radius. **b.** Let e represent this year's earnings. Then $4e+1.2$ million represents last year's earnings. **11.** **a.** $9v^2+3v-7$
b. $-7b+8$ **c.** x^2+6x **12.** **a.** $(3x+4)(3x-4)$ **b.** $v(2v-3)^2$
c. $(x+5)(x+3)(x-3)$ **13.** **a.** $5b^3$ **b.** $4a^{12}b^{12}$ **c.** $\frac{m^6}{8n^3}$ **d.** $\frac{25}{4}p^2q^2$
14. **a.** $-4ab$ **b.** $6.4\times 10^{-2}=0.064$ **c.** $\frac{a^{12}}{b^4c^8}$ **d.** -6
15. **a.** $9x^4-25y^2$ **b.** $4a^2+12ab+9b^2$
16. **a.** $7a^4-5a^3+8a^2-3a-18$ **b.** $-7x^4+4x^2+5x$ **17.** **a.** -1
b. $\frac{2+n}{2-n}$ **c.** $x-3$ **d.** $\frac{x-5}{3x-2}$ **e.** $\frac{x-5}{3x+1}$ **f.** $\frac{3(m+7)}{5(m+4)(m-3)}$
18. **a.** $|x+11|$ **b.** $\frac{-2}{3v}$ **c.** $\frac{64}{125}$ **d.** $-\frac{1}{2}+\frac{\sqrt{2}}{2}$ **e.** $11\sqrt{10}$
f. x^2-5 **g.** $\frac{\sqrt{10x}}{5x}$ **h.** $2(\sqrt{6}+\sqrt{2})$ **19.** $-0.5x^2+10x+1200$;
a. 10 decreases of 0.50 or \$5.00 **b.** Maximum revenue is \$1250.
20. 58 cm **21.** **a.** $b=6$ **b.** $n=4$ **c.** $m=-1$ **d.** $x=\frac{1}{6}$
e. $\{\}$ (contradiction) **f.** $g=10$
22. $3+\frac{1}{4}(n+12)=16$, the number is 40
23. **a.** $x=-2, x=2, x=7$ **b.** $r=0, r=-1, r=4$
c. $g=-3, g=-1, g=1, g=3$ **24.** **a.** $x=-\frac{1}{2}$ **b.** $h=-\frac{5}{3}, h=2$
c. $n=13$ (-2 is extraneous) **25.** **a.** $x=-3, x=3$
b. $x=-4, x=5$ **c.** $x=-1$ (7 is extraneous)

Index

Absolute maximum, 112
Absolute value
  of complex numbers, 213, 334
  explanation of, 173, A–80
  on graphing calculator, 137, 201
  limits and, 201
  multiplicative property of, 138
Absolute value equations
  distance and, 147
  explanation of, 136, 191
  on graphing calculator, 137
  graphs to solve, 142
  method to solve, 136–138
Absolute value functions
  characteristics of, 141, 163
  explanation of, 120, 191
Absolute value inequalities
  applications of, 142, 143
  distance and, 147
  explanation of, 191
  on graphing calculator, 142
  graphs to solve, 142
  limits and, 201
  methods to solve, 139
  solutions to "greater than," 140–141
  solutions to "less than," 139–140
Accumulated value, 472, 473
Acute angles, 510, 596
Addition
  associative property of, A–4, A–80
  commutative property of, A–4, A–80
  of complex numbers, 206–207
  distributive property of multiplication over, A–5
  of matrices, 907–908
  of ordinates, 273
  of polynomials, A–16 – A–17
  of radical expressions, A–69
  of rational expressions, A–55 – A–57
Addition method. *See* Elimination method
Additive identity, A–5, A–80
Additive inverse, A–5, A–80
Additive property of equality, A–24
Additive property of inequality, A–26 – A–27
Algebra
  to evaluate limits, 1193–1195
  of functions, 262–268, 270, 295
  fundamental theorem of, 320–323, 397
  of matrices, 905–913, 951
  of vectors, 776–778
  to verify identities, 655–656
Algebraic equations. *See* Equations
Algebraic expressions
  evaluation of, A–3 – A–4
  explanation of, A–1, A–24
  method to simplify, A–6
  translating English phrases into, A–2
Algebraic fractions. *See* Rational expressions
Algebraic methods
  to find inverse functions, 412–415
  trigonometric equations and, 721–723
Algebraic terms, A–1, A–2
Algebraic vectors, 778
Algorithms, division, 309
Allometric studies, 157
Alpha (α), 510
Alternating current (AC), 213, 807–809
Ambiguous case
  analysis of, 749
  applications of, 752–753
  explanation of, 748–749
  on graphing calculator, 750
  method to avoid, 761
  method to solve, 751–752
  scaled drawings and, 750–751
Amortization, 472–475, 480
Amplitude
  explanation of, 552
  of sine and cosine functions, 551–552
  variable, 645–646
Analytical geometry
  distance formula and, 962
  explanation of, 962, 1064
  midpoint formula and, 962
Analytic parabola, 997–1002, 1066
Angle-angle-side (AAS) triangles, 747, 764
Angle measurement
  degree, 510–512
  degree-radian conversions and, 517–520
  on graphing calculator, 515, 518–519
  radian, 514–517
Angle reduction formulas, 679
Angles
  acute, 510
  central, 515, 530
  complementary, 510, 511
  coterminal, 515, 617, 618
  of elevation/depression, 601–604
  explanation of, 510, 634
  between intersecting lines, 620
  negative, 514
  obtuse, 510
  positive, 514
  quadrantal, 515, 613
  reference, 531–532, 614–616, 635, 647
  right, 510
  standard, 646–647, 1040
  straight, 510
  supplementary, 510, 511
Angle-side-angle (ASA) triangles, 747, 764
Angular velocity, 520–521
Annuities, 472–475
Annuity formula, 473
Aphelion, 1044
Applications
  of absolute value, 142, 143
  of algebra of functions, 267–268
  of analytic parabola, 1002
  of annuities and amortization, 472–475
  of arithmetic sequence, 1095
  of basic geometry, A–31 – A–34
  of binomial theorem, 1150–1151
  of combinations, 1126–1127
  of completing the square, 18
  of complex numbers, 213, 807–809
  of composition of functions, 284–285
  of conics in polar form, 1044–1046
  of difference quotient, 283–286
  of direct variation, 178–180
  of exponential functions, 422, 428–429
  of exponential growth and decay, 475–477
  of foci, 978–979, 992–993
  of functions, 105
  of geometric series, 1107
  of identities, 686–688
  of inequalities, 390–391, A–31
  of interest, 469–472, 499
  of inverse functions, 417
  of inverse trigonometric functions, 704–705
  of inverse variation, 181
  of joint variation, 182
  of law of cosines, 762–763
  of law of sines, 752–753
  of limits, 1203–1212, 1217–1218
  of linear equations, 27–28, 56–58, A–30 – A–31
  of linear programming, 872–874
  of logarithms, 438–442, 452–453
  of matrices, 900–901, 938–939
  of parametric equations, 1057–1059, 1063
  of piecewise-defined functions, 170–171
  of polynomials, 347–348
  of power functions, 155–158
  problem-solving guide for, 71
  of Pythagorean theorem, 9, 598, 759, 760, 778, A–75
  of quadratic equations, 228–229
  of quadratic functions, 239–243, 251–253
  of quadratic inequalities, 229–230
  of rate of change, 255–256
  of rational functions, 155–158, 365, 377–380
  of regression, 86–87, 486–487, 626–627
  of remainder theorem, 316, 331
  of right triangles, 601–604
  of sequences, 1084–1085, 1095
  of sinking funds, 474
  of slope, 20
  of summation, 1119–1120
  of system of linear inequalities, 869–870
  of systems of linear equations, 844–848, 860–861
  of systems of nonlinear equations, 1013–1014
  of trigonometric equations, 721, 726–727
  of trigonometric functions, 579–580, 585–586, 588–589, 617–618
  of vectors, 779–782, 790–791
Approximations
  limits vs., 1170–1171
  real zeroes, 355
Archimedes, 1169
Arc length, 516, 1004
Arc length formula, 516, 519–520
Area. *See also* Surface area
  of circle, A–21, A–32
  of circular sector, 516–517, 731
  under curve, 304–305, 1210–1212, 1219–1220
  of ellipse, 981
  explanation of, A–31
  of inscribed polygon, 1170–1171
  of Norman window, 942
  of parallelogram, 620, A–86 – A–87
  of polygon, 558, 660, 1170–1171
  of rectangle, 876, 915, A–32
  of right parabolic segment, 1004
  of square, A–32
  of trapezoid, A–32
  of triangle, 381, 668, 763–766, 823, 876, 904, 936
  of vertical parabolic segment, 1017
Area functions, 505–506
Arithmetic sequences
  applications of, 1095
  explanation of, 32, 1089, 1155
  finding *n*th partial sum of, 1093–1094
  finding *n*th term of, 32, 1090–1093
  graphs of, 1092
  identifying and finding common difference in, 1089–1090
  quadratic functions and, 1098
Associated minor matrices, 923, 924
Associations
  linear/nonlinear, 80–81, 98
  positive/negative, 79–80, 98
Associative property of addition, A–4, A–80
Associative property of multiplication, A–4, A–80
Asymptotes
  of central hyperbola, A–94
  on graphing calculator, 156, 361
  to graph rational functions, 151–152
  horizontal, 150, 359–361
  of hyperbola, 986
  nonlinear, 374, 375
  oblique, 374–376
  vertical, 151, 356–359, 363

Asymptotic behavior, 150, 151
Asymptotic discontinuity, 1192
Augmented matrices
  matrix inverses and, 955–956
  of system of equations, 893–895
  triangularizing, 895–897
Average distance, 9
Average rate of change
  applications of, 255–256
  calculation of, 253–254
  difference quotient and, 281–283
  explanation of, 253, 295
  projectile velocity and, 255
Average rate of change formula, 254–255
Average value of function, 552, 560
Axes
  conjugate, 985
  rotation of, 1037–1039, 1041
  transverse, 985
  vertical, 853
Axis of symmetry, 121

Back-substitution, A–25

Circles
  area of, A–21, A–32
  center of, 10, 12
  central, 10, 515, 635, 972
  circumference of, 90, 516–517
  circumscribed, 17, 756, 963
  equations of, 8–13, 94, 527, 969, 970, 1065
  explanation of, 10, 963, A–95
  on graphing calculator, 13–14, 528, 530, 969
  graphs of, 9–13, 670, 969
  involute of, 621
  perimeter of, A–32
  radius of, 10, 12, 756
  standard form of equation of, 10, 11, 970
  symmetry and, 528, 529, 531–532
  unit, 527–534, 635–636
Circumference, 90, 516–517
Circumscribed circle, 17, 756, 963
Closed form solution, 219
Coefficients
  binomial, 1147–1148
  explanation of, A–1
  frictional, A–25
  polynomial equations with complex, 234
  tangent and cotangent functions and, 568–569
Cofactors, A–92
Cofunctions, 600–601
Coincident dependence, 854, 860
Coincident lines, 843
Collinear points, 936–937
Combinations
  applications of, 1126–1127
  explanation of, 1125–1126
  on graphing calculator, 1126
Combined variation, 182
Common binomial factors, A–39
Common difference *d,* of arithmetic sequence, 1089
Common logarithms
  explanation of, 434
  method to find, 435–436
Common ratio *r,* 1098–1099
Commutative property of addition, A–4, A–80
Commutative property of multiplication, A–4, A–80
Complementary angles, 510, 511
Complements
  of event, 1134–1136
  to write equivalent expressions, 600–601
Completely factored form, A–40
Completing the square
  applications of, 18
  to graph ellipse, 976–977
  to graph horizontal parabola, 999
  to graph hyperbola, 988–989
  to graph quadratic functions, 235–237
  process of, 1006–1007
  to solve quadratic equations, 219–221, 235
Complex conjugates
  explanation of, 208, 332
  product of, 208
  use of, 210
Complex conjugates theorem proof, A–84 – A–85
Complex numbers
  absolute value of, 213, 334
  addition and subtraction of, 206–207
  applications of, 213, 807–809
  converted from trigonometric form to rectangular form, 804–805
  cube of, 811
  De Movie's theorem to compute power of, 813–814
  division of, 210, 806–807
  explanation of, 205, 292–293
  geometric connections for product and quotients of, 805–806
  on graphing calculator, 207–210, 804, 806
  graphs of, 802
  historical background of, 204
  multiplication of, 207–209, 806–807
  *n*th roots of, 815–818
  principal square root of, 334
  standard form of, 205–206
  in trigonometric form, 803–804, 806–807, 825
Complex plane, 802, 811
Complex polynomial functions, 320–321
Complex roots, substitution to check, 208
Complex zeroes, 401–402
Component form, 773
Composite functions, 278–279
Composition of functions
  applications of, 284–286
  decomposition and, 278–279
  explanation of, 274–286, 296
  on graphing calculator, 277, 278
  method to find, 276–278
  notation for, 275
  numerical and graphical view of, 279–281
  transformations via, 288
Compound annual growth, 288
Compound fractions, 663, A–57–A–58
Compound inequalities
  explanation of, A–28
  method to solve, A–28 – A–30
Compound interest, 470–471
Compound interest formula, 471
Compressions, vertical, 126–127, 568, 569
Conditional equations, A–26
Cones
  characteristics of, 964
  volume of, 730, 876
Conic equations. *See also specific conics*
  ellipse, 965–966, 970–975, 1065, A–93
  hyperbola, 984–987, 995, 1065, A–93 – A–94
  in polar form, 1042–1044
Conic sections. *See also* Circles; Ellipses; Hyperbolas; Parabolas
  applications of, 1044–1046
  characteristics of, 964–966
  eccentricity of, 1043
  equations of, 1038, 1042–1044
  explanation of, 964, 1067–1068
  graphs of, 964
  identified by their equations, 990
  in polar form, 1042–1046
  rotated, 1035–1040
  use of discriminant to identify, 1040–1041
Conjugate axis, 985
Conjugates
  binomial, A–18 – A–19
  complex, 208, 210, 332
  simplifying radical expressions using, A–71
  verifying identities by multiplying, 664
Consecutive integers, 72
Consistent system, 844–845
Constant functions, 51
Constant of variation, 177
Constraint inequalities, 872
Constraints, 870
Continuous functions
  explanation of, 163, 1191, 1192
  piecewise and, 167, 169
Continuous graphs, 5
Continuously compounded interest, 471–472
Contour interval, 525
Contradictions, A–26
Convenient values
  decomposition using, 882–885
  explanation of, 882
Convex, 871
Coordinate grid, 3
Coordinate plane, 610–616, 641
Corner point, 868
Correlation, 81–83
Correlation coefficient, 92, 98
Cosecant function
  application of, 589
  characteristics of, 563
  explanation of, 532
  graphs of, 561–562, 637
  inverse, 702–704
Cosine
  law of, 759–763, A–88
  origin of term for, 600
  table of values for, 549
Cosine function
  amplitude of, 551–552
  applications of, 585, 586
  characteristics of, 550
  explanation of, 532
  graphs of, 549–554, 636–637
  inverse, 698–699, 704
  period and coefficient *B* of, 552–554
Cost-based pricing, 846

Cotangent function
  characteristics of, 567
  explanation of, 532
  graphs of, 566–567, 637–638
  hyperbolic, 506
  inverse, 702, 703
  table of values for, 566
Coterminal angles, 515, 617, 618, 813
Counting techniques
  combinations and, 1125–1127
  distinguishable permutations and, 1123–1124
  fundamental principle of, 1122–1123
  key concepts on, 1156–1157
  by listing using tree diagram, 1120–1122
  nondistinguishable permutations and, 1125
Cramer's rule, 934–936, 954–955
Critical points
  explanation of, 622, 642
  sinusoidal models and, 622–626
Cube root function, 120
Cube roots, A–65. *See also* Radical expressions
Cubes
  binomial, 213
  of complex number, 811
  perfect, A–65
  sum or difference of two perfect, A–43 – A–44
  volume of, A–21
Cubic equations, 393, 819
Cubic functions, 568
Cubic units, A–33
Current, 808, 849
Curves
  area under, 304–305, 1210–1212, 1219–1220
  conic sections as family of, 965
  from cycloid family, 1055–1056
  families of polar, A–95
  intersections of polar, 1074–1075
  parametric, 1051–1054
Cycloids, 1055–1056
Cylinders
  surface area of, 76, 233, 271, 381, A–51
  volume of, 90, 730, A–51
Cylindrical vents, 1016

Dampening factor, 632
Decay rate, 475
Decay rate constant, 475
Decibel (dB), 438
Decimal degrees, 511–512
Decimal notation, A–14 – A–15
Decision variables, 872
Declarative statements, 1186–1187
Decomposition
  of composite functions, 278–279
  to evaluate telescoping sum, 886–888
  explanation of, A–1
  on graphing calculator, 884, 888
  partial fraction, 837, 879–888, 950, 958
  of rational expressions, 879
  using convenient values, 882–885
  using system of equations, 885–886
Decomposition template, 879–882
Decreasing functions, 110–111
Degenerate cases, 18, 973, 997
Degrees
  as angle measurement, 510–512
  conversion between radians and, 517–520
  decimal, 511–512
  of polynomials, A–15
Degrees-minutes-seconds (DMS) method, 511
Delta (Δ), 21
Delta/epsilon form, 201–202
Demographics, 422
De Moivre's theorem
  to check solutions to polynomial equations, 814–815
  explanation of, 813–814
  *n*th root theorem and, 815–818
  proof of, A–88
Denominator
  lowest common, A–55 – A–59
  rationalizing the, A–70 – A–71
Density, 307
Dependent systems
  of linear equations in three variables, 858–860
  of linear equations in two variables, 843–844
  matrices and, 899–900
Dependent variables, 2
Depreciation, 57, 58, 428
Depression, angle of, 601–604
Derivatives, 201
Descartes, René, 204
Descartes' rule of signs, 328–329, 355, 397
Determinant formula for area of parallelogram, A–86 – A–87
Determinants
  of column rotation, 925
  to find area of triangle, 936
  of general matrix, A–92
  geometry of, 959
  singular matrices and, 922–927
  to solve system of linear equations, 933–934, 952
Diagonal entries, of matrix, 893
Dichotomy paradox, 1160
Difference of two squares, A–19, A–42
Difference quotient
  applications of, 283–286
  explanation of, 281, 296
  limit of, 1204–1209
  polynomial functions and, 303
  radical functions and, 304
  rates of change and, 259, 281–283, 303–304
Directed line segments, 771
Directrix
  explanation of, 964, 965
  of hyperbola, 991
  of parabola, 1000–1001
Direct substitution, 1192–1193
Direct variation
  applications of, 178–180
  explanation of, 177–178, 193
Discontinuities
  asymptotic, 1192
  explanation of, 1191
  jump, 1192
  nonremovable, 1192
  removable, 169, 372–373, 399, 1192
Discontinuous functions, 168–169
Discriminant
  of cubic equations, 393, 819
  explanation of, 223
  identifying conics using, 1040–1041
  of quadratic formula, 223–224
Diseconomies of scale, 1013
Distance
  absolute value and, 147
  area under graph to determine, 305
  perpendicular, 963, 967
  between point and line, 963
  from point to plane, 863
  viewing, 256
Distance formula, 9–10, 668, 962, 1033, 1064
Distinguishable permutations, 1123–1124
Distributive property of multiplication over addition, A–5, A–38
Division
  of complex numbers, 210
  factor theorem and, 313–315
  on graphing calculator, 313
  long, 308–309
  of polynomials, 308–315, 327
  of rational expressions, A–55
  remainder theorem and, 312–313
  synthetic, 309–312, 396–397, A–89 – A–90
Division algorithm, 309
Divisor, 309, 311
Domain
  of exponential functions, 422
  of functions, 36–39, 42, 95, 191, 262–264
  implied, 38–39
  of logarithmic functions, 437–438
  of piecewise-defined functions, 164–165
  of power functions, 153–154
  of rational functions, 149, 191
  of relations, 2, 48–49
  restricting, 413–414
  solving quadratic inequality to determine, 227–228
  of trigonometric functions, 535
Dominant term, 339
Dot products
  angle between two vectors and, 792–793
  explanation of, 792, 824
  properties of, 793–794
Double-angle formula, 682
Double-angle identities
  explanation of, 680–681, 694, 734
  use of, 681, 682
Dynamic trigonometry, 610

e, 425, 426
Eccentricity
  application of, 1044–1045
  of conics, 1043
  on graphing calculator, 1070
Economies of scale, 1013
Electrical resistance, A–9
Elementary row operations, 895
Elements of set, 37
Elevation, angle of, 601–604
Elimination method
  explanation of, 841
  Gaussian, 895
  Gauss-Jordan, 897–898, A–91
  to solve system of linear equations in three variables, 855–858
  to solve system of linear equations in two variables, 841–843
  to solve system of nonlinear equations, 1010–1012
Ellipses
  applications of, 978–979
  area of, 981
  central, 972
  definition of, 974, 975
  equation of, 965–966, 970–975, 1065, A–93
  foci of, 974–978
  on graphing calculator, 977, 978, 1038
  graphs of, 971–974, 976–977
  horizontal, 971–972
  perimeter of, 981
  polar equation of, 1046
  polar form of, 1049
  with rational/irrational values of *a* and *b,* 1071
  standard form of equation of, 971–973, 976
  vertical, 972–973
Empty set, A–80
Encryption, 940–942
End-behavior
  to analyze rational inequalities, 389
  explanation of, 111, 338
  of polynomial graphs, 338–341
  of quadratic functions, 338
  of rational functions, 149, 150
Endpoint maximum, 112
Endpoints, 36
Entries, of matrix, 893
Equality
  additive property of, A–24
  of matrices, 905–906
  multiplicative property of, A–24
  power property of, A–71, A–73
  square root property of, 217–219
Equation form, relations in, 3, 94
Equations. *See also* Linear equations; System of linear equations in three variables; System of linear equations in two variables; System of nonlinear equations; *specific types of equations*
  absolute value, 136–138, 142, 191
  of circle, 8–13, 94, 527, 969, 970, 1065

Witch of Agnesi, 1061
Four-leaf rose, 1029
45-45-90 triangles, 513, 514, 595, 596
Fractional coefficients, A–25
Fractions
compound, 663, A–57 – A–58
partial, 879, 886–888 (*See also* Partial fraction decomposition)
Frequency, 584
Function notation, 39–41, 1112
Functions. *See also* Polynomial functions; Trigonometric functions; *specific types of functions*
absolute value, 120, 141, 163, 191
of acute angles, 596
algebra of, 262–268, 270, 295
area, 505–506
base, 300
ceiling, 171
composite, 278–279
composition of, 274–280, 284–285
constant, 51
continuous, 163, 167, 169, 1191, 1192
cube root, 121
cubic, 568
discontinuous, 168–169
domain of, 36–39, 42, 95, 262–264
equations of, 152, 238, 265, 269–270
evaluation of, 40–41, 275
even, 106–107
explanation of, 33–34, 95, 189
exponential, 422–429, 496–497
in exponential form, 152, 434
family of, 120–121
floor, 170–171
graphical and numerical views of operations on, 265–267
on graphing calculator, 41, 127, 129, 373
graphs of, 106–108, 127–130, 151–155, 189
growth, 424
hyperbolic cotangent, 506
identity, 51
intervals and increasing or decreasing, 110–111
intervals and positive or negative, 108–110
inverse, 411–415
inverse trigonometric, 695–705, 735–736
linear, 51–52, 1098
logarithmic, 434, 436–438, 497
logistic, 837
maximum and minimum value of, 112–113, 405–407
monotonic, 423
nonlinear, 253–254
objective, 871, 873–874
odd, 107, 108, 546
one-to-one, 410–411, 424, 496
parent, 120, 128
periodic, 545
piecewise-defined, 163–171, 192
power, 152–158, 191, 196, 426
products and quotients of, 263–265
projectile, 246
quadratic, 151, 215–216, 235–243, 251–253, 321, 1098
radical, 304, 405, 1198–1199
range of, 37–38, 42, 95
rational, 148–152, 191, 356–365, 398–399, 1197
reciprocal, 148–151, 1035
relations as, 33–34
root, 152
sand dune, 173
sinusoidal, 632
smooth, 163
square root, 120
step, 170–171
sums and differences of, 262–263
symmetry and, 106–108
toolbox, 120–126, 177–180, 190
transcendental, 433, 723
transformations to graph, 127–130, 235
vertical line test for, 35–36, 95
wrapping, 577–578
zeroes of, 108, 109
Fundamental identities. *See also* Identities
algebra to verify, 655–656
explanation of, 654–655, 662, 733
trigonometric functions and, 657–658
Fundamental principle of counting (FPC), 1122, 1136
Fundamental properties of logarithms
explanation of, 446
to solve equations, 447–449
Fundamental property of rational expressions, A–52 – A–53
Fundamental theorem of algebra, 320–323, 397

identities and contradictions as, A–26 – A–28
intercept-intercept form of, 61
intercept method to graph, 20, 50
methods to solve, 50–51, A–81, A–A–24 – A–25
in one variable, A–24
of parallel and perpendicular lines, 25–27, 54–55
in point-slope form, 55–56
properties of equality to solve, A–24 – A–25
in slope-intercept form, 51–55
slope of line and rates of change and, 20–23
standard form of, 100
in two variables, 19–20
Linear factorization theorem
explanation of, 321, 322, 397
proof of, A–85
Linear function models, 83–85, 98
Linear functions, 51–52, 1098. *See also* Functions
Linear inequalities. *See also* Inequalities; System of linear inequalities
explanation of, 865
on graphing calculator, 867, 868–869
intersection-of-graphs method to solve, 68–69, 74
method to solve, 866–867, A–26 – A–28, A–81
system of, 867–870
in two variables, 865–867
Linear programming
explanation of, 870, 949
solutions to problems in, 870–874
Linear regression
on graphing calculator, 298
line of best fit and, 85–87
Linear systems. *See* System of linear equations in three variables; System of linear equations in two variables
Linear velocity, 520–521
Line of best fit
explanation of, 85
linear regression and, 85–87
Lines
characteristics of, 101
coincident, 843
distance between points and, 963
equations of, 52–55, 729, 1049
horizontal, 23–24, 101
horizontal boundary, 37–38, 96
parallel, 25–26, 53–55, 101
perpendicular, 26–27, 53–55, 101
relationships between, 101
secant, 54, 97, 576
slope-intercept form and graph of, 52–53, 96
tangent, 103, 576, 1073–1074, 1204, 1206
vertical, 23–24, 101
vertical boundary, 36–37, 96
Line segments
directed, 771
midpoint of, 8–9
Lissajous figure, 1052
Literal equations, 69–70
Local maximum, 112
Logarithmic equations
explanation of, 499
forms of, 462
on graphing calculator, 459–463
methods to solve, 447, 457–460
solutions to system of, 1011
Logarithmic form, 434, 435, 449
Logarithmic functions
domain of, 437–438
explanation of, 434, 497
graphs of, 436–437
Logarithmic scales, 438, 439
Logarithms
applications of, 438–442, 452–453, 463
change-of-base formula and, 452
common, 434
explanation of, 497
fundamental properties of, 446–449
on graphing calculator, 435, 436, 438, 442, 447–450, 459–465
natural, 434
product, quotient, and power properties of, 449–451, A–86
properties of, 456, 457, 498, 505
uniqueness property of, 458–459
Logistic equations
explanation of, 463
on graphing calculator, 463, 464
investigation of, 502
method to solve, 463–464
regression models and, 485–486
use of, 890
Logistic functions, 837
Logistic growth, 464, 466, 485
Logistic growth model, 485
Long division, 308–309
Longitude, 519
Lower bound, 330
Lowest common denominator (LCD), A–55 – A–59

Magnitude
of vector, 774–775, 784
of velocity, 771
Malus's law, 691
Mapping notation, 2, 3
Market equilibrium, 847–848
Mathematical induction
applied to sums, 1112–1115
explanation of, 1156
general principle of, 1115–1116
Mathematical models, translating written or verbal information into, A–2
Matrices
addition and subtraction of, 907–908
algebra of, 905–913, 951
applications of, 900–901, 938–939, 952
associated minor, 923
augmented, 893–895, 955–956
coefficient, 893–894
of constants, 893–894
decomposing rational expressions using, 937
determinants of, 922–926, A–92
to encrypt messages, 940–942
entries of, 893
equality of, 905–906
explanation of, 893
on graphing calculator, 898–901, 908, 911–913, 919–923, 926–927, 938–941
identity, 917–919
inconsistent and dependent systems and, 899–901
inverse of, 919–921, 930
multiplication and, 908–913
reduced row-echelon form of, 897, 898, A–91
singular, 922–927
to solve systems, 895–898
square, 893, 895
Matrix equations, 921–922, 926–927, 951
Matrix inverses, 955–956
Maximum values
explanation of, 112
of functions, 112, 238–243
on graphing calculator, 112–113, 239, 241–243, 645, 646
method to locate, 405–407, 744
Midinterval points, 344
Midpoint formula, 9, 962, 1033, 1064
Midpoint of line segment, 8–9, 94
Minimum values
explanation of, 112
of functions, 112
on graphing calculator, 112–113, 378, 380, 645, 646
method to locate, 405–407, 744
Minors, 923–924. *See also* Associated minor matrices

Points
corner, 868
critical, 622–626, 642
distance between lines and, 963
quadrantal, 527
trigonometric ratios and, 610–614
on unit circle, 527–528
Point-slope form
explanation of, 55, 96
linear equations in, 55–56, 100
Point-wise defined relations, 2, 3, 94
Polar axis, 1019
Polar-axis symmetry, 1028
Polar coordinates
converting between rectangular coordinates and, 1021–1024
distance formula in, 1033

explanation of, 1018, 1067
expressing points in, 1020–1021
on graphing calculator, 1026, 1027, 1029–1031
midpoint formula in, 1033
plotting points using, 1018–1020
Polar coordinate system, 1019
Polar equations
explanation of, 1067
graphs of, 1024, 1027, 1029
of planetary orbit, 1045
symmetry for graphs of certain, 1028
systems of, 1074–1075
Polar form
applications of conics in, 1044–1046
conic equations in, 1042–1044
converted to rectangular form, 652
of ellipse, 1049
of equation of line, 1049
use of, 1018
Polar graphs
explanation of, 1067, A–95
instantaneous rates of change and, 1073–1074
r-value analysis and, 1024–1027
symmetry in, 1027–1031, 1035
Polar symmetry, 1028
Pole, 1019
Polygons
area of, 558, 660, 1170–1171
perimeter of, 575
Polynomial equations
with complex coefficients, 234
complex coefficients solve, 234
de Moivre's theorem to check solutions to, 814–815
explanation of, A–45
factoring to solve, A–47
Polynomial form, 988
Polynomial functions
applying difference quotient to, 303
complex, 320–321
dominant term of, 339
graphs of, 337–346, 398
zeroes of, 320–331, 397
Polynomial graphs
end-behavior of, 338–341
guidelines for, 345–346
identification of, 337–338
symmetry in, 345
turning points and, 337, 338
zeroes of multiplicity and, 341–344
Polynomial inequalities
on graphing calculator, 386, 387
interval tests to solve, 387–388
method to solve, 385–387, 400
push principle to solve, 402–403
Polynomial modeling, 347–348
Polynomials
addition and subtraction of, A–16 – A–17
applications of, 347–348
characteristic, 946
degree of, A–15
division of, 308–315, 327
explanation of, 422, A–15, A–81
families of, A–15
identifying and classifying, A–15 – A–16
linear factorization theorem and, 322–323
prime, A–41
as product of linear factors, 321
products of, A–17 – A–20
quadratic, A–40 – A–42
quartic, 351
rational zeroes of, 326–330
in standard form, A–16
types of, A–15
use of remainder theorem to evaluate, 312–313
Population density, 367
Position vectors, 772, 773
Positive angles, 514
Positive association, 79–80, 98
Positive functions, 108–109
Positive slope, 22
Power functions
domain of, 153–154
explanation of, 152, 191, 426
transformations of, 154–155
variation and, 196
Power property, product to, A–11
Power property of equality, A–71, A–73
Power property of exponents, A–10 – A–11
Power property of logarithms, 449–451, 498, A–86
Power reduction formula, 682–683
Power reduction identities, 682–683, 694
Pressure, A–9
Pressure wave, 585–586
Prime polynomials, A–41
Principal *p,* 469
Principal roots
explanation of, 711
inverse functions and, 712
trigonometric equations and, 711–713
Principal square roots, 204, 334
Probability
binomial, 1150–1152
elementary, 1132–1133
of events, 1133, 1134
explanation of, 1132, 1157
on graphing calculator, 1137–1139
of nonexclusive events, 1137–1139
properties of, 1134–1136
quick-counting and, 1136–1137
Problem solving. *See also* Applications; Applications index
guide to, 71
trigonometry and, 832–833
Product property of exponents, A–10 – A–11, A–14
Product property of logarithms, 449–451, 498, A–86
Product property of radicals, A–67
Products. *See also* Multiplication
of complex conjugates, 208
of complex numbers, 805–806
of functions, 263–264
of polynomials, A–17 – A–20

applications of, 255–256
average, 253–256, 281–283, 295
difference quotient and, 259, 281–283, 303–304
limits and instantaneous, 1204–1209, 1217–1218
nonlinear functions and, 253–254
notation for, 21, 177
slope as, 21–23, 54, 56
slope-intercept form and, 53
Rate of growth, 1, 837
Ratio identities, 654, 662, 663, 693, 694
Rational equations, A–58 – A–59
Rational exponents
explanation of, A–66
simplifying expressions with, A–67
solving equations with, A–73

Rational expressions
addition and substraction of, A–55 – A–57
decomposition of, 879
explanation of, 879, A–52, A–81
fundamental property of, A–52 – A–54
on graphing calculator, A–53, A–59
multiplication and division of, A–54 – A–55, A–59
simplifying compound fractions and, A–57 – A–58
Rational functions
application of, 155–158, 365, 377–380
end-behavior of, 149, 150
equation of, 152, 364
explanation of, 148, 191, 356, 398
on graphing calculator, 150, 358, 361, 365
graphs of, 151–152, 356–365, 372–376, 398–399
horizontal asymptotes of, 150, 359–361
limits at infinity for, 1197
multiplicities and, 358–359
with oblique or nonlinear asymptotes, 374–376
reciprocal function and, 148–149
removable discontinuities and, 169, 372–373
vertical asymptotes of, 356–359, 363
Rational inequalities
analysis to solve, 388–389
end-behavior to analyze,400, 389
on graphing calculator, 389, 390
interval test method to solve, 387–390, 400
Rationalizing the denominator, A–70 – A–71
Rational zeroes theorem, 325–330, 355, 397
Ratios, trigonometric, 595–597, 610–614
Raw data, 79, 98
Ray, 510, 514
Real numbers
properties of, A–4 – A–6, A–80
trigonometry of, 534–537, 577–578
Real roots, 714–717
Real zeroes, 355
Reciprocal function
application of, 181
explanation of, 148, 149, 1035
transformations of, 151
trigonometric, 533
Reciprocal identities, 654, 662, 693, 694
Reciprocal quadratic functions, 151
Reciprocals, 26
Reciprocal square functions, 148–150
Rectangles
area of, 876
central, 986
explanation of, A–32
perimeter and area formulas for, A–32
reference, 547, 548, 550–551, 554, 562
Rectangular coordinates
converted to polar form, 1020–1021
converted to trigonometric form, 651–652
converting between polar coordinates and, 1021–1024
Rectangular coordinate system
explanation of, 3
vectors and, 772–775
Rectangular form
complex numbers in, 803–804
converted to trigonometric form, 651, 803–804
converting from polar to, 652
converting from trigonometric form to, 804–805
explanation of, 803
parametric equations in, 1054–1055
Rectangular method, 1165
Rectangular solid, 863
Recursive sequences, 1080–1081
Reduced row-echelon form, 897, 898, A–91
Reference angles
explanation of, 531–532, 635, 646
trigonometric functions and, 614–616
Reference arc, 534
Reference intensity, 439
Reference rectangles
explanation of, 547
to graph trigonometric functions, 548, 550–551, 554, 562
Reflections
horizontal, 125–126
vertical, 124–125
Regression
applications of, 86–87, 486–487
forms of, 482
on graphing calculator, 85–87, 92, 158, 298–299, 484–487, 626, 627
linear, 85–86
quadratic, 250–251, 299
sinusoidal, 626–627
Regression equations, 500
Regression line, 85
Regression models
exponential, 483–484
logarithmic, 484–485
logistic equations and, 485–486
selection of, 250, 500
sinusoidal, 627
Regular polygon, 558, 660, A–36
Relations
domain of, 2, 48–49
in equation form, 3, 94
explanation of, 2, 94
on graphing calculator, 6–8
graphs of, 3–6, 48–49
pointwise-defined, 2, 3, 94
range of, 2, 48–49
Remainder theorem
applications of, 316, 331
to evaluate polynomials, 312–313
explanation of, 312, 396
proof of, A–84
Removable discontinuity
explanation of, 372, 1192
rational functions and, 169, 372–373, 399
Repeated zeroes, 401–402
Residuals, 298, 482
Resistance, 808, 809, A–9
Resultant force, 779
Resultant vectors, 776, 802
Right angles, 510
Right-hand limits, 1174
Right parabolic segment, 1004
Right triangles
applications of, 601–604
explanation of, 524, A–74
to find function values, 597
relationships in, 524, 650
solutions to, 597–600
solved given one angle and one side, 597–599
solved given two sides, 599–600
trigonometry of, 595–601, 640
Rigid transformations, 128
Rise, 21
Root functions
explanation of, 152
transformations of, 154–155
Roots. *See also* Cube roots; Square roots
cube, A–65
of equations, A–24
extraneous, 457, A–59
principal, 711
real, 714–717
substitution to check complex, 208, 209
trigonometric equations and, 711–715
Roots tests for quartic polynomials, 351
Roses, A–95
Rotated conics, 1035–1040
Rotation of axes, 1037–1039, 1041
Rotation of axes formulas, 1037
Rule of fourths, 547, 551, 579, 580
r-value analysis, 1024–1027

Sample outcomes, 1121, 1134
Sample space, 1121–1122, 1133
Sand dune function, 173
Scalar, 771
Scalar measurement, 771
Scalar multiplication, 772, 908–913
Scalar quantities, 771
Scaled drawings
law of cosines and, 786–787
law of sines and, 750–751, 786–787
Scatterplots
correlation and, 81–82
explanation of, 79, 98
on graphing calculator, 348
linear/nonlinear association and, 80–81
positive/negative association and, 79–80
Scientific notation, exponents and, A–14 – A–15
Secant function
characteristics of, 563
explanation of, 532
graphs of, 562–563, 637
inverse, 702–704
Secant lines
explanation of, 54, 97
slope of, 576
Seconds, 511
Seed elements, 1080
Semicircle, graph of, 6
Semi-hyperbola, 995
Semimajor axis, 971
Semiminor axis, 971
Sequences. *See also* Series; *specific types of sequences*
applications of, 1084–1085, 1095, 1105–1106
arithmetic, 32, 1089–1095, 1155
explanation of, 1078, 1154
Fibonacci, 1080
finding terms of, 1078–1080
finite, 1078
geometric, 1098–1107, 1155
on graphing calculator, 1079–1081, 1091–1092, 1094, 1101–1102, 1104–1106, 1160–1161
infinite, 1078
*n*th term of, 1078, 1087
recursive, 1080–1081
summation notation and, 1082–1084
terms of, 1078
Series. *See also* Sequences
explanation of, 1078, 1081, 1154
finite, 1081–1082
summation notation and, 1082–1084
Set notation, 36, 37, A–80
Sets
intersection of, A–28
of numbers, A–80
Shifted form, of trigonometric functions, 582, 583
Shifts
horizontal, 123–124, 581–583
vertical, 122–123, 579
Side-angle-side (SAS) triangles, 747, 759–761, 763–764
Side-side-angle (SSA) triangles, 747–752
Side-side-side (SSS) triangles, 747, 761–762
Sigma notation. *See* Summation notation
Sign analysis, 616
Similar triangles, 512, 513
Simple interest, 185, 469
Simplest form
radical expressions in, A–70, A–71
rational expressions in, A–52 – A–54
Sine
law of, 746–753
sum and difference identities for, 672–675
table of values for, 542, 543
triple angle formula for, 756
Sine function
amplitude of, 551–552
applications of, 579–580, 585, 586
characteristics of, 546
explanation of, 532
graphs of, 542–549, 551–554, 636–637
inverse, 695–698, 704
period and coefficient *B* of, 552–554
Singular matrix, 922–927
Sinking funds, 474
Sinusoidal equations, 582–583
Sinusoidal functions, 632, 642
Sinusoidal graphs, 580
Sinusoidal models, 559, 622–626
Sinusoidal pattern, 578
Sinusoidal regression, 626–627
Slope
applications of, 20
explanation of, 20–21, 95
of horizontal and vertical lines, 24
of parallel lines, 25
of perpendicular lines, 26

positive and negative, 22
as rate of change, 21–23, 54, 56
of secant lines, 54
of tangent lines, 103, 1073–1074, 1205
Slope formula
explanation of, 21–22, 100
as rate of change, 22
use of, 24, 95
Slope-intercept form
explanation of, 51–52, 96, 100
graph of line using, 52–53, 96
rate of change and, 53
system of equations and, 839
Smooth functions, 163
Snell's law, 720
Solution region, 866, 870–871
Solutions
exact or closed form, 219
explanation of, A–24
unique, 854
Sound energy, 585
Sound waves, 585–586, 687–688, 739
Spheres, volume of, 124
Spiral of Archimedes, 621, 1034
Spring oscillation, 145
Springs, 584–585
Square matrix, 893, 895
Square root function, 120
Square root property of equality, 217
to solve equations, 217–219
Square roots. *See also* Radical expressions
of complex numbers, 334
explanation of, A–64
principal, 204, 334
simplification of, A–64 – A–65
Squares. *See also* Completing the square
binomial, A–19– A–20
difference of two, A–19, A–42
explanation of, A–32
perimeter and area formulas for, A–32
Standard angles, 646, 647, 1040
Standard form
of complex numbers, 205–206
of equation of circle, 10, 11, 970
of equation of ellipse, 971–973, 976
of equation of hyperbola, 986–988
of equations, 841
of linear equations, 100
of polynomial equations, A–45
of polynomial expressions, A–16
of quadratic equations, 215, 222
of trigonometric functions, 582, 583
Static equilibrium, 828–829
Static trigonometry, 610
Statistics, 1132
Step functions, 170–171

Symmetry
axis of, 121
even functions and, 106–107
to find function values, 543–544
graphs and, 345
identities due to, 661–662
to locate points on unit circle, 528, 529
odd functions and, 107, 108
in polar graphs, 1027–1031, 1035
in polynomial functions, 345
with respect to origin, 107
with respect to *y*-axis, 106, 107
unit circle and, 528, 529, 531–532, 661
Synthetic division
explanation of, 309–312, 396–397, A–89 – A–90
factor theorem and, 313–315, 397
polynomials and, 309–315, 327
remainder theorem and, 312–313, 396
System of linear equations
Cramer's rule to solve, 934–936
decomposition using, 885–886
determinants to solve, 933–934
explanation of, 838
graphs to solve, 839
matrices to solve, 895–901, 950
matrix equations to solve, 921–922, 951
System of linear equations in three variables
applications to, 860–861
Cramer's rule and, 935–936
elimination to solve, 855–858
explanation of, 853, 948–949
inconsistent and dependent, 858–860
solutions to, 854–855
visualizing solutions to, 853–854
System of linear equations in two variables
Cramer's rule and, 934–935
dependent, 844
elimination to solve, 841–843
equivalent, 841
explanation of, 838, 948
on graphing calculator, 838–840, 843–848
graphs to solve, 839
inconsistent and dependent, 843–844
independent, 844
modeling and, 844–848
solutions to, 838–839
substitution to solve, 840–841
in two unknowns, 838
System of linear inequalities
applications of, 869–870
explanation of, 867, 949
on graphing calculator, 868–869
linear programming and, 870–874
method to solve, 867–869
solution regions of, 870–871
System of nonlinear equations
applications of, 1013–1014
elimination to solve, 1010–1012
explanation of, 1007, 1066
on graphing calculator, 1008–1014
possible solutions for, 1007–1008
substitution to solve, 1008–1010
System of nonlinear inequalities, 1012–1013, 1066–1067
System of polar equations, 1074–1075

Tangent
meaning of term, 576
sum and difference identities for, 672–675
table of values for, 565
Tangent functions
applications of, 588
characteristics of, 567
explanation of, 532
graphs of, 563–566, 587, 637, 638
inverse, 699–700, 704
Tangent lines
explanation of, 576, 1204
slope of, 103, 1073–1074, 1205, 1206
Telescoping sums, 886–888
Temperature, 46, 850
Terminal points, 771, 772
Terminal side, 514, 612, 613
Terms
constant, A–1
explanation of, A–1, A–2
of sequence, 1078–1080
variable, A–1
Test for collinear points, 936–937
Theta (θ), 510
30-60-90 triangles, 513, 595, 596
3 × 3 systems. *See* System of linear equations in three variables
Threshold audibility, 438
Tidal motion, 645–646
Toolbox functions
direct variation and, 177–180, 193
explanation of, 120–121, 190
graphs of, 120–121
horizontal reflections and, 125–126
horizontal translations and, 123–124
transformations and, 121, 190
vertical reflections and, 124–125
vertical translations and, 122–123
Transcendental functions, 433, 723. *See also* Logarithmic functions; Trigonometric functions
Transformations
area under curve and, 304–305
explanation of, 121
of general functions, 127–130
to graph functions, 127–130, 235, 425, 436–437
on graphing calculator, 122–123
horizontal reflections and, 125–126
horizontal translations and, 123–124
nonrigid, 128
of parent function, 128
of parent graph, 121
of power functions, 154–155
of reciprocal functions, 151
rigid, 128
of root functions, 154–155
solving equations involving, 725–726
of trigonometric graphs, 547, 639
vertical reflection and, 124–125
vertical stretches or compressions and, 126–127
vertical translations and, 122–123
via composition, 288
Translations
horizontal, 123–124, 581–584, 586–597
vertical, 122–123, 578–581, 586–587
Transverse axis, of hyperbola, 985
Trapezoids
area of, A–32 – A–33
explanation of, A–32
perimeter of, 731, 768, A–32
Tree diagrams, 1120–1122
Trial-and-error method, A–41 – A–42
Trials, 1121
Triangles
angle-angle-side, 747, 764
angle-side-angle, 747, 764
area of, 381, 668, 763–766, 823, 904, 936, A–32
equilateral, 524, 811
explanation of, 512, 634, A–32
45-45-90, 513, 514
law of sines to solve, 746–753
oblique, 746–752, 822
Pascal's, 1145–1147
perimeter formula for, A–32
properties of, 512–513, 634
right, 524, 595–604, 640, 650, A–74
side-angle-side, 747, 759–761, 763–764
side-side-angle, 747–752

Triangles—*Cont.*
side-side-side, 747, 761–762

30-60-90, 513
unit circle and special, 529–532
Triangular form of matrix, 895
Triangularizing augmented matrix, 895–897
Trigonometric equation models
applications of, 622, 721
critical points and sinusoidal models and, 622–626, 642
sinusoidal regression and, 626–627
Trigonometric equations
algebraic methods and, 721–723
applications of, 721, 726–727
explanation of, 711
of form $A \sin (Bx \pm C) \pm D = k$, 725–726
on graphing calculator, 714, 717, 723–725
identities to solve, 723
methods to solve, 36, 712–717, 722–726, 737, 739–740
roots of, 711–712
Trigonometric form
complex numbers in, 803–804, 826
converted to rectangular form, 804–805
converting from rectangular form to, 651
equation of line in, 729
products and quotients in, 806–807
Trigonometric functions. *See also* Inverse trigonometric functions; *specific trigonometric functions*
of acute angles, 596
applications of, 559, 579–580, 585, 586, 617–618
domain of, 535
evaluation of, 533–534, 612, 614
explanation of, 532–534
fundamental identities and, 657–658
on graphing calculator, 545, 549, 551–554, 561–567, 598–601, 613, 658, 665, 666, 714, 717
graphs of, 542–554, 561–566
points on unit circle and, 534, 535
real numbers and, 534–537
reference angles and, 531–532, 614–616, 646
standard angles and, 646, 647
standard form of, 582, 583
value of, 536, 537
written in terms of another, 657–658
Trigonometric graphs
applications of, 588–589, 639
of cosecant function, 561–562
of cosine function, 549–554
of cotangent function, 566–567
explanation of, 116, 542
of secant function, 562–563
of sine function, 542–549, 551–554
of tangent function, 563–566
transformations of, 547, 578–584, 639
Trigonometric identities, 743–744
Trigonometric ratios
points and, 610–614
values of, 595–597
Trigonometric substitution, 743
Trigonometry
area of triangle and, 763–766
coordinate plane and, 610–616, 641
dynamic, 610
explanation of, 532
problem solving and, 832–833
of real numbers, 527–537, 577–578
of right triangles, 595–604, 640
static, 610
Trinomials. *See also* Polynomials

Tunnel clearance, 1016
Two-dimensional graphs, 853
Two-sided limits, 1171–1173
2×2 systems. *See* System of linear equations in two variables

Uniform motion, 72–73, 845–846, 849
Union, A–28
Uniqueness property
to solve exponential equations, 426–428
to solve logarithms, 458–459
Unique solutions, 854
Unit circle
equation of, 527
explanation of, 527, 635–636
points on, 527–528
special triangles and, 529–532
symmetry and, 528, 529, 531–532, 661
trigonometric functions and points on, 532–534
Unit vectors, 779
Upper and lower bounds property, 328, 330
Upper bound, 330
u-substitution
explanation of, 716
to factor expressions in quadratic form, A–44
to solve equations in quadratic form, A–74
to solve trigonometric equations, 716, 727

Variable amplitude, 645–646
Variable costs, 846
Variables
decision, 872
dependent, 2
independent, 2
objective, 69–70, 872
Variable terms, A–1
Variation
constant of, 177
direct, 177–180, 193
on graphing calculator, 180
graphs of, 178
inverse, 180–182, 193
joint or combined, 182, 193, 195
power functions and, 196
Variation equations, 177, 179
Vector projections, 789, 794–795
Vector quantities, 771
Vectors
algebraic, 778
applications of, 779–782, 790–791, 824
arithmetic operations on, 776–777
component of u along v, 788–790
dot products and angle between, 792–794, 824
equilibrium and, 787–789
equivalent, 772
explanation of, 771, 823–824
force, 779–780, 791
geometry of, 959
on graphing calculator, 773–775, 777, 792, 795, 797
horizontal and vertical components of, 773, 775, 778, 788
horizontal unit, 778
magnitude of, 774–775, 784
notation and geometry of, 771–772
orthogonal components of, 788, 794–795
position, 772, 773
projectile height and, 796–797
$\text{proj}_{\mathbf{v}}\mathbf{u}$ and, 794–795
properties of, 777
rectangular coordinate system and, 772–773
resultant, 776, 802
static equilibrium and, 828–829
in three dimensions, 833–834
unit, 779
vertical unit, 778
Velocity
angular, 520–521
average rate of change applied to projectile, 255
of falling object, 271
instantaneous, 1204–1207
linear, 520–521
Velocity formulas, 160, 271
Vertex
of cone, 964
explanation of, 510
of hyperbola, 985
of parabola, 5
of solution region, 868
Vertex formula, 237–238
Vertex/intercept formula, 245
Vertical asymptotes, 151, 356–359, 363
Vertical-axis symmetry, 1028
Vertical boundary lines, 36–37, 96
Vertical change, 20–21
Vertical component of vectors, 773, 775, 788
Vertical compressions, 126–127, 568, 569
Vertical ellipse, 972–973
Vertical format, A–3
Vertical hyperbola, 988
Vertical lines
explanation of, 23–24, 95
slope of, 24
Vertical line test, 35–36, 95, 149
Vertical parabola, 5, 1000
Vertical parabolic segment, 1017
Vertical reflections, 124–125
Vertical shifts, 122–123, 579
Vertical stretches, 568
Vertical translations, 122–123
Vertical unit vectors, 778
Voltage, 808, 809
Volume
of box, 318
of composite figure, A–34
of cone, 730, 876
of cube, A–21, A–33
of cylinder, 90, 730, A–51
explanation of, A–33
pressure and, A–9
of rectangular solid, A–33
of right circular cone, A–33
of right circular cylinder, A–33
of right pyramid, A–33
of sphere, 134, A–33

Witch of Agnesi, 1061
Work, 790–791
Wrapping function, 577–578
Written information
translated into equations, A–30 – A–31
translated into mathematical model, A–2

x-intercepts
explanation of, 20, 101
on graphing calculator, 215–216
method to find, 61
of quadratic functions, 215–216
as zeroes of function, 108–109
x-intercept/zeroes method. *See* Zeroes/*x*-intercept method
xy-plane, 3, 936

y-axis, 106, 107
y-intercept
explanation of, 20
method to find, 61

Zeno of Elea, 1160
Zeroes
approximation of real, 355
complex, 401–402
factor theorem to find, 315
of functions, 108, 109
intermediate value theorem to find, 324–325
irrational, 355
of multiplicity, 225, 322, 341–344
of polynomial functions, 320–331, 397
of quadratic functions, 215–217
rational, 325–330
repeated, 401–402
Zeroes/*x*-intercept method, 66–67, 97, 218, 220
Zero exponent property, A–12
Zero exponents, A–12, A–14
Zero placeholder, 310–311
Zero product property, A–46 – A–47
