About the Authors

Stephen A. Ross

Sloan School of Management,
Franco Modigliani Professor of Finance and Economics, Massachusetts Institute of Technology

Stephen A. Ross is the Franco Modigliani Professor of Finance and Economics at the Sloan School of Management, Massachusetts Institute of Technology. One of the most widely published authors in finance and economics, Professor Ross is recognized for his work in developing the Arbitrage Pricing Theory and his substantial contributions to the discipline through his research in signaling, agency theory, option pricing, and the theory of the term structure of interest rates, among other topics. A past president of the American Finance Association, he currently serves as an associate editor of several academic and practitioner journals. He is a trustee of CalTech.

Randolph W. Westerfield

Marshall School of Business,
University of Southern California

Randolph W. Westerfield is Dean Emeritus of the University of Southern California's Marshall School of Business and is the Charles B. Thornton Professor of Finance. He came to USC from the Wharton School, University of Pennsylvania, where he was the chairman of the finance department and a member of the finance faculty for 20 years. He is a member of several public company boards of directors including Health Management Associates, Inc., and the Nicholas Applegate Growth Fund. His areas of expertise include corporate financial policy, investment management, and stock market price behavior.

Bradford D. Jordan

Gatton College of Business and Economics, *University of Kentucky*

Bradford D. Jordan is Professor of Finance and holder of the Richard W. and Janis H. Furst Endowed Chair in Finance at the University of Kentucky. He has a long-standing interest in both applied and theoretical issues in corporate finance and has extensive experience teaching all levels of corporate finance and financial management policy. Professor Jordan has published numerous articles on issues such as the cost of capital, capital structure, and the behavior of security prices. He is a past president of the Southern Finance Association, and he is coauthor of *Fundamentals of Investments: Valuation and Management*, 5th edition, a leading investments text, also published by McGraw-Hill/Irwin.

From the Authors

When we first wrote *Essentials of Corporate Finance*, we thought there might be a small niche for a briefer book that really focused on what students with widely varying backgrounds and interests needed to carry away from an introductory finance course. We were wrong. There was a huge niche! What we learned is that our text closely matches the needs of instructors and faculty at hundreds of schools across the country. As a result, the growth we have experienced through the first six editions of *Essentials* has far exceeded anything we thought possible.

With the seventh edition of *Essentials of Corporate Finance*, we have continued to refine our focus on our target audience, which is the undergraduate student taking a core course in business or corporate finance. This can be a tough course to teach. One reason is that the class is usually required of all business students, so it is not uncommon for a majority of the students to be nonfinance majors. In fact, this may be the only finance course many of them will ever have. With this in mind, our goal in *Essentials* is to convey the most important concepts and principles at a level that is approachable for the widest possible audience.

To achieve our goal, we have worked to distill the subject down to its bare essentials (hence, the name of this book), while retaining a decidedly modern approach to finance. We have always maintained that the subject of corporate finance can be viewed as the working of a few very powerful intuitions. We also think that understanding the “why” is just as important, if not more so, than understanding the “how,” especially in an introductory course. Based on the gratifying market feedback we have received from our previous editions, as well as from our other text, *Fundamentals of Corporate Finance* (now in its ninth edition), many of you agree.

By design, this book is not encyclopedic. As the table of contents indicates, we have a total of 18 chapters. Chapter length is about 30 pages, so the text is aimed squarely at a single-term course, and most of the book can be realistically covered in a typical semester or quarter. Writing a book for a one-term course necessarily means some picking and choosing, with regard to both topics and depth of coverage. Throughout, we strike a balance by introducing and covering the essentials (there’s that word again!) while leaving some more specialized topics to follow-up courses.

The other things we have always stressed, and have continued to improve with this edition, are readability and pedagogy. *Essentials* is written in a relaxed, conversational style that invites the students to join in the learning process rather than being a passive information absorber. We have found that this approach dramatically increases students’ willingness to read and learn on their own. Between larger and larger class sizes and the ever-growing demands on faculty time, we think this is an essential (!) feature for a text in an introductory course.

Throughout the development of this book, we have continued to take a hard look at what is truly relevant and useful. In doing so, we have worked to downplay purely theoretical issues and minimize the use of extensive and elaborate calculations to illustrate points that are either intuitively obvious or of limited practical use.

As a result of this process, three basic themes emerge as our central focus in writing *Essentials of Corporate Finance*:

An Emphasis on Intuition We always try to separate and explain the principles at work on a commonsense, intuitive level before launching into any specifics. The underlying

ideas are discussed first in very general terms and then by way of examples that illustrate in more concrete terms how a financial manager might proceed in a given situation.

A Unified Valuation Approach We treat net present value (NPV) as the basic concept underlying corporate finance. Many texts stop well short of consistently integrating this important principle. The most basic and important notion, that NPV represents the excess of market value over cost, often is lost in an overly mechanical approach that emphasizes computation at the expense of comprehension. In contrast, every subject we cover is firmly rooted in valuation, and care is taken throughout to explain how particular decisions have valuation effects.

A Managerial Focus Students shouldn't lose sight of the fact that financial management concerns management. We emphasize the role of the financial manager as decision maker, and we stress the need for managerial input and judgment. We consciously avoid "black box" approaches to finance, and, where appropriate, the approximate, pragmatic nature of financial analysis is made explicit, possible pitfalls are described, and limitations are discussed.

Today, as we prepare to once again enter the market, our goal is to stick with and build on the principles that have brought us this far. However, based on an enormous amount of feedback we have received from you and your colleagues, we have made this edition and its package even more flexible than previous editions. We offer flexibility in coverage and pedagogy by providing a wide variety of features in the book to help students to learn about corporate finance. We also provide flexibility in package options by offering the most extensive collection of teaching, learning, and technology aids of any corporate finance text. Whether you use just the textbook, or the book in conjunction with other products, we believe you will find a combination with this edition that will meet your current as well as your changing needs.

Stephen A. Ross
Randolph W. Westerfield
Bradford D. Jordan

Organization of the Text

We designed *Essentials of Corporate Finance* to be as flexible and modular as possible. There are a total of nine parts, and, in broad terms, the instructor is free to decide the particular sequence. Further, within each part, the first chapter generally contains an overview and survey. Thus, when time is limited, subsequent chapters can be omitted. Finally, the sections placed early in each chapter are generally the most important, and later sections frequently can be omitted without loss of continuity. For these reasons, the instructor has great control over the topics covered, the sequence in which they are covered, and the depth of coverage.

Just to get an idea of the breadth of coverage in the seventh edition of *Essentials*, the following grid presents for each chapter some of the most significant new features, as well as a few selected chapter highlights. Of course, in every chapter, figures, opening vignettes, boxed features, and in-chapter illustrations and examples using real companies have been thoroughly updated as well. In addition, the end-of-chapter material has been completely revised.

Chapters	Selected Topics	Benefits to Users
PART ONE Overview of Financial Management		
Chapter 1	New opener on “Say on Pay.”	Highlights important development regarding the very current question of appropriate executive compensation.
	Updated corporate ethics box with Bank of America purchase of Merrill Lynch.	Describes ethical issues in the context of the Great Recession of 2008–2009 and the controversial BoA acquisition.
	New material on Microsoft/Yahoo! takeover battle.	Illustrates important aspects of corporate governance using these well-known companies.
	Goal of the firm and agency problems.	Stresses value creation as the most fundamental aspect of management and describes agency issues that can arise.
	Ethics, financial management, and executive compensation.	Brings in real-world issues concerning conflicts of interest and current controversies surrounding ethical conduct and management pay.
PART TWO Understanding Financial Statements and Cash Flow		
Chapter 2	Cash flow vs. earnings.	Clearly defines cash flow and spells out the differences between cash flow and earnings.
	Market values vs. book values.	Emphasizes the relevance of market values over book values.
	New box on fair value accounting.	Explains fair value accounting, which became highly controversial for banks in the 2008–2009 recession.

Chapters	Selected Topics	Benefits to Users
Chapter 3	<p>Additional explanation of alternative formulas for sustainable and internal growth rates.</p> <p><i>New example comparing ratios for Lowe's and Home Depot.</i></p> <p><i>New example comparing Du Pont breakdowns for Yahoo! and Google.</i></p>	<p>Expanded explanation of growth rate formulas clears up a common misunderstanding about these formulas and the circumstances under which alternative formulas are correct.</p> <p>Provides real-world context using two similar and familiar companies.</p> <p>Also provides real-world context using two similar and familiar companies.</p>
PART THREE Valuation of Future Cash Flows		
Chapter 4	First of two chapters on time value of money.	Relatively short chapter introduces just the basic ideas on time value of money to get students started on this traditionally difficult topic.
Chapter 5	Second of two chapters on time value of money.	Covers more advanced time value topics with numerous examples, calculator tips, and Excel spreadsheet exhibits. Contains many real-world examples.
PART FOUR Valuing Stocks and Bonds		
Chapter 6	<p>Bond valuation.</p> <p>Interest rates and inflation.</p> <p>"Clean" vs. "dirty" bond prices and accrued interest.</p> <p>NASD's TRACE system and transparency in the corporate bond market.</p> <p>"Make-whole" call provisions.</p>	<p>Thorough coverage of bond price/yield concepts.</p> <p>Highly intuitive discussion of inflation, the Fisher effect, and the term structure of interest rates.</p> <p>Clears up the pricing of bonds between coupon payment dates and also bond market quoting conventions.</p> <p>Up-to-date discussion of new developments in fixed income with regard to price, volume, and transactions reporting.</p> <p>Up-to-date discussion of relatively new type of call provision that has become very common.</p>
Chapter 7	<p>Stock valuation.</p> <p>NYSE and Nasdaq Market operations.</p> <p><i>New box on the BATS exchange.</i></p>	<p>Thorough coverage of constant and nonconstant growth models.</p> <p>Up-to-date description of major stock market operations.</p> <p>Explains how an Internet-based stock exchange operates.</p>
PART FIVE Capital Budgeting		
Chapter 8	<p><i>New opener on GE's "Ecomagination" program.</i></p> <p>First of two chapters on capital budgeting.</p> <p>NPV, IRR, MIRR, payback, discounted payback, accounting rate of return.</p>	<p>Illustrates the growing importance of "green" business.</p> <p>Relatively short chapter introduces key ideas on an intuitive level to help students with this traditionally difficult topic.</p> <p>Consistent, balanced examination of advantages and disadvantages of various criteria.</p>
Chapter 9	<p>Project cash flow.</p> <p>Scenario and sensitivity "what-if" analyses.</p>	<p>Thorough coverage of project cash flows and the relevant numbers for a project analysis.</p> <p>Illustrates how to actually apply and interpret these tools in a project analysis.</p>

Chapters	Selected Topics	Benefits to Users
PART SIX Risk and Return		
Chapter 10	<i>New international material on the stock market risk premium.</i>	Uses equity risk premiums for longer time periods across numerous countries to show that the U.S. experience has not been unusual.
	Capital market history.	Extensive coverage of historical returns, volatilities, and risk premiums.
	Market efficiency.	Efficient markets hypothesis discussed along with common misconceptions.
	Geometric vs. arithmetic returns.	Discusses calculation and interpretation of geometric returns. Clarifies common misconceptions regarding appropriate use of arithmetic vs. geometric average returns.
Chapter 11	Diversification, systematic, and unsystematic risk.	Illustrates basics of risk and return in a straightforward fashion.
	Beta and the security market line.	Develops the security market line with an intuitive approach that bypasses much of the usual portfolio theory and statistics.
PART SEVEN Long-Term Financing		
Chapter 12	<i>New opener on BASF's cost of capital.</i>	Shows that companies use the WACC for performance evaluation and planning purposes.
	Cost of capital estimation.	Intuitive development of the WACC and a complete, Web-based illustration of cost of capital for a real company.
	Geometric vs. arithmetic growth rates.	Both approaches are used in practice. Clears up issues surrounding growth rate estimates.
Chapter 13	Basics of financial leverage.	Illustrates effect of leverage on risk and return.
	Optimal capital structure.	Describes the basic trade-offs leading to an optimal capital structure.
	Financial distress and bankruptcy.	Briefly surveys the bankruptcy process.
Chapter 14	<i>New significantly rewritten to reflect latest research on dividend policy, including the life cycle theory and the impact of the 2003 dividend tax cut.</i>	Brings students the latest thinking on dividend policy and also the results of a natural experiment—the 2003 dividend tax cut.
	Dividends and dividend policy.	Describes dividend payments and the factors favoring higher and lower payout policies. Includes recent survey results on setting dividend policy.
Chapter 15	IPO valuation.	Extensive, up-to-date discussion of IPOs, including the 1999–2000 period.
	Dutch auctions.	Explains uniform price (“Dutch”) auctions using Google IPO as an example.
PART EIGHT Short-Term Financial Management		
Chapter 16	<i>New opener on inventory periods in the auto industry.</i>	Describes the importance of inventory periods in the context of the auto industry's distress in the 2008–2009 recession.
	Operating and cash cycles.	Stresses the importance of cash flow timing.
	Short-term financial planning.	Illustrates creation of cash budgets and potential need for financing.

Chapters	Selected Topics	Benefits to Users
Chapter 17	Cash collection and disbursement. Credit management. Inventory management.	Examination of systems used by firms to handle cash inflows and outflows. Analysis of credit policy and implementation. Brief overview of important inventory concepts.
PART NINE	Topics in Business Finance	
Chapter 18	<i>New opener on the U.S. dollar/Canadian "loonie" exchange rate.</i> Foreign exchange. International capital budgeting. Exchange rate and political risk.	Looks at the impact of exchange rate changes and explains how a strengthening currency isn't necessarily a good thing. Covers essentials of exchange rates and their determination. Shows how to adapt basic DCF approach to handle exchange rates. Discusses hedging and issues surrounding sovereign risk.

Learning Solutions

In addition to illustrating relevant concepts and presenting up-to-date coverage, *Essentials of Corporate Finance* strives to present the material in a way that makes it engaging and easy to understand. To meet the varied needs of the intended audience, *Essentials of Corporate Finance* is rich in valuable learning tools and support.

Each feature can be categorized by the benefit to the student:

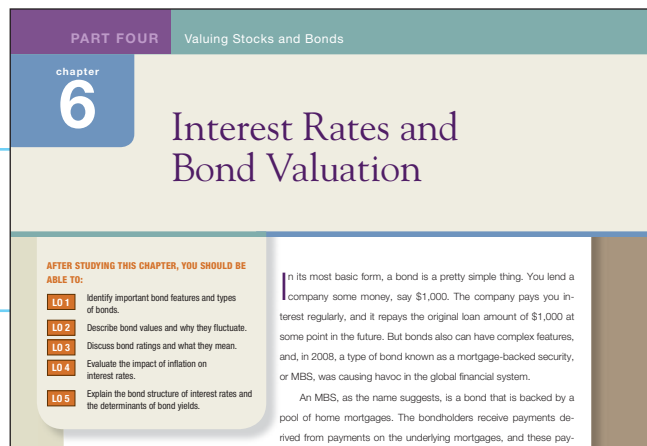

- Real financial decisions
- Application tools
- Study aids

REAL FINANCIAL DECISIONS

We have included two key features that help students connect chapter concepts to how decision makers use this material in the real world.

Chapter-Opening Vignettes

Each chapter begins with a contemporary real-world event to introduce students to chapter concepts.

REALITY BYTES

Collectibles as Investments?

It used to be that trading in collectibles such as baseball cards, art, and old toys occurred mostly at auctions, swap meets, and collectible shops, all of which were limited to regional traffic. However, with the growing popularity of online auctions such as eBay, trading in collectibles has expanded to an international arena. The most visible form of collectible is probably the baseball card, but Furbies, Beanie Babies, and Pokémon cards have been extremely hot collectibles in the recent past. However, it's not just fad items that spark interest from collectors; virtually anything of sentimental value from days gone by is considered collectible, and, more and more, collectibles are being viewed as investments.

Collectibles typically provide no cash flows, except when sold, and condition and buyer sentiment are the major determinants of value. The rates of return have been amazing at times, but care is needed in interpreting them. For example, in 2008, an Original Class I 1804 silver dollar sold for \$3,737,500. The coin was one of only eight of its type known to still exist. While this looks like a whopping price increase to the untrained eye, check for yourself that the actual return on the investment was

only about 7.70 percent per year. Not too bad, but nowhere near the return most people expect from looking at the sales price.

Comic books have recently grown in popularity among collectors. The X-Men, who first appeared in 1963, are a popular group of superheroes. The X-Men #1 comic book, which also introduced the world to arch villain Magneto, hit the shelves in September 1963 at a cover price of 50 cents. In August 2008, a copy of this issue had mutated to a price of \$53,775 at auction. This seems like a very high return to the untrained eye, and indeed it is! Check for yourself that the return was about 29.36 percent per year.

Stamp collecting (or philately) is a popular activity. Possibly the most desirable stamp in the world is the 1918 "inverted Jenny," which has a Curtiss JN-4 Jenny aircraft inadvertently printed upside down. Originally sold for 24 cents, one of these stamps was auctioned in 2009 for \$260,000. See for yourself that this represents an annual return of about 16.50 percent. Unfortunately for the seller, this particular stamp was slightly damaged. An undamaged inverted Jenny sold for \$977,500 at the end of 2007, an annual return of 18.65 percent.

Reality Bytes Boxes

Most chapters include at least one *Reality Bytes* box, which takes a chapter issue and shows how it is being used right now in everyday financial decision making.

Chapter Cases

Located at the end of most chapters, these cases focus on hypothetical company situations that embody corporate finance topics. Each case presents a new scenario, data, and a dilemma. Several questions at the end of each case require students to analyze and focus on all of the material they learned from the chapters in that part. Great for homework or in-class exercises and discussions!

CHAPTER CASE

FINANCING S&S AIR'S EXPANSION PLANS WITH A BOND ISSUE

Mark Sexton and Todd Story, the owners of S&S Air, have decided to expand their operations. They instructed their newly hired financial analyst, Chris Guthrie, to enlist an underwriter to help sell \$20 million in new 10-year bonds to finance construction. Chris has entered into discussions with Renata Harper, an underwriter from the firm of Crowe & Mallard, about which bond features S&S Air should consider and what coupon rate the issue will likely have.

Although Chris is aware of the bond features, he is uncertain as to the costs and benefits of some features, so he isn't clear on how each feature would affect the coupon rate of the bond issue. You are Renata's assistant, and she has asked you to prepare a memo to Chris describing the effect of each of the following bond features on the coupon rate of the bond. She would also like you to list any advantages or disadvantages of each feature.

QUESTIONS

1. The security of the bond, that is, whether the bond has collateral.
2. The seniority of the bond.
3. The presence of a sinking fund.
4. A call provision with specified call dates and call prices.
5. A deferred call accompanying the above call provision.
6. A make-whole call provision.
7. Any positive covenants. Also, discuss several possible positive covenants S&S Air might consider.
8. Any negative covenants. Also, discuss several possible negative covenants S&S Air might consider.
9. A conversion feature (note that S&S Air is not a publicly traded company).
10. A floating rate coupon.

APPLICATION TOOLS

Because there is more than one way to solve problems in corporate finance, we include many sections that encourage students to learn or brush up on different problem-solving methods, such as financial calculator and Excel spreadsheet skills.

Work the Web

These in-chapter boxes show students how to research financial issues using the Web and how to use the information they find to make business decisions. New to this edition, now all of the Work the Web boxes also include interactive follow-up questions and exercises.

WORK THE WEB

Bond quotes have become more available with the rise of the Web. One site where you can find current bond prices (from TRACE) is cxa.marketwatch.com/fmra/BondCenter. We went to the site and entered "Dell" for the well-known computer manufacturer. We found a total of four bond issues outstanding. Below you will see the information we pulled up.

Include in history?	Bond Symbol	Bond Name	Coupon	Maturity	Category	Moody's	BBB	BBB+	Price	Yield
<input type="checkbox"/>	DELL0P	DELL INCORPORATED	4.75	04/15/2013	YBB	A2	NR	A	99.850	4.791
<input type="checkbox"/>	DELL0Q	DELL INCORPORATED	5.00	04/15/2013	YBB	A2	NR	A	95.111	5.215
<input type="checkbox"/>	DELL0R	DELL INCORPORATED	7.12	04/15/2020	YBB	A2	A+	A	95.038	7.142
<input type="checkbox"/>	DELL0H	DELL INCORPORATED	5.50	04/15/2020	YBB	A2	A+	A	78.740	5.385

Most of the information is self-explanatory. The price and yield columns show the price and yield to maturity of the issues based on their most recent sales. If you need more information about a particular issue, clicking on it will give you more details such as coupon dates and call dates.

Questions

1. Go to this Web site and find the last bond shown above. When was this bond issued? What was the size of the bond issue? What were the yield to maturity and price when the bond was issued?
2. When you search for Chevron bonds (CVX), you will find bonds for several companies listed. Why do you think Chevron has bonds issued with different corporate names?

Explanatory Web Links

These Web links are provided in the margins of the text. They are specifically selected to accompany text material and provide students and instructors with a quick way to check for additional information using the Internet.

To learn more about TRACE, visit www.finra.org.

To purchase newly issued corporate bonds, go to www.internotes.com.

Bond Price Reporting

In 2002, transparency in the corporate bond market began to improve dramatically. Under new regulations, corporate bond dealers are now required to report trade information through what is known as the Transactions Report and Compliance Engine (TRACE). By 2009, transaction and price data were reported on more than 29,000 corporate bonds, which is essentially all publicly traded corporate bonds. More bonds will be added over time. A nearby *Work the Web* box shows how to get TRACE prices.

As we mentioned before, the U.S. Treasury market is the largest securities market in the world. As with bond markets in general, it is an OTC market, so there is limited transparency. However, unlike the situation with bond markets in general, trading in Treasury issues, particularly recently issued ones, is very heavy. Each day, representative prices for outstanding Treasury issues are reported.

Figure 6.3 shows a portion of the daily Treasury note and bond listings from *The Wall Street Journal* online. The only difference between a Treasury note and a Treasury bond is that notes have 10 years or less to maturity at the time of issuance. The entry that begins "2020 Feb 15" is highlighted. Reading from left to right, the "2020 Feb 15" tells us that the bond's maturity is February 15, 2020. The 8.500 is the bond's coupon rate. Treasury bonds all make semiannual payments and have a face value of \$1,000, so this bond will pay \$42.50 per six months until it matures.

What's On the Web?

These end-of-chapter activities show students how to use and learn from the vast amount of financial resources available on the Internet.

WHAT'S ON THE WEB?

- 14.1 Dividend Reinvestment Plans.** Dividend reinvestment plans (DRIPs) permit shareholders to automatically reinvest cash dividends in the company. To find out more about DRIPs, go to www.fool.com and answer the following questions about DRIPs. What are the advantages Motley Fool lists for DRIPs? What are the different types of DRIPs? What is a direct purchase plan? How does a direct purchase plan differ from a DRIP?
- 14.2 Dividends.** Go to www.earnings.com and find the list of dividends. How many companies went "ex" today? What is the largest declared dividend? For the stocks going "ex" today, what is the longest time until the payable date?

CALCULATOR HINTS

Annuity Present Values

To find annuity present values with a financial calculator, we need to use the **PMT** key (you were probably wondering what it was for). Compared to finding the present value of a single amount, there are two important differences. First, we enter the annuity cash flow using the **PMT** key, and, second, we don't enter anything for the future value, **FV**. So, for example, the problem we have been examining is a three-year, \$500 annuity. If the discount rate is 10 percent, we need to do the following (after clearing out the calculator):

Enter 3 10 500
N I/Y PMT PV FV
Solve for -1,243.43

As usual, we get a negative sign on the PV.

Calculator Hints

Calculator Hints is a self-contained section occurring in various chapters that first introduces students to calculator basics and then illustrates how to solve problems with the calculator. Appendix D goes into more detailed instructions by solving problems with two specific calculators.

Spreadsheet Strategies

The unique Spreadsheet Strategies feature is also in a self-contained section, showing students how to set up spreadsheets to solve problems—a vital part of every business student's education.

How to Calculate Present Values with Multiple Future Cash Flows Using a Spreadsheet

SPREADSHEET STRATEGIES

Just as we did in our previous chapter, we can set up a basic spreadsheet to calculate the present values of the individual cash flows as follows. Notice that we have simply calculated the present values one at a time and added them up.

	A	B	C	D	E	F
1						
2	Using a spreadsheet to value multiple cash flows					
3						
4	What is the present value of \$200 in one year, \$400 the next year, \$600 the next year, and					
5	\$800 the last year if the discount rate is 12 percent?					
6						
7	Rate:		.12			
8						
9	Year	Cash flows	Present values	Formula used		
10	1	\$200	\$178.57	=PV(\$B\$7,A10:0,-B10)		
11	2	\$400	\$318.88	=PV(\$B\$7,A11:0,-B11)		
12	3	\$600	\$427.07	=PV(\$B\$7,A12:0,-B12)		
13	4	\$800	\$508.41	=PV(\$B\$7,A13:0,-B13)		
14						
15		Total PV:	\$1,432.93	=SUM(C10:C13)		
16						
17	Notice the negative signs inserted in the PV formulas. These just make the present values have					
18	positive signs. Also, the discount rate in cell B7 is entered as \$B\$7 (an "absolute" reference)					
19	because it is used over and over. We could have just entered ".12" instead, but our approach is					
20	more flexible.					
21						
22						

L01

4. **Calculating Annuity Present Values.** An investment offers \$8,500 per year for 15 years, with the first payment occurring 1 year from now. If the required return is 9 percent, what is the value of the investment? What would the value be if the payments occurred for 40 years? For 75 years? Forever?

L01

5. **Calculating Annuity Cash Flows.** If you put up \$25,000 today in exchange for a 7.9 percent, 12-year annuity, what will the annual cash flow be?

L01

6. **Calculating Annuity Values.** Your company will generate \$45,000 in cash flow each year for the next nine years from a new information database. The computer system needed to set up the database costs \$260,000. If you can borrow the money to buy the computer system at 8.25 percent annual interest, can you afford the new system?

L01

7. **Calculating Annuity Values.** If you deposit \$4,000 at the end of each of the next 20 years into an account paying 9.5 percent interest, how much money

Spreadsheet Templates

Indicated by an Excel icon next to applicable end-of-chapter questions and problems, spreadsheet templates are available for selected problems on the Student Edition of the book's Web site, www.mhhe.com/rwj. For even more spreadsheet examples, check out Excel Master, also available on the Web site.

Learning Objectives

Each chapter begins with a number of learning objectives that are key to the student's understanding of the chapter. Learning objectives are also linked to end-of-chapter problems and test bank questions.

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Standardize financial statements for comparison purposes.
- LO 2** Compute and, more importantly, interpret some common ratios.
- LO 3** Assess the determinants of a firm's profitability and growth.
- LO 4** Identify and explain some of the problems and pitfalls in financial statement analysis.

STUDY AIDS

We want students to get the most from this book and this course, and we realize that students have different learning styles and study needs. We therefore present a number of study features to appeal to a wide range of students.

Pedagogical Use of Color

We continue to use a full color palette in *Essentials* not only to make the text more inviting, but, more importantly, as a functional element to help students follow the discussion. In almost every chapter, color plays an important, largely self-evident role. A guide to the use of color is found on the back endsheets.

FIGURE 14.1

Example of the procedure for dividend payment

1. **Declaration date:** The board of directors declares a payment of dividends.
2. **Ex-dividend date:** A share of stock goes ex dividend on the date the seller is entitled to keep the dividend; under NYSE rules, shares are traded ex dividend on and after the second business day before the record date.
3. **Record date:** The declared dividends are distributable to those who are shareholders of record as of this specific date.
4. **Payment date:** The dividend checks are mailed to shareholders of record.

Critical Thinking Questions

Every chapter ends with a set of critical thinking questions that challenge the students to apply the concepts they have learned in the chapter to new situations.

CRITICAL THINKING AND CONCEPTS REVIEW

- LO 2** 3.1 **Current Ratio.** What effect would the following actions have on a firm's current ratio? Assume that net working capital is positive.
 - a. Inventory is purchased.
 - b. A supplier is paid.
 - c. A short-term bank loan is repaid.
 - d. A long-term debt is paid off early.
 - e. A customer pays off a credit account.
 - f. Inventory is sold at cost.
 - g. Inventory is sold for a profit.
- LO 2** 3.2 **Current Ratio and Quick Ratio.** In recent years, Dixie Co. has greatly increased its current ratio. At the same time, the quick ratio has fallen. What has happened? Has the liquidity of the company improved?
- LO 2** 3.3 **Current Ratio.** Explain what it means for a firm to have a current ratio equal to .50. Would the firm be better off if the current ratio were 1.50? What if it were 15.0? Explain your answers.
- LO 2** 3.4 **Financial Ratios.** Fully explain the kind of information the following financial ratios provide about a firm:

Concept Questions

Chapter sections are intentionally kept short to promote a step-by-step, building-block approach to learning. Each section is then followed by a series of short concept questions that highlight the key ideas just presented. Students use these questions to make sure they can identify and understand the most important concepts as they read.

CONCEPT QUESTIONS

- 3.4a** What does a firm's internal growth rate tell us?
- 3.4b** What does a firm's sustainable growth rate tell us?
- 3.4c** Why is the sustainable growth rate likely to be larger than the internal growth rate?

Numbered Examples

Separate numbered and titled examples are extensively integrated into the chapters. These examples provide detailed applications and illustrations of the text material in a step-by-step format. Each example is completely self-contained so that students don't have to search for additional information. Based on our classroom testing, these examples are among the most useful learning aids because they provide both detail and explanation.

Portfolio Variance and Standard Deviation

EXAMPLE 11.4

In Example 11.3, what are the standard deviations on the two portfolios? To answer, we first have to calculate the portfolio returns in the two states. We will work with the second portfolio, which has 50 percent in Stock A and 25 percent in each of Stocks B and C. The relevant calculations can be summarized as follows:

State of Economy	Probability of State	Returns			
		Stock A	Stock B	Stock C	Portfolio
Boom	.40	10%	15%	20%	13.75%
Bust	.60	8	4	0	5.00

The portfolio return when the economy booms is calculated as:

$$.50 \times 10\% + .25 \times 15\% + .25 \times 20\% = 13.75\%$$

The return when the economy goes bust is calculated the same way. The expected return on the portfolio is .085. The variance is thus:

$$\sigma^2 = .40 \times (13.75 - .085)^2 + .60 \times (.05 - .085)^2 = .0018375$$

I. Internal growth rate

$$\text{Internal growth rate} = \frac{\text{ROA} \times b}{1 - \text{ROA} \times b}$$

where

ROA = Return on assets = Net income/Total assets

b = Plowback (retention) ratio

= Addition to retained earnings/Net income

= 1 - Dividend payout ratio

The internal growth rate is the maximum growth rate that can be achieved with no external financing of any kind.

II. Sustainable growth rate

$$\text{Sustainable growth rate} = \frac{\text{ROE} \times b}{1 - \text{ROE} \times b}$$

where

ROE = Return on equity = Net income/Total equity

b = Plowback (retention) ratio

= Addition to retained earnings/Net income

= 1 - Dividend payout ratio

The sustainable growth rate is the maximum growth rate that can be achieved with no external equity financing while maintaining a constant debt-equity ratio.

TABLE 3.9

Summary of internal and sustainable growth rates

Summary Tables

These tables succinctly restate key principles, results, and equations. They appear whenever it is useful to emphasize and summarize a group of related concepts.

Key Terms

These are printed in blue the first time they appear, and are defined within the text and in the margin.

RATIO ANALYSIS

3.2

Another way of avoiding the problems involved in comparing companies of different sizes is to calculate and compare **financial ratios**. Such ratios are ways of comparing and investigating the relationships between different pieces of financial information. We cover some of the more common ratios next, but there are many others that we don't touch on.

One problem with ratios is that different people and different sources frequently don't compute them in exactly the same way, and this leads to much confusion. The specific definitions we use here may or may not be the same as ones you have seen or will see elsewhere. If you are ever using ratios as a tool for analysis, you should be careful to document how you calculate each one, and, if you are comparing your numbers to those of another source, be sure you know how their numbers are computed.

financial ratios

Relationships determined from a firm's financial information and used for comparison purposes.

Total Debt Ratio The *total debt ratio* takes into account all debts of all maturities to all creditors. It can be defined in several ways, the easiest of which is:

$$\text{Total debt ratio} = \frac{\text{Total assets} - \text{Total equity}}{\text{Total assets}} = \frac{\$3,588 - 2,591}{\$3,588} = .28 \text{ times}$$

[3.4]

Key Equations

These are called out in the text and identified by equation numbers. Appendix B shows the key equations by chapter.

Highlighted Phrases

Throughout the text, important ideas are presented separately and printed in a green box to indicate their importance to the students.

Chapter Summary and Conclusions

These paragraphs review the chapter's key points and provide closure to the chapter.

SUMMARY AND CONCLUSIONS

This chapter has described how to go about putting together a discounted cash flow analysis and evaluating the results. In it, we covered:

1. The identification of relevant project cash flows. We discussed project cash flows and described how to handle some issues that often come up, including sunk costs, opportunity costs, financing costs, net working capital, and erosion.
2. Preparing and using pro forma, or projected, financial statements. We showed how pro forma financial statement information is useful in coming up with projected cash flows.
3. The use of scenario and sensitivity analysis. These tools are widely used to evaluate the impact of assumptions made about future cash flows and NPV estimates.
4. Additional issues in capital budgeting. We examined the managerial options implicit in many capital budgeting situations. We also discussed the capital rationing problem.

The discounted cash flow analysis we've covered here is a standard tool in the business world. It is a very powerful tool, so care should be taken in its use. The most important thing is to get the cash flows identified in a way that makes economic sense. This chapter gives you a good start on learning to do this.

Chapter Review and Self-Test Problems

Review and self-test problems appear after the chapter summaries. Detailed answers to the self-test problems immediately follow. These questions and answers allow students to test their abilities in solving key problems related to the content of the chapter.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

- 9.1 **Calculating Operating Cash Flow.** Mater Pasta, Inc., has projected a sales volume of \$1,432 for the second year of a proposed expansion project. Costs normally run 70 percent of sales, or about \$1,002 in this case. The depreciation expense will be \$80, and the tax rate is 34 percent. What is the operating cash flow?
- 9.2 **Scenario Analysis.** A project under consideration costs \$500,000, has a five-year life, and has no salvage value. Depreciation is straight-line to zero. The required return is 15 percent, and the tax rate is 34 percent. Sales are projected at 400 units per year. Price per unit is \$3,000, variable cost per unit is \$1,900, and fixed costs are \$250,000 per year. No net working capital is required.
- Suppose you think the unit sales, price, variable cost, and fixed cost projections are accurate to within 5 percent. What are the upper and lower bounds for these projections? What is the base-case NPV? What are the best- and worst-case scenario NPVs?

■ Answers to Chapter Review and Self-Test Problems

- 9.1 First, we can calculate the project's EBIT, its tax bill, and its net income.

$$\begin{aligned}\text{EBIT} &= \$1,432 - 1,002 - 80 = \$350 \\ \text{Taxes} &= \$350 \times .34 = \$119\end{aligned}$$

$$\text{Net income} = \$350 - 119 = \$231$$

With these numbers, operating cash flow is:

$$\begin{aligned}\text{OCF} &= \text{EBIT} + \text{Depreciation} - \text{Taxes} \\ &= \$350 + 80 - 119 \\ &= \$311\end{aligned}$$

End-of-Chapter Questions and Problems

We have found that many students learn better when they have plenty of opportunity to practice. We therefore provide extensive end-of-chapter questions and problems—now linked to Learning Objectives. The questions and problems are generally separated into three levels—Basic, Intermediate, and Challenge. All problems are fully annotated so that students and instructors can readily identify particular types. Throughout the text, we have worked to supply interesting problems that illustrate real-world applications of chapter material. Answers to selected end-of-chapter problems appear in Appendix C.

QUESTIONS AND PROBLEMS connect

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

L01

1. **Relevant Cash Flows.** Kenny, Inc., is looking at setting up a new manufacturing plant in South Park. The company bought some land six years ago for \$7 million in anticipation of using it as a warehouse and distribution site, but the company has since decided to rent facilities elsewhere. The land would net \$9.8 million if it were sold today. The company now wants to build its new manufacturing plant on this land; the plant will cost \$21 million to build, and the site requires \$850,000 worth of grading before it is suitable for construction. What is the proper cash flow amount to use as the initial investment in fixed assets when evaluating this project? Why?

L01

2. **Relevant Cash Flows.** Winnebagel Corp. currently sells 28,000 motor homes per year at \$73,000 each and 7,000 luxury motor coaches per year at \$115,000 each. The company wants to introduce a new portable camper to fill out its product line; it hopes to sell 23,000 of these campers per year at \$19,000 each. An independent consultant has determined that if Winnebagel introduces the new campers, it should boost the sales of its existing motor homes by 2,600 units per year and reduce the sales of its motor coaches by 850 units per year. What is the amount to use as the annual sales figure when evaluating this project? Why?

L02

3. **Calculating Projected Net Income.** A proposed new investment has projected sales of \$825,000. Variable costs are 55 percent of sales, and fixed costs are \$187,150; depreciation is \$91,000. Prepare a pro forma income statement assuming a tax rate of 35 percent. What is the projected net income?

Basic
(Questions 1–20)

Comprehensive Teaching and Learning Package

This edition of *Essentials* has more options than ever in terms of the textbook, instructor supplements, student supplements, and multimedia products. Mix and match to create a package that is perfect for your course!

INSTRUCTOR SUPPLEMENTS

Assurance of Learning

Many educational institutions today are focused on the notion of assurance of learning, an important element of some accreditation standards. This text is designed specifically to support your assurance of learning initiatives with a simple, yet powerful, solution.

Each test bank question maps to a specific chapter learning outcome/objective listed in the text. You can use the Test Bank software to easily query for learning outcomes/objectives that directly relate to the learning objectives for your course. You can then use the reporting features of the software to aggregate student results in similar fashion, making the collection and presentation of assurance of learning data simple and easy.

Instructor's CD-ROM

ISBN 0077260651

Keep all the supplements in one place! This CD contains all the necessary supplements—Instructor's Manual, Solutions, Test Bank, Computerized Test Bank, and PowerPoint—all in one useful product in an electronic format.

■ Instructor's Manual (IM)

Prepared by Lynn Kugele, The University of Mississippi

A great place to find new lecture ideas! This annotated outline for each chapter includes Lecture Tips, Real-World Tips, Ethics Notes, suggested PowerPoint slides, and, when appropriate, a video synopsis.

■ Solutions Manual (SM)

Prepared by Joseph Smolira, Belmont University

The *Essentials* Solutions Manual provides detailed solutions to the extensive end-of-chapter material, including concept review questions, quantitative problems, and cases. Select chapters also contain calculator solutions.

■ Test Bank

Prepared by Kay Johnson, Penn State University–Erie

Great format for a better testing process! All questions closely link with the text material, listing section number, Learning Objective, Bloom's Taxonomy Question Type, and AACSB topic when applicable. Each chapter is divided into five parts. Part I contains questions that test the understanding of the key terms in the book. Part II includes questions patterned after the learning objectives, concept questions, chapter opening vignettes, boxes, and highlighted phrases. Part III contains multiple-choice and true/false problems patterned after the end-of-chapter questions, in basic, intermediate, and challenge

levels. Part IV provides essay questions to test problem-solving skills and more advanced understanding of concepts. Part V is a new section that picks up questions directly from the end-of-chapter material and converts them into parallel test bank questions. For your reference, each test bank question in this part is linked with its corresponding question in the end-of-chapter. Also included are ready-made quizzes to hand out in class.

■ **Computerized Test Bank (Windows)**

Create your own tests in a snap! These additional questions are found in a computerized test bank utilizing McGraw-Hill's EZ Test testing software to quickly create customized exams. This user-friendly program allows instructors to sort questions by format, edit existing questions or add new ones, and scramble questions for multiple versions of the same test.

■ **PowerPoint Presentation System**

Prepared by Lynn Kugele, The University of Mississippi

Customize our content for your course! This presentation has been thoroughly revised to include more lecture-oriented slides, as well as exhibits and examples both from the book and from outside sources. Applicable slides have Web links that take you directly to specific Internet sites or spreadsheet links to show an example in Excel. You can also go to the Notes Page function for more tips in presenting the slides. New to this edition, additional PPT slides work through example problems for instructors to show in class. If you already have PowerPoint installed on your PC, you have the ability to edit, print, or rearrange the complete presentation to meet your specific needs.

Videos (DVD Format)

Current set of videos on hot topics! McGraw-Hill/Irwin has produced a series of finance videos that are 10-minute case studies on topics such as Financial Markets, Careers, Rightsizing, Capital Budgeting, EVA (Economic Value Added), Mergers and Acquisitions, and International Finance.

ONLINE SUPPORT

Online Learning Center at www.mhhe.com/rwj

The Online Learning Center (OLC) contains *free* access to additional Web-based study and teaching aids created for this text, such as:

■ **Student Support**

A great resource for those seeking additional practice, students can access self-grading quizzes, Excel template problems, and the new tutorial *Excel Master* designed by Brad Jordan and Joe Smolira.

Premium Content Access

iPod Content The library isn't the place to study! Students lead active and mobile lives. Harness the power of one of the most popular technology tools today and study on the go. Our innovative approach allows you to download Narrated PowerPoints and quizzes right into your iPod or other MP3 player device.

Narrated PowerPoint Slides *Created by Kent Ragan, Missouri State University.* The narrated PowerPoints provide real-world examples accompanied by step-by-step instructions and explanations for solving problems presented in the chapter. The Concept Checks from the text are also integrated into the slides to reinforce the key topics in the chapter. Designed specifically to appeal to different learning styles, the slides provide a visual and audio explanation of topics and problems. Click on the slide and listen to the accompanying narration! You can view this slides via computer or download them onto your video iPod.

■ Teaching Support

Along with having access to all of the same material your students can view on the book's OLC, you also have password protected access to the Instructor's Manual, solutions to end-of-chapter problems and cases, Instructor's Excel Master, Instructor's PowerPoint, Excel template solutions, video clips, and video projects and questions.

WebCT and Blackboard course cartridges allow instructors to manage their course and administer examinations online. Increase ease, organization, and efficiency and ask your representative for more details about course cartridges today!

McGraw-Hill *Connect Finance*

Less Managing. More Teaching. Greater Learning.

McGraw-Hill's *Connect Finance* is an online assignment and assessment solution that connects students with the tools and resources they'll need to achieve success.

Connect helps prepare students for their future by enabling faster learning, more efficient studying, and better retention of knowledge.

McGraw-Hill *Connect Finance* Features *Connect Finance* offers powerful tools and features to make managing assignments easier, so faculty can spend more time teaching. With *Connect Finance*, students can engage with their coursework anytime and anywhere, making the learning process more accessible and efficient. *Connect Finance* offers you the features described below.

Simple Assignment Management With *Connect Finance*, creating assignments is easier than ever, so you can spend more time teaching and less time managing. The assignment management function enables you to:

- Create and deliver assignments easily with selectable end-of-chapter questions and test bank items.
- Streamline lesson planning, student progress reporting, and assignment grading to make classroom management more efficient than ever.
- Go paperless with the eBook and online submission and grading of student assignments.

Smart Grading When it comes to studying, time is precious. *Connect Finance* helps students learn more efficiently by providing feedback and practice material when they need it, where they need it. When it comes to teaching, your time is also precious. The grading function enables you to:

- Have assignments scored automatically, giving students immediate feedback on their work and side-by-side comparisons with correct answers.
- Access and review each response; manually change grades or leave comments for students to review.
- Reinforce classroom concepts with practice tests and instant quizzes.

Instructor Library The *Connect Finance* Instructor Library is your repository for additional resources to improve student engagement in and out of class. You can select and use any asset that enhances your lecture.

Student Study Center The *Connect Finance* Student Study Center is the place for students to access additional resources. The Student Study Center:

- Offers students quick access to lectures, practice materials, eBooks, and more.

- Provides instant practice material and study questions, easily accessible on the go.
- Gives students access to the Personal Learning Plan described below.

Connect Study Feature This Study Feature connects each student to the learning resources needed for success in the course. For each chapter, students:

- Take a practice test to gauge understanding of the material.
- Immediately upon completing the practice test, see how their performance compares to the chapter objectives to be achieved within each section of the chapters.
- Receive a personal learning plan that recommends specific readings from the text, supplemental study material, and practice work that will improve their understanding and mastery of each learning objective.

Students Progress Tracking *Connect Finance* keeps instructors informed about how each student, section, and class is performing, allowing for more productive use of lecture and office hours. The progress-tracking function enables you to:

- View scored work immediately and track individual or group performance with assignment and grade reports.
- Access an instant view of student or class performance relative to learning objectives.

Lecture Capture through Tegrity Campus For an additional charge, Lecture Capture offers new ways for students to focus on the in-class discussion, knowing they can revisit important topics later. This can be delivered through Connect or separately. See below for more details.

McGraw-Hill Connect Plus Finance McGraw-Hill reinvents the textbook learning experience for the modern student with *Connect Plus Finance*. A seamless integration of an eBook and *Connect Finance*, *Connect Plus Finance* provides all of the *Connect Finance* features plus the following:

- An integrated eBook, allowing for anytime, anywhere access to the textbook.
- Dynamic links between the problems or questions you assign to your students and the location in the eBook where that problem or question is covered.
- A powerful search function to pinpoint and connect key concepts in a snap.

In short, *Connect Finance* offers you and your students powerful tools and features that optimize your time and energies, enabling you to focus on course content, teaching, and student learning. *Connect Finance* also offers a wealth of content resources for both instructors and students. This state-of-the-art, thoroughly tested system supports you in preparing students for the world that awaits.

For more information about Connect, go to www.mcgrawhillconnect.com, or contact your McGraw-Hill sales representative.

TEGRITY CAMPUS: LECTURES 24/7

Tegrity Campus is a service that makes class time available 24/7 by automatically capturing every lecture in a searchable format for students to review when they study and complete

assignments. With a simple one-click start-and-stop process, you capture all computer screens and corresponding audio. Students can reply any part of any class with easy-to-use browser-based viewing on a PC or Mac.

Educators know that the more students can see, hear, and experience class resources, the better they learn. In fact, studies prove it. With Tegrity Campus, students quickly recall key moments by using Tegrity Campus's unique search feature. This search helps students efficiently find what they need, when they need it, across an entire semester of class recordings. Help turn all your students' study time into learning moments immediately supported by your lecture.

To learn more about Tegrity watch a 2-minute Flash demo at <http://tegritycampus.mhhe.com>.

McGraw–Hill Customer Care Contact Information

At McGraw–Hill, we understand that getting the most from new technology can be challenging. That's why our services don't stop after you purchase our products. You can e-mail our Product Specialists 24 hours a day to get product training online. Or you can search our knowledge bank of Frequently Asked Questions on our support Web site. For Customer Support, call **800-331-5094**, e-mail hmsupport@mcgraw-hill.com, or visit www.mhhe.com/support. One of our Technical Support Analysts will be able to assist you in a timely fashion.

AVAILABLE FOR PURCHASE & PACKAGING

Student Problem Manual

Prepared by Thomas Eyssell, University of Missouri–St. Louis

ISBN 0-07-331313-0

Need additional reinforcement of the concepts? This valuable resource provides students with additional problems for practice. Each chapter begins with Concepts for Review, followed by Chapter Highlights. These re-emphasize the key terms and concepts in the chapter. A short Concept Test, averaging 10 questions and answers, appears next. Each chapter concludes with additional problems for the student to review. Answers to these problems appear at the end of the Student Problem Manual.

Financial Analysis with an Electronic Calculator, Sixth Edition

by Mark A. White, University of Virginia, McIntire School of Commerce

ISBN-10: 0-07-321709-3; ISBN-13: 978-0-07-321709-3

The information and procedures in this supplementary text enable students to master the use of financial calculators and develop a working knowledge of financial mathematics and problem solving. Complete instructions are included for solving all major problem types on four popular models: HP 10-B, HP 12-C, TI BA II Plus, and TI-84. Hands-on problems with detailed solutions allow students to practice the skills outlined in the text and obtain instant reinforcement. *Financial Analysis with an Electronic Calculator* is a self-contained supplement to the introductory financial management course.

Acknowledgments

Clearly, our greatest debt is to our many colleagues (and their students) around the world who, like us, wanted to try an alternative to what they were using and made the switch to our text. Our plan for developing and improving *Essentials, 7e*, revolved around the detailed feedback we received from many of our colleagues who had an interest in the book and regularly teach the introductory course. These dedicated scholars and teachers to whom we are very grateful are:

Vaughn S. Armstrong, *Utah Valley University*
Juan Avendano, *Augsburg College*

We owe a special debt to our colleagues for their dedicated work on the many supplements that accompany this text: Lynn Kugele, University of Mississippi, for her development of the Instructor's Manual and PowerPoint slides; Kay Johnson, Penn State–Erie, for her extensive revision and improvement of the Test Bank, revision of the Self-Study quizzes and the Test Bank quizzes; Thomas H. Eyssell, University of Missouri–St. Louis, for his revision of the Student Problem Manual; and Kent Ragan, Missouri State University, for his revision of the Narrated PowerPoints.

We also thank Joseph C. Smolira, Belmont University, for his work on this edition. Joe worked closely with us to develop the solutions manual, along with many of the vignettes and real-world examples we have added to this edition.

Laura Coogan, Steve Hailey, and Jacob Prewitt of the University of Kentucky did outstanding work on this edition of *Essentials*. To them fell the unenviable task of technical proofreading, and, in particular, careful checking of each and every calculation throughout the text.

Finally, in every phase of this project, we have been privileged to have the complete and unwavering support of a great organization, McGraw-Hill/Irwin. We especially thank the McGraw-Hill/Irwin sales organization. The suggestions they provided, their professionalism in assisting potential adopters, and their service to current adopters have been a major factor in our success.

We are deeply grateful to the select group of professionals who served as our development team on this edition: Michele Janicek, Executive Editor; Elizabeth Hughes,

Development Editor II; Christine Vaughan, Lead Project Manager; Brian Nacik, Media Project Manager; Pam Verros, Designer; and Carol Bielski, Lead Production Supervisor. Others at McGraw-Hill/Irwin, too numerous to list here, have improved the book in countless ways.

Throughout the development of this edition, we have taken great care to discover and eliminate errors. Our goal is to provide the best textbook available on the subject. To ensure that future editions are error-free, we will gladly offer \$10 per arithmetic error to the first individual reporting it as a modest token of our appreciation. More than this, we would like to hear from instructors and students alike. Please send us your comments by using the feedback form on the *Essentials of Corporate Finance* Online Learning Center at www.mhhe.com/rwj.

PART ONE

OVERVIEW OF FINANCIAL MANAGEMENT

CHAPTER 1

Introduction to Financial Management

1.1 Finance: A Quick Look 2

- The Four Basic Areas 2
 - Corporate Finance* 2
 - Investments* 2
 - Financial Institutions* 3
 - International Finance* 3
- Why Study Finance? 3
 - Marketing and Finance* 3
 - Accounting and Finance* 3
 - Management and Finance* 4
 - You and Finance* 4

1.2 Business Finance and the Financial Manager 4

- What Is Business Finance? 4
- The Financial Manager 5
- Financial Management Decisions 5
 - Capital Budgeting* 5
 - Capital Structure* 5
 - Working Capital Management* 6
 - Conclusion* 6

1.3 Forms of Business Organization 7

- Sole Proprietorship 7
- Partnership 7
- Corporation 8
- A Corporation by Another Name... 9

1.4 The Goal of Financial Management 10

- Profit Maximization 10
- The Goal of Financial Management in a Corporation 10
- A More General Financial Management Goal 11
- Sarbanes-Oxley Act 12

1.5 The Agency Problem and Control of the Corporation 12

- Agency Relationships 12
- Management Goals 13
- Do Managers Act in the Stockholders' Interests? 13
 - Managerial Compensation* 13
 - Control of the Firm* 14
 - Conclusion* 15
- Stakeholders 15

1.6 Financial Markets and the Corporation 15

- Cash Flows to and from the Firm 16
- Primary versus Secondary Markets 16
 - Primary Markets* 17
 - Secondary Markets* 17

Summary and Conclusions 18

Critical Thinking and Concepts Review 19

What's on the Web? 20

Chapter Case: The McGee Cake Company 21

PART TWO

UNDERSTANDING FINANCIAL STATEMENTS AND CASH FLOW

CHAPTER 2

Financial Statements, Taxes, and Cash Flow

2.1 The Balance Sheet 23

- Assets: The Left-Hand Side 23
- Liabilities and Owners' Equity: The Right-Hand Side 23
- Net Working Capital 24
- Liquidity 25
- Debt versus Equity 26
- Market Value versus Book Value 26

2.2 The Income Statement 27

- GAAP and the Income Statement 28
- Noncash Items 29
- Time and Costs 29
- Earnings Management 30

2.3 Taxes 31

- Corporate Tax Rates 32
- Average versus Marginal Tax Rates 32

2.4 Cash Flow 34

- Cash Flow from Assets 34
 - Operating Cash Flow* 34
 - Capital Spending* 35
 - Change in Net Working Capital* 36
 - Conclusion* 36
 - A Note on "Free" Cash Flow* 36
- Cash Flow to Creditors and Stockholders 36

<i>Cash Flow to Creditors</i>	37
<i>Cash Flow to Stockholders</i>	37
Conclusion	37
An Example: Cash Flows for Dole Cola	39
<i>Operating Cash Flow</i>	39
<i>Net Capital Spending</i>	39
<i>Change in NWC and Cash Flow from Assets</i>	39
<i>Cash Flow to Creditors and Stockholders</i>	40

Summary and Conclusions 41

Chapter Review and Self-Test Problem 41

Answer to Chapter Review and Self-Test Problem 42

Critical Thinking and Concepts Review 44

Questions and Problems 45

What's on the Web? 48

Chapter Case: Cash Flows and Financial Statements at Sunset Boards, Inc. 50

CHAPTER 3

Working with Financial Statements

3.1 Standardized Financial Statements 52

Common-Size Balance Sheets	53
Common-Size Income Statements	54

3.2 Ratio Analysis 55

Short-Term Solvency, or Liquidity, Measures	56
<i>Current Ratio</i>	56
<i>Quick (or Acid-Test) Ratio</i>	57
<i>Cash Ratio</i>	57
Long-Term Solvency Measures	58
<i>Total Debt Ratio</i>	58
<i>Times Interest Earned</i>	58
<i>Cash Coverage</i>	58
Asset Management, or Turnover, Measures	59
<i>Inventory Turnover and Days' Sales in Inventory</i>	59
<i>Receivables Turnover and Days' Sales in Receivables</i>	60
<i>Total Asset Turnover</i>	61
Profitability Measures	61
<i>Profit Margin</i>	61
<i>Return on Assets</i>	62
<i>Return on Equity</i>	62
Market Value Measures	62
<i>Price-Earnings Ratio</i>	62
<i>Price-Sales Ratio</i>	63
<i>Market-to-Book Ratio</i>	63

3.3 The Du Pont Identity 64

An Expanded Du Pont Analysis	66
------------------------------	----

3.4 Internal and Sustainable Growth 68

Dividend Payout and Earnings Retention	68
ROA, ROE, and Growth	69

<i>The Internal Growth Rate</i>	69
<i>The Sustainable Growth Rate</i>	70
<i>Determinants of Growth</i>	70
<i>A Note on Sustainable Growth Rate Calculations</i>	71

3.5 Using Financial Statement Information 72

Why Evaluate Financial Statements?	72
<i>Internal Uses</i>	72
<i>External Uses</i>	73
Choosing a Benchmark	73
<i>Time-Trend Analysis</i>	73
<i>Peer Group Analysis</i>	73
Problems with Financial Statement Analysis	78

Summary and Conclusions 80

Chapter Review and Self-Test Problems 80

Answers to Chapter Review and Self-Test Problems 82

Critical Thinking and Concepts Review 83

Questions and Problems 85

What's on the Web? 91

Chapter Case: Ratios and Financial Planning at S&S Air, Inc. 93

PART THREE

VALUATION OF FUTURE CASH FLOWS

CHAPTER 4

Introduction to Valuation: The Time Value of Money

4.1 Future Value and Compounding 96

Investing for a Single Period	96
Investing for More Than One Period	96

4.2 Present Value and Discounting 103

The Single-Period Case	103
Present Values for Multiple Periods	104

4.3 More on Present and Future Values 106

Present versus Future Value	106
Determining the Discount Rate	107
Finding the Number of Periods	110

Summary and Conclusions 114

Chapter Review and Self-Test Problems 114

Answers to Chapter Review and Self-Test Problems 114

Critical Thinking and Concepts Review 115

Questions and Problems 116

What's on the Web? 119

CHAPTER 5

Discounted Cash Flow Valuation

5.1 Future and Present Values of Multiple Cash Flows 121

- Future Value with Multiple Cash Flows 121
- Present Value with Multiple Cash Flows 124
- A Note on Cash Flow Timing 128

5.2 Valuing Level Cash Flows: Annuities and Perpetuities 130

- Present Value for Annuity Cash Flows 130
 - Annuity Tables* 131
 - Finding the Payment* 132
 - Finding the Rate* 134
- Future Value for Annuities 136
- A Note on Annuities Due 136
- Perpetuities 137

5.3 Comparing Rates: The Effect of Compounding Periods 139

- Effective Annual Rates and Compounding 139
- Calculating and Comparing Effective Annual Rates 140
- EARs and APRs 142
- EARs, APRs, Financial Calculators, and Spreadsheets 143

5.4 Loan Types and Loan Amortization 144

- Pure Discount Loans 144
- Interest-Only Loans 145
- Amortized Loans 145

Summary and Conclusions 149**Chapter Review and Self-Test Problems 150****Answers to Chapter Review and Self-Test Problems 150****Critical Thinking and Concepts Review 152****Questions and Problems 153****What's on the Web? 160****Chapter Case: S&S Air's Mortgage 161****6.2 More on Bond Features 172**

- Is It Debt or Equity? 173
- Long-Term Debt: The Basics 173
- The Indenture 174
 - Terms of a Bond* 175
 - Security* 175
 - Seniority* 176
 - Repayment* 176
 - The Call Provision* 176
 - Protective Covenants* 177

6.3 Bond Ratings 177**6.4 Some Different Types of Bonds 179**

- Government Bonds 179
- Zero Coupon Bonds 180
- Floating-Rate Bonds 181
- Other Types of Bonds 182

6.5 Bond Markets 183

- How Bonds Are Bought and Sold 184
- Bond Price Reporting 184
 - A Note on Bond Price Quotes* 187

6.6 Inflation and Interest Rates 187

- Real versus Nominal Rates 188
- The Fisher Effect 188

6.7 Determinants of Bond Yields 189

- The Term Structure of Interest Rates 189
- Bond Yields and the Yield Curve: Putting It All Together 191
- Conclusion 193

Summary and Conclusions 194**Chapter Review and Self-Test Problems 194****Answers to Chapter Review and Self-Test Problems 194****Critical Thinking and Concepts Review 195****Questions and Problems 196****What's on the Web? 199****Chapter Case: Financing S&S Air's Expansion Plans with a Bond Issue 201**

PART FOUR

VALUING STOCKS AND BONDS

CHAPTER 6

Interest Rates and Bond Valuation

6.1 Bonds and Bond Valuation 163

- Bond Features and Prices 163
- Bond Values and Yields 163
- Interest Rate Risk 166
- Finding the Yield to Maturity: More Trial and Error 168

CHAPTER 7

Equity Markets and Stock Valuation

7.1 Common Stock Valuation 203

- Cash Flows 203
- Some Special Cases 204
 - Zero Growth* 205
 - Constant Growth* 205
 - Nonconstant Growth* 208
- Components of the Required Return 210

7.2 Some Features of Common and Preferred Stock 212

- Common Stock Features 212
 - Shareholder Rights* 212

Proxy Voting	213
Classes of Stock	213
Other Rights	214
Dividends	214
Preferred Stock Features	215
Stated Value	215
Cumulative and Noncumulative Dividends	215
Is Preferred Stock Really Debt?	215
7.3 The Stock Markets	216
Dealers and Brokers	216
Organization of the NYSE	216
Members	216
Operations	217
Floor Activity	218
NASDAQ Operations	219
ECNs	219
Stock Market Reporting	220
Summary and Conclusions	223
Chapter Review and Self-Test Problems	223
Answers to Chapter Review and Self-Test Problems	224
Critical Thinking and Concepts Review	224
Questions and Problems	225
What's on the Web?	228
Chapter Case: Stock Valuation at Ragan, Inc.	229

PART FIVE

CAPITAL BUDGETING

CHAPTER 8

Net Present Value and Other Investment Criteria

8.1 Net Present Value	231
The Basic Idea	231
Estimating Net Present Value	232
8.2 The Payback Rule	235
Defining the Rule	235
Analyzing the Rule	237
Redeeming Qualities of the Rule	238
Summary of the Rule	238
8.3 The Average Accounting Return	239
8.4 The Internal Rate of Return	241
Problems with the IRR	244
Nonconventional Cash Flows	244
Mutually Exclusive Investments	246
Redeeming Qualities of the IRR	248

The Modified Internal Rate of Return (MIRR)	249
Method 1: The Discounting Approach	249
Method 2: The Reinvestment Approach	249
Method 3: The Combination Approach	249
MIRR or IRR: Which Is Better?	250

8.5 The Profitability Index	250
8.6 The Practice of Capital Budgeting	251
Summary and Conclusions	254
Chapter Review and Self-Test Problems	254
Answers to Chapter Review and Self-Test Problems	255
Critical Thinking and Concepts Review	256
Questions and Problems	258
What's on the Web?	265
Chapter Case: Bullock Gold Mining	266

CHAPTER 9

Making Capital Investment Decisions

9.1 Project Cash Flows: A First Look	268
Relevant Cash Flows	268
The Stand-Alone Principle	268
9.2 Incremental Cash Flows	269
Sunk Costs	269
Opportunity Costs	269
Side Effects	270
Net Working Capital	270
Financing Costs	270
Other Issues	271
9.3 Pro Forma Financial Statements and Project Cash Flows	271
Getting Started: Pro Forma Financial Statements	271
Project Cash Flows	272
Project Operating Cash Flow	272
Project Net Working Capital and Capital Spending	273
Projected Total Cash Flow and Value	273
The Tax Shield Approach	274
9.4 More on Project Cash Flow	275
A Closer Look at Net Working Capital	275
Depreciation	276
Modified ACRS (MACRS) Depreciation	277
Book Value versus Market Value	278
An Example: The Majestic Mulch and Compost Company (MMCC)	279
Operating Cash Flows	280
Changes in NWC	281
Capital Spending	281
Total Cash Flow and Value	281
Conclusion	283

9.5 Evaluating NPV Estimates	283
The Basic Problem	283
Forecasting Risk	284
Sources of Value	284
9.6 Scenario and Other What-If Analyses	285
Getting Started	285
Scenario Analysis	286
Sensitivity Analysis	287
9.7 Additional Considerations in Capital Budgeting	289
Managerial Options and Capital Budgeting	289
Contingency Planning	289
Strategic Options	291
Conclusion	291
Capital Rationing	291
Soft Rationing	291
Hard Rationing	292
Summary and Conclusions	292
Chapter Review and Self-Test Problems	293
Answers to Chapter Review and Self-Test Problems	293
Critical Thinking and Concepts Review	294
Questions and Problems	295
Chapter Case: Conch Republic Electronics	300

PART SIX

RISK AND RETURN

CHAPTER 10

Some Lessons from Capital Market History

10.1 Returns	302
Dollar Returns	302
Percentage Returns	304
10.2 The Historical Record	306
A First Look	307
A Closer Look	307
10.3 Average Returns: The First Lesson	312
Calculating Average Returns	312
Average Returns: The Historical Record	312
Risk Premiums	313
The First Lesson	313
10.4 The Variability of Returns: The Second Lesson	314
Frequency Distributions and Variability	314
The Historical Variance and Standard Deviation	315
The Historical Record	317
Normal Distribution	318
The Second Lesson	319

Using Capital Market History	320
More on the Stock Market Risk Premium	321

10.5 More on Average Returns	323
Arithmetic versus Geometric Averages	323
Calculating Geometric Average Returns	323
Arithmetic Average Return or Geometric Average Return?	325
10.6 Capital Market Efficiency	326
Price Behavior in an Efficient Market	326
The Efficient Markets Hypothesis	327
Some Common Misconceptions about the EMH	328
The Forms of Market Efficiency	329
Summary and Conclusions	330
Chapter Review and Self-Test Problems	330
Answers to Chapter Review and Self-Test Problems	331
Critical Thinking and Concepts Review	332
Questions and Problems	332
What's on the Web?	336
Chapter Case: A Job at S&S Air	337

CHAPTER 11

Risk and Return

11.1 Expected Returns and Variances	340
Expected Return	340
Calculating the Variance	342
11.2 Portfolios	344
Portfolio Weights	344
Portfolio Expected Returns	344
Portfolio Variance	346
11.3 Announcements, Surprises, and Expected Returns	347
Expected and Unexpected Returns	347
Announcements and News	348
11.4 Risk: Systematic and Unsystematic	350
Systematic and Unsystematic Risk	350
Systematic and Unsystematic Components of Return	350
11.5 Diversification and Portfolio Risk	351
The Effect of Diversification: Another Lesson from Market History	351
The Principle of Diversification	352
Diversification and Unsystematic Risk	352
Diversification and Systematic Risk	353
11.6 Systematic Risk and Beta	354
The Systematic Risk Principle	354
Measuring Systematic Risk	355
Portfolio Betas	356
11.7 The Security Market Line	358
Beta and the Risk Premium	358

<i>The Reward-to-Risk Ratio</i>	359
<i>The Basic Argument</i>	360
<i>The Fundamental Result</i>	362
The Security Market Line	363
Market Portfolios	363
<i>The Capital Asset Pricing Model</i>	363

11.8 The SML and the Cost of Capital: A Preview	366
The Basic Idea	366
The Cost of Capital	366
Summary and Conclusions	367
Chapter Review and Self-Test Problems	367
Answers to Chapter Review and Self-Test Problems	368
Critical Thinking and Concepts Review	369
Questions and Problems	371
What's on the Web?	375
Chapter Case: The Beta for FLIR Systems	376

PART SEVEN

LONG-TERM FINANCING

CHAPTER 12

Cost of Capital

12.1 The Cost of Capital: Some Preliminaries	378
Required Return versus Cost of Capital	378
Financial Policy and Cost of Capital	379
12.2 The Cost of Equity	380
The Dividend Growth Model Approach	380
<i>Implementing the Approach</i>	380
<i>Estimating g</i>	381
<i>Advantages and Disadvantages of the Approach</i>	381
The SML Approach	382
<i>Implementing the Approach</i>	382
<i>Advantages and Disadvantages of the Approach</i>	383
12.3 The Costs of Debt and Preferred Stock	383
The Cost of Debt	384
The Cost of Preferred Stock	384
12.4 The Weighted Average Cost of Capital	385
The Capital Structure Weights	385
Taxes and the Weighted Average Cost of Capital	386
Solving the Warehouse Problem and Similar Capital Budgeting Problems	388
Calculating the WACC for Eastman Chemical	389
<i>Eastman's Cost of Equity</i>	390
<i>Eastman's Cost of Debt</i>	392
<i>Eastman's WACC</i>	393

12.5 Divisional and Project Costs of Capital 395

The SML and the WACC	395
Divisional Cost of Capital	396
The Pure Play Approach	396
The Subjective Approach	397

Summary and Conclusions 399

Chapter Review and Self-Test Problems 399

Answers to Chapter Review and Self-Test Problems 399

Critical Thinking and Concepts Review 400

Questions and Problems 401

What's on the Web? 405

Chapter Case: Cost of Capital for Hubbard Computer, Inc. 406

CHAPTER 13

Leverage and Capital Structure

13.1 The Capital Structure Question 408

13.2 The Effect of Financial Leverage 409

The Impact of Financial Leverage	409
<i>Financial Leverage, EPS, and ROE: An Example</i>	409
<i>EPS versus EBIT</i>	410
Corporate Borrowing and Homemade Leverage	412

13.3 Capital Structure and the Cost of Equity Capital 414

M&M Proposition I: The Pie Model	414
The Cost of Equity and Financial Leverage: M&M Proposition II	415
Business and Financial Risk	416

13.4 Corporate Taxes and Capital Structure 417

The Interest Tax Shield	418
Taxes and M&M Proposition I	418
Conclusion	419

13.5 Bankruptcy Costs 420

Direct Bankruptcy Costs	420
Indirect Bankruptcy Costs	421

13.6 Optimal Capital Structure 421

The Static Theory of Capital Structure	422
Optimal Capital Structure and the Cost of Capital	423
Capital Structure: Some Managerial Recommendations	423
<i>Taxes</i>	423
<i>Financial Distress</i>	425

13.7 Observed Capital Structures 425

13.8 A Quick Look at the Bankruptcy Process 427

Liquidation and Reorganization	427
<i>Bankruptcy Liquidation</i>	427
<i>Bankruptcy Reorganization</i>	428
Financial Management and the Bankruptcy Process	429
Agreements to Avoid Bankruptcy	431

Summary and Conclusions	431
Chapter Review and Self-Test Problems	431
Answers to Chapter Review and Self-Test Problems	432
Critical Thinking and Concepts Review	432
Questions and Problems	433
What's on the Web?	436
Chapter Case: Stephenson Real Estate Recapitalization	437

CHAPTER 14

Dividends and Dividend Policy

14.1 Cash Dividends and Dividend Payment	439
Cash Dividends	440
Standard Method of Cash Dividend Payment	440
Dividend Payment: A Chronology	440
More on the Ex-Dividend Date	441
14.2 Does Dividend Policy Matter?	443
An Illustration of the Irrelevance of Dividend Policy	443
<i>Current Policy: Dividends Set Equal to Cash Flow</i>	443
<i>Alternative Policy: Initial Dividend Greater Than Cash Flow</i>	444
A Test	444
Some Real-World Factors Favoring a Low Payout	445
<i>Taxes</i>	445
<i>Flotation Costs</i>	445
<i>Dividend Restrictions</i>	446
Some Real-World Factors Favoring a High Payout	446
<i>Desire for Current Income</i>	446
<i>Tax and Legal Benefits from High Dividends</i>	446
Clientele Effects: A Resolution of Real-World Factors?	447
14.3 Stock Repurchase: An Alternative to Cash Dividends	448
Cash Dividends versus Repurchase	449
Real-World Considerations in a Repurchase	450
Share Repurchase and EPS	451
14.4 What We Know and Do Not Know about Dividend and Payout Policies	452
Dividends and Dividend Payers	452
Corporations Smooth Dividends	454
Putting It All Together	455
Some Survey Evidence on Dividends	457
14.5 Stock Dividends and Stock Splits	458
Value of Stock Splits and Stock Dividends	459
<i>The Benchmark Case</i>	459
<i>Popular Trading Range</i>	459
Reverse Splits	460
Summary and Conclusions	461

Chapter Review and Self-Test Problem	461
Answer to Chapter Review and Self-Test Problem	462
Critical Thinking and Concepts Review	462
Questions and Problems	463
What's on the Web?	466
Chapter Case: Electronic Timing, Inc.	467

CHAPTER 15

Raising Capital

15.1 The Financing Life Cycle of a Firm: Early-Stage Financing and Venture Capital	469
Venture Capital	469
Some Venture Capital Realities	470
Choosing a Venture Capitalist	470
Conclusion	471
15.2 Selling Securities to the Public: The Basic Procedure	471
15.3 Alternative Issue Methods	472
15.4 Underwriters	475
Choosing an Underwriter	475
Types of Underwriting	475
<i>Firm Commitment Underwriting</i>	475
<i>Best Efforts Underwriting</i>	476
<i>Dutch Auction Underwriting</i>	476
The Green Shoe Provision	476
The Aftermarket	477
Lockup Agreements	477
The Quiet Period	477
15.5 IPOs and Underpricing	478
Evidence on Underpricing	478
IPO Underpricing: The 1999–2000 Experience	481
Why Does Underpricing Exist?	483
15.6 New Equity Sales and the Value of the Firm	485
15.7 The Cost of Issuing Securities	486
15.8 Issuing Long-Term Debt	490
15.9 Shelf Registration	491
Summary and Conclusions	492
Chapter Review and Self-Test Problem	492
Answer to Chapter Review and Self-Test Problem	492
Critical Thinking and Concepts Review	492
Questions and Problems	495
What's on the Web?	495
Chapter Case: S&S Air Goes Public	496

PART EIGHT**SHORT-TERM FINANCIAL MANAGEMENT****CHAPTER 16****Short-Term Financial Planning**

- 16.1 Tracing Cash and Net Working Capital 498**
- 16.2 The Operating Cycle and the Cash Cycle 500**
 - Defining the Operating and Cash Cycles 500
 - The Operating Cycle 501*
 - The Cash Cycle 501*
 - The Operating Cycle and the Firm's Organizational Chart 502
 - Calculating the Operating and Cash Cycles 503
 - The Operating Cycle 503*
 - The Cash Cycle 504*
 - Interpreting the Cash Cycle 505
- 16.3 Some Aspects of Short-Term Financial Policy 507**
 - The Size of the Firm's Investment in Current Assets 507
 - Alternative Financing Policies for Current Assets 509
 - Which Financing Policy Is Best? 511
 - Current Assets and Liabilities in Practice 512
- 16.4 The Cash Budget 513**
 - Sales and Cash Collections 513
 - Cash Outflows 514
 - The Cash Balance 514
- 16.5 Short-Term Borrowing 516**
 - Unsecured Loans 516
 - Secured Loans 516
 - Accounts Receivable Financing 516*
 - Inventory Loans 517*
 - Other Sources 517
- 16.6 A Short-Term Financial Plan 518**
 - Summary and Conclusions 519**
 - Chapter Review and Self-Test Problems 519**
 - Answers to Chapter Review and Self-Test Problems 520**
 - Critical Thinking and Concepts Review 521**
 - Questions and Problems 522**
 - What's on the Web? 527**
 - Chapter Case: Piepkorn Manufacturing Working Capital Management, Part 1 528**

CHAPTER 17**Working Capital Management**

- 17.1 Float and Cash Management 530**
 - Reasons for Holding Cash 530
 - The Speculative and Precautionary Motives 530*

- The Transaction Motive 530*
- Benefits of Holding Cash 531*

Introduction to Financial Management

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Discuss the basic types of financial management decisions and the role of the financial manager.
- LO 2** Identify the goal of financial management.
- LO 3** Compare the financial implications of the different forms of business organizations.
- LO 4** Describe the conflicts of interest that can arise between managers and owners.

Compensation of corporate executives in the United States continues to be a hot-button issue. It is widely viewed that CEO pay has grown to exorbitant levels (at least in some cases). In response, in April 2007, the U.S. House of Representatives passed the “Say on Pay” bill. The bill requires corporations to allow a nonbinding shareholder vote on executive pay. (Note that because the bill applies to corporations, it does not give voters a “say on pay” for U.S. Representatives.)

Specifically, the measure allows shareholders to approve or disapprove a company’s executive compensation plans. Because the bill is nonbinding, it does not permit shareholders to veto a compensation package and does not place limits on executive pay. Some companies had actually already begun initiatives to allow shareholders a say on pay before Congress got involved. On May 5, 2008, Aflac, the insurance company with the well-known “spokesduck,” held the first shareholder vote on executive pay in the United States.

Of course, governmental involvement in corporate compensation did not end there. In early 2009, in the midst of a severe financial crisis, the Obama administration announced a cap of \$500,000 on executive salaries for companies that received bailout funds from the federal government. Additionally, executives were prohibited from receiving bonuses above their base pay.

Understanding how a corporation sets executive pay, and the role of shareholders in that process, takes us into issues involving the corporate form of organization, corporate goals, and corporate control, all of which we cover in this chapter.

Visit us at www.mhhe.com/rwj

To begin our study of financial management, we address two central issues. First: What is corporate, or business, finance, and what is the role of the financial manager? Second: What is the goal of financial management?

1.1

FINANCE: A QUICK LOOK

Before we plunge into our study of “corp. fin.,” we think a quick overview of the finance field might be a good idea. Our goal is to clue you in on some of the most important areas in finance and some of the career opportunities available in each. We also want to illustrate some of the ways finance fits in with other areas such as marketing, management, and accounting.

The Four Basic Areas

Traditionally, financial topics are grouped into four main areas:

1. Corporate finance
2. Investments
3. Financial institutions
4. International finance

We discuss each of these next.

Corporate Finance The first of these four areas, corporate finance, is the main subject of this book. We begin covering this subject with our next section, so we will wait until then to get into any details. One thing we should note is that the term *corporate finance* seems to imply that what we cover is only relevant to corporations, but the truth is that almost all of the topics we consider are much broader than that. Maybe *business finance* would be a little more descriptive, but even this is too narrow because at least half of the subjects we discuss in the pages ahead are really basic financial ideas and principles applicable across all the various areas of finance and beyond.

For job descriptions in finance and other areas, visit www.careers-in-business.com.

Investments Broadly speaking, the investments area deals with financial assets such as stocks and bonds. Some of the more important questions include:

1. What determines the price of a financial asset, such as a share of stock?
2. What are the potential risks and rewards associated with investing in financial assets?
3. What is the best mixture of the different types of financial assets to hold?

Students who specialize in the investments area have various career opportunities. Being a stockbroker is one of the most common. Stockbrokers often work for large companies such as Merrill Lynch, advising customers on what types of investments to consider and helping them make buy and sell decisions. Financial advisers play a similar role, but are not necessarily brokers.

Portfolio management is a second investments-related career path. Portfolio managers, as the name suggests, manage money for investors. For example, individual investors frequently buy into mutual funds. Such funds are simply a means of pooling money that is then invested by a portfolio manager. Portfolio managers also invest and manage money for pension funds, insurance companies, and many other types of institutions.

Security analysis is a third area. A security analyst researches individual investments, such as stock in a particular company, and makes a determination as to whether the price is right. To do so, an analyst delves deeply into company and industry reports, along with a variety of other information sources. Frequently, brokers and portfolio managers rely on security analysts for information and recommendations.

These investments-related areas, like many areas in finance, share an interesting feature. If they are done well, they can be very rewarding financially (translation: You can make a lot of money). The bad news, of course, is that they can be very demanding and very competitive, so they are definitely not for everybody.

Financial Institutions Financial institutions are basically businesses that deal primarily in financial matters. Banks and insurance companies would probably be the most familiar to you. Institutions such as these employ people to perform a wide variety of finance-related tasks. For example, a commercial loan officer at a bank would evaluate whether a particular business has a strong enough financial position to warrant extending a loan. At an insurance company, an analyst would decide whether a particular risk was suitable for insuring and what the premium should be.

International Finance International finance isn't so much an area as it is a specialization within one of the main areas we described above. In other words, careers in international finance generally involve international aspects of either corporate finance, investments, or financial institutions. For example, some portfolio managers and security analysts specialize in non-U.S. companies. Similarly, many U.S. businesses have extensive overseas operations and need employees familiar with such international topics as exchange rates and political risk. Banks frequently are asked to make loans across country lines, so international specialists are needed there as well.

Why Study Finance?

Who needs to know finance? In a word, you. In fact, there are many reasons you need a working knowledge of finance even if you are not planning a finance career. We explore some of these next.

Marketing and Finance If you are interested in marketing, you need to know finance because, for example, marketers constantly work with budgets, and they need to understand how to get the greatest payoff from marketing expenditures and programs. Analyzing costs and benefits of projects of all types is one of the most important aspects of finance, so the tools you learn in finance are vital in marketing research, the design of marketing and distribution channels, and product pricing, just to name a few areas.

Financial analysts rely heavily on marketing analysts, and the two frequently work together to evaluate the profitability of proposed projects and products. As we will see in a later chapter, sales projections are a key input in almost every type of new product analysis, and such projections are often developed jointly between marketing and finance.

Beyond this, the finance industry employs marketers to help sell financial products such as bank accounts, insurance policies, and mutual funds. Financial services marketing is one of the most rapidly growing types of marketing, and successful financial services marketers are very well compensated. To work in this area, you obviously need to understand financial products.

Accounting and Finance For accountants, finance is required reading. In smaller businesses in particular, accountants are often required to make financial decisions as well as perform traditional accounting duties. Further, as the financial world continues to grow

more complex, accountants have to know finance to understand the implications of many of the newer types of financial contracts and the impact they have on financial statements. Beyond this, cost accounting and business finance are particularly closely related, sharing many of the same subjects and concerns.

Financial analysts make extensive use of accounting information; they are some of the most important end users. Understanding finance helps accountants recognize what types of information are particularly valuable and, more generally, how accounting information is actually used (and abused) in practice.

Management and Finance One of the most important areas in management is strategy. Thinking about business strategy without simultaneously thinking about financial strategy is an excellent recipe for disaster, and, as a result, management strategists must have a very clear understanding of the financial implications of business plans.

In broader terms, management employees of all types are expected to have a strong understanding of how their jobs impact profitability, and they are also expected to be able to work within their areas to improve profitability. This is precisely what studying finance teaches you: What are the characteristics of activities that create value?

You and Finance Perhaps the most important reason to know finance is that you will have to make financial decisions that will be very important to you personally. Today, for example, when you go to work for almost any type of company, you will be asked to decide how you want to invest your retirement funds. We'll see in a later chapter that what you choose to do can make an enormous difference in your future financial well-being. On a different note, is it your dream to start your own business? Good luck if you don't understand basic finance before you start; you'll end up learning it the hard way. Want to know how big your student loan payments are going to be before you take out that next loan? Maybe not, but we'll show you how to calculate them anyway.

These are just a few of the ways that finance will affect your personal and business lives. Whether you want to or not, you are going to have to examine and understand financial issues, and you are going to have to make financial decisions. We want you to do so wisely, so keep reading.

CONCEPT QUESTIONS

1.1a What are the major areas in finance?

1.1b Besides wanting to pass this class, why do you need to understand finance?

1.2

BUSINESS FINANCE AND THE FINANCIAL MANAGER

Now we proceed to define business finance and the financial manager's job.

What Is Business Finance?

Imagine you were to start your own business. No matter what type you started, you would have to answer the following three questions in some form or another:

1. What long-term investments should you take on? That is, what lines of business will you be in, and what sorts of buildings, machinery, and equipment will you need?

2. Where will you get the long-term financing to pay for your investments? Will you bring in other owners, or will you borrow the money?
3. How will you manage your everyday financial activities, such as collecting from customers and paying suppliers?

These are not the only questions, but they are among the most important. Business finance, broadly speaking, is the study of ways to answer these three questions. We'll be looking at each of them in the chapters ahead.

The Financial Manager

The financial management function is usually associated with a top officer of the firm, often called the chief financial officer (CFO) or vice president of finance. Figure 1.1 is a simplified organizational chart that highlights the finance activity in a large firm. As shown, the vice president of finance coordinates the activities of the treasurer and the controller. The controller's office handles cost and financial accounting, tax payments, and management information systems. The treasurer's office is responsible for managing the firm's cash and credit, its financial planning, and its capital expenditures. These treasury activities are all related to the three general questions raised above, and the chapters ahead deal primarily with these issues. Our study thus bears mostly on activities usually associated with the treasurer's office. In a smaller firm, the treasurer and controller might be the same person, and there would be only one office.

For current issues facing CFOs, see www.cfo.com.

Financial Management Decisions

As our discussion above suggests, the financial manager must be concerned with three basic types of questions. We consider these in greater detail next.

Capital Budgeting The first question concerns the firm's long-term investments. The process of planning and managing a firm's long-term investments is called **capital budgeting**. In capital budgeting, the financial manager tries to identify investment opportunities that are worth more to the firm than they cost to acquire. Loosely speaking, this means that the value of the cash flow generated by an asset exceeds the cost of that asset.

capital budgeting

The process of planning and managing a firm's long-term investments.

Regardless of the specific investment under consideration, financial managers must be concerned with how much cash they expect to receive, when they expect to receive it, and how likely they are to receive it. Evaluating the *size*, *timing*, and *risk* of future cash flows is the essence of capital budgeting. In fact, whenever we evaluate a business decision, the size, timing, and risk of the cash flows will be, by far, the most important things we will consider.

Capital Structure The second question for the financial manager concerns how the firm obtains the financing it needs to support its long-term investments. A firm's **capital structure** (or financial structure) refers to the specific mixture of long-term debt and equity the firm uses to finance its operations. The financial manager has two concerns in this area. First: How much should the firm borrow? Second: What are the least expensive sources of funds for the firm?

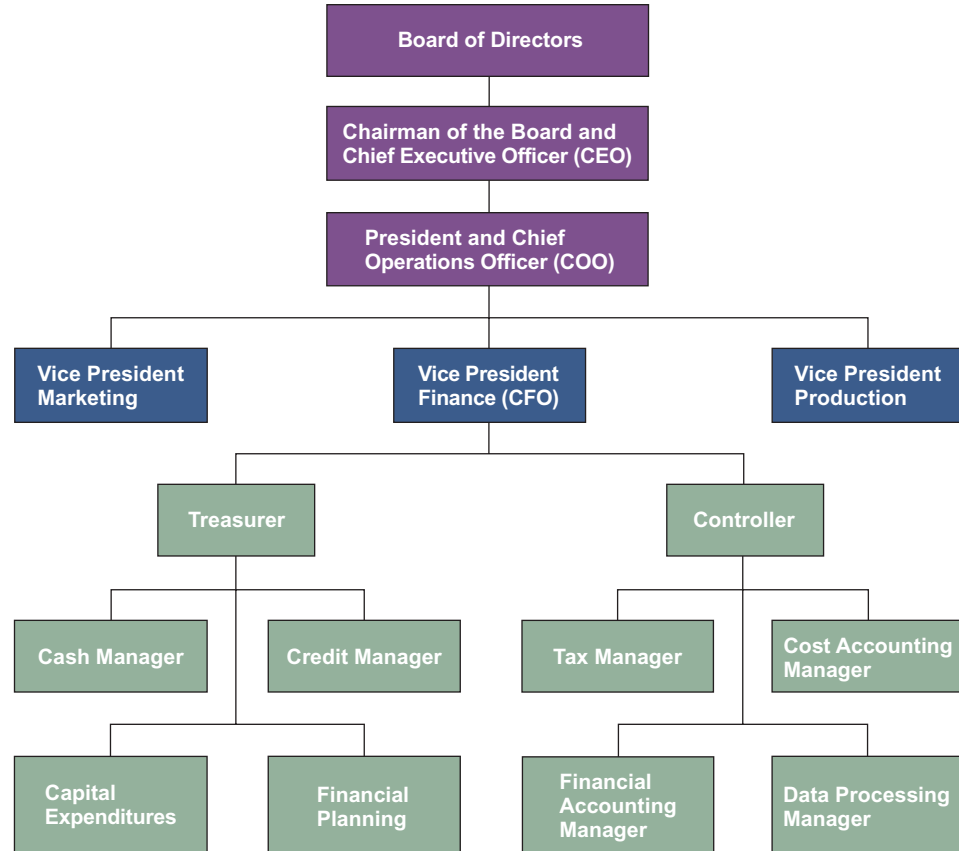

capital structure

The mixture of debt and equity maintained by a firm.

In addition to deciding on the financing mix, the financial manager has to decide exactly how and where to raise the money. The expenses associated with raising long-term financing can be considerable, so different possibilities must be carefully evaluated. Also,

FIGURE 1.1

A simplified organizational chart.
The exact titles and organization differ from company to company

businesses borrow money from a variety of lenders in a number of different ways. Choosing among lenders and among loan types is another job handled by the financial manager.

working capital

A firm's short-term assets and liabilities.

Working Capital Management The third question concerns **working capital** management. The term *working capital* refers to a firm's short-term assets, such as inventory, and its short-term liabilities, such as money owed to suppliers. Managing the firm's working capital is a day-to-day activity that ensures the firm has sufficient resources to continue its operations and avoid costly interruptions. This involves a number of activities related to the firm's receipt and disbursement of cash.

Some questions about working capital that must be answered are the following: (1) How much cash and inventory should we keep on hand? (2) Should we sell on credit to our customers? (3) How will we obtain any needed short-term financing? If we borrow in the short term, how and where should we do it? This is just a small sample of the issues that arise in managing a firm's working capital.

Conclusion The three areas of corporate financial management we have described—capital budgeting, capital structure, and working capital management—are very broad categories. Each includes a rich variety of topics, and we have indicated only a few of the questions that arise in the different areas. The chapters ahead contain greater detail.

CONCEPT QUESTIONS

- 1.2a** What is the capital budgeting decision?
- 1.2b** What do you call the specific mixture of long-term debt and equity that a firm chooses to use?
- 1.2c** Into what category of financial management does cash management fall?

FORMS OF BUSINESS ORGANIZATION

1.3

Large firms in the United States, such as IBM and Exxon, are almost all organized as corporations. We examine the three different legal forms of business organization—sole proprietorship, partnership, and corporation—to see why this is so.

Sole Proprietorship

A **sole proprietorship** is a business owned by one person. This is the simplest type of business to start and is the least regulated form of organization. For this reason, there are more proprietorships than any other type of business, and many businesses that later become large corporations start out as small proprietorships.

The owner of a sole proprietorship keeps all the profits. That's the good news. The bad news is that the owner has *unlimited liability* for business debts. This means that creditors can look to the proprietor's personal assets for payment. Similarly, there is no distinction between personal and business income, so all business income is taxed as personal income.

The life of a sole proprietorship is limited to the owner's life span, and, importantly, the amount of equity that can be raised is limited to the proprietor's personal wealth. This limitation often means that the business is unable to exploit new opportunities because of insufficient capital. Ownership of a sole proprietorship may be difficult to transfer since this requires the sale of the entire business to a new owner.

sole proprietorship

A business owned by a single individual.

For more information on forms of business organization, visit www.nolo.com.

Partnership

A **partnership** is similar to a proprietorship, except that there are two or more owners (partners). In a *general partnership*, all the partners share in gains or losses, and all have unlimited liability for all partnership debts, not just some particular share. The way partnership gains (and losses) are divided is described in the *partnership agreement*. This agreement can be an informal oral agreement, such as "let's start a lawn mowing business," or a lengthy, formal written document.

In a *limited partnership*, one or more *general partners* will run the business and have unlimited liability, but there will be one or more *limited partners* who do not actively participate in the business. A limited partner's liability for business debts is limited to the amount that partner contributes to the partnership. This form of organization is common in real estate ventures, for example.

The advantages and disadvantages of a partnership are basically the same as those for a proprietorship. Partnerships based on a relatively informal agreement are easy and

partnership

A business formed by two or more individuals or entities.

For more in-depth legal information concerning partnerships, go to www.business-law.freeadvice.com/partnerships/.

inexpensive to form. General partners have unlimited liability for partnership debts, and the partnership terminates when a general partner wishes to sell out or dies. All income is taxed as personal income to the partners, and the amount of equity that can be raised is limited to the partners' combined wealth. Ownership by a general partner is not easily transferred because a new partnership must be formed. A limited partner's interest can be sold without dissolving the partnership, but finding a buyer may be difficult.

Because a partner in a general partnership can be held responsible for all partnership debts, having a written agreement is very important. Failure to spell out the rights and duties of the partners frequently leads to misunderstandings later on. Also, if you are a limited partner, you must not become deeply involved in business decisions unless you are willing to assume the obligations of a general partner. The reason is that if things go badly, you may be deemed to be a general partner even though you say you are a limited partner.

Based on our discussion, the primary disadvantages of sole proprietorships and partnerships as forms of business organization are (1) unlimited liability for business debts on the part of the owners, (2) limited life of the business, and (3) difficulty of transferring ownership. These three disadvantages add up to a single, central problem: The ability of such businesses to grow can be seriously limited by an inability to raise cash for investment.

Corporation

corporation

A business created as a distinct legal entity owned by one or more individuals or entities.

The **corporation** is the most important form (in terms of size) of business organization in the United States. A corporation is a legal "person" separate and distinct from its owners, and it has many of the rights, duties, and privileges of an actual person. Corporations can borrow money and own property, can sue and be sued, and can enter into contracts. A corporation can even be a general partner or a limited partner in a partnership, and a corporation can own stock in another corporation.

Not surprisingly, starting a corporation is somewhat more complicated than starting the other forms of business organization. Forming a corporation involves preparing *articles of incorporation* (or a charter) and a set of *bylaws*. The articles of incorporation must contain a number of things, including the corporation's name, its intended life (which can be forever), its business purpose, and the number of shares that can be issued. This information must normally be supplied to the state in which the firm will be incorporated. For most legal purposes, the corporation is a "resident" of that state.

The bylaws are rules describing how the corporation regulates its own existence. For example, the bylaws describe how directors are elected. The bylaws may be amended or extended from time to time by the stockholders.

In a large corporation, the stockholders and the managers are usually separate groups. The stockholders elect the board of directors, who then select the managers. Management is charged with running the corporation's affairs in the stockholders' interests. In principle, stockholders control the corporation because they elect the directors.

As a result of the separation of ownership and management, the corporate form has several advantages. Ownership (represented by shares of stock) can be readily transferred, and the life of the corporation is therefore not limited. The corporation borrows money in its own name. As a result, the stockholders in a corporation have limited liability for corporate debts. The most they can lose is what they have invested.

The relative ease of transferring ownership, the limited liability for business debts, and the unlimited life of the business are the reasons why the corporate form is superior

when it comes to raising cash. If a corporation needs new equity, it can sell new shares of stock and attract new investors. The number of owners can be huge; larger corporations have many thousands or even millions of stockholders. For example, the General Electric Company (better known as GE) has about 10 billion shares outstanding and 4 million shareholders.

The corporate form has a significant disadvantage. Since a corporation is a legal person, it must pay taxes. Moreover, money paid out to stockholders in the form of dividends is taxed again as income to those stockholders. This is *double taxation*, meaning that corporate profits are taxed twice: at the corporate level when they are earned and again at the personal level when they are paid out.

Today all 50 states have enacted laws allowing for the creation of a relatively new form of business organization, the limited liability company (LLC). The goal of this entity is to operate and be taxed like a partnership but retain limited liability for owners, so an LLC is essentially a hybrid of a partnership and a corporation. Although states have differing definitions for LLCs, the more important scorekeeper is the Internal Revenue Service (IRS). The IRS will consider an LLC a corporation, thereby subjecting it to double taxation, unless it meets certain specific criteria. In essence, an LLC cannot be too corporationlike, or it will be treated as one by the IRS. LLCs have become common. For example, Goldman Sachs, one of Wall Street's last remaining partnerships, decided to convert from a private partnership to an LLC (it later "went public," becoming a publicly held corporation). Large accounting firms and law firms by the score have converted to LLCs.

How hard is it to form an LLC? Visit www.llc.com to find out.

A Corporation by Another Name . . .

The corporate form has many variations around the world. Exact laws and regulations differ, of course, but the essential features of public ownership and limited liability remain. These firms are often called *joint stock companies*, *public limited companies*, or *limited liability companies*.

Table 1.1 gives the names of a few well-known international corporations, their country of origin, and a translation of the abbreviation that follows the company name.

Company	Country of Origin	Type of Company	Translation	TABLE 1.1 International corporations

CONCEPT QUESTIONS

- 1.3a** What are the three forms of business organization?
- 1.3b** What are the primary advantages and disadvantages of sole proprietorships and partnerships?
- 1.3c** What is the difference between a general and a limited partnership?
- 1.3d** Why is the corporate form superior when it comes to raising cash?

1.4

THE GOAL OF FINANCIAL MANAGEMENT

To study financial decision making, we first need to understand the goal of financial management. Such an understanding is important because it leads to an objective basis for making and evaluating financial decisions.

Profit Maximization

Profit maximization would probably be the most commonly cited business goal, but this is not a very precise objective. Do we mean profits this year? If so, then actions such as deferring maintenance, letting inventories run down, and other short-run, cost-cutting measures will tend to increase profits now, but these activities aren't necessarily desirable.

The goal of maximizing profits may refer to some sort of "long-run" or "average" profits, but it's unclear exactly what this means. First, do we mean something like accounting net income or earnings per share? As we will see, these numbers may have little to do with what is good or bad for the firm. Second, what do we mean by the long run? As a famous economist once remarked, in the long run, we're all dead! More to the point, this goal doesn't tell us the appropriate trade-off between current and future profits.

The Goal of Financial Management in a Corporation

The financial manager in a corporation makes decisions for the stockholders of the firm. Given this, instead of listing possible goals for the financial manager, we really need to answer a more fundamental question: From the stockholders' point of view, what is a good financial management decision?

If we assume stockholders buy stock because they seek to gain financially, then the answer is obvious: Good decisions increase the value of the stock, and poor decisions decrease it.

Given our observations, it follows that the financial manager acts in the shareholders' best interests by making decisions that increase the value of the stock. The appropriate goal for the financial manager in a corporation can thus be stated quite easily:

The goal of financial management is to maximize the current value per share of the existing stock.

The goal of maximizing the value of the stock avoids the problems associated with the different goals we discussed above. There is no ambiguity in the criterion, and there is no short-run versus long-run issue. We explicitly mean that our goal is to maximize the *current* stock value. Of course, maximizing stock value is the same thing as maximizing the market price per share.

Find a business finance magazine site that discusses current issues facing the financial executive at www.businessfinancemag.com.

Corporate Ethics

Large companies are sometimes guilty of unethical behavior. Often this unethical behavior takes the form of false or misleading financial statements. In one of the largest corporate fraud cases in history, energy giant Enron Corporation was forced to file for bankruptcy in December 2001 amid allegations that the company's financial statements were deliberately misleading and false. Enron's bankruptcy not only destroyed that company, but its auditor Arthur Andersen as well.

More recently, the 2009 Bank of America acquisition of Merrill Lynch presented a sticky ethical question. Investment banks such as Merrill Lynch are noted for employee bonuses that can run well into the millions of dollars. Generally, these bonuses are paid after the year ends. But with a January 1, 2009, acquisition date looming, bonuses paid to Merrill Lynch employees would be decided by Bank of America management. In an unusual move, John Thain, the CEO of Merrill Lynch, asked the board of directors to decide the bonuses at its November 2008 meeting. Merrill Lynch ended up paying bonuses amounting to \$3.6 billion in December 2008, before its acquisition by Bank of America and in a year in which the company lost about \$28 billion. The decision resulted in public outcry over the bonuses, as well as an investigation by the New York attorney general's office to determine whether the timing of the bonuses was securities fraud.

The difference between ethical and unethical behavior can sometimes be murky. For example, many U.S. companies have

relocated to Bermuda for reasons beyond the beautiful pink beaches; namely, Bermuda has no corporate income taxes. With a population of less than 65,000, the island is home to more than 13,000 international companies. Stanley Works, the well-known maker of Stanley tools, was among the U.S. corporations that chose to move to the island paradise. By doing so, Stanley estimated that it would save \$30 million per year in taxes. Since the goal of the corporation is to maximize shareholder wealth, this would seem like a good move, and the practice is entirely legal. But is it ethical? What are the issues?

Another corporate activity that has generated much controversy is the practice of outsourcing, or offshoring, jobs to other countries. U.S. corporations engage in this practice when labor costs in another country are substantially lower than they are domestically. Again, this is done to maximize shareholder wealth. But, the ethical dilemma in this case is even trickier. Some U.S. workers do lose jobs when offshoring occurs. On the other hand, the Milken Institute estimated that every \$1 spent on offshoring a service job to India generated a net value to the United States of \$1.13, along with another \$.33 to India. And it gets even more complicated: What about foreign companies such as BMW and Toyota who "insource" jobs by building plants in the United States? Is it unethical to outsource U.S. jobs while, at the same time, insourcing jobs from other countries?

A More General Financial Management Goal

Given our goal as stated above (maximize the value of the stock), an obvious question comes up: What is the appropriate goal when the firm has no traded stock? Corporations are certainly not the only type of business, and the stock in many corporations rarely changes hands, so it's difficult to say what the value per share is at any given time.

As long as we are dealing with for-profit businesses, only a slight modification is needed. The total value of the stock in a corporation is simply equal to the value of the owners' equity. Therefore, a more general way of stating our goal is:

Maximize the market value of the existing owners' equity.

With this goal in mind, it doesn't matter whether the business is a proprietorship, a partnership, or a corporation. For each of these, good financial decisions increase the market value of the owners' equity and poor financial decisions decrease it.

Finally, our goal does not imply that the financial manager should take illegal or unethical actions in the hope of increasing the value of the equity in the firm. What we mean is that the financial manager best serves the owners of the business by identifying goods and services that add value to the firm because they are desired and valued in the free marketplace. Our nearby *Reality Bytes* box discusses some recent ethical issues and problems faced by well-known corporations.

Business ethics are considered at www.thecro.com.

Sarbanes-Oxley Act

In response to corporate scandals involving companies such as Enron, WorldCom, Tyco, and Adelphia, Congress enacted the Sarbanes-Oxley Act in 2002. The Act, which is better known as “Sarbox,” is intended to strengthen protection against corporate accounting fraud and financial malpractice. Key elements of Sarbox took effect on November 15, 2004.

Sarbox contains a number of requirements designed to insure that companies tell the truth in their financial statements. For example, the officers of a public corporation must review and sign the annual report. They must attest that the annual report does not contain false statements or material omissions and also that the financial statements fairly represent the company’s financial results. In essence, Sarbox makes management personally responsible for the accuracy of a company’s financial statements.

Because of its extensive requirements, compliance with Sarbox can be very costly, which has led to some unintended results. Since its implementation, hundreds of public firms have chosen to “go dark,” meaning that their shares would no longer be traded in the major stock markets, in which case Sarbox does not apply. Most of these companies stated that their reason was to avoid the cost of compliance. Ironically, in such cases, the law had the effect of eliminating public disclosure instead of improving it.

Sarbox has also probably affected the number of companies going public in the United States. Recently, many U.S.-based companies have chosen to go public on the London Stock Exchange’s Alternative Investment Market (AIM) instead. The cost savings can be enormous, especially for small companies. For example, Pronotex Technologies, a fuel cell developer based in Southborough, Massachusetts, estimated that it costs about \$1 million per year in compliance costs and mailings to stockholders to be listed on the AIM. In contrast, the annual cost to be listed on the NASDAQ would be about \$3 million, with a large part of the increase due to Sarbox compliance costs.

CONCEPT QUESTIONS

- 1.4a** What is the goal of financial management?
- 1.4b** What are some shortcomings of the goal of profit maximization?

1.5

THE AGENCY PROBLEM AND CONTROL OF THE CORPORATION

We’ve seen that the financial manager in a corporation acts in the best interests of the stockholders by taking actions that increase the value of the firm’s stock. However, we’ve also seen that in large corporations ownership can be spread over a huge number of stockholders. This dispersion of ownership arguably means that management effectively controls the firm. In this case, will management necessarily act in the best interests of the stockholders? Put another way, might not management pursue its own goals at the stockholders’ expense? We briefly consider some of the arguments below.

Agency Relationships

The relationship between stockholders and management is called an *agency relationship*. Such a relationship exists whenever someone (the principal) hires another (the agent) to represent his or her interest. For example, you might hire someone (an agent) to sell a car

that you own while you are away at school. In all such relationships, there is a possibility of conflict of interest between the principal and the agent. Such a conflict is called an **agency problem**.

Suppose you hire someone to sell your car and you agree to pay her a flat fee when she sells the car. The agent's incentive in this case is to make the sale, not necessarily to get you the best price. If you paid a commission of, say, 10 percent of the sales price instead of a flat fee, then this problem might not exist. This example illustrates that the way an agent is compensated is one factor that affects agency problems.

agency problem

The possibility of conflict of interest between the owners and management of a firm.

Management Goals

To see how management and stockholder interests might differ, imagine that a corporation is considering a new investment. The new investment is expected to favorably impact the stock price, but it is also a relatively risky venture. The owners of the firm will wish to take the investment (because the share value will rise), but management may not because there is the possibility that things will turn out badly and management jobs will be lost. If management does not take the investment, then the stockholders may lose a valuable opportunity. This is one example of an *agency cost*.

It is sometimes argued that, left to themselves, managers would tend to maximize the amount of resources over which they have control, or, more generally, business power or wealth. This goal could lead to an overemphasis on business size or growth. For example, cases where management is accused of overpaying to buy another company just to increase the size of the business or to demonstrate corporate power are not uncommon. Obviously, if overpayment does take place, such a purchase does not benefit the owners of the purchasing company.

Our discussion indicates that management may tend to overemphasize organizational survival to protect job security. Also, management may dislike outside interference, so independence and corporate self-sufficiency may be important goals.

Do Managers Act in the Stockholders' Interests?

Whether managers will, in fact, act in the best interests of stockholders depends on two factors. First, how closely are management goals aligned with stockholder goals? This question relates to the way managers are compensated. Second, can management be replaced if they do not pursue stockholder goals? This issue relates to control of the firm. As we will discuss, there are a number of reasons to think that, even in the largest firms, management has a significant incentive to act in the interests of stockholders.

Managerial Compensation Management will frequently have a significant economic incentive to increase share value for two reasons. First, managerial compensation, particularly at the top, is usually tied to financial performance in general and oftentimes to share value in particular. For example, managers are frequently given the option to buy stock at a fixed price. The more the stock is worth, the more valuable is this option. The second incentive managers have relates to job prospects. Better performers within the firm will tend to get promoted. More generally, those managers who are successful in pursuing stockholder goals will be in greater demand in the labor market and thus command higher salaries.

In fact, managers who are successful in pursuing stockholder goals can reap enormous rewards. For example, Larry Ellison, CEO of Oracle, received about \$193 million in 2008 alone, which is less than J. K. Rowling (\$300 million), but way more than Rachael Ray (\$18 million).

Control of the Firm Control of the firm ultimately rests with stockholders. They elect the board of directors, who, in turn, hires and fires management. The mechanism by which unhappy stockholders can act to replace existing management is called a *proxy fight*. A proxy is the authority to vote someone else's stock. A proxy fight develops when a group solicits proxies in order to replace the existing board, and thereby replace existing management.

Another way that management can be replaced is by takeover. Those firms that are poorly managed are more attractive as acquisitions than well-managed firms because a greater profit potential exists. Thus, avoiding a takeover by another firm gives management another incentive to act in the stockholders' interests. Information on executive compensation, along with a ton of other information, can be easily found on the Web for almost any public company. Our nearby *Work the Web* box shows you how to get started.

WORK THE WEB

The Web is a great place to learn about individual companies, and there are a slew of sites available to help you. Try pointing your Web browser to finance.yahoo.com. Once there, you should see something like this on the page:

To look up a company, you need its "ticker symbol" (or just ticker for short), which is a unique one-to-four letter identifier. Or, you can just type in a company's name to find the ticker. For example, we typed in "SIRI," which is the ticker symbol for Sirius XM Radio, the satellite radio provider. Here is a portion of what we got:

There is a lot of information here and a lot of other links for you to explore, so have at it. By the end of the term, we hope it all makes sense to you!

Questions

- Go to finance.yahoo.com and find the current stock prices for Southwest Airlines (LUV), Harley-Davidson (HOG), and Starwood Hotels & Resorts (HOT).
- Get a quote for American Express (AXP) and follow the "Key Statistics" link. What information is available on this link? What do *mrq*, *ttm*, *yoy*, and *1fy* mean?

Sometimes it's hard to tell if a company's management is really acting in the shareholders' best interests. For example, in the spring of 2008, Web portal Yahoo! was battling a \$42 billion unsolicited takeover bid from software giant Microsoft. Yahoo!'s management argued that the bid significantly undervalued the company, even though it was 62 percent higher than the then-current stock price. In an effort to thwart Microsoft's takeover attempt, Yahoo! entered into an advertising agreement with Internet search engine rival Google, and it began discussions with other companies such as AOL about a possible merger. In fact, Yahoo! spent \$79 million to fight off the Microsoft bid. In the aftermath, Yahoo! founder and CEO Jerry Yang was forced to step down, and Yahoo! stockholders were left saying "boo-hoo." However, in the spring of 2009, rumors were circulating that Microsoft and Yahoo! were again discussing a deal. If it occurs, it will be interesting to see how much more (or, more likely, less) Microsoft will pay compared to its original offer.

Conclusion The available theory and evidence are consistent with the view that stockholders control the firm and that stockholder wealth maximization is the relevant goal of the corporation. Even so, there will undoubtedly be times when management goals are pursued at the expense of the stockholders, at least temporarily.

Agency problems are not unique to corporations; they exist whenever there is a separation of ownership and management. This separation is most pronounced in corporations, but it certainly exists in partnerships and proprietorships as well.

Stakeholders

Our discussion thus far implies that management and stockholders are the only parties with an interest in the firm's decisions. This is an oversimplification, of course. Employees, customers, suppliers, and even the government all have a financial interest in the firm.

These various groups are called **stakeholders** in the firm. In general, a stakeholder is someone other than a stockholder or creditor who potentially has a claim on the cash flows of the firm. Such groups will also attempt to exert control over the firm, perhaps to the detriment of the owners.

stakeholder

Someone other than a stockholder or creditor who potentially has a claim on the cash flows of the firm.

CONCEPT QUESTIONS

- 1.5a** What is an agency relationship?
- 1.5b** What are agency problems and how do they arise? What are agency costs?
- 1.5c** What incentives do managers in large corporations have to maximize share value?

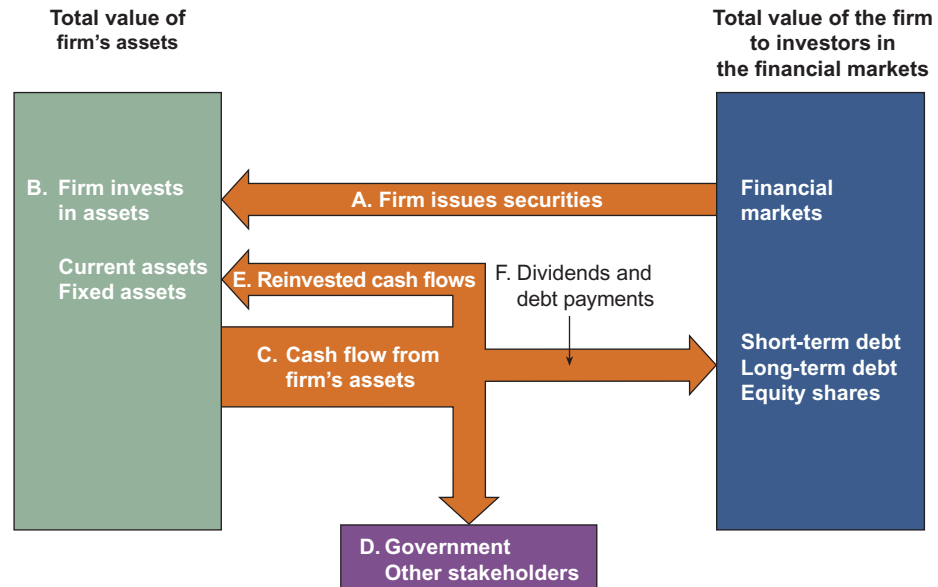

FINANCIAL MARKETS AND THE CORPORATION

1.6

We've seen that the primary advantages of the corporate form of organization are that ownership can be transferred more quickly and easily than with other forms and that money can be raised more readily. Both of these advantages are significantly enhanced by the existence of financial markets, and financial markets play an extremely important role in corporate finance.

FIGURE 1.2

Cash flows between the firm and the financial markets

- A. Firm issues securities to raise cash.
- B. Firm invests in assets.
- C. Firm's operations generate cash flow.
- D. Cash is paid to government as taxes. Other stakeholders may receive cash.
- E. Reinvested cash flows are plowed back into firm.
- F. Cash is paid out to investors in the form of interest and dividends.

Cash Flows to and from the Firm

The interplay between the corporation and the financial markets is illustrated in Figure 1.2. The arrows in Figure 1.2 trace the passage of cash from the financial markets to the firm and from the firm back to the financial markets.

Suppose we start with the firm selling shares of stock and borrowing money to raise cash. Cash flows to the firm from the financial markets (A). The firm invests the cash in current and fixed (or long-term) assets (B). These assets generate some cash (C), some of which goes to pay corporate taxes (D). After taxes are paid, some of this cash flow is reinvested in the firm (E). The rest goes back to the financial markets as cash paid to creditors and shareholders (F).

A financial market, like any market, is just a way of bringing buyers and sellers together. In financial markets, it is debt and equity securities that are bought and sold. Financial markets differ in detail, however. The most important differences concern the types of securities that are traded, how trading is conducted, and who the buyers and sellers are. Some of these differences are discussed next.

Primary versus Secondary Markets

Financial markets function as both primary and secondary markets for debt and equity securities. The term *primary market* refers to the original sale of securities by governments and corporations. The *secondary markets* are those in which these securities are bought and sold after the original sale. Equities are, of course, issued solely by corporations. Debt securities are issued by both governments and corporations. In the discussion that follows, we focus on corporate securities only.

Primary Markets In a primary-market transaction, the corporation is the seller, and the transaction raises money for the corporation. Corporations engage in two types of primary market transactions: public offerings and private placements. A public offering, as the name suggests, involves selling securities to the general public, whereas a private placement is a negotiated sale involving a specific buyer.

By law, public offerings of debt and equity must be registered with the Securities and Exchange Commission (SEC). Registration requires the firm to disclose a great deal of information before selling any securities. The accounting, legal, and selling costs of public offerings can be considerable.

Partly to avoid the various regulatory requirements and the expense of public offerings, debt and equity are often sold privately to large financial institutions such as life insurance companies or mutual funds. Such private placements do not have to be registered with the SEC and do not require the involvement of underwriters (investment banks that specialize in selling securities to the public).

Secondary Markets A secondary-market transaction involves one owner or creditor selling to another. It is therefore the secondary markets that provide the means for transferring ownership of corporate securities. Although a corporation is only directly involved in a primary-market transaction (when it sells securities to raise cash), the secondary markets are still critical to large corporations. The reason is that investors are much more willing to purchase securities in a primary-market transaction when they know that those securities can later be resold if desired.

Dealer versus auction markets There are two kinds of secondary markets: *auction* markets and *dealer* markets. Generally speaking, dealers buy and sell for themselves, at their own risk. A car dealer, for example, buys and sells automobiles. In contrast, brokers and agents match buyers and sellers, but they do not actually own the commodity that is bought or sold. A real estate agent, for example, does not normally buy and sell houses.

Dealer markets in stocks and long-term debt are called *over-the-counter* (OTC) markets. Most trading in debt securities takes place over the counter. The expression *over the counter* refers to days of old when securities were literally bought and sold at counters in offices around the country. Today, a significant fraction of the market for stocks and almost all of the market for long-term debt have no central location; the many dealers are connected electronically.

Auction markets differ from dealer markets in two ways. First, an auction market, or exchange, has a physical location (like Wall Street). Second, in a dealer market, most of the buying and selling is done by the dealer. The primary purpose of an auction market, on the other hand, is to match those who wish to sell with those who wish to buy. Dealers play a limited role.

Trading in corporate securities The equity shares of most of the large firms in the United States trade in organized auction markets. The largest such market is the New York Stock Exchange (NYSE), which accounts for more than 85 percent of all the shares traded in auction markets. Other auction exchanges include the American Stock Exchange (AMEX) and regional exchanges such as the Chicago Stock Exchange.

In addition to the stock exchanges, there is a large OTC market for stocks. In 1971, the National Association of Securities Dealers (NASD) made available to dealers and brokers an electronic quotation system called NASDAQ (NASD Automated Quotations system, pronounced “naz-dak”). There are roughly three times as many companies on NASDAQ as there are on NYSE, but they tend to be much smaller in size and trade less actively. There

To learn more about the SEC, visit www.sec.gov.

To learn more about the exchanges, visit www.nyse.com and www.nasdaq.com.

The Tokyo Stock Exchange in English: www.tse.or.jp/english.

are exceptions, of course. Both Microsoft and Intel trade OTC, for example. Nonetheless, the total value of NASDAQ stocks is significantly less than the total value of NYSE stocks.

There are many large and important financial markets outside the United States, of course, and U.S. corporations are increasingly looking to these markets to raise cash. The Tokyo Stock Exchange and the London Stock Exchange (TSE and LSE, respectively) are two well-known examples. The fact that OTC markets have no physical location means that national borders do not present a great barrier, and there is now a huge international OTC debt market. Because of globalization, financial markets have reached the point where trading in many instruments never stops; it just travels around the world.

The London Stock
Exchange:
[www.londonstock
exchange.com](http://www.londonstockexchange.com).

Listing Stocks that trade on an organized exchange (or market) are said to be *listed* on that exchange. In order to be listed, firms must meet certain minimum criteria concerning, for example, asset size and number of shareholders. These criteria differ for different exchanges.

NYSE has the most stringent requirements of the stock markets in the United States. There are minimums on earnings, assets, and number and market value of shares outstanding.

CONCEPT QUESTIONS

- 1.6a** What is a dealer market? How do dealer and auction markets differ?
- 1.6b** What is the largest auction market in the United States?
- 1.6c** What does *OTC* stand for? What is the large OTC market for stocks called?

SUMMARY AND CONCLUSIONS

This chapter has introduced you to some of the basic ideas in business finance. In it, we saw that:

1. Business finance has three main areas of concern:
 - a. Capital budgeting. What long-term investments should the firm take?
 - b. Capital structure. Where will the firm get the long-term financing to pay for its investments? In other words, what mixture of debt and equity should we use to fund our operations?
 - c. Working capital management. How should the firm manage its everyday financial activities?
2. The goal of financial management in a for-profit business is to make decisions that increase the value of the stock, or, more generally, increase the market value of the equity.
3. The corporate form of organization is superior to other forms when it comes to raising money and transferring ownership interests, but it has the significant disadvantage of double taxation.

4. There is the possibility of conflicts between stockholders and management in a large corporation. We called these conflicts agency problems and discussed how they might be controlled and reduced.

Of the topics we've discussed thus far, the most important is the goal of financial management. Throughout the text, we will be analyzing many different financial decisions, but we always ask the same question: How does the decision under consideration affect the value of the equity in the firm?

CRITICAL THINKING AND CONCEPTS REVIEW

- L0 1** 1.1 **The Financial Management Decision Process.** What are the three types of financial management decisions? For each type of decision, give an example of a business transaction that would be relevant.
- L0 3** 1.2 **Sole Proprietorships and Partnerships.** What are the four primary disadvantages to the sole proprietorship and partnership forms of business organization? What benefits are there to these types of business organization as opposed to the corporate form?
- L0 3** 1.3 **Corporations.** What is the primary disadvantage of the corporate form of organization? Name at least two of the advantages of corporate organization.
- L0 3** 1.4 **Corporate Finance Organization.** In a large corporation, what are the two distinct groups that report to the chief financial officer? Which group is the focus of corporate finance?
- L0 2** 1.5 **Goal of Financial Management.** What goal should always motivate the actions of the firm's financial manager?
- L0 4** 1.6 **Agency Problems.** Who owns a corporation? Describe the process whereby the owners control the firm's management. What is the main reason that an agency relationship exists in the corporate form of organization? In this context, what kinds of problems can arise?
- L0 3** 1.7 **Primary versus Secondary Markets.** You've probably noticed coverage in the financial press of an initial public offering (IPO) of a company's securities. Web search company Google is a relatively recent example. Is an IPO a primary-market transaction or a secondary-market transaction?
- L0 3** 1.8 **Auction versus Dealer Markets.** What does it mean when we say the New York Stock Exchange is an auction market? How are auction markets different from dealer markets? What kind of market is NASDAQ?
- L0 2** 1.9 **Not-for-Profit Firm Goals.** Suppose you were the financial manager of a not-for-profit business (a not-for-profit hospital, perhaps). What kinds of goals do you think would be appropriate?
- L0 2** 1.10 **Ethics and Firm Goals.** Can our goal of maximizing the value of the stock conflict with other goals, such as avoiding unethical or illegal behavior? In particular, do you think subjects such as customer and employee safety, the environment, and the general good of society fit in this framework, or are they essentially ignored? Try to think of some specific scenarios to illustrate your answer.
- L0 2** 1.11 **International Firm Goal.** Would our goal of maximizing the value of the stock be different if we were thinking about financial management in a foreign country? Why or why not?

LO 4

1.12 Agency Problems. Suppose you own stock in a company. The current price per share is \$25. Another company has just announced that it wants to buy your company and will pay \$35 per share to acquire all the outstanding stock. Your company's management immediately begins fighting off this hostile bid. Is management acting in the shareholders' best interests? Why or why not?

LO 4

1.13 Agency Problems and Corporate Ownership. Corporate ownership varies around the world. Historically, individuals have owned the majority of shares in public corporations in the United States. In Germany and Japan, however, banks, other large financial institutions, and other companies own most of the stock in public corporations. Do you think agency problems are likely to be more or less severe in Germany and Japan than in the United States? Why? In recent years, large financial institutions such as mutual funds and pension funds have been becoming the dominant owners of stock in the United States, and these institutions are becoming more active in corporate affairs. What are the implications of this trend for agency problems and corporate control?

LO 4

1.14 Executive Compensation. Critics have charged that compensation to top management in the United States is simply too high and should be cut back. For example, focusing on large corporations, Larry Ellison, CEO of Oracle, earned about \$193 million in 2008 and about \$429 million over the 2004–2008 period. Are such amounts excessive? In answering, it might be helpful to recognize that superstar athletes such as Tiger Woods, top entertainers such as Oprah Winfrey, and many others at the top of their respective fields earn at least as much, if not more.

LO 4

1.15 Sarbanes-Oxley. In response to the Sarbanes-Oxley Act, many small firms in the United States have opted to “go dark” and delist their stock. Why might a company choose this route? What are the costs of “going dark”?

WHAT'S ON THE WEB?

1.1 Listing Requirements. This chapter discussed some of the listing requirements for the NYSE and NASDAQ. Find the complete listing requirements for the New York Stock Exchange at www.nyse.com and NASDAQ at www.nasdaq.com. Which has more stringent listing requirements? Why don't they have the same listing requirements?

1.2 Business Formation. As you may (or may not) know, many companies incorporate in Delaware for a variety of reasons. Visit Bizfilings at www.bizfilings.com to find out why. Which state has the highest fee for incorporation? For an LLC? While at the site, look at the FAQ section regarding corporations and LLCs.

CHAPTER CASE

THE MCGEE CAKE COMPANY

In early 2003, Doc and Lyn McGee formed the McGee Cake Company. The company produced a full line of cakes, and its specialties included chess cake*, lemon pound cake, and double-iced, double-chocolate cake. The couple formed the company as an outside interest, and both continued to work at their current jobs. Doc did all the baking, and Lyn handled the marketing and distribution. With good product quality and a sound marketing plan, the company grew rapidly. In early 2008, the company was featured in a widely distributed entrepreneurial magazine. Later that year, the company was featured in *Gourmet Desserts*, a leading specialty food magazine. After the article appeared in *Gourmet Desserts*, sales exploded, and the company began receiving orders from all over the world.

* Chess cake is quite delicious and distinct from cheesecake. The origin of the name is obscure.

Because of the increased sales, Doc left his other job, followed shortly by Lyn. The company hired additional workers to meet demand. Unfortunately, the fast growth experienced by the company led to cash flow and capacity problems. The company is currently producing as many cakes as possible with the assets it owns, but demand for its cakes is still growing. Further, the company has been approached by a national supermarket chain with a proposal to put four of its cakes in all of the chain's stores, and a national restaurant chain has contacted the company about selling McGee cakes in its restaurants. The restaurant would sell the cakes without a brand name.

Doc and Lyn have operated the company as a sole proprietorship. They have approached you to help manage and direct the company's growth. Specifically, they have asked you to answer the following questions: ■

QUESTIONS

1. What are the advantages and disadvantages of changing the company organization from a sole proprietorship to an LLC?
2. What are the advantages and disadvantages of changing the company organization from a sole proprietorship to a corporation?
3. Ultimately, what action would you recommend the company undertake? Why?

chapter

2

Financial Statements, Taxes, and Cash Flow

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Differentiate between accounting value (or “book” value) and market value.
- LO 2** Distinguish accounting income from cash flow.
- LO 3** Explain the difference between average and marginal tax rates.
- LO 4** Determine a firm’s cash flow from its financial statements.

When a company announces a “write-off,” it frequently means that the value of the company’s assets has declined. For example, in the first quarter of 2009, luxury homebuilder Toll Brothers said it was writing down \$157 million in assets, much of which was a reflection of the reduced value of land the company owned. Of course, Toll Brothers was not the only homebuilder suffering. Hovnanian Enterprises announced it would take a \$132 million write-off, and Centex Corp. announced a \$590 million write-off. At the same time, D. R. Horton, the largest homebuilder by

volume, had a much smaller write-off of only \$56 million. However, D. R. Horton had already written off \$1.15 billion in the fourth quarter of 2008.

So did stockholders in these homebuilders lose hundreds of millions of dollars (or more) because of the write-offs? The answer is probably not. Understanding why ultimately leads us to the main subject of this chapter: that all important substance known as *cash flow*.

Visit us at www.mhhe.com/rwj

In this chapter, we examine financial statements, taxes, and cash flow. Our emphasis is not on preparing financial statements. Instead, we recognize that financial statements are frequently a key source of information for financial decisions, so our goal is to briefly examine such statements and point out some of their more relevant features. We pay special attention to some of the practical details of cash flow.

As you read, pay particular attention to two important differences: (1) the difference between accounting value and market value and (2) the difference between accounting income and cash flow. These distinctions will be important throughout the book.

THE BALANCE SHEET

The **balance sheet** is a snapshot of the firm. It is a convenient means of organizing and summarizing what a firm owns (its *assets*), what a firm owes (its *liabilities*), and the difference between the two (the firm's *equity*) at a given point in time. Figure 2.1 illustrates how the balance sheet is constructed. As shown, the left-hand side lists the assets of the firm, and the right-hand side lists the liabilities and equity.

2.1

balance sheet

Financial statement showing a firm's accounting value on a particular date.

Assets: The Left-Hand Side

Assets are classified as either *current* or *fixed*. A fixed asset is one that has a relatively long life. Fixed assets can either be *tangible*, such as a truck or a computer, or *intangible*, such as a trademark or patent. A current asset has a life of less than one year. This means that the asset will normally convert to cash within 12 months. For example, inventory would normally be purchased and sold within a year and is thus classified as a current asset. Obviously, cash itself is a current asset. Accounts receivable (money owed to the firm by its customers) is also a current asset.

Liabilities and Owners' Equity: The Right-Hand Side

The firm's liabilities are the first thing listed on the right-hand side of the balance sheet. These are classified as either *current* or *long-term*. Current liabilities, like current assets, have a life of less than one year (meaning they must be paid within the year), and they are listed before long-term liabilities. Accounts payable (money the firm owes to its suppliers) is one example of a current liability.

A debt that is not due in the coming year is classified as a long-term liability. A loan that the firm will pay off in five years is one such long-term debt. Firms borrow over the

Two excellent sites for company financial information are finance.yahoo.com and money.cnn.com.

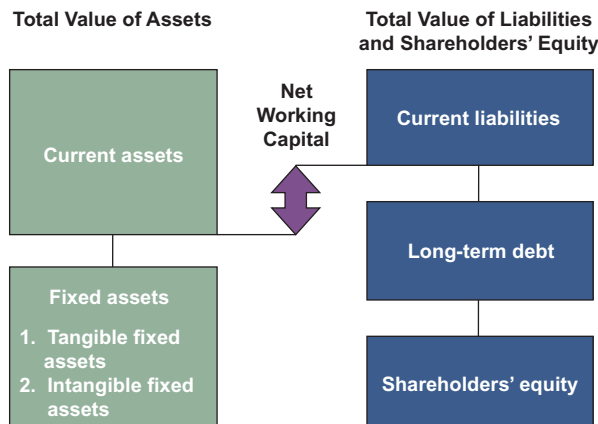

FIGURE 2.1

The balance sheet. Left side: Total value of assets. Right side: Total value of liabilities and shareholders' equity.

Disney has a good investor site at www.disney.com.

long term from a variety of sources. We will tend to use the terms *bonds* and *bondholders* generically to refer to long-term debt and long-term creditors, respectively.

Finally, by definition, the difference between the total value of the assets (current and fixed) and the total value of the liabilities (current and long-term) is the *shareholders' equity*, also called *common equity* or *owners' equity*. This feature of the balance sheet is intended to reflect the fact that, if the firm were to sell all of its assets and use the money to pay off its debts, then whatever residual value remained would belong to the shareholders. So, the balance sheet “balances” because the value of the left-hand side always equals the value of the right-hand side. That is, the value of the firm’s assets is equal to the sum of its liabilities and shareholders’ equity:¹

Assets = Liabilities + Shareholders' equity [2.1]

This is the balance sheet identity, or equation, and it always holds because shareholders’ equity is defined as the difference between assets and liabilities.

Net Working Capital

net working capital

Current assets less current liabilities.

As shown in Figure 2.1, the difference between a firm’s current assets and its current liabilities is called **net working capital**. Net working capital is positive when current assets exceed current liabilities. Based on the definitions of current assets and current liabilities, this means that the cash that will become available over the next 12 months exceeds the cash that must be paid over that same period. For this reason, net working capital is usually positive in a healthy firm.

Table 2.1 shows a simplified balance sheet for the fictitious U.S. Corporation. There are three particularly important things to keep in mind when examining a balance sheet: liquidity, debt versus equity, and market value versus book value.

EXAMPLE 2.1

Building the Balance Sheet

A firm has current assets of \$100, net fixed assets of \$500, short-term debt of \$70, and long-term debt of \$200. What does the balance sheet look like? What is shareholders’ equity? What is net working capital?

In this case, total assets are $\$100 + \$500 = \$600$ and total liabilities are $\$70 + \$200 = \$270$, so shareholders’ equity is the difference: $\$600 - \$270 = \$330$. The balance sheet would thus look like:

Assets		Liabilities and Shareholders' Equity	
Current assets	\$100	Current liabilities	\$ 70
Net fixed assets	<u>500</u>	Long-term debt	200
		Shareholders' equity	<u>330</u>
		Total liabilities and shareholders' equity	<u>\$600</u>
Total assets	<u>\$600</u>		

Net working capital is the difference between current assets and current liabilities, or $\$100 - \$70 = \$30$.

¹ The terms *owners' equity*, *shareholders' equity*, and *stockholders' equity* are used interchangeably to refer to the equity in a corporation. The term *net worth* is also used. Variations exist in addition to these.

U.S. CORPORATION

TABLE 2.1

Balance sheets for
U.S. Corporation

Liquidity

Liquidity refers to the speed and ease with which an asset can be converted to cash. Gold is a relatively liquid asset; a custom manufacturing facility is not. Liquidity really has two dimensions: ease of conversion versus loss of value. Any asset can be converted to cash quickly if we cut the price enough. A highly liquid asset is therefore one that can be quickly sold without significant loss of value. An illiquid asset is one that cannot be quickly converted to cash without a substantial price reduction.

Assets are normally listed on the balance sheet in order of decreasing liquidity, meaning that the most liquid assets are listed first. Current assets are relatively liquid and include cash and those assets that we expect to convert to cash over the next 12 months. Accounts receivable, for example, represent amounts not yet collected from customers on sales already made. Naturally, we hope these will convert to cash in the near future. Inventory is probably the least liquid of the current assets, at least for many businesses.

Fixed assets are, for the most part, relatively illiquid. These consist of tangible things such as buildings and equipment that don't convert to cash at all in normal business activity (they are, of course, used in the business to generate cash). Intangible assets, such as a trademark, have no physical existence but can be very valuable. Like tangible fixed assets, they won't ordinarily convert to cash and are generally considered illiquid.

Liquidity is valuable. The more liquid a business is, the less likely it is to experience financial distress (that is, difficulty in paying debts or buying needed assets). Unfortunately, liquid assets are generally less profitable to hold. For example, cash holdings are the most liquid of all investments, but they sometimes earn no return at all—they just sit there. There is therefore a trade-off between the advantages of liquidity and forgone potential profits.

Annual and quarterly financial statements (and lots more) for most public U.S. corporations can be found in the EDGAR database at www.sec.gov.

Debt versus Equity

To the extent that a firm borrows money, it usually gives first claim to the firm's cash flow to creditors. Equity holders are only entitled to the residual value, the portion left after creditors are paid. The value of this residual portion is the shareholders' equity in the firm, which is just the value of the firm's assets less the value of the firm's liabilities:

$$\text{Shareholders' equity} = \text{Assets} - \text{Liabilities}$$

This is true in an accounting sense because shareholders' equity is defined as this residual portion. More importantly, it is true in an economic sense: If the firm sells its assets and pays its debts, whatever cash is left belongs to the shareholders.

The use of debt in a firm's capital structure is called *financial leverage*. The more debt a firm has (as a percentage of assets), the greater is its degree of financial leverage. As we discuss in later chapters, debt acts like a lever in the sense that using it can greatly magnify both gains and losses. So, financial leverage increases the potential reward to shareholders, but it also increases the potential for financial distress and business failure.

The home page for the Financial Accounting Standards Board (FASB) is www.fasb.org.

Market Value versus Book Value

The true value of any asset is its *market* value, which is simply the amount of cash we would get if we actually sold it. In contrast, the values shown on the balance sheet for the firm's assets are *book values* and generally are not what the assets are actually worth. Under **Generally Accepted Accounting Principles (GAAP)**, audited financial statements in the United States generally show assets at *historical cost*. In other words, assets are "carried on the books" at what the firm paid for them, no matter how long ago they were purchased or how much they are worth today.

For current assets, market value and book value might be somewhat similar since current assets are bought and converted into cash over a relatively short span of time. In other circumstances, they might differ quite a bit. Moreover, for fixed assets, it would be purely a coincidence if the actual market value of an asset (what the asset could be sold for) were equal to its book value. For example, a railroad might own enormous tracts of land purchased a century or more ago. What the railroad paid for that land could be hundreds or thousands of times less than what it is worth today. The balance sheet would nonetheless show the historical cost.

Managers and investors will frequently be interested in knowing the market value of the firm. This information is not on the balance sheet. The fact that balance sheet assets are listed at cost means that there is no necessary connection between the total assets shown and the market value of the firm. Indeed, many of the most valuable assets that a firm might have—good management, a good reputation, talented employees—don't appear on the balance sheet at all. To give one example, one of the most valuable assets for many well-known companies is their brand name. According to one source, the names "Coca-Cola," "Microsoft," and "IBM" are all worth in excess of \$50 billion.

Similarly, the owners' equity figure on the balance sheet and the true market value of the equity need not be related. For financial managers, then, the accounting value of the equity is not an especially important concern; it is the market value that matters. Henceforth, whenever we speak of the value of an asset or the value of the firm, we will normally mean its *market value*. So, for example, when we say the goal of the financial manager is to increase the value of the stock, we mean the market value of the stock.

Generally Accepted Accounting Principles (GAAP)

The common set of standards and procedures by which audited financial statements are prepared.

Market versus Book Values

EXAMPLE 2.2

The Klingon Corporation has fixed assets with a book value of \$700 and an appraised market value of about \$1,000. Current assets are \$400 on the books, but approximately \$600 would be realized if they were liquidated. Klingon has \$500 in long-term debt, both book value and market value, and no current liabilities of any kind. What is the book value of the equity? What is the market value?

We can construct two simplified balance sheets, one in accounting (book value) terms and one in economic (market value) terms:

KLINGON CORPORATION Balance Sheets Market Value versus Book Value					
	Book	Market		Book	Market
Assets			Liabilities and Shareholders' Equity		
Current assets	\$ 400	\$ 600	Long-term debt	\$ 500	\$ 500
Net fixed assets	700	1,000	Shareholders' equity	600	1,100
	<u>\$1,100</u>	<u>\$1,600</u>		<u>\$1,100</u>	<u>\$1,600</u>

In this example, shareholders' equity is actually worth almost twice as much as what is shown on the books. The distinction between book and market values is important precisely because book values can be so different from true economic values.

CONCEPT QUESTIONS

- 2.1a** What is the balance sheet identity?
- 2.1b** What is liquidity? Why is it important?
- 2.1c** What do we mean by financial leverage?
- 2.1d** Explain the difference between accounting value and market value. Which is more important to the financial manager? Why?

THE INCOME STATEMENT

2.2

The **income statement** measures performance over some period of time, usually a quarter or a year. The income statement equation is:

$$\text{Revenues} - \text{Expenses} = \text{Income} \quad [2.2]$$

If you think of the balance sheet as a snapshot, then you can think of the income statement as a video recording covering the period between a before and an after picture. Table 2.2 gives a simplified income statement for U.S. Corporation.

The first thing reported on an income statement would usually be revenue and expenses from the firm's principal operations. Subsequent parts include, among other things, financing expenses such as interest paid. Taxes paid are reported separately. The last item is *net income* (the so-called bottom line). Net income is often expressed on a per-share basis and called *earnings per share (EPS)*.

As indicated, U.S. paid cash dividends of \$103. The difference between net income and cash dividends, \$309, is the addition to retained earnings for the year. This amount is

income statement

Financial statement summarizing a firm's performance over a period of time.

TABLE 2.2**Income statement for
U.S. Corporation****U.S. CORPORATION
2010 Income Statement
(\$ in Millions)**

Net sales		\$1,509
Cost of goods sold		750
Depreciation		65
Earnings before interest and taxes		\$ 694
Interest paid		70
Taxable income		\$ 624
Taxes		212
Net income		<u>\$ 412</u>
Dividends	\$103	
Addition to retained earnings	309	

added to the cumulative retained earnings account on the balance sheet. If you look back at the two balance sheets for U.S. Corporation, you'll see that retained earnings did go up by this amount, $\$1,320 + 309 = \$1,629$.

EXAMPLE 2.3**Earnings and Dividends per Share**

Suppose U.S. had 200 million shares outstanding at the end of 2010. Based on the income statement in Table 2.2, what was EPS? What were dividends per share?

From the income statement, U.S. had a net income of \$412 million for the year. Total dividends were \$103 million. Since 200 million shares were outstanding, we can calculate earnings per share and dividends per share as follows:

$$\begin{aligned}\text{Earnings per share} &= \text{Net income} / \text{Total shares outstanding} \\ &= \$412 / 200 = \$2.06 \text{ per share}\end{aligned}$$

$$\begin{aligned}\text{Dividends per share} &= \text{Total dividends} / \text{Total shares outstanding} \\ &= \$103 / 200 = \$0.515 \text{ per share}\end{aligned}$$

When looking at an income statement, the financial manager needs to keep three things in mind: GAAP, cash versus noncash items, and time and costs.

GAAP and the Income Statement

An income statement prepared using GAAP will show revenue when it accrues. This is not necessarily when the cash comes in. The general rule (the recognition principle) is to recognize revenue when the earnings process is virtually complete and the value of an exchange of goods or services is known or can be reliably determined. In practice, this principle usually means that revenue is recognized at the time of sale, which need not be the same as the time of collection.

Expenses shown on the income statement are based on the matching principle. The basic idea here is to first determine revenues as described above and then match those revenues with the costs associated with producing them. So, if we manufacture a product

and then sell it on credit, the revenue is recognized at the time of sale. The production and other costs associated with the sale of that product would likewise be recognized at that time. Once again, the actual cash outflows may have occurred at some very different times. Thus, as a result of the way revenues and expenses are reported, the figures shown on the income statement may not be at all representative of the actual cash inflows and outflows that occurred during a particular period.

Noncash Items

A primary reason that accounting income differs from cash flow is that an income statement contains **noncash items**. The most important of these is *depreciation*. Suppose a firm purchases a fixed asset for \$5,000 and pays in cash. Obviously, the firm has a \$5,000 cash outflow at the time of purchase. However, instead of deducting the \$5,000 as an expense, an accountant might depreciate the asset over a five-year period.

If the depreciation is straight-line and the asset is written down to zero over that period, then $\$5,000/5 = \$1,000$ would be deducted each year as an expense.² The important thing to recognize is that this \$1,000 deduction isn't cash—it's an accounting number. The actual cash outflow occurred when the asset was purchased.

The depreciation deduction is simply another application of the matching principle in accounting. The revenues associated with an asset would generally occur over some length of time. So, the accountant seeks to match the expense of purchasing the asset with the benefits produced from owning it.

As we will see, for the financial manager, the actual timing of cash inflows and outflows is critical in coming up with a reasonable estimate of market value, so we need to learn how to separate the cash flows from the noncash accounting entries. In reality, the difference between cash flow and accounting income can be pretty dramatic. For example, in the first quarter of 2009, media giant Cablevision, whose holdings include the New York Knicks and New York Rangers, reported a loss of \$321 million. Sounds bad, but Cablevision reported a *positive* operating cash flow of \$498 million! In large part, the difference was due to noncash charges associated with Cablevision's purchase of the *Newsday* newspaper the previous year.

noncash items

Expenses charged against revenues that do not directly affect cash flow, such as depreciation.

Time and Costs

It is often useful to think of the future as having two distinct parts: the short run and the long run. These are not precise time periods. The distinction has to do with whether costs are fixed or variable. In the long run, all business costs are variable. Given sufficient time, assets can be sold, debts can be paid, and so on.

If our time horizon is relatively short, however, some costs are effectively fixed—they must be paid no matter what (property taxes, for example). Other costs such as wages to laborers and payments to suppliers are still variable. As a result, even in the short run, the firm can vary its output level by varying expenditures in these areas.

The distinction between fixed and variable costs is important, at times, to the financial manager, but the way costs are reported on the income statement is not a good guide as to

² By “straight-line,” we mean that the depreciation deduction is the same every year. By “written down to zero,” we mean that the asset is assumed to have no value at the end of five years.

Fairly Accurate Financial Accounting?

A major objective of the Financial Accounting Standards Board (FASB) is to create rules that provide users of financial statements with information that can be used to make investment, credit, and other similar decisions. For example, beginning in September of 2007, FASB required banks to use fair value accounting, which only seems fair to us. However, this requirement proved to be controversial in the economic downturn of 2008 and 2009.

Under fair value accounting, banks have to value certain assets on their balance sheets according to what they could be sold for in the open market. This process is relatively simple for a security that is frequently traded. However, during 2008 and into 2009, trading essentially ground to a halt in many types of assets that banks held in great quantity. So, how do you price an asset for the value at which it could be sold when no one will buy it?

Banks argued that market prices for much of what they held were, in essence, fire sale prices and that the assets were actually worth more than they would fetch in such a distress sale. Using fair value accounting, they said, was really unfair because prices were so distorted. Proponents of fair value accounting argued that removing or relaxing fair value accounting would weaken the value of financial statements.

In the end, the fair value accounting issue ended up at a hearing at the U.S. House of Representatives, which, we should note, is not known for its financial accounting prowess. At the hearing, members of the House panel suggested that FASB modify its stance. In the end, the chair of FASB agreed to relax fair value accounting to provide banks with more flexibility in valuing their assets.

which costs are which. The reason is that, in practice, accountants tend to classify costs as either product costs or period costs.

Product costs include such things as raw materials, direct labor expense, and manufacturing overhead. These are reported on the income statement as costs of goods sold, but they include both fixed and variable costs. Similarly, period costs are incurred during a particular time period and might be reported as selling, general, and administrative expenses. Once again, some of these period costs may be fixed and others may be variable. The company president's salary, for example, is a period cost and is probably fixed, at least in the short run.

The balance sheets and income statement we have been using thus far are hypothetical. Our nearby *Work the Web* box shows how to find actual balance sheets and income statements online for almost any company.

Earnings Management

The way that firms are required by GAAP to report financial results is intended to be objective and precise. In reality, there is plenty of wiggle room, and, as a result, companies have significant discretion over their reported earnings. For example, corporations frequently like to show investors that they have steadily growing earnings. To do this, they might take steps to over- or understate earnings at various times to smooth out dips and surges. Doing so falls under the heading of *earnings management*. Our nearby *Reality Bytes* box goes into more depth on this subject.

CONCEPT QUESTIONS

- 2.2a** What is the income statement equation?
- 2.2b** What are the three things to keep in mind when looking at an income statement?
- 2.2c** Why is accounting income not the same as cash flow?

WORK THE WEB

The U.S. Securities and Exchange Commission (SEC) requires that most public companies file regular reports, including annual and quarterly financial statements. The SEC has a public site named EDGAR that makes these reports available free at www.sec.gov. We went to “Search for Company Filings” and searched for “Microsoft.” When we got our results, we limited our search to Form 10-K. Here is what we got:

MICROSOFT CORP CIK# 0000789019 (see all company filings)

SIC: 7372 - SERVICES-PREPACKAGED SOFTWARE
 State location: WA | State of Inc: WA | Fiscal Year End: 0630

As of the date of this search, EDGAR had 15 of these reports for Microsoft available for downloading. The 10-K is the annual report filed with the SEC. It includes, among other things, the list of officers and their salaries, financial statements for the previous fiscal year, and an explanation by the company for the financial results. Here is an exercise for you: Go to the “Descriptions of SEC Forms” page and find the different forms companies must file with the SEC. What is a 10-Q report?

Questions

- As you can imagine, electronic filing of documents with the SEC has not been around for very long. Go to www.sec.gov and find the filings for General Electric. What is the date of the oldest 10-K available on the Web site for General Electric? Look up the 10-K forms for IBM and Apple to see if the year of the first electronic filing is the same for these companies.
- Go to www.sec.gov and find out when the following forms are used: Form DEF 14A, Form 8-K, and Form 6-K.

TAXES

2.3

Taxes can be one of the largest cash outflows that a firm experiences. For example, for the fiscal year 2008, Walmart's earnings before taxes were about \$20.2 billion. Its tax bill, including all taxes paid worldwide, was a whopping \$6.9 billion, or about 34 percent of its pretax

TABLE 2.3

Corporate tax rates

Taxable Income		Tax Rate
\$	0– 50,000	15%
	50,001– 75,000	25
	75,001– 100,000	34
	100,001– 335,000	39
	335,001– 10,000,000	34
	10,000,001– 15,000,000	35
	15,000,001– 18,333,333	38
	18,333,334+	35

earnings. The size of the tax bill is determined through the tax code, an often-amended set of rules. In this section, we examine corporate tax rates and how taxes are calculated. Taxes for partnerships and proprietorships are computed using the personal income tax schedules; we don’t discuss these here, but the general procedures are the same as for corporate taxes.

If the various rules of taxation seem a little bizarre or convoluted to you, keep in mind that the tax code is the result of political, not economic, forces. As a result, there is no reason why it has to make economic sense.

Corporate Tax Rates

The IRS has a great Web site! (www.irs.gov)

Corporate tax rates in effect for 2010 are shown in Table 2.3. A peculiar feature is that corporate tax rates are not strictly increasing. As shown, corporate tax rates rise from 15 percent to 39 percent, but they drop back to 34 percent on income over \$335,000. They then rise to 38 percent and subsequently fall to 35 percent.

According to the originators of the current tax rules, there are only four corporate rates: 15 percent, 25 percent, 34 percent, and 35 percent. The 38 and 39 percent brackets arise because of “surcharges” applied on top of the 34 and 35 percent rates. A tax is a tax is a tax, however, so there are really six corporate tax brackets, as we have shown.

Average versus Marginal Tax Rates

average tax rate
Total taxes paid divided by total taxable income.

marginal tax rate
Amount of tax payable on the next dollar earned.

In making financial decisions, it is frequently important to distinguish between average and marginal tax rates. Your **average tax rate** is your tax bill divided by your taxable income, in other words, the percentage of your income that goes to pay taxes. Your **marginal tax rate** is the extra tax you would pay if you earned one more dollar. The percentage tax rates shown in Table 2.3 are all marginal rates. Put another way, the tax rates in Table 2.3 apply to the part of income in the indicated range only, not all income.

The difference between average and marginal tax rates can be best illustrated with a simple example. Suppose our corporation has a taxable income of \$200,000. What is the tax bill? From Table 2.3, we can figure our tax bill as:

.15(\$ 50,000)

= \$ 7,500

.25(\$ 75,000 – 50,000)

= 6,250

.34(\$100,000 – 75,000)

= 8,500

.39(\$200,000 – 100,000)

= 39,000

\$61,250

Our total tax is thus \$61,250.

50,000,000	35	17,500,000	35.00	
100,000,000	35	35,000,000	35.00	

In our example, what is the average tax rate? We had a taxable income of \$200,000 and a tax bill of \$61,250, so the average tax rate is $\$61,250/200,000 = 30.625\%$. What is the marginal tax rate? If we made one more dollar, the tax on that dollar would be 39 cents, so our marginal rate is 39 percent.

Table 2.4 summarizes some different taxable incomes, marginal tax rates, and average tax rates for corporations. Notice how the average and marginal tax rates come together at 35 percent.

Deep in the Heart of Taxes

EXAMPLE 2.4

Algernon, Inc., has a taxable income of \$85,000. What is its tax bill? What is its average tax rate? Its marginal tax rate?

From Table 2.3, the tax rate applied to the first \$50,000 is 15 percent; the rate applied to the next \$25,000 is 25 percent; and the rate applied after that up to \$100,000 is 34 percent. So, Algernon must pay $.15 \times \$50,000 + .25 \times 25,000 + .34 \times (85,000 - 75,000) = \$17,150$. The average tax rate is thus $\$17,150/85,000 = 20.18\%$. The marginal rate is 34 percent since Algernon's taxes would rise by 34 cents if it had another dollar in taxable income.

With a *flat-rate tax*, there is only one tax rate, and this rate is the same for all income levels. With such a tax, the marginal tax rate is always the same as the average tax rate. As it stands now, corporate taxation in the United States is based on a modified flat-rate tax, which becomes a true flat rate for the highest incomes.

In looking at Table 2.4, notice that the more a corporation makes, the greater is the percentage of taxable income paid in taxes. Put another way, under current tax law, the average tax rate never goes down, even though the marginal tax rate does. As illustrated, for corporations, average tax rates begin at 15 percent and rise to a maximum of 35 percent.

It will normally be the marginal tax rate that is relevant for financial decision making. The reason is that any new cash flows will be taxed at that marginal rate. Since financial decisions usually involve new cash flows or changes in existing ones, this rate will tell us the marginal effect on our tax bill.

There is one last thing to notice about the tax code as it affects corporations. It's easy to verify that the corporate tax bill is just a flat 35 percent of taxable income if our taxable income is more than \$18.33 million. Also, for the many midsize corporations with taxable incomes in the \$335,000 to \$10,000,000 range, the tax rate is a flat 34 percent. Since we will usually be talking about large corporations, you can assume that the average and marginal tax rates are 35 percent unless we explicitly say otherwise.

CONCEPT QUESTIONS

- 2.3a** What is the difference between a marginal and an average tax rate?
- 2.3b** Do the wealthiest corporations receive a tax break in terms of a lower tax rate? Explain.

2.4

CASH FLOW

At this point, we are ready to discuss perhaps one of the most important pieces of financial information that can be gleaned from financial statements: *cash flow*. By cash flow, we simply mean the difference between the number of dollars that came in and the number that went out. For example, if you were the owner of a business, you might be very interested in how much cash you actually took out of your business in a given year. How to determine this amount is one of the things we discuss next.

There is no standard financial statement that presents this information in the way that we wish. We will therefore discuss how to calculate cash flow for U.S. Corporation and point out how the result differs from that of standard financial statement calculations. Important note: There is a standard financial accounting statement called the *statement of cash flows*, but it is concerned with a somewhat different issue that should not be confused with what is discussed in this section.

From the balance sheet identity, we know that the value of a firm's assets is equal to the value of its liabilities plus the value of its equity. Similarly, the cash flow from the firm's assets must equal the sum of the cash flow to creditors and the cash flow to stockholders (or owners, if the business is not a corporation):

$$\text{Cash flow from assets} = \text{Cash flow to creditors} + \text{Cash flow to stockholders} \quad [2.3]$$

This is the cash flow identity. What it reflects is the fact that a firm generates cash through its various activities, and that cash either is used to pay creditors or else is paid out to the owners of the firm. We discuss the various things that make up these cash flows next.

Cash Flow from Assets

Cash flow from assets

The total of cash flow to creditors and cash flow to stockholders, consisting of the following: operating cash flow, capital spending, and change in net working capital.

operating cash flow

Cash generated from a firm's normal business activities.

Cash flow from assets involves three components: operating cash flow, capital spending, and change in net working capital. **Operating cash flow** refers to the cash flow that results from the firm's day-to-day activities of producing and selling. Expenses associated with the firm's financing of its assets are not included since they are not operating expenses.

In the normal course of events, some portion of the firm's cash flow is reinvested in the firm. *Capital spending* refers to the net spending on fixed assets (purchases of fixed assets less sales of fixed assets). Finally, *the change in net working capital* is the amount spent on net working capital. It is measured as the change in net working capital over the period being examined and represents the net increase or decrease in current assets over current liabilities. The three components of cash flow are examined in more detail below. In all our examples, all amounts are in millions of dollars.

Operating Cash Flow To calculate operating cash flow (OCF), we want to calculate revenues minus costs, but we don't want to include depreciation since it's not a cash outflow, and we don't want to include interest because it's a financing expense. We do want to include taxes because taxes are, unfortunately, paid in cash.

If we look at U.S. Corporation's income statement (Table 2.2), we see that earnings before interest and taxes (EBIT) are \$694. This is almost what we want since it doesn't include interest paid. We need to make two adjustments. First, recall that depreciation is a noncash expense. To get cash flow, we first add back the \$65 in depreciation since it wasn't a cash deduction. The other adjustment is to subtract the \$212 in taxes since these were paid in cash. The result is operating cash flow:

U.S. CORPORATION 2010 Operating Cash Flow	
Earnings before interest and taxes	\$694
+ Depreciation	65
– Taxes	212
Operating cash flow	<u>\$547</u>

U.S. Corporation thus had a 2010 operating cash flow of \$547.

Operating cash flow is an important number because it tells us, on a very basic level, whether or not a firm's cash inflows from its business operations are sufficient to cover its everyday cash outflows. For this reason, a negative operating cash flow is often a sign of trouble.

There is an unpleasant possibility for confusion when we speak of operating cash flow. In accounting practice, operating cash flow is often defined as net income plus depreciation. For U.S. Corporation, this would amount to $\$412 + \$65 = \$477$. The accounting definition of operating cash flow differs from ours in one important way: Interest is deducted when net income is computed. Notice that the difference between the \$547 operating cash flow we calculated and this \$477 is \$70, the amount of interest paid for the year. This definition of cash flow thus considers interest paid to be an operating expense. Our definition treats it properly as a financing expense. If there were no interest expense, the two definitions would be the same.

To finish our calculation of cash flow from assets for U.S. Corporation, we need to consider how much of the \$547 operating cash flow was reinvested in the firm. We consider spending on fixed assets first.

Capital Spending Net capital spending is just money spent on fixed assets less money received from the sale of fixed assets. At the end of 2009, net fixed assets for U.S. Corporation (Table 2.1) were \$1,644. During the year, we wrote off (depreciated) \$65 worth of fixed assets on the income statement. So, if we didn't purchase any new fixed assets, net fixed assets would have been $\$1,644 - \$65 = \$1,579$ at year's end. The 2010 balance sheet shows \$1,709 in net fixed assets, so we must have spent a total of $\$1,709 - \$1,579 = \$130$ on fixed assets during the year:

Ending net fixed assets	\$1,709
– Beginning net fixed assets	1,644
+ Depreciation	65
Net investment in fixed assets	<u>\$ 130</u>

This **\$130** is our net capital spending for 2010.

Could net capital spending be negative? The answer is yes. This would happen if the firm sold off more assets than it purchased. The *net* here refers to purchases of fixed assets net of any sales of fixed assets.

Change in Net Working Capital In addition to investing in fixed assets, a firm will also invest in current assets. For example, going back to the balance sheet in Table 2.1, we see that at the end of 2010, U.S. had current assets of \$1,403. At the end of 2009, current assets were \$1,112, so, during the year, U.S. invested $\$1,403 - 1,112 = \291 in current assets.

As the firm changes its investment in current assets, its current liabilities will usually change as well. To determine the change in net working capital, the easiest approach is just to take the difference between the beginning and ending net working capital (NWC) figures. Net working capital at the end of 2010 was $\$1,403 - 389 = \$1,014$. Similarly, at the end of 2009, net working capital was $\$1,112 - 428 = \684 . So, given these figures, we have:

Ending NWC	\$1,014
– Beginning NWC	684
Change in NWC	<u>\$ 330</u>

Net working capital thus increased by \$330. Put another way, U.S. Corporation had a net investment of \$330 in NWC for the year.

Conclusion Given the figures we’ve come up with, we’re ready to calculate cash flow from assets. The total cash flow from assets is given by operating cash flow less the amounts invested in fixed assets and net working capital. So, for U.S., we have:

U.S. CORPORATION	
2010 Cash Flow from Assets	
Operating cash flow	\$547
– Net capital spending	130
– Change in NWC	330
Cash flow from assets	<u>\$ 87</u>

From the cash flow identity above, this \$87 cash flow from assets equals the sum of the firm’s cash flow to creditors and its cash flow to stockholders. We consider these next.

It wouldn’t be at all unusual for a growing corporation to have a negative cash flow. As we shall see below, a negative cash flow means that the firm raised more money by borrowing and selling stock than it paid out to creditors and stockholders that year.

A Note on “Free” Cash Flow Cash flow from assets sometimes goes by a different name, **free cash flow**. Of course, there is no such thing as “free” cash (we wish!). Instead, the name refers to cash that the firm is free to distribute to creditors and stockholders because it is not needed for working capital or fixed asset investments. We will stick with “cash flow from assets” as our label for this important concept because, in practice, there is some variation in exactly how free cash flow is computed; different users calculate it in different ways. Nonetheless, whenever you hear the phrase “free cash flow,” you should understand that what is being discussed is cash flow from assets or something quite similar.

free cash flow

Another name for cash flow from assets.

cash flow to creditors

A firm’s interest payments to creditors less net new borrowings.

Cash Flow to Creditors and Stockholders

The cash flows to creditors and stockholders represent the net payments to creditors and owners during the year. They are calculated in a similar way. **Cash flow to creditors** is

interest paid less net new borrowing; **cash flow to stockholders** is dividends paid less net new equity raised.

cash flow to stockholders

Dividends paid out by a firm less net new equity raised.

Cash Flow to Creditors Looking at the income statement in Table 2.2, we see that U.S. paid \$70 in interest to creditors. From the balance sheets in Table 2.1, long-term debt rose by $\$454 - 408 = \46 . So, U.S. Corporation paid out \$70 in interest, but it borrowed an additional \$46. Net cash flow to creditors is thus:

U.S. CORPORATION 2010 Cash Flow to Creditors	
Interest paid	\$70
– Net new borrowing	46
Cash flow to creditors	<u>\$24</u>

Cash flow to creditors is sometimes called *cash flow to bondholders*; we will use these terms interchangeably.

Cash Flow to Stockholders From the income statement, dividends paid to stockholders amount to \$103. To get net new equity raised, we need to look at the common stock and paid-in surplus account. This account tells us how much stock the company has sold. During the year, this account rose by \$40, so \$40 in net new equity was raised. Given this, we have:

U.S. CORPORATION 2010 Cash Flow to Stockholders	
Dividends paid	\$103
– Net new equity raised	40
Cash flow to stockholders	<u>\$ 63</u>

The cash flow to stockholders for 2010 was thus **\$63**.

Conclusion

The last thing that we need to do is to verify that the cash flow identity holds to be sure that we didn't make any mistakes. From above, cash flow from assets is \$87. Cash flow to creditors and stockholders is $\$24 + 63 = \87 , so everything checks out. Table 2.5 contains a summary of the various cash flow calculations for future reference.

As our discussion indicates, it is essential that a firm keep an eye on its cash flow. The following serves as an excellent reminder of why doing so is a good idea, unless the firm's owners wish to end up in the poorhouse.

Quoth the Banker, "Watch Cash Flow"

*Once upon a midnight dreary as I pondered weak and weary
Over many a quaint and curious volume of accounting lore,
Seeking gimmicks (without scruple) to squeeze through
some new tax loophole,
Suddenly I heard a knock upon my door,
Only this, and nothing more.*

*Then I felt a queasy tingling and I heard the cash a-jingling
As a fearsome banker entered whom I'd often seen before.*

TABLE 2.5

Cash flow summary

I. The cash flow identity
Cash flow from assets = Cash flow to creditors (bondholders) + Cash flow to stockholders (owners)
II. Cash flow from assets
Cash flow from assets = Operating cash flow – Net capital spending – Change in net working capital (NWC)
where
Operating cash flow = Earnings before interest and taxes (EBIT) + Depreciation – Taxes
Net capital spending = Ending net fixed assets – Beginning net fixed assets + Depreciation
Change in NWC = Ending NWC – Beginning NWC
III. Cash flow to creditors (bondholders)
Cash flow to creditors = Interest paid – Net new borrowing
IV. Cash flow to stockholders (owners)
Cash flow to stockholders = Dividends paid – Net new equity raised

*His face was money-green and in his eyes there could be seen
Dollar-signs that seemed to glitter as he reckoned up the score.
“Cash flow,” the banker said, and nothing more.*

*I had always thought it fine to show a jet black bottom line.
But the banker sounded a resounding, “No.
Your receivables are high, mounting upward toward the sky;
Write-offs loom. What matters is cash flow.”
He repeated, “Watch cash flow.”*

*Then I tried to tell the story of our lovely inventory
Which, though large, is full of most delightful stuff.
But the banker saw its growth, and with a mighty oath
He waved his arms and shouted, “Stop! Enough!
Pay the interest, and don’t give me any guff!”*

*Next I looked for noncash items which could add ad infinitum
To replace the ever-outward flow of cash,
But to keep my statement black I’d held depreciation back,
And my banker said that I’d done something rash.
He quivered, and his teeth began to gnash.*

*When I asked him for a loan, he responded, with a groan,
That the interest rate would be just prime plus eight,
And to guarantee my purity he’d insist on some security—
All my assets plus the scalp upon my pate.
Only this, a standard rate.*

*Though my bottom line is black, I am flat upon my back,
My cash flows out and customers pay slow.
The growth of my receivables is almost unbelievable:
The result is certain unremitting woe!
And I hear the banker utter an ominous low mutter,
“Watch cash flow.”*

To which we can only add: “Amen.”

An Example: Cash Flows for Dole Cola

This extended example covers the various cash flow calculations discussed in the chapter. It also illustrates a few variations that may arise.

Operating Cash Flow During the year, Dole Cola, Inc., had sales and cost of goods sold of \$600 and \$300, respectively. Depreciation was \$150, and interest paid was \$30. Taxes were calculated at a straight 34 percent. Dividends were \$30. (All figures are in millions of dollars.) What was operating cash flow for Dole? Why is this different from net income?

The easiest thing to do here is to go ahead and create an income statement. We can then pick up the numbers we need. Dole Cola's income statement is given below.

DOLE COLA 2010 Income Statement	
Net sales	\$600
Cost of goods sold	300
Depreciation	150
Earnings before interest and taxes	\$150
Interest paid	30
Taxable income	\$120
Taxes	41
Net income	<u>\$ 79</u>
Dividends	\$30
Addition to retained earnings	49

Net income for Dole was thus \$79. We now have all the numbers we need. Referring back to the U.S. Corporation example and Table 2.5, we have:

DOLE COLA 2010 Operating Cash Flow	
Earnings before interest and taxes	\$150
+ Depreciation	150
– Taxes	41
Operating cash flow	<u>\$259</u>

As this example illustrates, operating cash flow is not the same as net income, because depreciation and interest are subtracted out when net income is calculated. If you recall our earlier discussion, we don't subtract these out in computing operating cash flow because depreciation is not a cash expense and interest paid is a financing expense, not an operating expense.

Net Capital Spending Suppose beginning net fixed assets were \$500 and ending net fixed assets were \$750. What was the net capital spending for the year?

From the income statement for Dole, depreciation for the year was \$150. Net fixed assets rose by \$250. Dole thus spent \$250 along with an additional \$150, for a total of \$400.

Change in NWC and Cash Flow from Assets Suppose Dole Cola started the year with \$2,130 in current assets and \$1,620 in current liabilities. The corresponding ending figures were \$2,260 and \$1,710. What was the change in NWC during the year? What was cash flow from assets? How does this compare to net income?

Net working capital started out as $\$2,130 - 1,620 = \510 and ended up at $\$2,260 - 1,710 = \550 . The change in NWC was thus $\$550 - 510 = \40 . Putting together all the information for Dole Cola, we have:

DOLE COLA 2010 Cash Flow from Assets	
Operating cash flow	\$259
– Net capital spending	400
– Change in NWC	40
Cash flow from assets	<u><u>–\$181</u></u>

Dole had a cash flow from assets of $-\$181$. Net income was positive at $\$79$. Is the fact that cash flow from assets was negative a cause for alarm? Not necessarily. The cash flow here is negative primarily because of a large investment in fixed assets. If these are good investments, then the resulting negative cash flow is not a worry.

Cash Flow to Creditors and Stockholders We saw that Dole Cola had cash flow from assets of $-\$181$. The fact that this is negative means that Dole raised more money in the form of new debt and equity than it paid out for the year. For example, suppose we know that Dole didn't sell any new equity for the year. What was cash flow to stockholders? To creditors?

Since it didn't raise any new equity, Dole's cash flow to stockholders is just equal to the cash dividend paid:

DOLE COLA 2010 Cash Flow to Stockholders	
Dividends paid	\$30
– Net new equity	0
Cash flow to stockholders	<u><u>\$30</u></u>

Now, from the cash flow identity, the total cash paid to creditors and stockholders was $-\$181$. Cash flow to stockholders is $\$30$, so cash flow to creditors must be equal to $-\$181 - 30 = -\211 :

$$\begin{aligned}
 \text{Cash flow to creditors} + \text{Cash flow to stockholders} &= -\$181 \\
 \text{Cash flow to creditors} + \$30 &= -\$181 \\
 \text{Cash flow to creditors} &= -\$211
 \end{aligned}$$

Since we know that cash flow to creditors is $-\$211$ and interest paid is $\$30$ (from the income statement), we can now determine net new borrowing. Dole must have borrowed $\$241$ during the year to help finance the fixed asset expansion:

DOLE COLA 2010 Cash Flow to Creditors	
Interest paid	\$ 30
– Net new borrowing	241
Cash flow to creditors	<u><u>–\$211</u></u>

CONCEPT QUESTIONS

- 2.4a** What is the cash flow identity? Explain what it says.
- 2.4b** What are the components of operating cash flow?
- 2.4c** Why is interest paid not a component of operating cash flow?

SUMMARY AND CONCLUSIONS

This chapter has introduced you to some of the basics of financial statements, taxes, and cash flow. In it, we saw that:

1. The book values on an accounting balance sheet can be very different from market values. The goal of financial management is to maximize the market value of the stock, not its book value.
2. Net income as it is computed on the income statement is not cash flow. A primary reason is that depreciation, a noncash expense, is deducted when net income is computed.
3. Marginal and average tax rates can be different, and it is the marginal tax rate that is relevant for most financial decisions.
4. The marginal tax rate paid by the corporations with the largest incomes is 35 percent.
5. There is a cash flow identity much like the balance sheet identity. It says that cash flow from assets equals cash flow to creditors and stockholders.

The calculation of cash flow from financial statements isn't difficult. Care must be taken in handling noncash expenses, such as depreciation, and in not confusing operating costs with financing costs. Most of all, it is important not to confuse book values with market values and accounting income with cash flow.

CHAPTER REVIEW AND SELF-TEST PROBLEM

- 2.1 Cash Flow for Rasputin Corporation.** This problem will give you some practice working with financial statements and figuring cash flow. Based on the following information for Rasputin Corporation, prepare an income statement for 2010 and balance sheets for 2009 and 2010. Next, following our U.S. Corporation examples in the chapter, calculate cash flow from assets for Rasputin, cash flow to creditors, and cash flow to stockholders for 2010. Use a 34 percent tax rate throughout. You can check your answers below.

	2009	2010
Sales	\$3,790	\$3,990
Cost of goods sold	2,043	2,137
Depreciation	975	1,018
Interest	225	267
Dividends	200	225
Current assets	2,140	2,346
Net fixed assets	6,770	7,087
Current liabilities	994	1,126
Long-term debt	2,869	2,956

Answer to Chapter Review and Self-Test Problem

- 2.1** In preparing the balance sheets, remember that shareholders' equity is the residual. With this in mind, Rasputin's balance sheets are as follows:

RASPUTIN CORPORATION Balance Sheets as of December 31, 2009 and 2010					
	2009	2010		2009	2010
Current assets	\$2,140	\$2,346	Current liabilities	\$ 994	\$1,126
Net fixed assets	<u>6,770</u>	<u>7,087</u>	Long-term debt	<u>2,869</u>	<u>2,956</u>
			Equity	<u>5,047</u>	<u>5,351</u>
			Total liabilities and shareholders' equity	<u>\$8,910</u>	<u>\$9,433</u>
Total assets	<u>\$8,910</u>	<u>\$9,433</u>			

The income statement is straightforward:

RASPUTIN CORPORATION 2010 Income Statement	
Sales	\$3,990
Cost of goods sold	<u>2,137</u>
Depreciation	<u>1,018</u>
Earnings before interest and taxes	\$ 835
Interest paid	<u>267</u>
Taxable income	\$ 568
Taxes (34%)	<u>193</u>
Net income	<u>\$ 375</u>
Dividends	\$225
Addition to retained earnings	150

Notice that we've used a flat 34 percent tax rate. Also, notice that the addition to retained earnings is just net income less cash dividends.

We can now pick up the figures we need to get operating cash flow:

RASPUTIN CORPORATION 2010 Operating Cash Flow	
Earnings before interest and taxes	\$ 835
+ Depreciation	1,018
– Current taxes	<u>193</u>
Operating cash flow	<u>\$1,660</u>

Next, we get the capital spending for the year by looking at the change in fixed assets, remembering to account for the depreciation:

Ending fixed assets	\$7,087
– Beginning fixed assets	<u>6,770</u>
+ Depreciation	<u>1,018</u>
Net investment in fixed assets	<u>\$1,335</u>

After calculating beginning and ending NWC, we take the difference to get the change in NWC:

Ending NWC	\$1,220
– Beginning NWC	<u>1,146</u>
Change in NWC	<u><u>\$ 74</u></u>

We now combine operating cash flow, net capital spending, and the change in net working capital to get the total cash flow from assets:

RASPUTIN CORPORATION 2010 Cash Flow from Assets	
Operating cash flow	\$1,660
– Net capital spending	<u>1,335</u>
– Change in NWC	<u>74</u>
Cash flow from assets	<u><u>\$ 251</u></u>

To get cash flow to creditors, notice that long-term borrowing increased by \$87 during the year and that interest paid was \$267, so:

RASPUTIN CORPORATION 2010 Cash Flow to Creditors	
Interest paid	\$267
– Net new borrowing	<u>87</u>
Cash flow to creditors	<u><u>\$180</u></u>

Finally, dividends paid were \$225. To get net new equity, we have to do some extra calculating. Total equity was up by $\$5,351 - \$5,047 = \$304$. Of this increase, \$150 was from additions to retained earnings, so \$154 in new equity was raised during the year. Cash flow to stockholders was thus:

RASPUTIN CORPORATION 2010 Cash Flow to Stockholders	
Dividends paid	\$225
– Net new equity	<u>154</u>
Cash flow to stockholders	<u><u>\$ 71</u></u>

As a check, notice that cash flow from assets (\$251) does equal cash flow to creditors plus cash flow to stockholders ($\$180 + \$71 = \$251$).

CRITICAL THINKING AND CONCEPTS REVIEW

- L0 1** 2.1 **Liquidity.** What does liquidity measure? Explain the trade-off a firm faces between high-liquidity and low-liquidity levels.
- L0 2** 2.2 **Accounting and Cash Flows.** Why is it that the revenue and cost figures shown on a standard income statement may not be representative of the actual cash inflows and outflows that occurred during a period?
- L0 1** 2.3 **Book Values versus Market Values.** In preparing a balance sheet, why do you think standard accounting practice focuses on historical cost rather than market value?
- L0 2** 2.4 **Operating Cash Flow.** In comparing accounting net income and operating cash flow, what two items do you find in net income that are not in operating cash flow? Explain what each is and why it is excluded in operating cash flow.
- L0 1** 2.5 **Book Values versus Market Values.** Under standard accounting rules, it is possible for a company's liabilities to exceed its assets. When this occurs, the owners' equity is negative. Can this happen with market values? Why or why not?
- L0 4** 2.6 **Cash Flow from Assets.** Suppose a company's cash flow from assets was negative for a particular period. Is this necessarily a good sign or a bad sign?
- L0 4** 2.7 **Operating Cash Flow.** Suppose a company's operating cash flow was negative for several years running. Is this necessarily a good sign or a bad sign?
- L0 4** 2.8 **Net Working Capital and Capital Spending.** Could a company's change in NWC be negative in a given year? (Hint: Yes.) Explain how this might come about. What about net capital spending?
- L0 4** 2.9 **Cash Flow to Stockholders and Creditors.** Could a company's cash flow to stockholders be negative in a given year? (Hint: Yes.) Explain how this might come about. What about cash flow to creditors?
- L0 4** 2.10 **Firm Values.** Referring back to the homebuilder examples used at the beginning of the chapter, note that we suggested that stockholders probably didn't suffer as a result of the reported loss. What do you think was the basis for our conclusion?
- In June 2002, WorldCom, the telecommunications giant, surprised investors when it announced that it had overstated net income in the prior two years by \$3.8 billion. At the center of the controversy was Scott D. Sullivan, the former CFO. WorldCom had leased telephone lines from local companies with the expectation of reselling the use of the lines at a higher price. Under GAAP, these costs should have been reported as an expense on the income statement. Reportedly, however, Mr. Sullivan ordered that the costs be treated as money spent to purchase a fixed asset, so they were to be shown on the balance sheet as an asset and subsequently depreciated.
- L0 2** 2.11 **Corporate Ethics.** In the wake of this scandal, Mr. Sullivan was charged with fraud. Do you think this should be considered fraud? Why? Why was this unethical?
- L0 4** 2.12 **Net Income and Cash Flows.** How did Mr. Sullivan's reclassifying some costs as asset purchases affect net income at the time? In the future? How did this action affect cash flows? What does this tell you about the importance of examining cash flow relative to net income?

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

Basic

(Questions 1–13)

- L0 1** 1. **Building a Balance Sheet.** Arredondo, Inc., has current assets of \$2,170, net fixed assets of \$9,300, current liabilities of \$1,350, and long-term debt of \$3,980. What is the value of the shareholders' equity account for this firm? How much is net working capital?
- L0 2** 2. **Building an Income Statement.** Lifeline, Inc., has sales of \$585,000, costs of \$273,000, depreciation expense of \$71,000, interest expense of \$38,000, and a tax rate of 35 percent. What is the net income for this firm?
- L0 2** 3. **Dividends and Retained Earnings.** Suppose the firm in Problem 2 paid out \$36,000 in cash dividends. What is the addition to retained earnings?
- L0 2** 4. **Per-Share Earnings and Dividends.** Suppose the firm in Problem 3 had 40,000 shares of common stock outstanding. What is the earnings per share, or EPS, figure? What is the dividends per share figure?
- L0 1** 5. **Market Values and Book Values.** Klingon Widgets, Inc., purchased new cloaking machinery three years ago for \$4 million. The machinery can be sold to the Romulans today for \$6.2 million. Klingon's current balance sheet shows net fixed assets of \$2.8 million, current liabilities of \$710,000, and net working capital of \$130,000. If all the current assets were liquidated today, the company would receive \$825,000 cash. What is the book value of Klingon's assets today? What is the market value?
- L0 3** 6. **Calculating Taxes.** The SGS Co. had \$275,000 in taxable income. Using the rates from Table 2.3 in the chapter, calculate the company's income taxes.
- L0 3** 7. **Tax Rates.** In Problem 6, what is the average tax rate? What is the marginal tax rate?
- L0 2** 8. **Calculating OCF.** Hammett, Inc., has sales of \$19,570, costs of \$9,460, depreciation expense of \$2,130, and interest expense of \$1,620. If the tax rate is 35 percent, what is the operating cash flow, or OCF?
- L0 4** 9. **Calculating Net Capital Spending.** Rotweiler Obedience School's December 31, 2009, balance sheet showed net fixed assets of \$1.725 million, and the December 31, 2010, balance sheet showed net fixed assets of \$2.04 million. The company's 2010 income statement showed a depreciation expense of \$321,000. What was Rotweiler's net capital spending for 2010?
- L0 4** 10. **Calculating Additions to NWC.** The December 31, 2009, balance sheet of Anna's Tennis Shop, Inc., showed current assets of \$1,015 and current liabilities of \$870. The December 31, 2010, balance sheet showed current assets of \$1,230 and current liabilities of \$905. What was the company's 2010 change in net working capital, or NWC?
- L0 4** 11. **Cash Flow to Creditors.** The December 31, 2009, balance sheet of Schism, Inc., showed long-term debt of \$1.375 million, and the December 31, 2010, balance sheet showed long-term debt of \$1.53 million. The 2010 income statement showed an interest expense of \$91,500. What was the firm's cash flow to creditors during 2010?
- L0 4** 12. **Cash Flow to Stockholders.** The December 31, 2009, balance sheet of Schism, Inc., showed \$135,000 in the common stock account and \$2.6 million in the additional paid-in surplus account. The December 31, 2010, balance sheet showed \$145,000 and \$2.9 million in the same two accounts, respectively. If the company paid out \$140,000 in cash dividends during 2010, what was the cash flow to stockholders for the year?

Intermediate

(Questions 14–23)

L0 4

- 13. Calculating Total Cash Flows.** Given the information for Schism, Inc., in Problems 11 and 12, suppose you also know that the firm's net capital spending for 2010 was \$910,000, and that the firm reduced its net working capital investment by \$120,000. What was the firm's 2010 operating cash flow, or OCF?

L0 4

- 14. Calculating Total Cash Flows.** Sheffield Co. shows the following information on its 2010 income statement: sales = \$153,000; costs = \$81,900; other expenses = \$5,200; depreciation expense = \$10,900; interest expense = \$8,400; taxes = \$16,330; dividends = \$7,200. In addition, you're told that the firm issued \$2,600 in new equity during 2010, and redeemed \$3,900 in outstanding long-term debt.

- What is the 2010 operating cash flow?
- What is the 2010 cash flow to creditors?
- What is the 2010 cash flow to stockholders?
- If net fixed assets increased by \$20,250 during the year, what was the addition to NWC?

L0 2

- 15. Using Income Statements.** Given the following information for Sookie's Cookies Co., calculate the depreciation expense: sales = \$51,000; costs = \$39,800; addition to retained earnings = \$2,300; dividends paid = \$925; interest expense = \$1,580; tax rate = 40 percent.

L0 1

- 16. Preparing a Balance Sheet.** Prepare a balance sheet for Alaskan Orange Corp. as of December 31, 2010, based on the following information: cash = \$193,000; patents and copyrights = \$847,000; accounts payable = \$296,000; accounts receivable = \$253,000; tangible net fixed assets = \$5,100,000; inventory = \$538,000; notes payable = \$189,000; accumulated retained earnings = \$4,586,000; long-term debt = \$1,250,000.

L0 1

- 17. Residual Claims.** Irrational, Inc., is obligated to pay its creditors \$8,400 during the year.

- What is the value of the shareholders' equity if assets equal \$9,300?
- What if assets equal \$6,900?

L0 3

- 18. Marginal versus Average Tax Rates.** (Refer to Table 2.3.) Corporation Growth has \$89,000 in taxable income, and Corporation Income has \$8,900,000 in taxable income.

- What is the tax bill for each firm?
- Suppose both firms have identified a new project that will increase taxable income by \$10,000. How much in additional taxes will each firm pay? Why is this amount the same?

**L0 2**

- 19. Net Income and OCF.** During the year, Belyk Paving Co. had sales of \$2,400,000. Cost of goods sold, administrative and selling expenses, and depreciation expense were \$1,425,000, \$435,000, and \$490,000, respectively. In addition, the company had an interest expense of \$215,000 and a tax rate of 35 percent. (Ignore any tax loss carryback or carryforward provisions.)

- What is Belyk's net income?
- What is its operating cash flow?
- Explain your results in (a) and (b).

L0 2

- 20. Accounting Values versus Cash Flows.** In Problem 19, suppose Belyk Paving Co. paid out \$400,000 in cash dividends. Is this possible? If no new investments were made in net fixed assets or net working capital, and if no new stock was issued during the year, what do you know about the firm's long-term debt account?

- LO 4** 21. **Calculating Cash Flows.** Titan Football Manufacturing had the following operating results for 2010: sales = \$19,780; cost of goods sold = \$13,980; depreciation expense = \$2,370; interest expense = \$345; dividends paid = \$550. At the beginning of the year, net fixed assets were \$13,800, current assets were \$2,940, and current liabilities were \$2,070. At the end of the year, net fixed assets were \$16,340, current assets were \$3,280, and current liabilities were \$2,160. The tax rate for 2010 was 35 percent.
- What is net income for 2010?
 - What is the operating cash flow for 2010?
 - What is the cash flow from assets for 2010? Is this possible? Explain.
 - If no new debt was issued during the year, what is the cash flow to creditors? What is the cash flow to stockholders? Explain and interpret the positive and negative signs of your answers in (a) through (d).
- LO 4** 22. **Calculating Cash Flows.** Consider the following abbreviated financial statements for Cabo Wabo, Inc.:

CABO WABO, INC. Partial Balance Sheets as of December 31, 2009 and 2010					
	2009	2010		2009	2010
Assets			Liabilities and Owners' Equity		
Current assets	\$ 2,665	\$ 2,824	Current liabilities	\$1,151	\$1,691
Net fixed assets	12,355	12,917	Long-term debt	6,739	7,862

CABO WABO, INC. 2010 Income Statement	
Sales	\$39,870
Costs	19,994
Depreciation	3,367
Interest paid	624

- What is owners' equity for 2009 and 2010?
- What is the change in net working capital for 2010?
- In 2010, Cabo Wabo purchased \$5,616 in new fixed assets. How much in fixed assets did Cabo Wabo sell? What is the cash flow from assets for the year? (The tax rate is 40 percent.)
- During 2010, Cabo Wabo raised \$1,690 in new long-term debt. How much long-term debt must Cabo Wabo have paid off during the year? What is the cash flow to creditors?

- LO 4** 23. **Cash Flow Identity.** Graffiti Advertising, Inc., reported the following financial statements for the last two years. Construct the cash flow identity for the company. Explain what each number means.

2010 Income Statement	
Sales	\$565,200
Cost of goods sold	274,025
Selling & administrative	124,733
Depreciation	54,576
EBIT	\$111,866
Interest	19,296
EBT	\$ 92,570
Taxes	48,137
Net income	\$ 44,433
Dividends	\$ 9,600
Addition to retained earnings	\$ 34,833

GRAFFITI ADVERTISING, INC.
Balance Sheet as of December 31, 2009

Cash	\$ 13,320	Accounts payable	\$ 9,504
Accounts receivable	18,994	Notes payable	14,508
Inventory	13,794	Current liabilities	\$ 24,012
Current assets	\$ 46,108	Long-term debt	\$136,800
Net fixed assets	<u>\$344,426</u>	Owners' equity	<u>\$229,722</u>
		Total liabilities and owners' equity	<u>\$390,534</u>
Total assets	<u>\$390,534</u>		

GRAFFITI ADVERTISING, INC.
Balance Sheet as of December 31, 2010

Cash	\$ 14,306	Accounts payable	\$ 10,512
Accounts receivable	21,099	Notes payable	16,466
Inventory	22,754	Current liabilities	\$ 26,978
Current assets	\$ 58,159	Long-term debt	\$152,000
Net fixed assets	<u>\$406,311</u>	Owners' equity	<u>\$285,492</u>
		Total liabilities and owners' equity	<u>\$464,470</u>
Total assets	<u>\$464,470</u>		

LO 4

Challenge

(Questions 24–25)

- 24. Net Fixed Assets and Depreciation.** On the balance sheet, the net fixed assets (NFA) account is equal to the gross fixed assets (FA) account (which records the acquisition cost of fixed assets) minus the accumulated depreciation (AD) account (which records the total depreciation taken by the firm against its fixed assets). Using the fact that $NFA = FA - AD$, show that the expression given in the chapter for net capital spending, $NFA_{\text{end}} - NFA_{\text{beg}} + D$ (where D is the depreciation expense during the year), is equivalent to $FA_{\text{end}} - FA_{\text{beg}}$.

LO 3

- 25. Tax Rates.** Refer to the corporate marginal tax rate information in Table 2.3.
- Why do you think the marginal tax rate jumps up from 34 percent to 39 percent at a taxable income of \$100,001, and then falls back to a 34 percent marginal rate at a taxable income of \$335,001?
 - Compute the average tax rate for a corporation with exactly \$335,001 in taxable income. Does this confirm your explanation in part (a)? What is the average tax rate for a corporation with exactly \$18,333,334? Is the same thing happening here?
 - Both the 39 percent and 38 percent tax rates represent what is called a tax “bubble.” Suppose the government wanted to lower the upper threshold of the 39 percent marginal tax bracket from \$335,000 to \$200,000. What would the new 39 percent bubble rate have to be?

**WHAT'S ON
THE WEB?**

- 2.1 Change in Net Working Capital.** Visit Alcoa at www.alcoa.com. Find the most recent annual report and locate the balance sheets for the past two years. Use these balance sheets to calculate the change in net working capital. How do you interpret this number?

- 2.2 Book Values versus Market Values.** The home page for Coca-Cola Company can be found at www.coca-cola.com. Locate the most recent annual report, which contains a balance sheet for the company. What is the book value of equity for Coca-Cola? The market value of a company is the number of shares of stock outstanding times the price per share. This information can be found at finance.yahoo.com using the ticker symbol for Coca-Cola (KO). What is the market value of equity? Which number is more relevant for shareholders?
- 2.3 Net Working Capital.** Duke Energy is one of the world's largest energy companies. Go to the company's home page at www.dukeenergy.com, follow the link to the investor's page, and locate the annual reports. What was Duke Energy's net working capital for the most recent year? Does this number seem low to you given Duke's current liabilities? Does this indicate that Duke Energy may be experiencing financial problems? Why or why not?
- 2.4 Cash Flows to Stockholders and Creditors.** Cooper Tire and Rubber Company provides financial information for investors on its Web site at www.coopertires.com. Follow the "Investors" link and find the most recent annual report. Using the consolidated statement of cash flows, calculate the cash flow to stockholders and the cash flow to creditors.

CHAPTER CASE

CASH FLOWS AND FINANCIAL STATEMENTS AT SUNSET BOARDS, INC.

Sunset Boards is a small company that manufactures and sells surfboards in Malibu. Tad Marks, the founder of the company, is in charge of the design and sale of the surfboards, but his background is in surfing, not business. As a result, the company's financial records are not well maintained.

The initial investment in Sunset Boards was provided by Tad and his friends and family. Because the initial investment was relatively small, and the company has made surfboards only for its own store, the investors haven't required detailed financial statements from Tad. But thanks to word of mouth among professional surfers, sales have picked up recently, and Tad is considering a major expansion. His plans include opening another surfboard store in Hawaii, as well as supplying his "sticks" (surfer lingo for boards) to other sellers.

Tad's expansion plans require a significant investment, which he plans to finance with a combination of additional funds from outsiders plus some money borrowed from banks. Naturally, the new investors and creditors require more organized and detailed financial statements than Tad has previously prepared. At the urging of his investors, Tad has hired financial analyst Paula Wolfe to evaluate the performance of the company over the past year.

After rooting through old bank statements, sales receipts, tax returns, and other records, Paula has assembled the following information:

	2009	2010
Cost of goods sold	\$141,641	\$178,839
Cash	20,437	30,880
Depreciation	39,983	45,192
Interest expense	8,702	9,962
Selling & administrative expenses	27,854	36,355
Accounts payable	36,120	40,908
Net fixed assets	176,400	214,184
Sales	277,855	338,688
Accounts receivable	14,482	18,785
Notes payable	16,464	17,976
Long-term debt	89,040	102,480
Inventory	30,475	41,821
New equity	0	16,800

Sunset Boards currently pays out 50 percent of net income as dividends to Tad and the other original investors, and has a 20 percent tax rate. You are Paula's assistant, and she has asked you to prepare the following:

1. An income statement for 2009 and 2010.
2. A balance sheet for 2009 and 2010.
3. Operating cash flow for each year.
4. Cash flow from assets for 2010.
5. Cash flow to creditors for 2010.
6. Cash flow to stockholders for 2010.

QUESTIONS

1. How would you describe Sunset Boards' cash flows for 2010? Write a brief discussion.
2. In light of your discussion in the previous question, what do you think about Tad's expansion plans?

Working with Financial Statements

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Standardize financial statements for comparison purposes.
- LO 2** Compute and, more importantly, interpret some common ratios.
- LO 3** Assess the determinants of a firm's profitability and growth.
- LO 4** Identify and explain some of the problems and pitfalls in financial statement analysis.

In February 2009, shares of famed candy maker Tootsie Roll were trading for about \$22. At that price, Tootsie Roll had a price-earnings, or PE, ratio of 29, meaning that investors were willing to pay \$29 for every dollar in income earned by Tootsie Roll. At the same time, investors were willing to pay \$82 for each dollar earned by credit card company Visa, but only a meager \$4 and \$5 for each dollar earned by Harley Davidson and Anadarko Petroleum, respectively. And there were stocks like Eli Lilly, which, despite having no earnings (a loss actually), had a stock price of about \$33 per share. Meanwhile, the average stock in the Standard and Poor's (S&P's) 500 index, which

contains 500 of the largest publicly traded companies in the United States, had a PE ratio of about 29, so Tootsie Roll was about average in this regard.

As we look at these numbers, an obvious question arises: Why were investors willing to pay so much for a dollar of Visa earnings and so much less for a dollar earned by Anadarko Petroleum? To understand the answer, we need to delve into subjects such as relative profitability and growth potential, and we also need to know how to compare financial and operating information across companies. By a remarkable coincidence, that is precisely what this chapter is about.

The PE ratio is just one example of a financial ratio. As we will see in this chapter, there are a wide variety of such ratios, all designed to summarize specific aspects of a firm's financial position. In addition to discussing financial ratios and what they mean, we will have quite a bit to say about who uses this information and why.

Everybody needs to understand ratios. Managers will find that almost every business characteristic, from profitability to employee productivity, is summarized in some kind of ratio. Marketers examine ratios dealing with costs, markups, and margins. Production personnel focus on ratios

dealing with issues such as operating efficiency. Accountants need to understand ratios because, among other things, ratios are one of the most common and important forms of financial statement information.

In fact, regardless of your field, you may very well find that your compensation is tied to some ratio or group of ratios. Perhaps that is the best reason to study up!

In Chapter 2, we discussed some of the essential concepts of financial statements and cash flows. This chapter continues where our earlier discussion left off. Our goal here is to expand your understanding of the uses (and abuses) of financial statement information.

A good working knowledge of financial statements is desirable simply because such statements, and numbers derived from those statements, are the primary means of communicating financial information both within the firm and outside the firm. In short, much of the language of business finance is rooted in the ideas we discuss in this chapter.

In the best of all worlds, the financial manager has full market value information about all of the firm's assets. This will rarely (if ever) happen. So, the reason we rely on accounting figures for much of our financial information is that we are almost always unable to obtain all (or even part) of the market information that we want. The only meaningful yardstick for evaluating business decisions is whether or not they create economic value (see Chapter 1). However, in many important situations, it will not be possible to make this judgment directly because we can't see the market value effects.

We recognize that accounting numbers are often just pale reflections of economic reality, but they frequently are the best available information. For privately held corporations, not-for-profit businesses, and smaller firms, for example, very little direct market value information exists at all. The accountant's reporting function is crucial in these circumstances.

Clearly, one important goal of the accountant is to report financial information to the user in a form useful for decision making. Ironically, the information frequently does not come to the user in such a form. In other words, financial statements don't come with a user's guide. This chapter is a first step in filling this gap.

Company financial information can be found in many places on the Web, including www.financials.com and finance.google.com.

3.1

STANDARDIZED FINANCIAL STATEMENTS

One obvious thing we might want to do with a company's financial statements is to compare them to those of other, similar companies. We would immediately have a problem, however. It's almost impossible to directly compare the financial statements for two companies because of differences in size.

For example, Ford and GM are obviously serious rivals in the auto market, but GM was historically much larger (in terms of assets), so it was difficult to compare them directly. For that matter, it's difficult to even compare financial statements from different points in time for the same company if the company's size has changed. The size problem is compounded if we try to compare GM and, say, Toyota. If Toyota's financial statements are denominated in yen, then we have a size *and* a currency difference.

PRUFROCK CORPORATION
Balance Sheets as of December 31, 2009 and 2010
(\$ in millions)

TABLE 3.1

	2009	2010
Assets		
Current assets		
Cash	\$ 84	\$ 98
Accounts receivable	165	188
Inventory	393	422
Total	<u>\$ 642</u>	<u>\$ 708</u>
Fixed assets		
Net plant and equipment	<u>\$2,731</u>	<u>\$2,880</u>
Total assets	<u><u>\$3,373</u></u>	<u><u>\$3,588</u></u>
Liabilities and Owners' Equity		
Current liabilities		
Accounts payable	\$ 312	\$ 344
Notes payable	231	196
Total	<u>\$ 543</u>	<u>\$ 540</u>
Long-term debt	<u>\$ 531</u>	<u>\$ 457</u>
Owners' equity		
Common stock and paid-in surplus	\$ 500	\$ 550
Retained earnings	1,799	2,041
Total	<u>\$2,299</u>	<u>\$2,591</u>
Total liabilities and owners' equity	<u><u>\$3,373</u></u>	<u><u>\$3,588</u></u>

To start making comparisons, one obvious thing we might try to do is to somehow standardize the financial statements. One very common and useful way of doing this is to work with percentages instead of total dollars. The resulting financial statements are called **common-size statements**. We consider these next.

Common-Size Balance Sheets

For easy reference, Prufrock Corporation's 2009 and 2010 balance sheets are provided in Table 3.1. Using these, we construct common-size balance sheets by expressing each item as a percentage of total assets. Prufrock's 2009 and 2010 common-size balance sheets are shown in Table 3.2.

Notice that some of the totals don't check exactly because of rounding errors. Also notice that the total change has to be zero since the beginning and ending numbers must add up to 100 percent.

In this form, financial statements are relatively easy to read and compare. For example, just looking at the two balance sheets for Prufrock, we see that current assets were 19.7 percent of total assets in 2010, up from 19.1 percent in 2009. Current liabilities declined from 16.0 percent to 15.1 percent of total liabilities and equity over that same time. Similarly, total equity rose from 68.1 percent of total liabilities and equity to 72.2 percent.

Overall, Prufrock's liquidity, as measured by current assets compared to current liabilities, increased over the year. Simultaneously, Prufrock's indebtedness diminished as a percentage of total assets. We might be tempted to conclude that the balance sheet has grown "stronger."

common-size statement

A standardized financial statement presenting all items in percentage terms. Balance sheet items are shown as a percentage of assets and income statement items as a percentage of sales.

IBM's Web site has a good guide to reading financial statements. Visit www.ibm.com/investor.

TABLE 3.2

PRUFROCK CORPORATION Common-Size Balance Sheets December 31, 2009 and 2010			
	2009	2010	Change
Assets			
Current assets			
Cash	2.5%	2.7%	+ .2%
Accounts receivable	4.9	5.2	+ .3
Inventory	11.7	11.8	+ .1
Total	19.1	19.7	+ .6
Fixed assets			
Net plant and equipment	80.9	80.3	− .6
Total assets	100.0%	100.0%	.0%
Liabilities and Owners' Equity			
Current liabilities			
Accounts payable	9.2%	9.6%	+ .4%
Notes payable	6.8	5.5	− 1.3
Total	16.0	15.1	− .9
Long-term debt	15.7	12.7	− 3.0
Owners' equity			
Common stock and paid-in surplus	14.8	15.3	+ .5
Retained earnings	53.3	56.9	+ 3.6
Total	68.1	72.2	+ 4.1
Total liabilities and owners' equity	100.0%	100.0%	.0%

TABLE 3.3

PRUFROCK CORPORATION 2010 Income Statement (\$ in millions)	
Sales	\$2,311
Cost of goods sold	1,344
Depreciation	276
Earnings before interest and taxes	\$ 691
Interest paid	141
Taxable income	\$ 550
Taxes (34%)	187
Net income	\$ 363
Dividends	\$121
Addition to retained earnings	242

Common-Size Income Statements

A useful way of standardizing the income statement shown in Table 3.3 is to express each item as a percentage of total sales, as illustrated for Prufrock in Table 3.4.

This income statement tells us what happens to each dollar in sales. For Prufrock, interest expense eats up \$.061 out of every sales dollar, and taxes take another \$.081. When all is said and done, \$.157 of each dollar flows through to the bottom line (net income), and that amount is split into \$.105 retained in the business and \$.052 paid out in dividends.

PRUFROCK CORPORATION
Common-Size Income Statement
2010

TABLE 3.4

Sales	100.0%
Cost of goods sold	58.2
Depreciation	11.9
Earnings before interest and taxes	29.9
Interest paid	6.1
Taxable income	23.8
Taxes (34%)	8.1
Net income	15.7%
Dividends	5.2%
Addition to retained earnings	10.5

These percentages are very useful in comparisons. For example, a very relevant figure is the cost percentage. For Prufrock, \$.582 of each \$1.00 in sales goes to pay for goods sold. It would be interesting to compute the same percentage for Prufrock's main competitors to see how Prufrock stacks up in terms of cost control.

CONCEPT QUESTIONS

- 3.1a** Why is it often necessary to standardize financial statements?
- 3.1b** Describe how common-size balance sheets and income statements are formed.

RATIO ANALYSIS**3.2**

Another way of avoiding the problems involved in comparing companies of different sizes is to calculate and compare **financial ratios**. Such ratios are ways of comparing and investigating the relationships between different pieces of financial information. We cover some of the more common ratios next, but there are many others that we don't touch on.

One problem with ratios is that different people and different sources frequently don't compute them in exactly the same way, and this leads to much confusion. The specific definitions we use here may or may not be the same as ones you have seen or will see elsewhere. If you are ever using ratios as a tool for analysis, you should be careful to document how you calculate each one, and, if you are comparing your numbers to those of another source, be sure you know how their numbers are computed.

We will defer much of our discussion of how ratios are used and some problems that come up with using them until a bit later in the chapter. For now, for each of the ratios we discuss, several questions come to mind:

1. How is it computed?
2. What is it intended to measure, and why might we be interested?
3. What is the unit of measurement?
4. What might a high or low value be telling us? How might such values be misleading?
5. How could this measure be improved?

financial ratios

Relationships determined from a firm's financial information and used for comparison purposes.

Go to

www.money.cnn.com

and find the ratios link to examine ratios for a huge number of companies, their industry, and a market index.

Financial ratios are traditionally grouped into the following categories:

1. Short-term solvency, or liquidity, ratios.
2. Long-term solvency, or financial leverage, ratios.
3. Asset management, or turnover, ratios.
4. Profitability ratios.
5. Market value ratios.

We will consider each of these in turn. In calculating these numbers for Prufrock, we will use the ending balance sheet (2010) figures unless we explicitly say otherwise. Also notice that the various ratios are color keyed to indicate which numbers come from the **income statement** and which come from the **balance sheet**.

Short-Term Solvency, or Liquidity, Measures

As the name suggests, short-term solvency ratios as a group are intended to provide information about a firm's liquidity, and these ratios are sometimes called *liquidity measures*. The primary concern is the firm's ability to pay its bills over the short run without undue stress. Consequently, these ratios focus on current assets and current liabilities.

For obvious reasons, liquidity ratios are particularly interesting to short-term creditors. Since financial managers are constantly working with banks and other short-term lenders, an understanding of these ratios is essential.

One advantage of looking at current assets and liabilities is that their book values and market values are likely to be similar. Often (though not always), these assets and liabilities just don't live long enough for the two to get seriously out of step. On the other hand, like any type of near-cash, current assets and liabilities can and do change fairly rapidly, so today's amounts may not be a reliable guide to the future.

Current Ratio One of the best-known and most widely used ratios is the *current ratio*. As you might guess, the current ratio is defined as:

$$\text{Current ratio} = \frac{\text{Current assets}}{\text{Current liabilities}} \quad [3.1]$$

For Prufrock, the 2010 current ratio is:

$$\text{Current ratio} = \frac{\$708}{\$540} = 1.31 \text{ times}$$

Because current assets and liabilities are, in principle, converted to cash over the following 12 months, the current ratio is a measure of short-term liquidity. The unit of measurement is either dollars or times. So, we could say Prufrock has \$1.31 in current assets for every \$1 in current liabilities, or we could say Prufrock has its current liabilities covered 1.31 times over.

To a creditor, particularly a short-term creditor such as a supplier, the higher the current ratio, the better. To the firm, a high current ratio indicates liquidity, but it also may indicate an inefficient use of cash and other short-term assets. Absent some extraordinary circumstances, we would expect to see a current ratio of at least 1, because a current ratio of less than 1 would mean that net working capital (current assets less current liabilities) is negative. This would be unusual in a healthy firm, at least for most types of businesses.

The current ratio, like any ratio, is affected by various types of transactions. For example, suppose the firm borrows over the long term to raise money. The short-run effect would be an increase in cash from the issue proceeds and an increase in long-term debt. Current liabilities would not be affected, so the current ratio would rise.

Finally, note that an apparently low current ratio may not be a bad sign for a company with a large reserve of untapped borrowing power.

Current Events

EXAMPLE 3.1

Suppose a firm were to pay off some of its suppliers and short-term creditors. What would happen to the current ratio? Suppose a firm buys some inventory. What happens in this case? What happens if a firm sells some merchandise?

The first case is a trick question. What happens is that the current ratio moves away from 1. If it is greater than 1 (the usual case), it will get bigger, but if it is less than 1, it will get smaller. To see this, suppose the firm has \$4 in current assets and \$2 in current liabilities for a current ratio of 2. If we use \$1 in cash to reduce current liabilities, then the new current ratio is $(\$4 - 1)/(\$2 - 1) = 3$. If we reverse the original situation to \$2 in current assets and \$4 in current liabilities, then the change will cause the current ratio to fall to $1/3$ from $1/2$.

The second case is not quite as tricky. Nothing happens to the current ratio because cash goes down while inventory goes up—total current assets are unaffected.

In the third case, the current ratio would usually rise because inventory is normally shown at cost, and the sale would normally be at something greater than cost (the difference is the markup). The increase in either cash or receivables is therefore greater than the decrease in inventory. This increases current assets, and the current ratio rises.

Quick (or Acid-Test) Ratio Inventory is often the least liquid current asset. It's also the one for which the book values are least reliable as measures of market value since the quality of the inventory isn't considered. Some of the inventory may later turn out to be damaged, obsolete, or lost.

More to the point, relatively large inventories are often a sign of short-term trouble. The firm may have overestimated sales and overbought or overproduced as a result. In this case, the firm may have a substantial portion of its liquidity tied up in slow-moving inventory.

To further evaluate liquidity, the *quick*, or *acid-test*, *ratio* is computed just like the current ratio, except inventory is omitted:

$$\text{Quick ratio} = \frac{\text{Current assets} - \text{Inventory}}{\text{Current liabilities}} \quad [3.2]$$

Notice that using cash to buy inventory does not affect the current ratio, but it reduces the quick ratio. Again, the idea is that inventory is relatively illiquid compared to cash.

For Prufrock, this ratio in 2010 was:

$$\text{Quick ratio} = \frac{\$708 - 422}{\$540} = .53 \text{ times}$$

The quick ratio here tells a somewhat different story than the current ratio, because inventory accounts for more than half of Prufrock's current assets. To exaggerate the point, if this inventory consisted of, say, unsold nuclear power plants, then this would be a cause for concern.

To give an example of current versus quick ratios, based on recent financial statements, Wal-Mart and Manpower, Inc., had current ratios of .88 and 1.61, respectively. However, Manpower carries no inventory to speak of, whereas Wal-Mart's current assets are virtually all inventory. As a result, Wal-Mart's quick ratio was only .26, whereas Manpower's was 1.61, the same as its current ratio.

Cash Ratio A very short-term creditor might be interested in the *cash ratio*:

$$\text{Cash ratio} = \frac{\text{Cash}}{\text{Current liabilities}} \quad [3.3]$$

You can verify that this works out to be .18 times for Prufrock.

Long-Term Solvency Measures

Long-term solvency ratios are intended to address the firm's long-run ability to meet its obligations, or, more generally, its financial leverage. These ratios are sometimes called *financial leverage ratios* or just *leverage ratios*. We consider three commonly used measures and some variations.

Total Debt Ratio The *total debt ratio* takes into account all debts of all maturities to all creditors. It can be defined in several ways, the easiest of which is:

$$\begin{aligned}\text{Total debt ratio} &= \frac{\text{Total assets} - \text{Total equity}}{\text{Total assets}} \\ &= \frac{\$3,588 - 2,591}{\$3,588} = .28 \text{ times}\end{aligned}\quad [3.4]$$

In this case, an analyst might say that Prufrock uses 28 percent debt.¹ Whether this is high or low or whether it even makes any difference depends on whether or not capital structure matters, a subject we discuss in a later chapter.

Prufrock has \$.28 in debt for every \$1 in assets. Therefore, there is \$.72 in equity (= \$1 - .28) for every \$.28 in debt. With this in mind, we can define two useful variations on the total debt ratio, the *debt-equity ratio* and the *equity multiplier*:

$$\begin{aligned}\text{Debt-equity ratio} &= \text{Total debt} / \text{Total equity} \\ &= \$.28 / \$.72 = .39 \text{ times}\end{aligned}\quad [3.5]$$

$$\begin{aligned}\text{Equity multiplier} &= \text{Total assets} / \text{Total equity} \\ &= \$1 / \$.72 = 1.39 \text{ times}\end{aligned}\quad [3.6]$$

The fact that the equity multiplier is 1 plus the debt-equity ratio is not a coincidence:

$$\begin{aligned}\text{Equity multiplier} &= \text{Total assets} / \text{Total equity} = \$1 / \$.72 = 1.39 \text{ times} \\ &= (\text{Total equity} + \text{Total debt}) / \text{Total equity} \\ &= 1 + \text{Debt-equity ratio} = 1.39 \text{ times}\end{aligned}$$

The thing to notice here is that given any one of these three ratios, you can immediately calculate the other two, so they all say exactly the same thing.

Times Interest Earned Another common measure of long-term solvency is the *times interest earned* (TIE) *ratio*. Once again, there are several possible (and common) definitions, but we'll stick with the most traditional:

$$\begin{aligned}\text{Times interest earned ratio} &= \frac{\text{EBIT}}{\text{Interest}} \\ &= \frac{\$691}{\$141} = 4.9 \text{ times}\end{aligned}\quad [3.7]$$

As the name suggests, this ratio measures how well a company has its interest obligations covered, and it is often called the interest coverage ratio. For Prufrock, the interest bill is covered 4.9 times over.

Cash Coverage A problem with the TIE ratio is that it is based on EBIT, which is not really a measure of cash available to pay interest. The reason is that depreciation, a noncash

¹ Total equity here includes preferred stock (discussed in Chapter 7), if there is any. An equivalent numerator in this ratio would be (Current liabilities + Long-term debt).

expense, has been deducted out. Since interest is most definitely a cash outflow (to creditors), one way to define the *cash coverage ratio* is:

$$\begin{aligned}\text{Cash coverage ratio} &= \frac{\text{EBIT} + \text{Depreciation}}{\text{Interest}} \\ &= \frac{\$691 + 276}{\$141} = \frac{\$967}{\$141} = 6.9 \text{ times}\end{aligned}\quad [3.8]$$

The numerator here, EBIT plus depreciation, is often abbreviated EBITD (earnings before interest, taxes, and depreciation—say “ebbit-dee”). It is a basic measure of the firm’s ability to generate cash from operations, and it is frequently used as a measure of cash flow available to meet financial obligations.

A common variation on EBITD is earnings before interest, taxes, depreciation, and amortization (EBITDA—say “ebbit-dah”). Here *amortization* refers to a noncash deduction similar conceptually to depreciation, except it applies to an intangible asset (such as a patent) rather than a tangible asset (such as machine). Note that the word *amortization* here does not refer to the repayment of debt, a subject we discuss in a later chapter.

Asset Management, or Turnover, Measures

We next turn our attention to the efficiency with which Prufrock uses its assets. The measures in this section are sometimes called *asset utilization ratios*. The specific ratios we discuss can all be interpreted as measures of turnover. What they are intended to describe is how efficiently, or intensively, a firm uses its assets to generate sales. We first look at two important current assets: inventory and receivables.

Inventory Turnover and Days’ Sales in Inventory During the year, Prufrock had a cost of goods sold of \$1,344. Inventory at the end of the year was \$422. With these numbers, *inventory turnover* can be calculated as:

$$\begin{aligned}\text{Inventory turnover} &= \frac{\text{Cost of goods sold}}{\text{Inventory}} \\ &= \frac{\$1,344}{\$422} = 3.2 \text{ times}\end{aligned}\quad [3.9]$$

In a sense, we sold off, or turned over, the entire inventory 3.2 times. As long as we are not running out of stock and thereby forgoing sales, the higher this ratio is, the more efficiently we are managing inventory.

If we know that we turned our inventory over 3.2 times during the year, then we can immediately figure out how long it took us to turn it over on average. The result is the average *days’ sales in inventory*:

$$\begin{aligned}\text{Days’ sales in inventory} &= \frac{365 \text{ days}}{\text{Inventory turnover}} \\ &= \frac{365}{3.2} = 114 \text{ days}\end{aligned}\quad [3.10]$$

This tells us that, roughly speaking, inventory sits 114 days on average before it is sold. Alternatively, assuming we used the most recent inventory and cost figures, it will take about 114 days to work off our current inventory.

For example, in February 2009, General Motors had a 161-day supply of cars and trucks, much higher than the 60-day supply considered normal. This means that at the then-current rate of sales, it would have taken General Motors 161 days to deplete the available supply, or, equivalently, that General Motors had 161 days of vehicle sales in inventory. Because of the economic slowdown, General Motors was not the only company with too

much inventory. Chrysler, Ford, and Toyota had inventory levels representing 151, 120, and 91 days of sales, respectively. This type of information is useful to auto manufacturers in planning future marketing and production decisions, and all indications pointed to a slowdown in auto manufacturing for 2009.

It might make more sense to use the average inventory in calculating turnover. Inventory turnover would then be $\$1,344/[(\$393 + 422)/2] = 3.3$ times.² It depends on the purpose of the calculation. If we are interested in how long it will take us to sell our current inventory, then using the ending figure (as we did initially) is probably better.

In many of the ratios we discuss in the following pages, average figures could just as well be used. Again, it depends on whether we are worried about the past, in which case averages are appropriate, or the future, in which case ending figures might be better. Also, using ending figures is common in reporting industry averages; so, for comparison purposes, ending figures should be used in such cases. In any event, using ending figures is definitely less work, so we'll continue to use them.

Receivables Turnover and Days' Sales in Receivables Our inventory measures give some indication of how fast we can sell products. We now look at how fast we collect on those sales. The *receivables turnover* is defined in the same way as inventory turnover:

$$\begin{aligned}\text{Receivables turnover} &= \frac{\text{Sales}}{\text{Accounts receivable}} \\ &= \frac{\$2,311}{\$188} = 12.3 \text{ times}\end{aligned}\quad [3.11]$$

Loosely speaking, we collected our outstanding credit accounts and reloaned the money 12.3 times during the year.³

This ratio makes more sense if we convert it to days, so the *days' sales in receivables* is:

$$\begin{aligned}\text{Days' sales in receivables} &= \frac{365 \text{ days}}{\text{Receivables turnovers}} \\ &= \frac{365}{12.3} = 30 \text{ days}\end{aligned}\quad [3.12]$$

Therefore, on average, we collect on our credit sales in 30 days. For obvious reasons, this ratio is very frequently called the *average collection period* (ACP).

Also note that if we are using the most recent figures, we can also say that we have 30 days' worth of sales currently uncollected. We will learn more about this subject when we study credit policy in a later chapter.

EXAMPLE 3.2

Payables Turnover

Here is a variation on the receivables collection period. How long, on average, does it take for Prufrock Corporation to *pay* its bills? To answer, we need to calculate the accounts payable turnover rate using cost of goods sold. We will assume that Prufrock purchases everything on credit.

The cost of goods sold is \$1,344, and accounts payable are \$344. The turnover is therefore $\$1,344/\$344 = 3.9$ times. So, payables turned over about every $365/3.9 = 94$ days. On average, then, Prufrock takes 94 days to pay. As a potential creditor, we might take note of this fact.

² Notice that we calculated the average as (Beginning value + Ending value)/2.

³ Here we have implicitly assumed that all sales are credit sales. If they were not, then we would simply use total credit sales in these calculations, not total sales.

Total Asset Turnover Moving away from specific accounts like inventory or receivables, we can consider an important “big picture” ratio, the *total asset turnover* ratio. As the name suggests, total asset turnover is:

$$\begin{aligned}\text{Total asset turnover} &= \frac{\text{Sales}}{\text{Total assets}} \\ &= \frac{\$2,311}{\$3,588} = .64 \text{ times}\end{aligned}\quad [3.13]$$

In other words, for every dollar in assets, we generated \$.64 in sales.

A closely related ratio, the *capital intensity ratio*, is simply the reciprocal of (that is, 1 divided by) total asset turnover. It can be interpreted as the dollar investment in assets needed to generate \$1 in sales. High values correspond to capital-intensive industries (such as public utilities). For Prufrock, total asset turnover is .64, so, if we flip this over, we get that capital intensity is $1/.64 = \$1.56$. That is, it takes Prufrock \$1.56 in assets to create \$1 in sales.

It might seem that a high total asset turnover ratio is always a good sign for a company, but it isn't necessarily. Consider a company with old assets. The assets would be almost fully depreciated and might be very outdated. In this case, the book value of assets is low, contributing to a higher asset turnover. Plus, the high turnover might also mean that the company will need to make major capital outlays in the near future. A low asset turnover might seem bad, but it could indicate the opposite: The company could have just purchased a lot of new equipment, which implies that the book value of assets is relatively high. These new assets could be more productive and efficient than those used by the company's competitors.

The eXtensible Business Reporting Language (XBRL) is designed to make extracting EDGAR data easier. You can learn more about it at www.xbrl.org.

More Turnover

EXAMPLE 3.3

Suppose you find that a particular company generates \$.40 in sales for every dollar in total assets. How often does this company turn over its total assets?

The total asset turnover here is .40 times per year. It takes $1/.40 = 2.5$ years to turn assets over completely.

Profitability Measures

The three measures we discuss in this section are probably the best known and most widely used of all financial ratios. In one form or another, they are intended to measure how efficiently the firm uses its assets and how efficiently the firm manages its operations. The focus in this group is on the bottom line—net income.

Profit Margin Companies pay a great deal of attention to their *profit margin*:

$$\begin{aligned}\text{Profit margin} &= \frac{\text{Net income}}{\text{Sales}} \\ &= \frac{\$363}{\$2,311} = 15.7\%\end{aligned}\quad [3.14]$$

This tells us that Prufrock, in an accounting sense, generates a little less than 16 cents in profit for every dollar in sales.

All other things being equal, a relatively high profit margin is obviously desirable. This situation corresponds to low expense ratios relative to sales. However, we hasten to add that other things are often not equal.

For example, lowering our sales price will usually increase unit volume, but will normally cause profit margins to shrink. Total profit (or, more importantly, operating cash flow) may go up or down, so the fact that margins are smaller isn't necessarily bad. After

all, isn't it possible that, as the saying goes, "Our prices are so low that we lose money on everything we sell, but we make it up in volume!"?⁴

Return on Assets *Return on assets* (ROA) is a measure of profit per dollar of assets. It can be defined several ways, but the most common is:

$$\begin{aligned}\text{Return on assets} &= \frac{\text{Net income}}{\text{Total assets}} \\ &= \frac{\$363}{\$3,588} = 10.12\%\end{aligned}\quad [3.15]$$

Return on Equity *Return on equity* (ROE) is a measure of how the stockholders fared during the year. Since benefiting shareholders is our goal, ROE is, in an accounting sense, the true bottom-line measure of performance. ROE is usually measured as:

$$\begin{aligned}\text{Return on equity} &= \frac{\text{Net income}}{\text{Total equity}} \\ &= \frac{\$363}{\$2,591} = 14\%\end{aligned}\quad [3.16]$$

Therefore, for every dollar in equity, Prufrock generated 14 cents in profit, but, again, this is only correct in accounting terms.

Because ROA and ROE are such commonly cited numbers, we stress that it is important to remember they are accounting rates of return. For this reason, these measures should properly be called *return on book assets* and *return on book equity*. In addition, ROE is sometimes called *return on net worth*. Whatever it's called, it would be inappropriate to compare the result to, for example, an interest rate observed in the financial markets.

The fact that ROE exceeds ROA reflects Prufrock's use of financial leverage. We will examine the relationship between these two measures in more detail below.

Market Value Measures

Our final group of measures is based, in part, on information not necessarily contained in financial statements—the market price per share of the stock. Obviously, these measures can be calculated directly only for publicly traded companies.

We assume that Prufrock has 33 million shares outstanding and the stock sold for \$88 per share at the end of the year. If we recall that Prufrock's net income was \$363 million, then we can calculate that its earnings per share were:

$$\text{EPS} = \frac{\text{Net income}}{\text{Shares outstanding}} = \frac{\$363}{33} = \$11 \quad [3.17]$$

Price-Earnings Ratio The first of our market value measures, the *price-earnings*, or PE, *ratio* (or multiple), is defined as:

$$\begin{aligned}\text{PE ratio} &= \frac{\text{Price per share}}{\text{Earnings per share}} \\ &= \frac{\$88}{\$11} = 8 \text{ times}\end{aligned}\quad [3.18]$$

In the vernacular, we would say that Prufrock shares sell for eight times earnings, or we might say that Prufrock shares have, or "carry," a PE multiple of 8.

Since the PE ratio measures how much investors are willing to pay per dollar of current earnings, higher PEs are often taken to mean that the firm has significant prospects for future growth. Of course, if a firm had no or almost no earnings, its PE would probably be quite large; so, as always, care is needed in interpreting this ratio.

⁴ No, it's not; margins can be small, but they do need to be positive!

Price-Sales Ratio In some cases, companies will have negative earnings for extended periods, so their PE ratios are not very meaningful. A good example is a recent start-up. Such companies usually do have some revenues, so analysts will often look at the *price-sales ratio*:

$$\text{Price-sales ratio} = \text{Price per share} / \text{Sales per share} \quad [3.19]$$

In Prufrock's case, sales were \$2,311, so here is the price-sales ratio:

$$\text{Price-sales ratio} = \$88 / (\$2,311 / 33) = \$88 / \$70 = 1.26$$

As with PE ratios, whether a particular price-sales ratio is high or low depends on the industry involved.

Market-to-Book Ratio A second commonly quoted measure is the *market-to-book ratio*:

$$\begin{aligned} \text{Market-to-book ratio} &= \frac{\text{Market value per share}}{\text{Book value per share}} \\ &= \frac{\$88}{2,591/33} = \frac{\$88}{\$78.5} = 1.12 \text{ times} \end{aligned} \quad [3.20]$$

Notice that book value per share is total equity (not just common stock) divided by the number of shares outstanding.

Since book value per share is an accounting number, it reflects historical costs. In a loose sense, the market-to-book ratio therefore compares the market value of the firm's investments to their cost. A value less than 1 could mean that the firm has not been successful overall in creating value for its stockholders.

This completes our definition of some common ratios. We could tell you about more of them, but these are enough for now. We'll leave it here and go on to discuss some ways of using these ratios instead of just how to calculate them. Table 3.5 summarizes the ratios

TABLE 3.5**Common financial ratios****I. Short-term solvency, or liquidity, ratios**

$$\text{Current ratio} = \frac{\text{Current assets}}{\text{Current liabilities}}$$

$$\text{Quick ratio} = \frac{\text{Current assets} - \text{Inventory}}{\text{Current liabilities}}$$

$$\text{Cash ratio} = \frac{\text{Cash}}{\text{Current liabilities}}$$

II. Long-term solvency, or financial leverage, ratios

$$\text{Total debt ratio} = \frac{\text{Total assets} - \text{Total equity}}{\text{Total assets}}$$

$$\text{Debt-equity ratio} = \text{Total debt} / \text{Total equity}$$

$$\text{Equity multiplier} = \text{Total assets} / \text{Total equity}$$

$$\text{Times interest earned ratio} = \frac{\text{EBIT}}{\text{Interest}}$$

$$\text{Cash coverage ratio} = \frac{\text{EBIT} + \text{Depreciation}}{\text{Interest}}$$

III. Asset utilization, or turnover, ratios

$$\text{Inventory turnover} = \frac{\text{Cost of goods sold}}{\text{Inventory}}$$

$$\text{Days' sales in inventory} = \frac{365 \text{ days}}{\text{Inventory turnover}}$$

$$\text{Receivables turnover} = \frac{\text{Sales}}{\text{Accounts receivable}}$$

$$\text{Days' sales in receivables} = \frac{365 \text{ days}}{\text{Receivables turnover}}$$

$$\text{Total asset turnover} = \frac{\text{Sales}}{\text{Total assets}}$$

$$\text{Capital intensity} = \frac{\text{Total assets}}{\text{Sales}}$$

IV. Profitability ratios

$$\text{Profit margin} = \frac{\text{Net Income}}{\text{Sales}}$$

$$\text{Return on assets (ROA)} = \frac{\text{Net income}}{\text{Total assets}}$$

$$\text{Return on equity (ROE)} = \frac{\text{Net income}}{\text{Total equity}}$$

$$\text{ROE} = \frac{\text{Net income}}{\text{Sales}} \times \frac{\text{Sales}}{\text{Assets}} \times \frac{\text{Assets}}{\text{Equity}}$$

V. Market value ratios

$$\text{Price-earnings ratio} = \frac{\text{Price per share}}{\text{Earnings per share}}$$

$$\text{Price-sales ratio} = \frac{\text{Price per share}}{\text{Sales per share}}$$

$$\text{Market-to-book ratio} = \frac{\text{Market value per share}}{\text{Book value per share}}$$

TABLE 3.6

Financial information from 2008 for Lowe's and Home Depot (numbers in millions except for per-share data)

	Lowe's	Home Depot
Sales	\$48,283	\$77,349
Net income	2,809	4,395
Current assets	8,686	14,674
Current liabilities	7,751	12,406
Total assets	30,869	44,324
Total debt	14,771	26,610
Total equity	16,098	17,714
Price per share	25.13	27.95
Book value per share	11.03	10.54
Earnings per share	1.92	2.62
Current ratio	1.12	1.18
Debt-equity ratio	0.92	1.50
Total asset turnover	1.56	1.75
Profit margin	5.82%	5.68%
ROE	17.45%	24.81%
ROA	9.10%	9.92%
Market-to-book ratio	2.28	2.65
Price-earnings ratio	13.06	10.68

we've discussed. Table 3.6 provides some information for the well-known home supply stores Lowe's and Home Depot for their fiscal years ending in 2008. As you can see, the current ratio is similar for both companies, but Home Depot has a higher debt-equity ratio and a slightly higher total asset turnover. The companies have similar profitability ratios, but Home Depot has a greater ROE because of its increased use of leverage and higher total asset turnover, something we will discuss in the next section.

The market-to-book ratio and price-earnings ratio are also close for Lowe's and Home Depot. Overall, these companies appear to be similar based on this abbreviated financial analysis. Of course, if we really want to examine these two companies, we would want to look at more ratios than the ones presented here.

CONCEPT QUESTIONS

- 3.2a** What are the five groups of ratios? Give two or three examples of each kind.
- 3.2b** Turnover ratios all have one of two figures as numerators. What are these two figures? What do these ratios measure? How do you interpret the results?
- 3.2c** Profitability ratios all have the same figure in the numerator. What is it? What do these ratios measure? How do you interpret the results?
- 3.2d** Given the total debt ratio, what other two ratios can be computed? Explain how.

3.3

THE DU PONT IDENTITY

As we mentioned in discussing ROA and ROE, the difference between these two profitability measures is a reflection of the use of debt financing, or financial leverage. We illustrate the relationship between these measures in this section by investigating a famous way of decomposing ROE into its component parts.

To begin, let's recall the definition of ROE:

$$\text{Return on equity} = \frac{\text{Net income}}{\text{Total equity}}$$

If we were so inclined, we could multiply this ratio by Assets/Assets without changing anything:

$$\begin{aligned}\text{Return on equity} &= \frac{\text{Net income}}{\text{Total equity}} = \frac{\text{Net income}}{\text{Total equity}} \times \frac{\text{Assets}}{\text{Assets}} \\ &= \frac{\text{Net income}}{\text{Assets}} \times \frac{\text{Assets}}{\text{Total equity}}\end{aligned}$$

Notice that we have expressed the ROE as the product of two other ratios—ROA and the equity multiplier:

$$\text{ROE} = \text{ROA} \times \text{Equity multiplier} = \text{ROA} \times (1 + \text{Debt-equity ratio})$$

Looking back at Prufrock, for example, we see that the debt-equity ratio was .39 and ROA was 10.12 percent. Our work here implies that Prufrock's ROE, as we previously calculated, is:

$$\text{ROE} = 10.12\% \times 1.39 = 14\%$$

We can further decompose ROE by multiplying the top and bottom by total sales:

$$\text{ROE} = \frac{\text{Sales}}{\text{Sales}} \times \frac{\text{Net income}}{\text{Assets}} \times \frac{\text{Assets}}{\text{Total equity}}$$

If we rearrange things a bit, ROE is:

$$\begin{aligned}\text{ROE} &= \frac{\text{Net income}}{\text{Sales}} \times \frac{\text{Sales}}{\text{Assets}} \times \frac{\text{Assets}}{\text{Total equity}} \\ &\quad \text{Return on assets} \qquad \qquad \qquad [3.21] \\ &= \text{Profit margin} \times \text{Total asset turnover} \times \text{Equity multiplier}\end{aligned}$$

What we have now done is to partition ROA into its two component parts, profit margin and total asset turnover. This last expression is called the **Du Pont identity**, after the Du Pont Corporation, which popularized its use.

We can check this relationship for Prufrock by noting that the profit margin was 15.7 percent and the total asset turnover was .64. ROE should thus be:

$$\begin{aligned}\text{ROE} &= \text{Profit margin} \times \text{Total asset turnover} \times \text{Equity multiplier} \\ &= .157 \times .64 \times 1.39 \\ &= .14 = 14\%\end{aligned}$$

This 14 percent ROE is exactly what we had before.

The Du Pont identity tells us that ROE is affected by three things:

1. Operating efficiency (as measured by profit margin).
2. Asset use efficiency (as measured by total asset turnover).
3. Financial leverage (as measured by the equity multiplier).

Weakness in either operating or asset use efficiency (or both) will show up in a diminished return on assets, which will translate into a lower ROE.

Considering the Du Pont identity, it appears that a firm could leverage up its ROE by increasing its amount of debt. It turns out this will only happen if the ratio of EBIT to total assets is greater than the interest rate. More importantly, the use of debt financing has a number of other effects, and, as we discuss at some length in later chapters, the amount of leverage a firm uses is governed by its capital structure policy.

The decomposition of ROE we've discussed in this section is a convenient way of systematically approaching financial statement analysis. If ROE is unsatisfactory by some measure, then the Du Pont identity tells you where to start looking for the reasons. To give an example, take a look at the information about Internet companies Yahoo! and Google in Table 3.7. As you can see, in 2008, Yahoo! had a relatively low ROE of 3.8 percent,

Du Pont identity

Popular expression breaking ROE into three parts: operating efficiency, asset use efficiency, and financial leverage.

TABLE 3.7**Du Pont analysis for
Yahoo! and Google**

Yahoo!							
Year	ROE	=	Profit margin	×	Total asset turnover	×	Equity multiplier
2008	3.8%	=	5.9%	×	0.527	×	1.22
2007	6.9%	=	9.5%	×	0.570	×	1.28
2006	8.2%	=	11.7%	×	0.558	×	1.26

Google							
Year	ROE	=	Profit margin	×	Total asset turnover	×	Equity multiplier
2008	18.9%	=	19.4%	×	0.686	×	1.42
2007	21.1%	=	25.3%	×	0.655	×	1.27
2006	18.1%	=	29.0%	×	0.574	×	1.08

down from its ROE in 2006 of 8.2 percent. In contrast, in 2008, Google had an ROE of 18.9 percent, up from its ROE in 2006 of 18.1 percent. Given this information, why is Google's ROE so much higher than Yahoo!'s over this period of time, and what accounts for the decline in Yahoo!'s ROE?

Looking at the Du Pont breakdown, we see that Yahoo!'s profit margin declined sharply, dropping to 5.9 percent from 11.7 percent. Google's profit margin was 19.4 percent in 2008, also a considerable drop from the level two years before. Google's total asset turnover improved somewhat while Yahoo!'s did not. Finally, Google's leverage rose while Yahoo!'s fell slightly.

Taken together, the numbers paint a relatively clear picture. Yahoo!'s ROE fell mostly because of a sharp drop in profit margins, which was amplified somewhat by decreases in total asset turnover and leverage. Google's ROE was relatively steady. Its profit margin declined, but that was offset by improvements in total asset turnover and increased leverage. The most noticeable difference between the companies is Google's much higher profit margin, suggesting that Google is able to generate revenues at far lower cost than Yahoo!, which results in a much higher ROE.

An Expanded Du Pont Analysis

So far, we've seen how the Du Pont equation lets us break down ROE into its basic three components: profit margin, total asset turnover, and financial leverage. We now extend this analysis to take a closer look at how key parts of a firm's operations feed into ROE. To get going, we went to the SEC Web site (www.sec.gov) and found the 10-K for chemical products giant Du Pont. In the 10-K, we located the financial statements for 2008. What we found is summarized in Table 3.8.

Using the information in Table 3.8, Figure 3.1 shows how we can construct an expanded Du Pont analysis for Du Pont and present that analysis in chart form. The advantage of the extended Du Pont chart is that it lets us examine several ratios at once, thereby getting a better overall picture of a company's performance and also allowing us to determine possible items to improve.

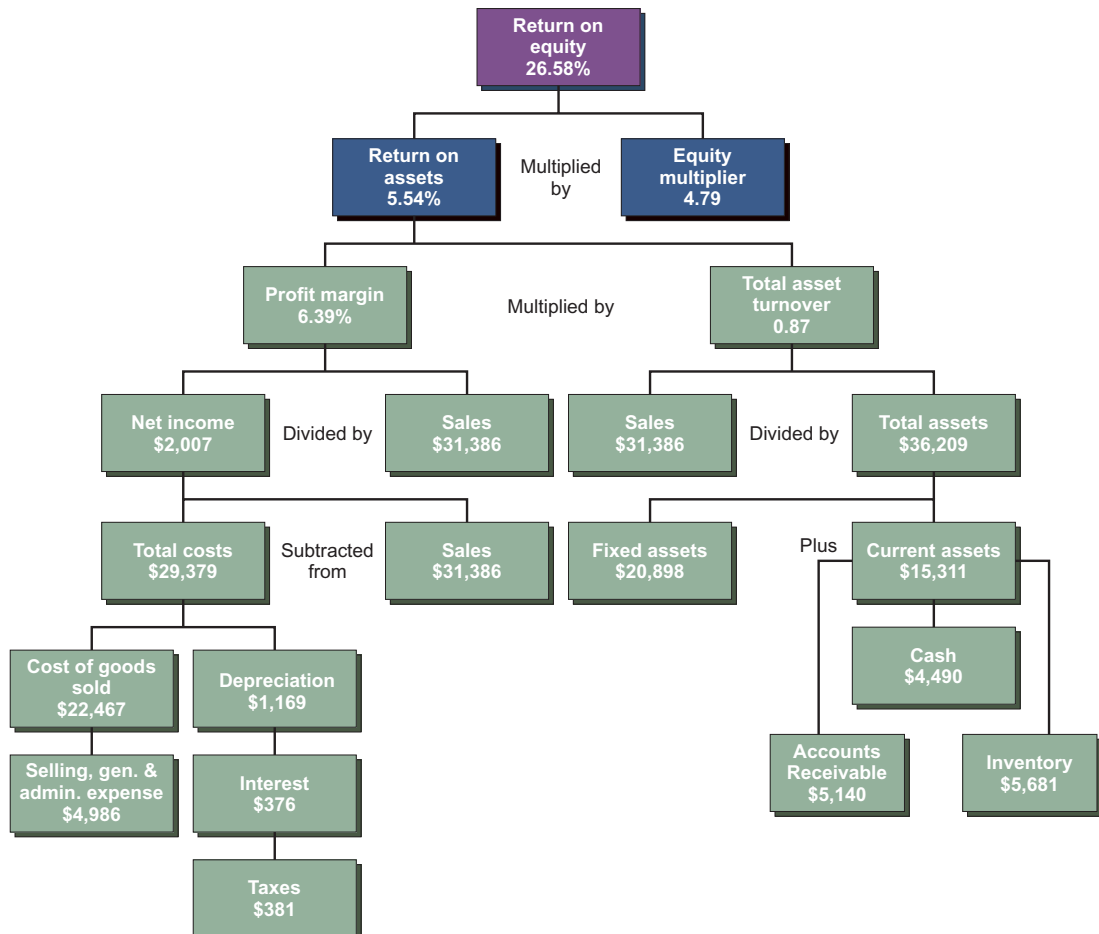

Looking at the left-hand side of our Du Pont chart in Figure 3.1, we see items related to profitability. As always, profit margin is calculated as net income divided by sales. But, as our chart emphasizes, net income depends on sales and a variety of costs, such as cost of goods sold (CoGS) and selling, general, and administrative expenses (SG&A expense). Du Pont can increase its ROE by increasing sales and also by reducing one or more of these costs. In other words, if we want to improve profitability, our chart clearly shows us the areas on which we should focus.

The regulatory filings of publicly traded corporations may be found at www.sec.gov.

TABLE 3.8

FINANCIAL STATEMENTS FOR DU PONT
12 months ending December 31, 2008
 (All numbers are in millions)

Income Statement		Balance Sheet	
Sales	\$31,386	Current assets	
CoGS	22,467	Cash	\$ 4,490
Gross profit	\$ 8,919	Accounts receivable	5,140
SG&A expense	4,986	Inventory	5,681
Depreciation	1,169	Total	\$15,311
EBIT	\$ 2,764	Fixed assets	\$20,898
Interest	376	Total assets	\$36,209
EBT	\$ 2,388		
Taxes	381	Current liabilities	
Net income	\$ 2,007	Accounts payable	\$ 3,128
		Notes payable	2,012
		Other	4,570
		Total	\$ 9,710
		Total long-term debt	\$18,947
		Total equity	\$ 7,552
		Total liabilities and equity	\$36,209

FIGURE 3.1**Extended Du Pont Chart for Du Pont**

Turning to the right-hand side of Figure 3.1, we have an analysis of the key factors underlying total asset turnover. Thus, for example, we see that reducing inventory holdings through more efficient management reduces current assets, which reduces total assets, which then improves total asset turnover.

CONCEPT QUESTIONS	
3.3a	Return on assets, or ROA, can be expressed as the product of two ratios. Which two?
3.3b	Return on equity, or ROE, can be expressed as the product of three ratios. Which three?

3.4

INTERNAL AND SUSTAINABLE GROWTH

A firm’s return on assets and return on equity are frequently used to calculate two additional numbers, both of which have to do with the firm’s ability to grow. We examine these next, but first we introduce two basic ratios.

Dividend Payout and Earnings Retention

As we have seen in various places, a firm’s net income gets divided into two pieces. The first piece is cash dividends paid to stockholders. Whatever is left over is the addition to retained earnings. For example, from Table 3.3, Prufrock’s net income was \$363, of which \$121 was paid out in dividends. If we express dividends paid as a percentage of net income, the result is the *dividend payout ratio*:

You can find growth rates under the research links at finance.yahoo.com.

Dividend payout ratio = Cash dividends/Net income

= \$121/\$363

= 33⅓%

[3.22]

What this tells us is that Prufrock pays out one-third of its net income in dividends. Anything Prufrock does not pay out in the form of dividends must be retained in the firm, so we can define the *retention ratio* as:

Retention ratio = Addition to retained earnings/Net income

= \$242/\$363

= 66⅔%

[3.23]

So, Prufrock retains two-thirds of its net income. The retention ratio is also known as the *plowback ratio* because it is, in effect, the portion of net income that is plowed back into the business.

Notice that net income must be either paid out or plowed back, so the dividend payout and plowback ratios have to add up to 1. Put differently, if you know one of these figures, you can figure the other one immediately.

EXAMPLE 3.4

Payout and Retention

The Manson-Marilyn Corporation routinely pays out 40 percent of net income in the form of dividends. What is its plowback ratio? If net income was \$800, how much did stockholders actually receive?
If the payout ratio is 40 percent, then the retention, or plowback, ratio must be 60 percent since the two have to add up to 100 percent. Dividends were 40 percent of \$800, or \$320.

How Fast Is Too Fast?

Growth rates are an important tool for evaluating a company, and, as we will see later, an important tool for valuing a company's stock. When thinking about (and calculating) growth rates, a little common sense goes a long way. For example, in 2008, retailing giant Walmart had about 1.1 billion square feet of stores, distribution centers, and so forth. The company expected to increase its square footage by about 6 percent over the next year. This doesn't sound too outrageous, but can Walmart grow its square footage at 6 percent indefinitely?

We'll get into the calculation in our next chapter, but if you assume that Walmart grows at 6 percent per year over the next 196 years, the company will have about 100 trillion square feet of property, which is about the total land mass of the entire United States! In other words, if Walmart keeps growing at 6 percent, the entire country will eventually be one big Walmart. Scary.

Sirius XM Satellite Radio is another example. The company had total revenues of about \$805,000 in 2002 and \$922 million in 2008. This represents an annual increase of 171 percent! How likely do you think it is that the company can continue this growth rate? If this growth continued, the company would have revenues of about \$19.7 trillion in just 10 years, which exceeds

the gross domestic product (GDP) of the United States. Obviously, Sirius XM Radio's growth rate will slow substantially in the next several years.

What about growth in cash flow? As of the beginning of 2009, cash flow for Internet auction Web site eBay had grown at an annual rate of about 51 percent for the past five years. The company generated about \$2.5 billion in cash flow for 2008. If eBay's cash flow grew at the same rate for the next 15 years, the company would generate about \$1.2 trillion dollars per year, or more than the \$829 billion of U.S. currency circulating in the world.

As these examples show, growth rates can be deceiving. It is fairly easy for a small company to grow very fast. If a company has \$100 dollars in sales, it only has to increase sales by another \$100 to have a 100 percent increase in sales. If the company's sales are \$10 billion, it has to increase sales by another \$10 billion to achieve the same 100 percent increase. So, long-term growth rate estimates must be chosen very carefully. As a rule of thumb, for really long-term growth estimates, you should probably assume that a company will not grow much faster than the economy as a whole, which is about 1 to 3 percent (inflation-adjusted).

ROA, ROE, and Growth

Investors and others are frequently interested in knowing how rapidly a firm's sales can grow. The important thing to recognize is that if sales are to grow, assets have to grow as well, at least over the long run. Further, if assets are to grow, then the firm must somehow obtain the money to pay for the needed acquisitions. In other words, growth has to be financed, and as a direct corollary, a firm's ability to grow depends on its financing policies.

A firm has two broad sources of financing: *internal* and *external*. Internal financing simply refers to what the firm earns and subsequently plows back into the business. External financing refers to funds raised by either borrowing money or selling stock.

The Internal Growth Rate Suppose a firm has a policy of financing growth using only internal financing. This means that the firm won't borrow any funds and won't sell any new stock. How rapidly can the firm grow? The answer is given by the **internal growth rate**:

$$\text{Internal growth rate} = \frac{\text{ROA} \times b}{1 - \text{ROA} \times b} \quad [3.24]$$

where ROA is, as usual, return on assets, and b is the retention, or plowback, ratio we just discussed.

For example, for the Prufrock Corporation, we earlier calculated ROA as 10.12 percent. We also saw that the retention ratio is $66\frac{2}{3}$ percent, or $\frac{2}{3}$, so the internal growth rate is:

$$\begin{aligned} \text{Internal growth rate} &= \frac{\text{ROA} \times b}{1 - \text{ROA} \times b} \\ &= \frac{.1012 \times \frac{2}{3}}{1 - .1012 \times \frac{2}{3}} \\ &= 7.23\% \end{aligned}$$

internal growth rate

The maximum possible growth rate for a firm that relies only on internal financing.

Thus, if Prufrock relies solely on internally generated financing, it can grow at a maximum rate of 7.23 percent per year.

The Sustainable Growth Rate If a firm only relies on internal financing, then, through time, its total debt ratio will decline. The reason is that assets will grow, but total debt will remain the same (or even fall if some is paid off). Frequently, firms have a particular total debt ratio or equity multiplier that they view as optimal (why this is so is the subject of Chapter 13).

With this in mind, we now consider how rapidly a firm can grow if (1) it wishes to maintain a particular total debt ratio and (2) it is unwilling to sell new stock. There are various reasons why a firm might wish to avoid selling stock, and equity sales by established firms are actually a relatively rare occurrence. Given these two assumptions, the maximum growth rate that can be achieved, called the **sustainable growth rate**, is:

sustainable growth rate

The maximum possible growth rate for a firm that maintains a constant debt ratio and doesn't sell new stock.

$$\text{Sustainable growth rate} = \frac{\text{ROE} \times b}{1 - \text{ROE} \times b} \quad [3.25]$$

Notice that this is the same as the internal growth rate, except that ROE is used instead of ROA.

Looking at Prufrock, we earlier calculated ROE as 14 percent, and we know that the retention ratio is $\frac{2}{3}$, so we can easily calculate sustainable growth as:

$$\begin{aligned} \text{Sustainable growth rate} &= \frac{\text{ROE} \times b}{1 - \text{ROE} \times b} \\ &= \frac{.14 \times \frac{2}{3}}{1 - .14 \times \frac{2}{3}} \\ &= 10.29\% \end{aligned}$$

If you compare this sustainable growth rate of 10.29 percent to the internal growth rate of 7.23 percent, you might wonder why it is larger. The reason is that, as the firm grows, it will have to borrow additional funds if it is to maintain a constant debt ratio. This new borrowing is an extra source of financing in addition to internally generated funds, so Prufrock can expand more rapidly.

Determinants of Growth In our previous section, we saw that the return on equity, or ROE, could be decomposed into its various components using the Du Pont identity. Since ROE appears so prominently in the determination of the sustainable growth rate, the factors important in determining ROE are also important determinants of growth.

As we saw, ROE can be written as the product of three factors:

$$\text{ROE} = \text{Profit margin} \times \text{Total asset turnover} \times \text{Equity multiplier}$$

If we examine our expression for the sustainable growth rate, we see that anything that increases ROE will increase the sustainable growth rate by making the top bigger and the bottom smaller. Increasing the plowback ratio will have the same effect.

Putting it all together, what we have is that a firm's ability to sustain growth depends explicitly on the following four factors:

1. Profit margin. An increase in profit margin will increase the firm's ability to generate funds internally and thereby increase its sustainable growth.
2. Total asset turnover. An increase in the firm's total asset turnover increases the sales generated for each dollar in assets. This decreases the firm's need for new assets as sales grow and thereby increases the sustainable growth rate. Notice that increasing total asset turnover is the same thing as decreasing capital intensity.

I. Internal growth rate

$$\text{Internal growth rate} = \frac{\text{ROA} \times b}{1 - \text{ROA} \times b}$$

where

ROA = Return on assets = Net income/Total assets

b = Plowback (retention) ratio

= Addition to retained earnings/Net income

= $1 - \text{Dividend payout ratio}$

The internal growth rate is the maximum growth rate that can be achieved with no external financing of any kind.

II. Sustainable growth rate

$$\text{Sustainable growth rate} = \frac{\text{ROE} \times b}{1 - \text{ROE} \times b}$$

where

ROE = Return on equity = Net income/Total equity

b = Plowback (retention) ratio

= Addition to retained earnings/Net income

= $1 - \text{Dividend payout ratio}$

The sustainable growth rate is the maximum growth rate that can be achieved with no external equity financing while maintaining a constant debt-equity ratio.

TABLE 3.9

Summary of internal and sustainable growth rates

3. Financial policy. An increase in the debt-equity ratio increases the firm's financial leverage. Since this makes additional debt financing available, it increases the sustainable growth rate.
4. Dividend policy. A decrease in the percentage of net income paid out as dividends will increase the retention ratio. This increases internally generated equity and thus increases internal and sustainable growth.

The sustainable growth rate is a very useful number. What it illustrates is the explicit relationship between the firm's four major areas of concern: its operating efficiency as measured by profit margin, its asset use efficiency as measured by total asset turnover, its financial policy as measured by the debt-equity ratio, and its dividend policy as measured by the retention ratio. If sales are to grow at a rate higher than the sustainable growth rate, the firm must increase profit margins, increase total asset turnover, increase financial leverage, increase earnings retention, or sell new shares.

The two growth rates, internal and sustainable, are summarized in Table 3.9.

A Note on Sustainable Growth Rate Calculations Very commonly, the sustainable growth rate is calculated using just the numerator in our expression, $\text{ROE} \times b$. This causes some confusion, which we can clear up here. The issue has to do with how ROE is computed. Recall that ROE is calculated as net income divided by total equity. If total equity is taken from an ending balance sheet (as we have done consistently, and is commonly done in practice), then our formula is the right one. However, if total equity is from the beginning of the period, then the simpler formula is the correct one.

In principle, you'll get exactly the same sustainable growth rate regardless of which way you calculate it (as long as you match up the ROE calculation with the right formula). In reality, you may see some differences because of accounting-related complications. By the way, if you use the average of beginning and ending equity (as some advocate), yet another formula is needed. Also, all of our comments here apply to the internal growth rate as well.

A simple example is useful to illustrate these points. Suppose a firm has a net income of \$20 and a retention ratio of .60. Beginning assets are \$100. The debt-equity ratio is .25, so beginning equity is \$80.

If we use beginning numbers, we get the following:

$$\text{ROE} = \$20/\$80 = .25 = 25\%$$

$$\text{Sustainable growth} = .25 \times .60 = .15 = 15\%$$

For the same firm, ending equity is $\$80 + .60 \times \$20 = \$92$. So, we can calculate this:

$$\text{ROE} = \$20/\$92 = .2174 = 21.74\%$$

$$\text{Sustainable growth} = .2174 \times .60/(1 - .2174 \times .60) = .15 = 15\%$$

These growth rates are exactly the same (after accounting for a small rounding error in the second calculation). See if you don't agree that the internal growth rate is 12%.

CONCEPT QUESTIONS

- 3.4a** What does a firm's internal growth rate tell us?
- 3.4b** What does a firm's sustainable growth rate tell us?
- 3.4c** Why is the sustainable growth rate likely to be larger than the internal growth rate?

3.5

USING FINANCIAL STATEMENT INFORMATION

Our last task in this chapter is to discuss in more detail some practical aspects of financial statement analysis. In particular, we will look at reasons for doing financial statement analysis, how to go about getting benchmark information, and some of the problems that come up in the process.

Why Evaluate Financial Statements?

As we have discussed, the primary reason for looking at accounting information is that we don't have, and can't reasonably expect to get, market value information. It is important to emphasize that, whenever we have market information, we will use it instead of accounting data. Also, if there is a conflict between accounting and market data, market data should be given precedence.

Financial statement analysis is essentially an application of "management by exception." In many cases, such analysis will boil down to comparing ratios for one business with some kind of average or representative ratios. Those ratios that seem to differ the most from the averages are tagged for further study.

Internal Uses Financial statement information has a variety of uses within a firm. Among the most important of these is performance evaluation. For example, managers are frequently evaluated and compensated on the basis of accounting measures of performance such as profit margin and return on equity. Also, firms with multiple divisions frequently compare the performance of those divisions using financial statement information.

Another important internal use of financial statement information involves planning for the future. Historical financial statement information is very useful for generating projections about the future and for checking the realism of assumptions made in those projections.

External Uses Financial statements are useful to parties outside the firm, including short-term and long-term creditors and potential investors. For example, we would find such information quite useful in deciding whether or not to grant credit to a new customer.

We would also use this information to evaluate suppliers, and suppliers would use our statements before deciding to extend credit to us. Large customers use this information to decide if we are likely to be around in the future. Credit-rating agencies rely on financial statements in assessing a firm's overall creditworthiness. The common theme here is that financial statements are a prime source of information about a firm's financial health.

We would also find such information useful in evaluating our main competitors. We might be thinking of launching a new product. A prime concern would be whether the competition would jump in shortly thereafter. In this case, we would be interested in our competitors' financial strength to see if they could afford the necessary development.

Finally, we might be thinking of acquiring another firm. Financial statement information would be essential in identifying potential targets and deciding what to offer.

Choosing a Benchmark

Given that we want to evaluate a division or a firm based on its financial statements, a basic problem immediately comes up. How do we choose a benchmark, or a standard of comparison? We describe some ways of getting started in this section.

Time-Trend Analysis One standard we could use is history. Suppose we found that the current ratio for a particular firm is 2.4 based on the most recent financial statement information. Looking back over the last 10 years, we might find that this ratio has declined fairly steadily over that period.

Based on this, we might wonder if the liquidity position of the firm has deteriorated. It could be, of course, that the firm has made changes that allow it to use its current assets more efficiently, that the nature of the firm's business has changed, or that business practices have changed. If we investigate, we might find any of these possible explanations. This is an example of what we mean by management by exception—a deteriorating time trend may not be bad, but it does merit investigation.

Peer Group Analysis The second means of establishing a benchmark is to identify firms similar in the sense that they compete in the same markets, have similar assets, and operate in similar ways. In other words, we need to identify a *peer group*. There are obvious problems with doing this since no two companies are identical. Ultimately, the choice of which companies to use as a basis for comparison is subjective.

One common way of identifying potential peers is based on **Standard Industrial Classification (SIC) codes**. These are four-digit codes established by the U.S. government for statistical reporting purposes. Firms with the same SIC code are frequently assumed to be similar.

The first digit in an SIC code establishes the general type of business. For example, firms engaged in finance, insurance, and real estate have SIC codes beginning with 6. Each additional digit narrows down the industry. So, companies with SIC codes beginning with 60 are mostly banks and banklike businesses; those with codes beginning with 602 are mostly commercial banks; and SIC code 6025 is assigned to national banks that are members of the Federal Reserve system. Table 3.10 is a list of selected two-digit codes (the first two digits of the four-digit SIC codes) and the industries they represent.

Beginning in 1997, a new industry classification system was instituted. Specifically, the North American Industry Classification System (NAICS, pronounced “nakes”) is intended to

Standard Industrial Classification (SIC) code

U.S. government code used to classify a firm by its type of business operations.

Learn more about NAICS at www.naics.com.

TABLE 3.10**Selected two-digit
SIC codes**

Agriculture, Forestry, and Fishing	Retail Trade
01 Agriculture production—crops	54 Food stores

35 Machinery, except electrical	
37 Transportation equipment	
Transportation, Communication, Electric, Gas, and Sanitary Service	
45 Transportation by air	
49 Electric, gas, and sanitary services	

replace the older SIC codes, and it probably will eventually. Currently, however, SIC codes are widely used.

SIC codes are far from perfect. For example, suppose you were examining financial statements for Walmart, the largest retailer in the United States. In a quick scan of the nearest financial database, you might find about 20 large, publicly owned corporations with this same SIC code, but you might not be too comfortable with some of them. Target would seem to be a reasonable peer, but Neiman-Marcus also carries the same industry code. Are Walmart and Neiman-Marcus really comparable?

As this example illustrates, it is probably not appropriate to blindly use SIC code-based averages. Instead, analysts often identify a set of primary competitors and then compute a set of averages based on just this group. Also, we may be more concerned with a group of the top firms in an industry, not the average firm. Such a group is called an *aspirant group*, because we aspire to be like them. In this case, a financial statement analysis reveals how far we have to go.

With these caveats about SIC codes in mind, we can now take a look at a specific industry. Suppose we are in the retail hardware business. Table 3.11 contains some condensed common-size financial statements for this industry from RMA, one of many sources of such information. Table 3.12 contains selected ratios from the same source.

There is a large amount of information here, most of which is self-explanatory. On the right in Table 3.11, we have current information reported for different groups based on sales. Within each sales group, common-size information is reported. For example, firms with sales in the \$10 million to \$25 million range have cash and equivalents equal to 7 percent of total assets. There are 38 companies in this group, out of 326 in all.

On the left, we have three years' worth of summary historical information for the entire group. For example, operating expenses rose from 32.6 percent of sales to 34.2 percent over that time.

Table 3.12 contains some selected ratios, again reported by sales groups on the right and time period on the left. To see how we might use this information, suppose our firm has a current ratio of 2. Based on the ratios, is this value unusual?

Looking at the current ratio for the overall group for the most recent year (third column from the left in Table 3.12), we see that three numbers are reported. The one in the middle, 2.5, is the median, meaning that half of the 326 firms had current ratios that were lower and half had bigger current ratios. The other two numbers are the upper and lower

Interpretation of Statement Studies Figures: RMA cautions that the studies be regarded only as a general guideline and not as an absolute industry norm. This is due to limited samples within categories, the categorization of companies by their primary Standard Industrial Classification (SIC) number only, and different methods of operations by companies within the same industry. For these reasons, RMA recommends that the figures be used only as general guidelines in addition to other methods of financial analysis.

quartiles. So, 25 percent of the firms had a current ratio larger than 3.9 and 25 percent had a current ratio smaller than 1.6. Our value of 2 falls comfortably within these bounds, so it doesn't appear too unusual. This comparison illustrates how knowledge of the range of ratios is important in addition to knowledge of the average. Notice how stable the current ratio has been for the last three years.

More Ratios

EXAMPLE 3.5

Take a look at the most recent numbers reported for Sales/Receivables and EBIT/Interest in Table 3.12. What are the overall median values? What are these ratios?

If you look back at our discussion, you will see that these are the receivables turnover and the times interest earned, or TIE, ratios. The median value for receivables turnover for the entire group is 28.6 times. So, the days in receivables would be $365/28.6 = 13$, which is the bold-faced number reported. The median for the TIE is 3.0 times. The number in parentheses indicates that the calculation is meaningful for, and therefore based on, only 304 of the 326 companies. In this case, the reason is that only 304 companies paid any significant amount of interest.

There are many sources of ratio information in addition to the one we examine here. Our nearby *Work the Web* box shows how to get this information for just about any company, along with some very useful benchmarking information. Be sure to look it over and then benchmark your favorite company.

WORK THE WEB

As we discussed in this chapter, ratios are an important tool for examining a company's performance, but gathering the necessary information can be tedious and time consuming. Fortunately, many sites on the Web provide this information for free. One of the best is investing.businessweek.com. We went there, entered the ticker symbol "GPS" (for The Gap), and then went to the ratio page. Here is an abbreviated look at the results:

Source: Reprinted by permission of *BusinessWeek*. Copyright © 2009 by the McGraw-Hill Companies, Inc.

This Web site is unique in that it shows the ratios compared to the industry quintile ratios. As you can see, The Gap is in the top 20th percentile for its return on assets and return on capital and in the 20th to 40th percentile in return on equity.

Questions

1. Go to investing.businessweek.com and find the major ratio categories listed on this Web site. How do the categories differ from the categories listed in the textbook?
2. Go to investing.businessweek.com and find all the ratios for The Gap. How is the company performing in each ratio category presented on this Web site?

Other Web sites provide different information about a company's ratios. For example, www.reuters.com provides some ratio analyses for five-year periods.

Problems with Financial Statement Analysis

We close out our chapter on working with financial statements by discussing some additional problems that can arise in using financial statements. In one way or another, the basic problem with financial statement analysis is that there is no underlying theory to help us identify which items or ratios to look at and to guide us in establishing benchmarks.

As we discuss in other chapters, there are many cases where financial theory and economic logic provide guidance in making judgments about value and risk. Very little such help exists with financial statements. This is why we can't say which ratios matter the most and what a high or low value might be.

What's in a Ratio?

Abraham Briloff, a well-known financial commentator, famously remarked that “financial statements are like fine perfume; to be sniffed but not swallowed.” As you have probably figured out by now, his point is that information gleaned from financial statements—and ratios and growth rates computed from that information—should be taken with a grain of salt.

For example, looking back at our chapter opener regarding PE ratios, investors must really think that Visa will have extraordinary growth. After all, they are willing to pay about \$82 for every dollar the company currently earns, which definitely makes it look like a growth company. In fact, this is exactly what happened. From 2007 to 2008, Visa's revenue increased by 400 percent, and its net income doubled even with a large write-off. Even with the financial problems around it, Visa's customers still seemed to be paying their bills.

Another problem that can occur with ratio analysis is negative equity. Let's look at Sirius XM Satellite Radio for example. The company reported a loss of about \$565 million dollars during 2007, and its book value of equity was negative \$793 million. If you calculate the ROE for the company you will find that it is about 71.2 percent, which is outstanding. Unfortunately, if you examine the ROE a little closer you will find something unusual: The more the company loses, the higher the ROE becomes.

That's a “Sirius” problem! Also, in this case, the market-to-book and PE ratios are both negative. How do you interpret a negative PE? We're not really sure either. Whenever a company has a negative book value of equity, it means the losses for the company have been so large that they have erased all the book equity. In this case, ROE, PE ratios, and market-to-book ratios are usually not reported because they lack meaning.

Even if a company's book equity is positive, you still have to be careful. For example, consider automobile parts retailer AutoZone, which had a market-to-book ratio of about 34 at the end of the company's 2008 fiscal year. Since this ratio measures the value created by the company for shareholders, things look pretty good for the company. But a closer look shows that AutoZone's book value of equity per share was \$7.02 in 2007, but it dropped to \$3.99 in 2008 even though the company posted a positive net income for the year. As it happens, the drop was due to accounting changes made by the company, not economic gains or losses, but it nonetheless dramatically increased the market-to-book ratio during this period.

Financial ratios are important tools used in evaluating companies of all types, but you cannot simply take a number as given. Instead, before doing any analysis, the first step is to ask whether the number actually makes sense.

One particularly severe problem is that many firms, such as General Electric (GE), are conglomerates owning more or less unrelated lines of business. The consolidated financial statements for such firms don't really fit any neat industry category. More generally, the kind of peer group analysis we have been describing is going to work best when the firms are strictly in the same line of business, the industry is competitive, and there is only one way of operating.

Another problem that is becoming increasingly common is that major competitors and natural peer group members in an industry may be scattered around the globe. The automobile industry is an obvious example. The problem here is that financial statements from outside the United States do not necessarily conform to all to GAAP (more precisely, different countries can have different GAAPs). The existence of different standards and procedures makes it very difficult to compare financial statements across national borders.

Even companies that are clearly in the same line of business may not be comparable. For example, electric utilities engaged primarily in power generation are all classified in the same group (SIC 4911). This group is often thought to be relatively homogeneous. However, utilities generally operate as regulated monopolies, so they don't compete with each other. Many have stockholders, and many are organized as cooperatives with no stockholders. There are several different ways of generating power, ranging from hydroelectric to nuclear, so the operating activities can differ quite a bit. Finally, profitability is strongly affected by regulatory environment, so utilities in different locations can be very similar but show very different profits.

Several other general problems frequently crop up. First, different firms use different accounting procedures—for inventory, for example. This makes it difficult to compare statements. Second, different firms end their fiscal years at different times. For firms in seasonal businesses (such as a retailer with a large Christmas season), this can lead to difficulties in comparing balance sheets because of fluctuations in accounts during the year. Finally, for any particular firm, unusual or transient events, such as a one-time profit from an asset sale, may affect financial performance. In comparing firms, such events can give misleading signals. Our nearby *Reality Bytes* box discusses some additional issues.

CONCEPT QUESTIONS

- 3.5a** What are some uses for financial statement analysis?
- 3.5b** What are SIC codes and how might they be useful?
- 3.5c** Why do we say that financial statement analysis is management by exception?
- 3.5d** What are some of the problems that can come up with financial statement analysis?

SUMMARY AND CONCLUSIONS

This chapter has discussed aspects of financial statement analysis, including:

1. Standardized financial statements. We explained that differences in firm size make it difficult to compare financial statements, and we discussed how to form common-size statements to make comparisons easier.
2. Ratio analysis. Evaluating ratios of accounting numbers is another way of comparing financial statement information. We therefore defined and discussed a number of the most commonly reported and used financial ratios. We also discussed the famous Du Pont identity as a way of analyzing financial performance, and we examined the connection between profitability, financial policy, and growth.
3. Using financial statements. We described how to establish benchmarks for comparison purposes and discussed some of the types of information that are available. We then examined some of the potential problems that can arise.

After you have studied this chapter, we hope that you will have some perspective on the uses and abuses of financial statements. You should also find that your vocabulary of business and financial terms has grown substantially.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

- 3.1 Common-Size Statements.** Below are the most recent financial statements for Wildhack. Prepare a common-size income statement based on this information. How do you interpret the standardized net income? What percentage of sales goes to cost of goods sold?

WILDHACK CORPORATION 2010 Income Statement (\$ in millions)	
Sales	\$3,756
Cost of goods sold	2,453
Depreciation	490
Earnings before interest and taxes	\$ 813
Interest paid	613
Taxable income	\$ 200
Taxes (34%)	68
Net income	<u>\$ 132</u>
Dividends	\$46
Addition to retained earnings	86

WILDHACK CORPORATION Balance Sheets as of December 31, 2009 and 2010 (\$ in millions)				
	2009	2010	2009	2010
Assets			Liabilities and Owners' Equity	
Current assets			Current liabilities	
Cash	\$ 120	\$ 88	Accounts payable	\$ 124
Accounts receivable	224	192	Notes payable	1,412
Inventory	424	368	Total	<u>\$1,536</u>
Total	<u>\$ 768</u>	<u>\$ 648</u>	Long-term debt	<u>\$1,804</u>
Fixed assets			Owners' equity	
Net plant and equipment	<u>\$5,228</u>	<u>\$5,354</u>	Common stock and paid-in surplus	\$ 300
			Retained earnings	2,356
Total assets	<u>\$5,996</u>	<u>\$6,002</u>	Total	<u>\$2,656</u>
			Total liabilities and owners' equity	<u>\$5,996</u>
				<u>\$6,002</u>

3.2 Financial Ratios. Based on the balance sheets and income statement in the previous problem, calculate the following ratios for 2010:

Current ratio	_____
Quick ratio	_____
Cash ratio	_____
Inventory turnover	_____
Receivables turnover	_____
Days' sales in inventory	_____
Days' sales in receivables	_____
Total debt ratio	_____
Times interest earned ratio	_____
Cash coverage ratio	_____

- 3.3 ROE and the Du Pont Identity.** Calculate the 2010 ROE for the Wildhack Corporation and then break down your answer into its component parts using the Du Pont identity.
- 3.4 Sustainable Growth.** Based on the following information, what growth rate can Corwin maintain if no external financing is used? What is the sustainable growth rate?

CORWIN COMPANY						
Financial Statements						
Income Statement			Balance Sheet			
Sales	\$2,750		Current assets	\$ 600	Long-term debt	\$ 200
Cost of sales	2,400		Net fixed assets	800	Equity	1,200
Tax (34%)	119		Total	<u>\$1,400</u>	Total	<u>\$1,400</u>
Net income	<u>\$ 231</u>					
Dividends	\$ 77					

Answers to Chapter Review and Self-Test Problems

- 3.1** We've calculated the common-size income statement below. Remember that we simply divide each item by total sales.

WILDHACK CORPORATION 2010 Common-Size Income Statement	
Sales	100.0%
Cost of goods sold	65.3
Depreciation	13.0
Earnings before interest and taxes	21.6
Interest paid	16.3
Taxable income	5.3
Taxes (34%)	1.8
Net income	<u>3.5%</u>
Dividends	1.2%
Addition to retained earnings	2.3

Net income is 3.5 percent of sales. Since this is the percentage of each sales dollar that makes its way to the bottom line, the standardized net income is the firm's profit margin. Cost of goods sold is 65.3 percent of sales.

We've calculated the ratios below based on the ending figures. If you don't remember a definition, refer back to Table 3.5.

Current ratio	\$648/\$1,183	= .55 times
Quick ratio	\$280/\$1,183	= .24 times
Cash ratio	\$88/\$1,183	= .07 times
Inventory turnover	\$2,453/\$368	= 6.7 times
Receivables turnover	\$3,756/\$192	= 19.6 times
Days' sales in inventory	365/6.7	= 54.5 days
Days' sales in receivables	365/19.6	= 18.6 days

Total debt ratio	\$3,260/\$6,002	= 54.3%
Times interest earned ratio	\$813/\$613	= 1.33 times
Cash coverage ratio	\$1,303/\$613	= 2.13 times

The return on equity is the ratio of net income to total equity. For Wildhack, this is $\$132/\$2,742 = 4.8\%$, which is not outstanding. Given the Du Pont identity, ROE can be written as:

$$\begin{aligned}\text{ROE} &= \text{Profit margin} \times \text{Total asset turnover} \times \text{Equity multiplier} \\ &= \$132/\$3,756 \times \$3,756/\$6,002 \times \$6,002/\$2,742 \\ &= 3.5\% \times .626 \times 2.19 \\ &= 4.8\%\end{aligned}$$

Notice that return on assets, ROA, is $3.5\% \times .626 = 2.2\%$.

Corwin retains $b = (1 - .33) = \frac{2}{3} \approx .67$ of net income. Return on assets is $\$231/\$1,400 = 16.5\%$. The internal growth rate is:

$$\frac{\text{ROA} \times b}{1 - \text{ROA} \times b} = \frac{.165 \times \frac{2}{3}}{1 - .165 \times \frac{2}{3}} = 12.36\%$$

Return on equity for Corwin is $\$231/\$1,200 = 19.25\%$, so we can calculate the sustainable growth rate as:

$$\frac{\text{ROE} \times b}{1 - \text{ROE} \times b} = \frac{.1925 \times \frac{2}{3}}{1 - .1925 \times \frac{2}{3}} = 14.72\%$$

CRITICAL THINKING AND CONCEPTS REVIEW

L0 2

3.1 Current Ratio. What effect would the following actions have on a firm's current ratio? Assume that net working capital is positive.

- Inventory is purchased.
- A supplier is paid.
- A short-term bank loan is repaid.
- A long-term debt is paid off early.
- A customer pays off a credit account.
- Inventory is sold at cost.
- Inventory is sold for a profit.

L0 2

3.2 Current Ratio and Quick Ratio. In recent years, Dixie Co. has greatly increased its current ratio. At the same time, the quick ratio has fallen. What has happened? Has the liquidity of the company improved?

L0 2

3.3 Current Ratio. Explain what it means for a firm to have a current ratio equal to .50. Would the firm be better off if the current ratio were 1.50? What if it were 15.0? Explain your answers.

L0 2

3.4 Financial Ratios. Fully explain the kind of information the following financial ratios provide about a firm:

- Quick ratio
- Cash ratio
- Capital intensity ratio
- Total asset turnover
- Equity multiplier

- f. Times interest earned ratio
- g. Profit margin
- h. Return on assets
- i. Return on equity
- j. Price-earnings ratio

- L0 1** **3.5 Standardized Financial Statements.** What types of information do common-size financial statements reveal about the firm? What is the best use for these common-size statements?
- L0 2** **3.6 Peer Group Analysis.** Explain what peer group analysis means. As a financial manager, how could you use the results of peer group analysis to evaluate the performance of your firm? How is a peer group different from an aspirant group?
- L0 3** **3.7 Du Pont Identity.** Why is the Du Pont identity a valuable tool for analyzing the performance of a firm? Discuss the types of information it reveals as compared to ROE considered by itself.
- L0 2** **3.8 Industry-Specific Ratios.** Specialized ratios are sometimes used in specific industries. For example, the so-called book-to-bill ratio is closely watched for semiconductor manufacturers. A ratio of .93 indicates that for every \$100 worth of chips shipped over some period, only \$93 worth of new orders were received. In January 2009, the North American semiconductor equipment industry's book-to-bill ratio was 0.48, with orders of \$285.6 million and billings of \$579.1 million. The most recent peak in the book-to-bill ratio was in December 2003 when it reached 1.23. Orders for January 2009 declined 54 percent from the January 2008 level of \$1.28 billion. What is this ratio intended to measure? Why do you think it is so closely followed?
- L0 2** **3.9 Industry-Specific Ratios.** So-called same-store sales are a very important measure for companies as diverse as McDonald's and Sears. As the name suggests, examining same-store sales means comparing revenues from the same stores or restaurants at two different points in time. Why might companies focus on same-store sales rather than total sales?
- L0 2** **3.10 Industry-Specific Ratios.** There are many ways of using standardized financial information beyond those discussed in this chapter. The usual goal is to put firms on an equal footing for comparison purposes. For example, for auto manufacturers, it is common to express sales, costs, and profits on a per-car basis. For each of the following industries, give an example of an actual company and discuss one or more potentially useful means of standardizing financial information:
- a. Public utilities
 - b. Large retailers
 - c. Airlines
 - d. Online services
 - e. Hospitals
 - f. College textbook publishers
- L0 2** **3.11 Financial Statement Analysis.** You are examining the common-size income statements for a company for the past five years and have noticed that the cost of goods as a percentage of sales has been increasing steadily. At the same time, EBIT as a percentage of sales has been decreasing. What might account for the trends in these ratios?

- L0 2** **3.12 Financial Statement Analysis.** In the previous question, what actions might managers take to improve these ratios?

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

Basic
(Questions 1–25)

- L0 2** **1. Calculating Liquidity Ratios.** SDJ, Inc., has net working capital of \$1,410, current liabilities of \$5,810, and inventory of \$1,315. What is the current ratio? What is the quick ratio?
- L0 2** **2. Calculating Profitability Ratios.** Here and Gone, Inc., has sales of \$18 million, total assets of \$13 million, and total debt of \$3.8 million. If the profit margin is 8 percent, what is net income? What is ROA? What is ROE?
- L0 2** **3. Calculating the Average Collection Period.** Pujols Lumber Yard has a current accounts receivable balance of \$438,516. Credit sales for the year just ended were \$6,257,380. What is the receivables turnover? The days' sales in receivables? How long did it take on average for credit customers to pay off their accounts during the past year?
- L0 2** **4. Calculating Inventory Turnover.** Ermy Corporation has ending inventory of \$682,173 and cost of goods sold for the year just ended was \$6,487,318. What is the inventory turnover? The days' sales in inventory? How long on average did a unit of inventory sit on the shelf before it was sold?
- L0 2** **5. Calculating Leverage Ratios.** Boyd, Inc., has a total debt ratio of 0.45. What is its debt-equity ratio? What is its equity multiplier?
- L0 2** **6. Calculating Market Value Ratios.** Crabtree, Inc., had additions to retained earnings for the year just ended of \$625,000. The firm paid out \$130,000 in cash dividends, and it has ending total equity of \$7.2 million. If the company currently has 570,000 shares of common stock outstanding, what are earnings per share? Dividends per share? What is book value per share? If the stock currently sells for \$29 per share, what is the market-to-book ratio? The price-earnings ratio? If total sales were \$10.5 million, what is the price-sales ratio?
- L0 3** **7. Du Pont Identity.** If iPhone, Inc., has an equity multiplier of 1.35, total asset turnover of 1.64, and a profit margin of 7 percent, what is its ROE?
- L0 3** **8. Du Pont Identity.** Jiminy Cricket Removal has a profit margin of 8 percent, total asset turnover of 1.16, and ROE of 14.30 percent. What is this firm's debt-equity ratio?
- L0 2** **9. Calculating Average Payables Period.** For the past year, De Vries, Inc., had a cost of goods sold of \$59,382. At the end of the year, the accounts payable balance was \$13,689. How long on average did it take the company to pay off its suppliers during the year? What might a large value for this ratio imply?
- L0 2** **10. Equity Multiplier and Return on Equity.** Rainbow Company has a debt-equity ratio of 1.25. Return on assets is 7.5 percent, and total equity is \$625,000. What is the equity multiplier? Return on equity? Net income?
- L0 3** **11. Internal Growth.** If Mudvayne, Inc., has a 9 percent ROA and a 15 percent payout ratio, what is its internal growth rate?
- L0 3** **12. Sustainable Growth.** If the Crash Davis Driving School has a 13.1 percent ROE and a 30 percent payout ratio, what is its sustainable growth rate?

- L0 3** 13. **Sustainable Growth.** Based on the following information, calculate the sustainable growth rate for Southern Lights Co.:

Profit margin = 8.4%

Capital intensity ratio = 0.45

Debt-equity ratio = 0.60

Net income = \$95,000

Dividends = \$40,000

- L0 3** 14. **Sustainable Growth.** Assuming the following ratios are constant, what is the sustainable growth rate?

Total asset turnover = 2.15

Profit margin = 4.3%

Equity multiplier = 1.62

Payout ratio = 40%

Bethesda Mining Company reports the following balance sheet information for 2009 and 2010. Use this information to work Problems 15 through 17.

BETHESDA MINING COMPANY
Balance Sheets as of December 31, 2009 and 2010

	2009	2010		2009	2010
Assets			Liabilities and Owners' Equity		
Current assets			Current liabilities		
Cash	\$ 23,774	\$ 31,437	Accounts payable	\$194,922	\$202,611
Accounts receivable	57,281	77,639	Notes payable	90,020	141,588
Inventory	135,341	202,574	Total	\$284,942	\$344,199
Total	<u>\$216,396</u>	<u>\$311,650</u>	Long-term debt	247,000	183,750
			Owners' equity		
Fixed assets			Common stock and paid-in surplus	\$208,000	\$208,000
Net plant and equipment	\$657,147	\$589,178	Accumulated retained earnings	133,601	164,879
Total assets	<u>\$873,543</u>	<u>\$900,828</u>	Total	\$341,601	\$372,879
			Total liabilities and owners' equity	<u>\$873,543</u>	<u>\$900,828</u>

- L0 1** 15. **Preparing Standardized Financial Statements.** Prepare the 2009 and 2010 common-size balance sheets for Bethesda Mining.

- L0 2** 16. **Calculating Financial Ratios.** Based on the balance sheets given for Bethesda Mining, calculate the following financial ratios for each year:

- Current ratio
- Quick ratio
- Cash ratio
- Debt-equity ratio and equity multiplier
- Total debt ratio

- L0 3** 17. **Du Pont Identity.** Suppose that the Bethesda Mining Company had sales of \$2,156,873 and net income of \$109,381 for the year ending December 31, 2010. Calculate the Du Pont identity.

- L0 3** 18. **Du Pont Identity.** The Delson Company has an ROA of 9 percent, an 8 percent profit margin, and an ROE of 14 percent. What is the company's total asset turnover? What is the equity multiplier?

- L0 2** 19. **Return on Assets.** Hahn's Pianos has a profit margin of 6.35 percent on sales of \$22,000,000. If the firm has debt of \$8,400,000 and total assets of \$15,000,000, what is the firm's ROA?

- L0 3** 20. **Calculating Internal Growth.** The most recent financial statements for Shinoda Manufacturing Co. are shown below:

Income Statement		Balance Sheet			
Sales	\$62,800	Current assets	\$21,000	Debt	\$37,200
Costs	<u>45,380</u>	Fixed assets	<u>73,900</u>	Equity	<u>57,700</u>
Taxable income	\$17,420	Total	<u>\$94,900</u>	Total	<u>\$94,900</u>
Tax (35%)	<u>6,097</u>				
Net Income	<u>\$11,323</u>				

Assets and costs are proportional to sales. Debt and equity are not. The company maintains a constant 40 percent dividend payout ratio. No external financing is possible. What is the internal growth rate?

- L0 3** 21. **Calculating Sustainable Growth.** For Shinoda Manufacturing in Problem 20, what is the sustainable growth rate?
- L0 2** 22. **Total Asset Turnover.** Kaleb's Karate Supply had a profit margin of 10 percent, sales of \$21 million, and total assets of \$9.5 million. What was total asset turnover? If management set a goal of increasing total asset turnover to 2.75 times, what would the new sales figure need to be, assuming no increase in total assets?
- L0 2** 23. **Return on Equity.** Xero, Inc., has a total debt ratio of 0.55, total debt of \$315,000, and net income of \$38,250. What is the company's return on equity?
- L0 2** 24. **Market Value Ratios.** Young Trucking, Inc., has a current stock price of \$46. For the past year, the company had net income of \$6,250,000, total equity of \$21,580,000, sales of \$39,000,000, and 4.1 million shares of stock outstanding. What are earnings per share (EPS)? Price-earnings ratio? Price-sales ratio? Book value per share? Market-to-book ratio?
- L0 3** 25. **Profit Margin.** Dimeback Co. has total assets of \$8,500,000 and a total asset turnover of 2.35 times. If the return on assets is 9 percent, what is its profit margin?
- L0 3** 26. **Using the Du Pont Identity.** Y3K, Inc., has sales of \$7,385, total assets of \$3,480, and a debt-equity ratio of 0.25. If its return on equity is 16 percent, what is its net income?
- L0 2** 27. **Ratios and Fixed Assets.** The Hooya Company has a long-term debt ratio (i.e., the ratio of long-term debt to long-term debt plus equity) of 0.45 and a current ratio of 1.25. Current liabilities are \$2,385, sales are \$10,435, profit margin is 9 percent, and ROE is 14 percent. What is the amount of the firm's net fixed assets?
- L0 2** 28. **Profit Margin.** In response to complaints about high prices, a grocery chain runs the following advertising campaign: "If you pay your child \$1 to go buy \$33 worth of groceries, then your child makes twice as much on the trip as we do." You've collected the following information from the grocery chain's financial statements:

Intermediate
(Questions 26–45)

(millions)	
Sales	\$750.00
Net income	11.25
Total assets	310.00
Total debt	151.50

Evaluate the grocery chain's claim. What is the basis for the statement? Is this claim misleading? Why or why not?

- L0 3** 29. **Using the Du Pont Identity.** The Rose Company has net income of \$149,850. There are currently 25.45 days' sales in receivables. Total assets are \$838,000, total receivables are \$146,300, and the debt-equity ratio is 0.75. What is the company's profit margin? Its total asset turnover? Its ROE?
- L0 2** 30. **Calculating the Cash Coverage Ratio.** Delectable Radish, Inc.'s, net income for the most recent year was \$8,912. The tax rate was 34 percent. The firm paid \$3,987 in total interest expense and deducted \$4,873 in depreciation expense. What was the company's cash coverage ratio for the year?
- L0 2** 31. **Calculating the Times Interest Earned Ratio.** For the most recent year, Grohl, Inc., had sales of \$435,000, cost of goods sold of \$219,600, depreciation expense of \$59,300, and additions to retained earnings of \$51,500. The firm currently has 20,000 shares of common stock outstanding, and the previous year's dividends per share were \$1.25. Assuming a 34 percent income tax rate, what was the times interest earned ratio?
- L0 2** 32. **Return on Assets.** A fire has destroyed a large percentage of the financial records of the Inferno Company. You have the task of piecing together information in order to release a financial report. You have found the return on equity to be 14.3 percent. Sales were \$1,735,000, the total debt ratio was 0.35, and total debt was \$648,000. What is the return on assets (ROA)?
- L0 2** 33. **Ratios and Foreign Companies.** Prince Albert Canning PLC had a 2010 net loss of £24,382 on sales of £489,162. What was the company's profit margin? Does the fact that these figures are quoted in a foreign currency make any difference? Why? In dollars, sales were \$695,266. What was the net loss in dollars?

Some recent financial statements for Smolira Golf, Inc., follow. Use this information to work Problems 34 through 37.

SMOLIRA GOLF, INC.					
Balance Sheets as of December 31, 2009 and 2010					
	2009	2010		2009	2010
Assets			Liabilities and Owners' Equity		
Current assets			Current liabilities		
Cash	\$ 3,291	\$ 3,507	Accounts payable	\$ 2,133	\$ 2,560
Accounts receivable	4,787	5,821	Notes payable	1,730	2,076
Inventory	12,398	13,822	Other	86	103
Total	<u>\$20,476</u>	<u>\$23,150</u>	Total	<u>\$ 3,949</u>	<u>\$ 4,739</u>
			Long-term debt	\$13,800	\$16,560
			Owners' equity		
			Common stock		
			and paid-in surplus	\$36,000	\$36,000

Net plant and equipment	48,907	72,969	Total	<u>\$51,634</u>	<u>\$74,820</u>
Total assets	<u>\$69,383</u>	<u>\$96,119</u>	Total liabilities and owners' equity	<u>\$69,383</u>	<u>\$96,119</u>

SMOLIRA GOLF, INC. 2010 Income Statement	
Sales	\$186,570
Cost of goods sold	125,803
Depreciation	5,373
EBIT	\$ 55,394
Interest paid	1,470
Taxable income	\$ 53,924
Taxes	18,873
Net income	<u>\$ 35,051</u>
Dividends	\$11,865
Retained earnings	23,186

- L0 2** 34. **Calculating Financial Ratios.** Find the following financial ratios for Smolira Golf (use year-end figures rather than average values where appropriate):

Short-term solvency ratios

- a. Current ratio _____
 b. Quick ratio _____
 c. Cash ratio _____

Asset utilization ratios

- d. Total asset turnover _____
 e. Inventory turnover _____
 f. Receivables turnover _____

Long-term solvency ratios

- g. Total debt ratio _____
 h. Debt-equity ratio _____
 i. Equity multiplier _____
 j. Times interest earned ratio _____
 k. Cash coverage ratio _____

Profitability ratios

- l. Profit margin _____
 m. Return on assets _____
 n. Return on equity _____

- L0 3** 35. **Du Pont Identity.** Construct the Du Pont identity for Smolira Golf.

- L0 2** 36. **Market Value Ratios.** Smolira Golf has 10,000 shares of common stock outstanding, and the market price for a share of stock at the end of 2010 was \$73. What is the price-earnings ratio? What is the price-sales ratio? What are the dividends per share? What is the market-to-book ratio at the end of 2010?

- L0 2** 37. **Interpreting Financial Ratios.** After calculating the ratios for Smolira Golf, you have uncovered the following industry ratios for 2010:

	Lower Quartile	Median	Upper Quartile
Current ratio	1.3	2.6	5.3
Total asset turnover	2.1	2.7	4.1
Debt-equity ratio	.25	.40	.60
Profit margin	8.4%	11.9%	16.3%

How is Smolira Golf performing based on these ratios?

- L0 3** 38. **Growth and Profit Margin.** Fulkerson Manufacturing wishes to maintain a sustainable growth rate of 8 percent a year, a debt-equity ratio of 0.55, and a dividend payout ratio of 25 percent. The ratio of total assets to sales is constant at 1.20. What profit margin must the firm achieve?
- L0 2** 39. **Market Value Ratios.** Abercrombie & Fitch and Ann Taylor reported the following numbers (in millions) for fiscal year 2008. Calculate the earnings per share, market-to-book ratio, and price-earnings ratio for each company.

	Abercrombie	Ann Taylor
Net income	\$ 475.70	\$ 97.24
Shares outstanding	87.05	57.10
Stock price	\$ 80.59	\$ 25.26
Total equity	\$1,618.31	\$839.48

- L0 3** 40. **Growth and Assets.** A firm wishes to maintain an internal growth rate of 6.5 percent and a dividend payout ratio of 30 percent. The current profit margin is 5.2 percent and the firm uses no external financing sources. What must total asset turnover be?
- L0 3** 41. **Sustainable Growth.** Based on the following information, calculate the sustainable growth rate for Perks, Inc.:
- Profit margin = 4.3%
- Total asset turnover = 2.10
- Total debt ratio = 0.30
- Payout ratio = 15%
- What is the ROA here?
- L0 3** 42. **Sustainable Growth and Outside Financing.** You've collected the following information about Fox, Inc.:
- Sales = \$245,000
- Net income = \$17,000
- Dividends = \$5,800
- Total debt = \$53,000
- Total equity = \$84,000
- What is the sustainable growth rate for the company? If it does grow at this rate, how much new borrowing will take place in the coming year, assuming a constant debt-equity ratio? What growth rate could be supported with no outside financing at all?
- L0 4** 43. **Constraints on Growth.** High Flyer, Inc., wishes to maintain a growth rate of 13 percent per year and a debt-equity ratio of 0.30. The profit margin is 5 percent, and total asset turnover is constant at 1.20. Is this growth rate possible? To answer, determine what the dividend payout ratio must be. How do you interpret the result?
- L0 3** 44. **Internal and Sustainable Growth Rates.** Best Buy reported the following numbers (in millions) for the years ending February 2007 and 2008. What are the internal and sustainable growth rates? What are the internal and sustainable

growth rates using $\text{ROE} \times b$ (and $\text{ROA} \times b$) and the end of period equity (assets)? What are the growth rates if you use the beginning of period equity in this equation? Why aren't the growth rates the same? What is your best estimate of the internal and sustainable growth rates?

	2007	2008
Net income		\$ 1,407
Dividends		204
Total assets	\$13,570	12,758
Total equity	6,201	4,484

L0 3

- 45. Expanded Du Pont Identity.** Hershey Co. reported the following income statement and balance sheet (in millions) for 2008. Construct the expanded Du Pont identity similar to Figure 3.1. What is the company's return on equity?

Income Statement		Balance Sheet			
		Assets		Liabilities & Equity	
Sales	\$5,132.768	Current assets		Current liabilities	\$1,270.212
CoGS	3,375.050	Cash	\$ 37.103	Long-term debt	\$2,014.560
Other costs	940.637	Accounts receivable	715.312	Shareholders' equity	\$ 349.947
Depreciation	227.183	Inventory	592.530	Total liabilities and shareholders' equity	\$3,634.719
EBIT	\$ 589.898	Total	\$1,344.945		
Interest	97.876	Fixed assets	\$2,289.774		
EBT	\$ 492.022	Total assets	\$3,634.719		
Taxes	180.617				
Net income	\$ 311.405				

- 3.1 Du Pont Identity.** You can find financial statements for Walt Disney Company at Disney's home page, www.disney.com. For the three most recent years, calculate the Du Pont identity for Disney. How has ROE changed over this period? How have changes in each component of the Du Pont identity affected ROE over this period?

- 3.2 Ratio Analysis.** You want to examine the financial ratios for Dell Computer Corporation. Go to www.reuters.com and type in the ticker symbol for the company (DELL). Next, go to the ratio link. You should find financial ratios for Dell and the industry, sector, and S&P 500 averages for each ratio.

- What do TTM and MRQ mean?
- How do Dell's recent profitability ratios compare to their values over the past five years? To the industry averages? To the sector averages? To the S&P 500 averages? Which is the better comparison group for Dell: the industry, sector, or S&P 500 averages? Why?
- In what areas does Dell seem to outperform its competitors based on the financial ratios? Where does Dell seem to lag behind its competitors?
- Dell's inventory turnover ratio is much larger than that for all comparison groups. Why do you think this is?

WHAT'S ON THE WEB?

- 3.3 Standardized Financial Statements.** Go to www.att.com and find the income statements and balance sheets for the two most recent years at this link. Using this information, prepare the common-size income statements and balance sheets for the two years.
- 3.4 Asset Utilization Ratios.** Find the most recent financial statements for Walmart at www.walmart.com and Boeing at www.boeing.com. Calculate the asset utilization ratio for these two companies. What does this ratio measure? Is the ratio similar for both companies? Why or why not?

CHAPTER CASE

RATIOS AND FINANCIAL PLANNING AT S&S AIR, INC.

Chris Guthrie was recently hired by S&S Air, Inc., to assist the company with its financial planning, and to evaluate the company's performance. Chris graduated from college five years ago with a finance degree. He has been employed in the finance department of a Fortune 500 company since then.

S&S Air was founded 10 years ago by friends Mark Sexton and Todd Story. The company has manufactured and sold light airplanes over this period, and the company's products have received high reviews for safety and reliability. The company has a niche market in that it sells primarily to individuals who own and fly their own airplanes. The company has two models, the Birdie, which sells for \$53,000, and the Eagle, which sells for \$78,000.

While the company manufactures aircraft, its operations are different from commercial aircraft companies. S&S Air builds aircraft to order. By using prefabricated parts, the company is able to complete the manufacture of an airplane in only five weeks. The company also receives a deposit on each order, as well as another

partial payment before the order is complete. In contrast, a commercial airplane may take one and one-half to two years to manufacture once the order is placed.

Mark and Todd have provided the following financial statements. Chris has gathered the industry ratios for the light airplane manufacturing industry. ■

S&S Air, Inc. 2009 Income Statement	
Sales	\$20,077,000
Cost of goods sold	14,985,000
Other expenses	2,399,000
Depreciation	655,000
EBIT	\$ 2,038,000
Interest	362,000
Taxable income	\$ 1,676,000
Taxes (40%)	670,400
Net income	<u>\$ 1,005,600</u>
Dividends	\$205,000
Add. to retained earnings	800,600

S&S Air, Inc. 2009 Balance Sheet			
Assets		Liabilities & Equity	
Current assets		Current liabilities	
Cash	\$ 365,040	Accounts payable	\$ 715,680
Accounts receivable	1,534,680	Notes payable	1,446,400
Inventory	1,238,500	Total current liabilities	<u>\$ 2,162,080</u>
Total current assets	<u>\$ 3,138,220</u>		
Fixed assets		Long-term debt	
Net plant and equipment	\$12,315,680	Shareholder equity	
		Common stock	\$ 150,000
		Retained earnings	9,316,820
		Total equity	<u>\$ 9,466,820</u>
Total assets	<u>\$15,453,900</u>	Total liabilities & equity	<u>\$15,453,900</u>

Light Airplane Industry Ratios			
	Lower Quartile	Median	Upper Quartile
Current ratio	0.50	1.43	1.89
Quick ratio	0.64	0.84	1.05
Cash ratio	0.08	0.21	0.39
Total asset turnover	0.68	0.85	1.28
Inventory turnover	4.89	6.15	10.89
Receivables turnover	6.27	9.82	11.51
Total debt ratio	0.31	0.52	0.61
Debt-equity ratio	0.58	1.08	1.56
Equity multiplier	1.58	2.08	2.56
Times interest earned	5.18	8.06	9.83
Cash coverage ratio	5.84	8.43	10.27
Profit margin	4.05%	5.15%	6.47%
Return on assets	6.05%	10.53%	13.21%
Return on equity	9.93%	16.54%	26.15%

QUESTIONS

1. Calculate the ratios for S&S Air that are shown for the industry.
2. Mark and Todd agree that a ratio analysis can provide a measure of the company's performance. They have chosen Boeing as an aspirant company. Would you choose Boeing as an aspirant company? Why or why not?
3. Compare the performance of S&S Air to the industry. For each ratio, comment on why it might be viewed as positive or negative relative to the industry. Suppose you create an inventory ratio calculated by inventory divided by current liabilities. How do you think S&S Air's ratio would compare to the industry average?
4. Calculate the internal growth rate and sustainable growth rate for S&S Air. What do these numbers mean?

Introduction to Valuation: The Time Value of Money

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Determine the future value of an investment made today.
- LO 2** Determine the present value of cash to be received at a future date.
- LO 3** Calculate the return on an investment.
- LO 4** Predict how long it takes for an investment to reach a desired value.

On March 28, 2008, Toyota Motor Credit Corporation (TMCC), a subsidiary of Toyota Motor, offered some securities for sale to the public. Under the terms of the deal, TMCC promised to repay the owner of one of these securities \$100,000 on March 28, 2038, but investors would receive nothing until then. Investors paid TMCC \$24,099 for each of these securities; so they gave up \$24,099 on March 28, 2008, for the promise of a \$100,000 payment 30 years later.

Such a security, for which you pay some amount today in exchange for a promised lump sum to be received at a future date, is about the simplest possible type.

Is giving up \$24,099 in exchange for \$100,000 in 30 years a good deal? On the plus side, you get back about \$4 for every \$1 you put up. That probably sounds good, but, on the downside, you have to wait 30 years to get it. What you need to know is how to analyze this trade-off; this chapter gives you the tools you need.

Specifically, our goal here is to introduce you to one of the most important principles in finance, the time value of money. What you will learn is how to determine the value today of some cash flow to be received later. This is a very basic business skill, and it underlies the analysis of many different types of investments and financing arrangements. In fact, almost all business activities, whether they originate in marketing, management, operations, or strategy, involve comparing outlays made today to benefits projected for the future. How to do this comparison is something everyone needs to understand; this chapter gets you started.

Visit us at www.mhhe.com/rwj

One of the basic problems faced by the financial manager is how to determine the value today of cash flows expected in the future. For example, the jackpot in a PowerBall™ lottery drawing was \$110 million. Does this mean the winning ticket was worth \$110 million? The answer is no because the jackpot was actually going to pay out over a 20-year period at a rate of \$5.5 million per year. How much was the ticket worth then? The answer depends on the time value of money, the subject of this chapter.

In the most general sense, the phrase *time value of money* refers to the fact that a dollar in hand today is worth more than a dollar promised at some time in the future. On a practical level, one reason for this is that you could earn interest while you waited; so, a dollar today would grow to more than a dollar later. The trade-off between money now and money later thus depends on, among other things, the rate you can earn by investing. Our goal in this chapter is to explicitly evaluate this trade-off between dollars today and dollars at some future time.

A thorough understanding of the material in this chapter is critical to understanding material in subsequent chapters, so you should study it with particular care. We will present a number of examples in this chapter. In many problems, your answer may differ from ours slightly. This can happen because of rounding and is not a cause for concern.

4.1

future value (FV)

The amount an investment is worth after one or more periods.

FUTURE VALUE AND COMPOUNDING

The first thing we will study is future value. **Future value (FV)** refers to the amount of money an investment will grow to over some period of time at some given interest rate. Put another way, future value is the cash value of an investment at some time in the future. We start out by considering the simplest case, a single-period investment.

Investing for a Single Period

Suppose you were to invest \$100 in a savings account that pays 10 percent interest per year. How much would you have in one year? You would have \$110. This \$110 is equal to your original *principal* of \$100 plus \$10 in interest that you earn. We say that \$110 is the future value of \$100 invested for one year at 10 percent, and we simply mean that \$100 today is worth \$110 in one year, given that 10 percent is the interest rate.

In general, if you invest for one period at an interest rate of r , your investment will grow to $(1 + r)$ per dollar invested. In our example, r is 10 percent, so your investment grows to $1 + .10 = 1.1$ dollars per dollar invested. You invested \$100 in this case, so you ended up with $100 \times 1.10 = \$110$.

Investing for More Than One Period

Going back to our \$100 investment, what will you have after two years, assuming the interest rate doesn't change? If you leave the entire \$110 in the bank, you will earn $110 \times .10 = \$11$ in interest during the second year, so you will have a total of $110 + 11 = \$121$. This \$121 is the future value of \$100 in two years at 10 percent. Another way of looking at it is that one year from now you are effectively investing \$110 at 10 percent for a year. This is a single-period problem, so you'll end up with \$1.1 for every dollar invested, or $110 \times 1.1 = \$121$ total.

This \$121 has four parts. The first part is the \$100 original principal. The second part is the \$10 in interest you earn in the first year, and the third part is another \$10 you earn in

the second year, for a total of \$120. The last \$1 you end up with (the fourth part) is interest you earn in the second year on the interest paid in the first year: $\$10 \times .10 = \1 .

This process of leaving your money and any accumulated interest in an investment for more than one period, thereby reinvesting the interest, is called **compounding**. Compounding the interest means earning **interest on interest**, so we call the result **compound interest**. With **simple interest**, the interest is not reinvested, so interest is earned each period only on the original principal.

compounding

The process of accumulating interest in an investment over time to earn more interest.

Interest on Interest

EXAMPLE 4.1

Suppose you locate a two-year investment that pays 14 percent per year. If you invest \$325, how much will you have at the end of the two years? How much of this is simple interest? How much is compound interest?

At the end of the first year, you will have $\$325 \times (1 + .14) = \370.50 . If you reinvest this entire amount, and thereby compound the interest, you will have $\$370.50 \times 1.14 = \422.37 at the end of the second year. The total interest you earn is thus $\$422.37 - 325 = \97.37 . Your \$325 original principal earns $\$325 \times .14 = \45.50 in interest each year, for a two-year total of \$91 in simple interest. The remaining $\$97.37 - 91 = \6.37 results from compounding. You can check this by noting that the interest earned in the first year is \$45.50. The interest on interest earned in the second year thus amounts to $\$45.50 \times .14 = \6.37 , as we calculated.

We now take a closer look at how we calculated the \$121 future value. We multiplied \$110 by 1.1 to get \$121. The \$110, however, was \$100 also multiplied by 1.1. In other words:

$$\begin{aligned}\$121 &= \$110 \times 1.1 \\ &= (\$100 \times 1.1) \times 1.1 \\ &= \$100 \times (1.1 \times 1.1) \\ &= \$100 \times 1.1^2 \\ &= \$100 \times 1.21\end{aligned}$$

At the risk of belaboring the obvious, let's ask: How much would our \$100 grow to after three years? Once again, in two years, we'll be investing \$121 for one period at 10 percent. We'll end up with \$1.1 for every dollar we invest, or $\$121 \times 1.1 = \133.1 total. This \$133.1 is thus:

$$\begin{aligned}\$133.1 &= \$121 \times 1.1 \\ &= (\$110 \times 1.1) \times 1.1 \\ &= (\$100 \times 1.1) \times 1.1 \times 1.1 \\ &= \$100 \times (1.1 \times 1.1 \times 1.1) \\ &= \$100 \times 1.1^3 \\ &= \$100 \times 1.331\end{aligned}$$

You're probably noticing a pattern to these calculations, so we can now go ahead and state the general result. As our examples suggest, the future value of \$1 invested for t periods at a rate of r per period is:

$$\text{Future value} = \$1 \times (1 + r)^t \quad [4.1]$$

The expression $(1 + r)^t$ is sometimes called the *future value interest factor* (or just *future value factor*) for \$1 invested at r percent for t periods and can be abbreviated as $FVIF(r, t)$.

interest on interest

Interest earned on the reinvestment of previous interest payments.

compound interest

Interest earned on both the initial principal and the interest reinvested from prior periods.

simple interest

Interest earned only on the original principal amount invested.

TABLE 4.1	Year	Beginning Amount	Interest Earned	Ending Amount
Future value of \$100 at 10 percent	1	\$100.00	\$10.00	\$110.00
	2	110.00	11.00	121.00
	3	121.00	12.10	133.10
	4	133.10	13.31	146.41
	5	146.41	14.64	161.05
			Total interest	\$61.05

In our example, what would your \$100 be worth after five years? We can first compute the relevant future value factor as:

$$(1 + r)^t = (1 + .10)^5 = 1.1^5 = 1.6105$$

Your \$100 will thus grow to:

$$\$100 \times 1.6105 = \$161.05$$

The growth of your \$100 each year is illustrated in Table 4.1. As shown, the interest earned in each year is equal to the beginning amount multiplied by the interest rate of 10 percent.

In Table 4.1, notice that the total interest you earn is \$61.05. Over the five-year span of this investment, the simple interest is $\$100 \times .10 = \10 per year, so you accumulate \$50 this way. The other \$11.05 is from compounding.

Figure 4.1 illustrates the growth of the compound interest in Table 4.1. Notice how the simple interest is constant each year, but the compound interest you earn gets bigger every year. The size of the compound interest keeps increasing because more and more interest builds up and there is thus more to compound.

Future values depend critically on the assumed interest rate, particularly for long-lived investments. Figure 4.2 illustrates this relationship by plotting the growth of \$1 for different rates and lengths of time. Notice that the future value of \$1 after 10 years is about \$6.20 at a 20 percent rate, but it is only about \$2.60 at 10 percent. In this case, doubling the interest rate more than doubles the future value.

To solve future value problems, we need to come up with the relevant future value factors. There are several different ways of doing this. In our example, we could have multiplied 1.1 by itself five times. This would work just fine, but it would get to be very tedious for, say, a 30-year investment.

Fortunately, there are several easier ways to get future value factors. Most calculators have a key labeled “y^x.” You can usually just enter 1.1, press this key, enter 5, and press the “=” key to get the answer. This is an easy way to calculate future value factors because it’s quick and accurate.

Alternatively, you can use a table that contains future value factors for some common interest rates and time periods. Table 4.2 contains some of these factors. Table A.1 in Appendix A at the end of the book contains a much larger set. To use the table, find the column that corresponds to 10 percent. Then look down the rows until you come to five periods. You should find the factor that we calculated, 1.6105.

Tables such as Table 4.2 are not as common as they once were because they predate inexpensive calculators and are only available for a relatively small number of rates. Interest rates are often quoted to three or four decimal places, so the tables needed to deal with these accurately would be quite large. As a result, the “real world” has moved away from using them. We will emphasize the use of a calculator in this chapter.

A brief introduction to key financial concepts is available at www.teachmefinance.com.

**FIGURE 4.1**

Future value,
simple interest, and
compound interest

Growth of \$100 original amount at 10% per year. Blue shaded area represents the portion of the total that results from compounding of interest.

**FIGURE 4.2**

Future value of \$1 for
different periods and
rates

Number of Periods	Interest Rates			
	5%	10%	15%	20%
1	1.0500	1.1000	1.1500	1.2000
2	1.1025	1.2100	1.3225	1.4400
3	1.1576	1.3310	1.5209	1.7280
4	1.2155	1.4641	1.7490	2.0736
5	1.2763	1.6105	2.0114	2.4883

TABLE 4.2

Future value interest
factors

These tables still serve a useful purpose. To make sure you are doing the calculations correctly, pick a factor from the table and then calculate it yourself to see that you get the same answer. There are plenty of numbers to choose from.

EXAMPLE 4.2

Compound Interest

You've located an investment that pays 12 percent. That rate sounds good to you, so you invest \$400. How much will you have in three years? How much will you have in seven years? At the end of seven years, how much interest have you earned? How much of that interest results from compounding?

Based on our discussion, we can calculate the future value factor for 12 percent and three years as:

$$(1 + r)^t = 1.12^3 = 1.4049$$

Your \$400 thus grows to:

$$\$400 \times 1.4049 = \$561.97$$

After seven years, you will have:

$$\$400 \times 1.12^7 = \$400 \times 2.2107 = \$884.27$$

Thus, you will more than double your money over seven years.

Since you invested \$400, the interest in the \$884.27 future value is $\$884.27 - \$400 = \$484.27$. At 12 percent, your \$400 investment earns $\$400 \times .12 = \48 in simple interest every year. Over seven years, the simple interest thus totals $7 \times \$48 = \336 . The other $\$484.27 - \$336 = \$148.27$ is from compounding.

How much do you need at retirement? Locate the "Retirement Planning" link at www.about.com.

The effect of compounding is not great over short time periods, but it really starts to add up as the horizon grows. To take an extreme case, suppose one of your more frugal ancestors had invested \$5 for you at a 6 percent interest rate 200 years ago. How much would you have today? The future value factor is a substantial $1.06^{200} = 115,125.90$ (you won't find this one in a table), so you would have $\$5 \times 115,125.90 = \$575,629.50$ today. Notice that the simple interest is just $\$5 \times .06 = \0.30 per year. After 200 years, this amounts to \$60. The rest is from reinvesting. Such is the power of compound interest!

EXAMPLE 4.3

How Much for That Island?

To further illustrate the effect of compounding for long horizons, consider the case of Peter Minuit and the Indians. In 1626, Minuit bought all of Manhattan Island for about \$24 in goods and trinkets. This sounds cheap, but the Indians may have gotten the better end of the deal. To see why, suppose the Indians had sold the goods and invested the \$24 at 10 percent. How much would it be worth today?

Roughly 383 years have passed since the transaction. At 10 percent, \$24 will grow by quite a bit over that time. How much? The future value factor is approximately:

$$(1 + r)^t = 1.1^{383} \approx 7,000,000,000,000$$

That is, 7 followed by 15 zeroes. The future value is thus on the order of $\$24 \times 7$ quadrillion, or about \$170 *quadrillion* (give or take a few hundreds of trillions).

Well, \$170 quadrillion is a lot of money. How much? If you had it, you could buy the United States. All of it. Cash. With money left over to buy Canada, Mexico, and the rest of the world, for that matter.

This example is something of an exaggeration, of course. In 1626, it would not have been easy to locate an investment that would pay 10 percent every year without fail for the next 383 years.

Using a Financial Calculator

CALCULATOR HINTS

Although there are the various ways of calculating future values we have described so far, many of you will decide that a financial calculator is the way to go. If you are planning on using one, you should read this extended hint; otherwise, skip it.

A financial calculator is simply an ordinary calculator with a few extra features. In particular, it knows some of the most commonly used financial formulas, so it can directly compute things like future values.

Financial calculators have the advantage that they handle a lot of the computation, but that is really all. In other words, you still have to understand the problem; the calculator just does some of the arithmetic. In fact, there is an old joke (somewhat modified) that goes like this: Anyone can make a mistake on a time value of money problem, but to really screw one up takes a financial calculator! We therefore have two goals for this section. First, we'll discuss how to compute future values. After that, we'll show you how to avoid the most common mistakes people make when they start using financial calculators.

How to Calculate Future Values with a Financial Calculator Examining a typical financial calculator, you will find five keys of particular interest. They usually look like this:

For now, we need to focus on four of these. The keys labeled **PV** and **FV** are just what you would guess: present value and future value. The key labeled **N** refers to the number of periods, which is what we have been calling t . Finally, **I/Y** stands for the interest rate, which we have called r .¹

If we have the financial calculator set up right (see our next section), then calculating a future value is very simple. Take a look back at our question involving the future value of \$100 at 10 percent for five years. We have seen that the answer is \$161.05. The exact keystrokes will differ depending on what type of calculator you use, but here is basically all you do:

1. Enter -100 . Press the **PV** key. (The negative sign is explained below.)
2. Enter 10. Press the **I/Y** key. (Notice that we entered 10, not .10; see below.)
3. Enter 5. Press the **N** key.

Now we have entered all of the relevant information. To solve for the future value, we need to ask the calculator what the FV is. Depending on your calculator, you either press the button labeled "CPT" (for compute) and then press **FV**, or else you just press **FV**. Either way, you should get 161.05. If you don't (and you probably won't if this is the first time you have used a financial calculator!), we will offer some help in our next section.

Before we explain the kinds of problems that you are likely to run into, we want to establish a standard format for showing you how to use a financial calculator. Using the example we just looked at, in the future, we will illustrate such problems like this:

Enter	5	10		-100	
	N	I/Y	PMT	PV	FV
Solve for					161.05

¹ The reason financial calculators use N and I/Y is that the most common use for these calculators is determining loan payments. In this context, N is the number of payments and I/Y is the interest rate on the loan. But, as we will see, there are many other uses of financial calculators that don't involve loan payments and interest rates.

Here is an important tip: Appendix D in the back of the book contains some more detailed instructions for the most common types of financial calculators. See if yours is included, and, if it is, follow the instructions there if you need help. Of course, if all else fails, you can read the manual that came with the calculator.

How to Get the Wrong Answer Using a Financial Calculator There are a couple of common (and frustrating) problems that cause a lot of trouble with financial calculators. In this section, we provide some important *dos* and *don'ts*. If you just can't seem to get a problem to work out, you should refer back to this section.

There are two categories we examine: three things you need to do only once and three things you need to do every time you work a problem. The things you need to do just once deal with the following calculator settings:

1. *Make sure your calculator is set to display a large number of decimal places.* Most financial calculators only display two decimal places; this causes problems because we frequently work with numbers like—interest rates—that are very small.
2. *Make sure your calculator is set to assume only one payment per period or per year.* Some financial calculators assume monthly payments (12 per year) unless you say otherwise.
3. *Make sure your calculator is in “end” mode.* This is usually the default, but you can accidentally change to “begin” mode.

If you don't know how to set these three things, see Appendix D or your calculator's operating manual.

There are also three things you need to do *every time you work a problem*:

1. *Before you start, completely clear out the calculator.* This is very important. Failure to do this is the number one reason for wrong answers; you simply must get in the habit of clearing the calculator every time you start a problem. How you do this depends on the calculator (see Appendix D), but you must do more than just clear the display. For example, on a Texas Instruments BA II Plus, you must press **2nd** then **CLR TVM** for *clear time value of money*. There is a similar command on your calculator. Learn it!

Note that turning the calculator off and back on won't do it. Most financial calculators remember everything you enter, even after you turn them off. In other words, they remember all your mistakes unless you explicitly clear them out. Also, if you are in the middle of a problem and make a mistake, *clear it out and start over*. Better to be safe than sorry.

2. *Put a negative sign on cash outflows.* Most financial calculators require you to put a negative sign on cash outflows and a positive sign on cash inflows. As a practical matter, this usually just means that you should enter the present value amount with a negative sign (because normally the present value represents the amount you give up today in exchange for cash inflows later). You enter a negative value on the BA II Plus by first entering a number and then pressing the **+/-** key. By the same token, when you solve for a present value, you shouldn't be surprised to see a negative sign.
3. *Enter the rate correctly.* Financial calculators assume that rates are quoted in percent, so if the rate is .08 (or 8 percent), you should enter 8, not .08.

If you follow these guidelines (especially the one about clearing out the calculator), you should have no problem using a financial calculator to work almost all of the problems in this and the next few chapters. We'll provide some additional examples and guidance where appropriate.

CONCEPT QUESTIONS

- 4.1a** What do we mean by the future value of an investment?
- 4.1b** What does it mean to compound interest? How does compound interest differ from simple interest?
- 4.1c** In general, what is the future value of \$1 invested at r per period for t periods?

PRESENT VALUE AND DISCOUNTING

4.2

When we discuss future value, we are thinking of questions such as the following: What will my \$2,000 investment grow to if it earns a 6.5 percent return every year for the next six years? The answer to this question is what we call the future value of \$2,000 invested at 6.5 percent for six years (verify that the answer is about \$2,918).

There is another type of question that comes up even more often in financial management that is obviously related to future value. Suppose you need to have \$10,000 in 10 years, and you can earn 6.5 percent on your money. How much do you have to invest today to reach your goal? You can verify that the answer is \$5,327.26. How do we know this? Read on.

The Single-Period Case

We've seen that the future value of \$1 invested for one year at 10 percent is \$1.10. We now ask a slightly different question: How much do we have to invest today at 10 percent to get \$1 in one year? In other words, we know the future value here is \$1, but what is the **present value (PV)**? The answer isn't too hard to figure out. Whatever we invest today will be 1.1 times bigger at the end of the year. Since we need \$1 at the end of the year:

$$\text{Present value} \times 1.1 = \$1$$

Or, solving for the present value:

$$\text{Present value} = \$1/1.1 = \$.909$$

In this case, the present value is the answer to the following question: What amount, invested today, will grow to \$1 in one year if the interest rate is 10 percent? Present value is thus just the reverse of future value. Instead of compounding the money forward into the future, we **discount** it back to the present.

present value (PV)

The current value of future cash flows discounted at the appropriate discount rate.

discount

Calculate the present value of some future amount.

Single-Period PV

EXAMPLE 4.4

Suppose you need \$400 to buy textbooks next year. You can earn 7 percent on your money. How much do you have to put up today?

We need to know the PV of \$400 in one year at 7 percent. Proceeding as above:

$$\text{Present value} \times 1.07 = \$400$$

We can now solve for the present value:

$$\text{Present value} = \$400 \times (1/1.07) = \$373.83$$

Thus, \$373.83 is the present value. Again, this just means that investing this amount for one year at 7 percent will result in a future value of \$400.

From our examples, the present value of \$1 to be received in one period is generally given as:

$$PV = \$1 \times [1/(1 + r)] = \$1/(1 + r)$$

We next examine how to get the present value of an amount to be paid in two or more periods into the future.

Present Values for Multiple Periods

Suppose you need to have \$1,000 in two years. If you can earn 7 percent, how much do you have to invest to make sure that you have the \$1,000 when you need it? In other words, what is the present value of \$1,000 in two years if the relevant rate is 7 percent?

Based on your knowledge of future values, you know that the amount invested must grow to \$1,000 over the two years. In other words, it must be the case that:

$$\begin{aligned} \$1,000 &= PV \times 1.07 \times 1.07 \\ &= PV \times 1.07^2 \\ &= PV \times 1.1449 \end{aligned}$$

Given this, we can solve for the present value:

$$\text{Present value} = \$1,000/1.1449 = \$873.44$$

Therefore, \$873.44 is the amount you must invest in order to achieve your goal.

EXAMPLE 4.5

Saving Up

You would like to buy a new automobile. You have \$50,000, but the car costs \$68,500. If you can earn 9 percent, how much do you have to invest today to buy the car in two years? Do you have enough? Assume the price will stay the same.

What we need to know is the present value of \$68,500 to be paid in two years, assuming a 9 percent rate. Based on our discussion, this is:

$$PV = \$68,500/1.09^2 = \$68,500/1.1881 = \$57,655.08$$

You're still about \$7,655 short, even if you're willing to wait two years.

As you have probably recognized by now, calculating present values is quite similar to calculating future values, and the general result looks much the same. The present value of \$1 to be received t periods into the future at a discount rate of r is:

$$PV = \$1 \times [1/(1 + r)^t] = \$1/(1 + r)^t \quad [4.2]$$

discount rate

The rate used to calculate the present value of future cash flows.

discounted cash flow (DCF) valuation

Valuation calculating the present value of a future cash flow to determine its value today.

The quantity in brackets, $1/(1 + r)^t$, goes by several different names. Since it's used to discount a future cash flow, it is often called a *discount factor*. With this name, it is not surprising that the rate used in the calculation is often called the **discount rate**. We will tend to call it this in talking about present values. The quantity in brackets is also called the *present value interest factor* (or just *present value factor*) for \$1 at r percent for t periods and is sometimes abbreviated as PVIF(r , t). Finally, calculating the present value of a future cash flow to determine its worth today is commonly called **discounted cash flow (DCF) valuation**.

To illustrate, suppose you need \$1,000 in three years. You can earn 15 percent on your money. How much do you have to invest today? To find out, we have to determine the

Number of Periods	Interest Rates			
	5%	10%	15%	20%
1	.9524	.9091	.8696	.8333
2	.9070	.8264	.7561	.6944
3	.8638	.7513	.6575	.5787
4	.8227	.6830	.5718	.4823
5	.7835	.6209	.4972	.4019

TABLE 4.3**Present value interest factors**

present value of \$1,000 in three years at 15 percent. We do this by discounting \$1,000 back three periods at 15 percent. With these numbers, the discount factor is:

$$1/(1 + .15)^3 = 1/1.5209 = \mathbf{.6575}$$

The amount you must invest is thus:

$$\mathbf{\$1,000} \times \mathbf{.6575} = \mathbf{\$657.50}$$

We say that \$657.50 is the present, or discounted, value of \$1,000 to be received in three years at 15 percent.

There are tables for present value factors just as there are tables for future value factors, and you use them in the same way (if you use them at all). Table 4.3 contains a small set of these factors. A much larger set can be found in Table A.2 in Appendix A.

In Table 4.3, the discount factor we just calculated, **.6575**, can be found by looking down the column labeled “15%” until you come to the third row. Of course, you could use a financial calculator, as we illustrate next.

As the length of time until payment grows, present values decline. As Example 4.6 illustrates, present values tend to become small as the time horizon grows. If you

You solve present value problems on a financial calculator just like you do future value problems. For the example we just examined (the present value of \$1,000 to be received in three years at 15 percent), you would do the following:

CALCULATOR HINTS

Enter	3	15		1,000
	N	1/Y	PMT	PV
				FV

Solve for -657.50

Notice that the answer has a negative sign; as we discussed above, that's because it represents an outflow today in exchange for the \$1,000 inflow later.

Deceptive Advertising**EXAMPLE 4.6**

Recently, some businesses have been saying things like “Come try our product. If you do, we'll give you \$100 just for coming by!” If you read the fine print, what you find out is that they will give you a savings certificate that will pay you \$100 in 25 years or so. If the going interest rate on such certificates is 10 percent per year, how much are they really giving you today?

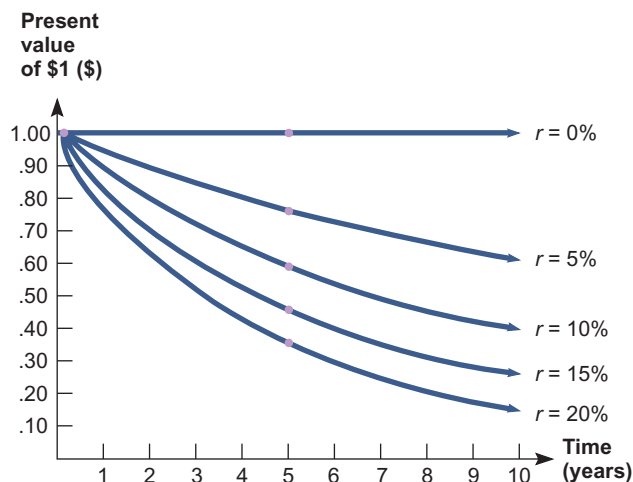

What you're actually getting is the present value of \$100 to be paid in 25 years. If the discount rate is 10 percent per year, then the discount factor is:

$$1/1.1^{25} = 1/10.8347 = .0923$$

This tells you that a dollar in 25 years is worth a little more than nine cents today, assuming a 10 percent discount rate. Given this, the promotion is actually paying you about $.0923 \times \$100 = \9.23 . Maybe this is enough to draw customers, but it's not \$100.

FIGURE 4.3

Present value of \$1 for different periods and rates

look out far enough, they will always get close to zero. Also, for a given length of time, the higher the discount rate is, the lower is the present value. Put another way, present values and discount rates are inversely related. Increasing the discount rate decreases the PV and vice versa.

The relationship between time, discount rates, and present values is illustrated in Figure 4.3. Notice that by the time we get to 10 years, the present values are all substantially smaller than the future amounts.

CONCEPT QUESTIONS

- 4.2a** What do we mean by the present value of an investment?
- 4.2b** The process of discounting a future amount back to the present is the opposite of doing what?
- 4.2c** What do we mean by discounted cash flow, or DCF, valuation?
- 4.2d** In general, what is the present value of \$1 to be received in t periods, assuming a discount rate of r per period?

4.3

MORE ON PRESENT AND FUTURE VALUES

If you look back at the expressions we came up with for present and future values, you will see there is a very simple relationship between the two. We explore this relationship and some related issues in this section.

Present versus Future Value

What we called the present value factor is just the reciprocal of (that is, 1 divided by) the future value factor:

$$\text{Future value factor} = (1 + r)^t$$

$$\text{Present value factor} = 1/(1 + r)^t$$

In fact, the easy way to calculate a present value factor on many calculators is to first calculate the future value factor and then press the **1/x** key to flip it over.

For a downloadable, Windows-based financial calculator, go to www.calculator.org.

If we let FV_t stand for the future value after t periods, then the relationship between future value and present value can be written very simply as one of the following:

$$\begin{aligned} PV \times (1 + r)^t &= FV_t \\ PV &= FV_t / (1 + r)^t = FV_t \times [1 / (1 + r)^t] \end{aligned} \quad [4.3]$$

We will call this last result the *basic present value equation*. We will use it throughout the text. There are a number of variations that come up, but this simple equation underlies many of the most important ideas in finance.

Evaluating Investments

EXAMPLE 4.7

To give you an idea of how we will be using present and future values, consider the following simple investment. Your company proposes to buy an asset for \$335. This investment is very safe. You will sell off the asset in three years for \$400. You know you could invest the \$335 elsewhere at 10 percent with very little risk. What do you think of the proposed investment?

This is not a good investment. Why not? Because you can invest the \$335 elsewhere at 10 percent. If you do, after three years it will grow to:

$$\begin{aligned} \$335 \times (1 + r)^t &= \$335 \times 1.1^3 \\ &= \$335 \times 1.331 \\ &= \$445.89 \end{aligned}$$

Since the proposed investment only pays out \$400, it is not as good as other alternatives we have. Another way of saying the same thing is to notice that the present value of \$400 in three years at 10 percent is:

$$\$400 \times [1 / (1 + r)^t] = \$400 / 1.1^3 = \$400 / 1.331 = \$300.53$$

This tells us that we only have to invest about \$300 to get \$400 in three years, not \$335. We will return to this type of analysis later on.

Determining the Discount Rate

It will turn out that we will frequently need to determine what discount rate is implicit in an investment. We can do this by looking at the basic present value equation:

$$PV = FV_t / (1 + r)^t$$

There are only four parts to this equation: the present value (PV), the future value (FV_t), the discount rate (r), and the life of the investment (t). Given any three of these, we can always find the fourth.

Finding r for a Single-Period Investment

EXAMPLE 4.8

You are considering a one-year investment. If you put up \$1,250, you will get back \$1,350. What rate is this investment paying?

First, in this single-period case, the answer is fairly obvious. You are getting a total of \$100 in addition to your \$1,250. The implicit rate on this investment is thus $\$100 / \$1,250 = 8$ percent.

More formally, from the basic present value equation, the present value (the amount you must put up today) is \$1,250. The future value (what the present value grows to) is \$1,350. The time involved is one period, so we have:

$$\begin{aligned} \$1,250 &= \$1,350 / (1 + r)^t \\ 1 + r &= \$1,350 / \$1,250 = 1.08 \\ r &= 8\% \end{aligned}$$

In this simple case, of course, there was no need to go through this calculation, but, as we describe below, it gets a little harder when there is more than one period.

To illustrate what happens with multiple periods, let's say that we are offered an investment that costs us \$100 and will double our money in eight years. To compare this to other investments, we would like to know what discount rate is implicit in these numbers. This discount rate is called the *rate of return*, or sometimes just *return*, on the investment. In this case, we have a present value of \$100, a future value of \$200 (double our money), and an eight-year life. To calculate the return, we can write the basic present value equation as:

$$\begin{aligned} PV &= FV_t / (1 + r)^t \\ \$100 &= \$200 / (1 + r)^8 \end{aligned}$$

It could also be written as:

$$(1 + r)^8 = \$200 / \$100 = 2$$

We now need to solve for r . There are three ways we could do it:

1. Use a financial calculator. (See below.)
2. Solve the equation for $1 + r$ by taking the eighth root of both sides. Since this is the same thing as raising both sides to the power of $1/8$, or .125, this is actually easy to do with the y^x key on a calculator. Just enter 2, then press y^x , enter .125, and press the $=$ key. The eighth root should be about 1.09, which implies that r is 9 percent.
3. Use a future value table. The future value factor for eight years is equal to 2. If you look across the row corresponding to eight periods in Table A.1, you will see that a future value factor of 2 corresponds to the 9 percent column, again implying that the return here is 9 percent.

Why does the Rule of 72 work? See

www.moneychimp.com.

Actually, in this particular example, there is a useful “back of the envelope” means of solving for r —the Rule of 72. For reasonable rates of return, the time it takes to double your money is given approximately by $72/r\%$. In our example, this means that $72/r\% = 8$ years, implying that r is 9 percent as we calculated. This rule is fairly accurate for discount rates in the 5 percent to 20 percent range.

The nearby *Reality Bytes* box provides some examples of rates of return on collectibles. See if you can verify the numbers reported there.

EXAMPLE 4.9

Double Your Fun

You have been offered an investment that promises to double your money every 10 years. What is the approximate rate of return on the investment?

From the Rule of 72, the rate of return is given approximately by $72/r\% = 10$, so the rate is approximately $72/10 = 7.2\%$. Verify that the exact answer is 7.177 percent.

A slightly more extreme example involves money bequeathed by Benjamin Franklin, who died on April 17, 1790. In his will, he gave 1,000 pounds sterling to Massachusetts and the city of Boston. He gave a like amount to Pennsylvania and the city of Philadelphia. The money was paid to Franklin when he held political office, but he believed that politicians should not be paid for their service (it appears that this view is not widely shared by modern-day politicians).

Franklin originally specified that the money should be paid out 100 years after his death and used to train young people. Later, however, after some legal wrangling, it was agreed

Collectibles as Investments?

It used to be that trading in collectibles such as baseball cards, art, and old toys occurred mostly at auctions, swap meets, and collectible shops, all of which were limited to regional traffic. However, with the growing popularity of online auctions such as eBay, trading in collectibles has expanded to an international arena. The most visible form of collectible is probably the baseball card, but Furbies, Beanie Babies, and Pokémon cards have been extremely hot collectibles in the recent past. However, it's not just fad items that spark interest from collectors; virtually anything of sentimental value from days gone by is considered collectible, and, more and more, collectibles are being viewed as investments.

Collectibles typically provide no cash flows, except when sold, and condition and buyer sentiment are the major determinants of value. The rates of return have been amazing at times, but care is needed in interpreting them. For example, in 2008, an Original Class I 1804 silver dollar sold for \$3,737,500. The coin was one of only eight of its type known to still exist. While this looks like a whopping price increase to the untrained eye, check for yourself that the actual return on the investment was

only about 7.70 percent per year. Not too bad, but nowhere near the return most people expect from looking at the sales price.

Comic books have recently grown in popularity among collectors. The X-Men, who first appeared in 1963, are a popular group of superheroes. The *X-Men* #1 comic book, which also introduced the world to arch villain Magneto, hit the shelves in September 1963 at a cover price of 50 cents. In August 2008, a copy of this issue had mutated to a price of \$53,775 at auction. This seems like a very high return to the untrained eye, and indeed it is! Check for yourself that the return was about 29.36 percent per year.

Stamp collecting (or philately) is a popular activity. Possibly the most desirable stamp in the world is the 1918 "inverted Jenny," which has a Curtiss JN-4 Jenny aircraft inadvertently printed upside down. Originally sold for 24 cents, one of these stamps was auctioned in 2009 for \$260,000. See for yourself that this represents an annual return of about 16.50 percent. Unfortunately for the seller, this particular stamp was slightly damaged. An undamaged inverted Jenny sold for \$977,500 at the end of 2007, an annual return of 18.65 percent.

that the money would be paid out in 1990, 200 years after Franklin's death. By that time, the Pennsylvania bequest had grown to about \$2 million; the Massachusetts bequest had grown to \$4.5 million. The money was used to fund the Franklin Institutes in Boston and Philadelphia. Assuming that 1,000 pounds sterling was equivalent to 1,000 dollars, what rate of return did the two states earn (the dollar did not become the official U.S. currency until 1792)?

For Pennsylvania, the future value is \$2 million and the present value is \$1,000. There are 200 years involved, so we need to solve for r in the following:

$$\begin{aligned} \$1,000 &= \$2 \text{ million} / (1 + r)^{200} \\ (1 + r)^{200} &= 2,000 \end{aligned}$$

Solving for r , we see that the Pennsylvania money grew at about 3.87 percent per year. The Massachusetts money did better; verify that the rate of return in this case was 4.3 percent. Small differences can add up!

We can illustrate how to calculate unknown rates using a financial calculator using these numbers. For Pennsylvania, you would do the following:

Enter 200 -1,000 2,000,000

N **I/Y** **PMT** **PV** **FV**

Solve for 3.87

**CALCULATOR
HINTS**

As in our previous examples, notice the minus sign on the present value, representing Franklin's outlay made many years ago. What do you change to work the problem for Massachusetts?

EXAMPLE 4.10**Saving for College**

You estimate that you will need about \$80,000 to send your child to college in eight years. You have about \$35,000 now. If you can earn 20 percent per year, will you make it? At what rate will you just reach your goal?

If you can earn 20 percent, the future value of your \$35,000 in eight years will be:

$$FV = \$35,000 \times 1.20^8 = \$35,000 \times 4.2998 = \$150,493.59$$

So, you will make it easily. The minimum rate is the unknown r in the following:

$$FV = \$35,000 \times (1 + r)^8 = \$80,000$$

$$(1 + r)^8 = \$80,000/\$35,000 = 2.2857$$

Therefore, the future value factor is 2.2857. Looking at the row in Table A.1 that corresponds to eight periods, we see that our future value factor is roughly halfway between the ones shown for 10 percent (2.1436) and 12 percent (2.4760), so you will just reach your goal if you earn approximately 11 percent. To get the exact answer, we could use a financial calculator or we could solve for r :

$$(1 + r)^8 = \$80,000/\$35,000 = 2.2857$$

$$1 + r = 2.2857^{(1/8)} = 2.2857^{.125} = 1.1089$$

$$r = 10.89\%$$

EXAMPLE 4.11**Only 18,262.5 Days to Retirement**

You would like to retire in 50 years as a millionaire. If you have \$10,000 today, what rate of return do you need to earn to achieve your goal?

The future value is \$1,000,000. The present value is \$10,000, and there are 50 years until retirement. We need to calculate the unknown discount rate in the following:

$$\$10,000 = \$1,000,000/(1 + r)^{50}$$

$$(1 + r)^{50} = 100$$

The future value factor is thus 100. You can verify that the implicit rate is about 9.65 percent.

Finding the Number of Periods

Suppose we were interested in purchasing an asset that costs \$50,000. We currently have \$25,000. If we can earn 12 percent on this \$25,000, how long until we have the \$50,000? Finding the answer involves solving for the last variable in the basic present value equation, the number of periods. You already know how to get an approximate answer to this particular problem. Notice that we need to double our money. From the Rule of 72, this will take about $72/12 = 6$ years at 12 percent.

To come up with the exact answer, we can again manipulate the basic present value equation. The present value is \$25,000, and the future value is \$50,000. With a 12 percent discount rate, the basic equation takes one of the following forms:

$$\$25,000 = \$50,000/1.12^t$$

$$\$50,000/\$25,000 = 1.12^t = 2$$

We thus have a future value factor of 2 for a 12 percent rate. We now need to solve for t . If you look down the column in Table A.1 that corresponds to 12 percent, you will see that a future value factor of 1.9738 occurs at six periods. It will thus take about six years, as

we calculated. To get the exact answer, we have to explicitly solve for t (or use a financial calculator). If you do this, you will find that the answer is 6.1163 years, so our approximation was quite close in this case.

If you do use a financial calculator, here are the relevant entries:

Enter		12		-25,000	50,000
	N	I/Y	PMT	PV	FV
Solve for	6.1163				

CALCULATOR HINTS

Waiting for Godot

EXAMPLE 4.12

You've been saving up to buy the Godot Company. The total cost will be \$10 million. You currently have about \$2.3 million. If you can earn 5 percent on your money, how long will you have to wait? At 16 percent, how long must you wait?

At 5 percent, you'll have to wait a long time. From the basic present value equation:

$$\$2.3 = \$10/1.05^t$$

$$1.05^t = 4.35$$

$$t = 30 \text{ years}$$

At 16 percent, things are a little better. Verify for yourself that it will take about 10 years.

This example finishes our introduction to basic time value of money concepts. Table 4.4 on page 112 summarizes present value and future value calculations for future reference. As the *Work the Web* box in this section shows, online calculators are widely available to handle these calculations, but it is still important to know what is going on.

Using a Spreadsheet for Time Value of Money Calculations

SPREADSHEET STRATEGIES

More and more, businesspeople from many different areas (and not just finance and accounting) rely on spreadsheets to do all the different types of calculations that come up in the real world. As a result, in this section, we will show you how to use a spreadsheet to handle the various time value of money problems we presented in this chapter. We will use Microsoft Excel™, but the commands are similar for other types of software. We assume you are already familiar with basic spreadsheet operations.

As we have seen, you can solve for any one of the following four potential unknowns: future value, present value, the discount rate, or the number of periods. With a spreadsheet, there is a separate formula for each. In Excel, these are as follows:

To Find	Enter This Formula
Future value	= FV (rate,nper,pmt,pv)
Present value	= PV (rate,nper,pmt,fv)
Discount rate	= RATE (nper,pmt,pv,fv)
Number of periods	= NPER (rate,pmt,pv,fv)

(continued)

Learn more about using Excel for time value of money and other calculations at www.studyfinance.com.

In these formulas, *pv* and *fv* are present and future value, *nper* is the number of periods, and *rate* is the discount, or interest, rate.

There are two things that are a little tricky here. First, unlike a financial calculator, the spreadsheet requires that the rate be entered as a decimal. Second, as with most financial calculators, you have to put a negative sign on either the present value or the future value to solve for the rate or the number of periods. For the same reason, if you solve for a present value, the answer will have a negative sign unless you input a negative future value. The same is true when you compute a future value.

To illustrate how you might use these formulas, we will go back to an example in the chapter. If you invest \$25,000 at 12 percent per year, how long until you have \$50,000? You might set up a spreadsheet like this:

	A	B	C	D	E	F	G	H
1								
2	Using a spreadsheet for time value of money calculations							
3								
4	If we invest \$25,000 at 12 percent, how long until we have \$50,000? We need to solve for the							
5	unknown number of periods, so we use the formula NPER (rate, pmt, pv, fv).							
6								
7	Present value (pv):	\$25,000						
8	Future value (fv):	\$50,000						
9	Rate (rate):	.12						
10								
11	Periods:	6.116255						
12								
13	The formula entered in cell B11 is =NPER(B9,0,-B7,B8); notice that pmt is zero and that pv has a							
14	negative sign on it. Also notice that the rate is entered as a decimal, not a percentage.							

TABLE 4.4

Summary of time value of money calculations

I. Symbols

PV = Present value, what future cash flows are worth today

FV_t = Future value, what cash flows are worth in the future

r = Interest rate, rate of return, or discount rate per period—typically, but not always, one year

t = Number of periods—typically, but not always, the number of years

C = Cash amount

II. Future value of C invested at r percent per period for t periods

$$FV_t = C \times (1 + r)^t$$

The term $(1 + r)^t$ is called the future value factor.

III. Present value of C to be received in t periods at r percent per period

$$PV = C / (1 + r)^t$$

The term $1 / (1 + r)^t$ is called the *present value factor*.

IV. The basic present value equation giving the relationship between present and future value is

$$PV = FV_t / (1 + r)^t$$

WORK THE WEB

How important is the time value of money? A recent search on one Web engine returned over 88.7 million hits! It is important to understand the calculations behind the time value of money, but the advent of financial calculators and spreadsheets has eliminated the need for tedious calculations. In fact, many Web sites offer time value of money calculators. The following is an example from Moneychimp's Web site, www.moneychimp.com. You need \$100,000 in 25 years and will invest your money at 10.2 percent. How much do you need to deposit today? To use the calculator, you simply enter the values and hit "Calculate." The results look like this:

Inputs	
Future Value:	\$ 100,000.00
Years:	25
Discount Rate:	10.2 %
<input type="button" value="Calculate"/>	
Results	
Present Value:	\$ 8,819.83

Who said time value of money calculations are hard?

Questions

1. Use the present value calculator on this Web site to answer the following: Suppose you want to have \$140,000 in 25 years. If you can earn a 10 percent return, how much do you have to invest today?
2. Use the future value calculator on this Web site to answer the following question: Suppose you have \$8,000 today that you plan to save for your retirement in 40 years. If you earn a return of 10.8 percent per year, how much will this account be worth when you are ready to retire?

CONCEPT QUESTIONS

- 4.3a** What is the basic present value equation?
- 4.3b** What is the Rule of 72?

SUMMARY AND CONCLUSIONS

This chapter has introduced you to the basic principles of present value and discounted cash flow valuation. In it, we explained a number of things about the time value of money, including:

1. For a given rate of return, the value at some point in the future of an investment made today can be determined by calculating the future value of that investment.
2. The current worth of a future cash flow can be determined for a given rate of return by calculating the present value of the cash flow involved.
3. The relationship between present value and future value for a given rate, r , and time, t , is given by the basic present value equation:

$$PV = FV_t / (1 + r)^t$$

As we have shown, it is possible to find any one of the four components (PV , FV_t , r , or t) given the other three.

The principles developed in this chapter will figure prominently in the chapters to come. The reason for this is that most investments, whether they involve real assets or financial assets, can be analyzed using the discounted cash flow, or DCF, approach. As a result, the DCF approach is broadly applicable and widely used in practice. Before going on, therefore, you might want to do some of the problems below.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

- 4.1 Calculating Future Values.** Assume you deposit \$1,000 today in an account that pays 8 percent interest. How much will you have in four years?
- 4.2 Calculating Present Values.** Suppose you have just celebrated your 19th birthday. A rich uncle set up a trust fund for you that will pay you \$100,000 when you turn 25. If the relevant discount rate is 11 percent, how much is this fund worth today?
- 4.3 Calculating Rates of Return.** You've been offered an investment that will double your money in 12 years. What rate of return are you being offered? Check your answer using the Rule of 72.
- 4.4 Calculating the Number of Periods.** You've been offered an investment that will pay you 7 percent per year. If you invest \$10,000, how long until you have \$20,000? How long until you have \$30,000?

■ Answers to Chapter Review and Self-Test Problems

- 4.1** We need to calculate the future value of \$1,000 at 8 percent for four years. The future value factor is:

$$1.08^4 = 1.3605$$
 The future value is thus $\$1,000 \times 1.3605 = \$1,360.50$.
- 4.2** We need the present value of \$100,000 to be paid in six years at 11 percent. The discount factor is:

$$1/1.11^6 = 1/1.8704 = .5346$$
 The present value is thus about $\$53,460$.

- 4.3** Suppose you invest, say, \$100. You will have \$200 in 12 years with this investment. So, \$100 is the amount you have today, the present value, and \$200 is the amount you will have in 12 years, or the future value. From the basic present value equation, we have:

$$\begin{aligned} \$200 &= \$100 \times (1 + r)^{12} \\ 2 &= (1 + r)^{12} \end{aligned}$$

From here, we need to solve for r , the unknown rate. As shown in the chapter, there are several different ways to do this. We will take the 12th root of 2 (by raising 2 to the power of $1/12$):

$$\begin{aligned} 2^{(1/12)} &= 1 + r \\ 1.0595 &= 1 + r \\ r &= 5.95\% \end{aligned}$$

Using the Rule of 72, we have $72/t = r\%$, or $72/12 = 6\%$, so our answer looks good (remember that the Rule of 72 is only an approximation).

- 4.4** The basic equation is:

$$\begin{aligned} \$20,000 &= \$10,000 \times (1 + .07)^t \\ 2 &= (1 + .07)^t \end{aligned}$$

If we solve for t , we get that $t = 10.24$ years. Using the Rule of 72, we get $72/7 = 10.29$ years, so, once again, our answer looks good. To get \$30,000, verify for yourself that you will have to wait 16.24 years.

CRITICAL THINKING AND CONCEPTS REVIEW

- L0 1** **4.1 Compounding.** What is compounding? What is discounting?
- L0 1** **4.2 Compounding and Periods.** As you increase the length of time involved, what happens to future values? What happens to present values?
- L0 1** **4.3 Compounding and Interest Rates.** What happens to a future value if you increase the rate, r ? What happens to a present value?
- L0 1** **4.4 Future Values.** Suppose you deposit a large sum in an account that earns a low interest rate and simultaneously deposit a small sum in an account with a high interest rate. Which account will have the larger future value?
- L0 3** **4.5 Ethical Considerations.** Take a look back at Example 4.6. Is it deceptive advertising? Is it unethical to advertise a future value like this without a disclaimer?
- To answer the next five questions, refer to the TMCC security we discussed to open the chapter.
- L0 2** **4.6 Time Value of Money.** Why would TMCC be willing to accept such a small amount today (\$24,099) in exchange for a promise to repay about 4 times that amount (\$100,000) in the future?
- L0 3** **4.7 Call Provisions.** TMCC has the right to buy back the securities on the anniversary date at a price established when the securities were issued (this feature is a term of this particular deal). What impact does this feature have on the desirability of this security as an investment?
- L0 3** **4.8 Time Value of Money.** Would you be willing to pay \$24,099 today in exchange for \$100,000 in 30 years? What would be the key considerations

in answering yes or no? Would your answer depend on who is making the promise to repay?

- L0 3** 4.9 **Investment Comparison.** Suppose that when TMCC offered the security for \$24,099, the U.S. Treasury had offered an essentially identical security. Do you think it would have had a higher or lower price? Why?

- L0 3** 4.10 **Length of Investment.** The TMCC security is bought and sold on the New York Stock Exchange. If you looked at the price today, do you think the price would exceed the \$24,099 original price? Why? If you looked in the year 2018, do you think the price would be higher or lower than today's price? Why?

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

Basic

(Questions 1–15)

- L0 1** 1. **Simple Interest versus Compound Interest.** First City Bank pays 7 percent simple interest on its savings account balances, whereas Second City Bank pays 8 percent interest compounded annually. If you made an \$8,000 deposit in each bank, how much more money would you earn from your Second City Bank account at the end of 10 years?

- L0 1** 2. **Calculating Future Values.** For each of the following, compute the future value:

Present Value	Years	Interest Rate	Future Value
\$ 3,150	6	18%	
8,453	19	6	
89,305	13	11	
227,382	29	5	

- L0 2** 3. **Calculating Present Values.** For each of the following, compute the present value:

Present Value	Years	Interest Rate	Future Value
	12	4%	\$ 17,328
	4	9	41,517
	16	12	790,382
	21	11	647,816

- L0 3** 4. **Calculating Interest Rates.** Solve for the unknown interest rate in each of the following:

Present Value	Years	Interest Rate	Future Value
\$ 715	6		\$ 1,381
905	7		1,718
15,000	18		141,832
70,300	21		312,815

- L0 4** 5. **Calculating the Number of Periods.** Solve for the unknown number of years in each of the following:

Present Value	Years	Interest Rate	Future Value
\$ 250		9%	\$ 1,105
1,941		7	3,700
32,805		12	387,120
32,500		19	198,212

- L0 3** 6. **Calculating Interest Rates.** Assume the total cost of a college education will be \$320,000 when your child enters college in 18 years. You presently have \$50,000 to invest. What annual rate of interest must you earn on your investment to cover the cost of your child's college education?
- L0 4** 7. **Calculating the Number of Periods.** At 7 percent interest, how long does it take to double your money? To quadruple it?
- L0 3** 8. **Calculating Rates of Return.** In 2009, an 1893 Morgan silver dollar sold for \$6,450. What was the rate of return on this investment?
- L0 4** 9. **Calculating the Number of Periods.** You're trying to save to buy a new \$160,000 Ferrari. You have \$25,000 today that can be invested at your bank. The bank pays 3.2 percent annual interest on its accounts. How long will it be before you have enough to buy the car?
- L0 2** 10. **Calculating Present Values.** Imprudential, Inc., has an unfunded pension liability of \$750 million that must be paid in 25 years. To assess the value of the firm's stock, financial analysts want to discount this liability back to the present. If the relevant discount rate is 8 percent, what is the present value of this liability?
- L0 2** 11. **Calculating Present Values.** You have just received notification that you have won the \$2 million first prize in the Centennial Lottery. However, the prize will be awarded on your 100th birthday (assuming you're around to collect), 80 years from now. What is the present value of your windfall if the appropriate discount rate is 9 percent?
- L0 1** 12. **Calculating Future Values.** Your coin collection contains 50 1952 silver dollars. If your grandparents purchased them for their face value when they were new, how much will your collection be worth when you retire in 2062, assuming they appreciate at a 5.7 percent annual rate?
- L0 1** 13. **Calculating Interest Rates and Future Values.** In 1895, the first U.S. Open Golf Championship was held. The winner's prize money was \$150. In 2009, the winner's check was \$1,350,000. What was the annual percentage increase in the winner's check over this period? If the winner's prize increases at the same rate, what will it be in 2045?
- L0 3** 14. **Calculating Rates of Return.** In 2009, a \$5 silver certificate from 1896 was sold for \$10,500. For this to have been true, what was the annual increase in the value of the certificate?
- L0 3** 15. **Calculating Rates of Return.** Although appealing to more refined tastes, art as a collectible has not always performed so profitably. During 2003, Sotheby's sold the Edgar Degas bronze sculpture *Petite danseuse de quatorze ans* at auction for a price of \$10,311,500. Unfortunately for the previous owner, he had purchased it in 1999 at a price of \$12,377,500. What was his annual rate of return on this sculpture?

Intermediate

(Questions 16–25)

L0 3

16. Calculating Rates of Return. Referring to the TMCC security we discussed at the very beginning of the chapter:

- Based on the \$24,099 price, what rate was TMCC paying to borrow money?
- Suppose that, on March 28, 2016, this security's price is \$39,583. If an investor had purchased it for \$24,099 at the offering and sold it on this day, what annual rate of return would she have earned?
- If an investor had purchased the security at market on March 28, 2016, and held it until it matured, what annual rate of return would she have earned?

L0 2

17. Calculating Present Values. Suppose you are still committed to owning a \$160,000 Ferrari (see Question 9). If you believe your mutual fund can achieve a 10.25 percent annual rate of return, and you want to buy the car in 10 years on the day you turn 30, how much must you invest today?

**L0 1**

18. Calculating Future Values. You have just made your first \$5,000 contribution to your individual retirement account. Assuming you earn a 10.5 percent rate of return and make no additional contributions, what will your account be worth when you retire in 45 years? What if you wait 10 years before contributing? (Does this suggest an investment strategy?)

L0 1

19. Calculating Future Values. You are scheduled to receive \$13,000 in two years. When you receive it, you will invest it for six more years at 9 percent per year. How much will you have in eight years?

L0 4

20. Calculating the Number of Periods. You expect to receive \$25,000 at graduation in two years. You plan on investing it at 9 percent until you have \$160,000. How long will you wait from now? (Better than the situation in Question 9, but still no Ferrari.)

L0 1

21. Calculating Future Values. You have \$9,000 to deposit. Regency Bank offers 12 percent per year compounded monthly (1 percent per month), while King Bank offers 12 percent but will only compound annually. How much will your investment be worth in 20 years at each bank?

L0 3

22. Calculating Interest Rates. An investment offers to quadruple your money in 24 months (don't believe it). What rate per three months are you being offered?

L0 4

23. Calculating the Number of Periods. You can earn 0.35 percent per month at your bank. If you deposit \$1,800, how long must you wait until your account has grown to \$3,500?

L0 2

24. Calculating Present Values. You need \$75,000 in 10 years. If you can earn 0.42 percent per month, how much will you have to deposit today?

L0 2

25. Calculating Present Values. You have decided that you want to be a millionaire when you retire in 45 years. If you can earn an 11 percent annual return, how much do you have to invest today? What if you can earn 5.5 percent?

L0 1

26. Calculating Future Values. You have \$15,000 you want to invest for the next 40 years. You are offered an investment plan that will pay you 8 percent per year for the next 20 years and 12 percent per year for the last 20 years. How much will you have at the end of the 40 years? Does it matter if the investment plan pays you 12 percent per year for the first 20 years and 8 percent per year for the next 20 years? Why or why not?

Challenge

(Question 26)

**WHAT'S ON
THE WEB?**

- 4.1 Calculating Future Values.** Go to www.dinkytown.net and find the “Savings Calculator” calculator. If you currently have \$10,000 and invest this money at 9 percent, how much will you have in 30 years? Assume you will not make any additional contributions. How much will you have if you can earn 11 percent?
- 4.2 Calculating the Number of Periods.** Go to www.dinkytown.net and find the “Cool Million” calculator. You want to be a millionaire. You can earn 11.5 percent per year. Using your current age, at what age will you become a millionaire if you have \$25,000 to invest, assuming you make no other deposits (ignore inflation)?
- 4.3 Calculating the Number of Periods.** Go to www.moneychimp.com and find the “Compound Interest” calculator. You want to buy a Lamborghini Murciélago. Assume the price of the car is \$330,000 and you have \$35,000. If you can earn an 11 percent return, how long must you wait to buy this car (assuming the price stays the same)?
- 4.4 Calculating Rates of Return.** Use the Return Rate calculator at www.moneychimp.com to solve the following problem. You still want to buy the Lamborghini Murciélago, but you have \$60,000 to invest and want to buy the car in 15 years. What interest rate do you have to earn to accomplish this (assuming the price stays the same)?
- 4.5 Future Values and Taxes.** Taxes can greatly affect the future value of your investment. The Financial Calculators Web site at www.fincalc.com has a financial calculator that adjusts your return for taxes. Go to this page and find this calculator. Suppose you have \$50,000 to invest today. If you can earn a 12 percent return, and you have no additional savings, how much will you have in 20 years? (Enter 0 percent as the tax rate.) Now, assume that your marginal tax rate is 27.5 percent. How much will you have at this tax rate?

Discounted Cash Flow Valuation

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- L0 1** Determine the future and present value of investments with multiple cash flows.
- L0 2** Calculate loan payments and find the interest rate on a loan.
- L0 3** Describe how loans are amortized or paid off.
- L0 4** Explain how interest rates are quoted (and misquoted).

Visit us at www.mhhe.com/rwj

What do baseball players Jason Varitek, Mark Teixeira, and C. C. Sabathia have in common? All three athletes signed big contracts in late 2008 or early 2009. The contract values were reported as \$10 million, \$180 million, and \$161.5 million, respectively. That's definitely major league money, but, even so, reported numbers like these can be misleading. For example, in February 2009, Varitek signed with the Boston Red Sox. His contract called for a salary of \$5 million with a club option for \$5 million for 2010, for a total of

\$10 million. Not Teixeira or Sabathia money, but still not too shabby for someone who makes a living using the "tools of ignorance" (jock jargon for a catcher's equipment).

A closer look at the numbers shows that Jason, Mark, and C. C. did pretty well, but nothing like the quoted figures. Using Mark's contract as an example, although the value was reported to be \$180 million, it was actually payable over several years. It consisted of a \$5 million signing bonus plus \$175 million in future salaries and bonuses. The \$175 million was to be distributed as \$20 million per year in 2009 and 2010 and \$22.5 million per year for 2011 through 2016. Because the payments were spread out over time, we must consider the time value of money, which means his contract was worth less than reported. How much did he really get? This chapter gives you the "tools of knowledge" to answer this question.

In our previous chapter, we learned how to examine single, lump-sum future payments to determine their current, or present, value. This is a useful skill, but we need to go further and figure out how to handle multiple future payments because that is the much more common situation. For example, most loans (including student loans) involve receiving a lump sum today and making future payments.

More generally, most types of business decisions, including decisions concerning marketing, operations, and strategy, involve the comparison of costs incurred today with cash inflows hoped for later. Evaluating the cost-benefit trade-off requires the tools that we develop in this chapter.

Because discounted cash flow valuation is so important, students who learn this material well will find that life is much easier down the road. Getting it straight now will save you a lot of headaches later.

In our previous chapter, we covered the basics of discounted cash flow valuation. However, so far, we have only dealt with single cash flows. In reality, most investments have multiple cash flows. For example, if Sears is thinking of opening a new department store, there will be a large cash outlay in the beginning and then cash inflows for many years. In this chapter, we begin to explore how to value such investments.

When you finish this chapter, you should have some very practical skills. For example, you will know how to calculate your own car payments or student loan payments. You will also be able to determine how long it will take to pay off a credit card if you make the minimum payment each month (a practice we do not recommend). We will show you how to compare interest rates to determine which are the highest and which are the lowest, and we will also show you how interest rates can be quoted in different, and at times deceptive, ways.

FUTURE AND PRESENT VALUES OF MULTIPLE CASH FLOWS

5.1

Thus far, we have restricted our attention to either the future value of a lump-sum present amount or the present value of some single future cash flow. In this section, we begin to study ways to value multiple cash flows. We start with future value.

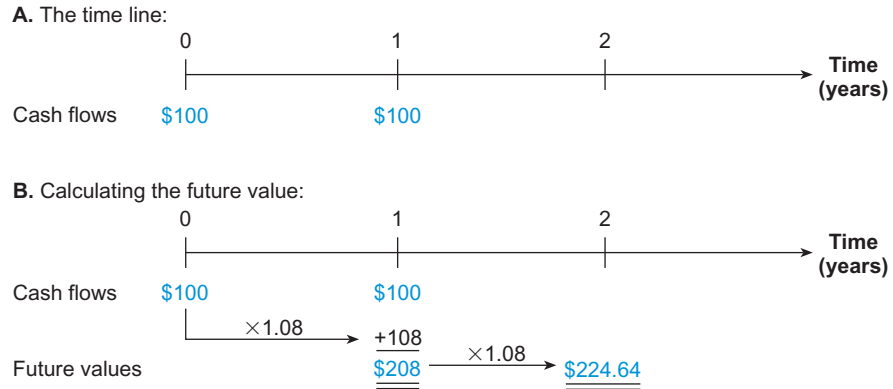

Future Value with Multiple Cash Flows

Suppose you deposit \$100 today in an account paying 8 percent. In one year, you will deposit another \$100. How much will you have in two years? This particular problem is relatively easy. At the end of the first year, you will have \$108 plus the second \$100 you deposit, for a total of \$208. You leave this \$208 on deposit at 8 percent for another year. At the end of this second year, the account is worth:

$$\text{\$208} \times \text{1.08} = \text{\$224.64}$$

Figure 5.1 is a *time line* that illustrates the process of calculating the future value of these two \$100 deposits. Figures such as this one are very useful for solving complicated problems. Anytime you are having trouble with a present or future value problem, drawing a time line will usually help you to see what is happening.

In the first part of Figure 5.1, we show the cash flows on the time line. The most important thing is that we write them down where they actually occur. Here, the first cash flow occurs today, which we label as Time 0. We therefore put **\$100** at Time 0 on the time

FIGURE 5.1**Drawing and using a time line**

line. The second \$100 cash flow occurs one year from today, so we write it down at the point labeled as Time 1. In the second part of Figure 5.1, we calculate the future values one period at a time to come up with the final \$224.64.

EXAMPLE 5.1**Saving Up Revisited**

You think you will be able to deposit \$4,000 at the end of each of the next three years in a bank account paying 8 percent interest. You currently have \$7,000 in the account. How much will you have in three years? In four years?

At the end of the first year, you will have:

$$\$7,000 \times 1.08 + 4,000 = \$11,560$$

At the end of the second year, you will have:

$$\$11,560 \times 1.08 + 4,000 = \$16,484.80$$

Repeating this for the third year gives:

$$\$16,484.80 \times 1.08 + 4,000 = \$21,803.58$$

Therefore, you will have \$21,803.58 in three years. If you leave this on deposit for one more year (and don't add to it), at the end of the fourth year, you'll have:

$$\$21,803.58 \times 1.08 = \$23,547.87$$

When we calculated the future value of the two \$100 deposits, we simply calculated the balance as of the beginning of each year and then rolled that amount forward to the next year. We could have done it another, quicker way. The first \$100 is on deposit for two years at 8 percent, so its future value is:

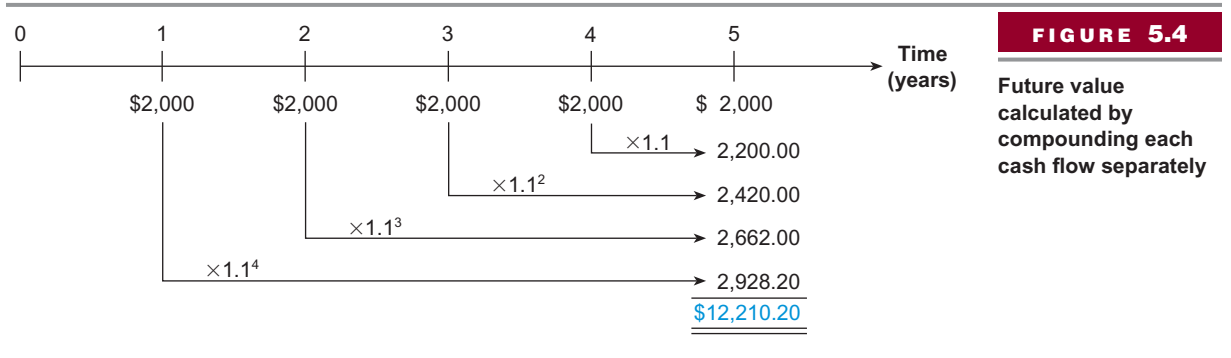

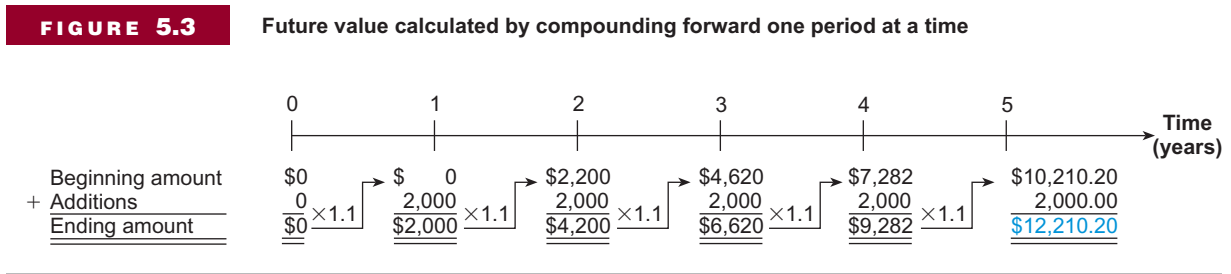

$$\mathbf{\$100 \times 1.08^2 = \$100 \times 1.1664 = \$116.64}$$

The second \$100 is on deposit for one year at 8 percent, and its future value is thus:

$$\mathbf{\$100 \times 1.08 = \$108.00}$$

The total future value, as we previously calculated, is equal to the sum of these two future values:

$$\mathbf{\$116.64 + 108 = \$224.64}$$

Based on this example, there are two ways to calculate future values for multiple cash flows: (1) compound the accumulated balance forward one year at a time or (2) calculate the future value of each cash flow first and then add these up. Both give the same answer, so you can do it either way.

To illustrate the two different ways of calculating future values, consider the future value of \$2,000 invested at the end of each of the next five years. The current balance is zero, and the rate is 10 percent. We first draw a time line as shown in Figure 5.2.

On the time line, notice that nothing happens until the end of the first year when we make the first \$2,000 investment. This first \$2,000 earns interest for the next four (not five) years. Also notice that the last \$2,000 is invested at the end of the fifth year, so it earns no interest at all.

Figure 5.3 illustrates the calculations involved if we compound the investment one period at a time. As illustrated, the future value is \$12,210.20.

Figure 5.4 goes through the same calculations, but it uses the second technique. Naturally, the answer is the same.

EXAMPLE 5.2**Saving Up Once Again**

If you deposit \$100 in one year, \$200 in two years, and \$300 in three years, how much will you have in three years? How much of this is interest? How much will you have in five years if you don't add additional amounts? Assume a 7 percent interest rate throughout.

We will calculate the future value of each amount in three years. Notice that the \$100 earns interest for two years, and the \$200 earns interest for one year. The final \$300 earns no interest. The future values are thus:

$$\begin{array}{rcl}
 \$100 \times 1.07^2 & = & \$114.49 \\
 \$200 \times 1.07 & = & 214.00 \\
 + \$300 & = & \underline{300.00} \\
 \text{Total future value} & = & \underline{\underline{\$628.49}}
 \end{array}$$

The future value is thus \$628.49. The total interest is:

$$\$628.49 - (100 + 200 + 300) = \$28.49$$

How much will you have in five years? We know that you will have \$628.49 in three years. If you leave that in for two more years, it will grow to:

$$\$628.49 \times 1.07^2 = \$628.49 \times 1.1449 = \$719.56$$

Notice that we could have calculated the future value of each amount separately. Once again, be careful about the lengths of time. As we previously calculated, the first \$100 earns interest for only four years, the second deposit earns three years' interest, and the last earns two years' interest:

$$\begin{array}{rcl}
 \$100 \times 1.07^4 & = & \$100 \times 1.3108 = \$131.08 \\
 \$200 \times 1.07^3 & = & \$200 \times 1.2250 = 245.01 \\
 + \$300 \times 1.07^2 & = & \$300 \times 1.1449 = \underline{343.47} \\
 \text{Total future value} & = & \underline{\underline{\$719.56}}
 \end{array}$$

Present Value with Multiple Cash Flows

It will turn out that we will very often need to determine the present value of a series of future cash flows. As with future values, there are two ways we can do it. We can either discount back one period at a time, or we can just calculate the present values individually and add them up.

Suppose you need \$1,000 in one year and \$2,000 more in two years. If you can earn 9 percent on your money, how much do you have to put up today to exactly cover these amounts in the future? In other words, what is the present value of the two cash flows at 9 percent?

The present value of \$2,000 in two years at 9 percent is:

$$\mathbf{\$2,000/1.09^2 = \$1,683.36}$$

The present value of \$1,000 in one year is:

$$\mathbf{\$1,000/1.09 = \$917.43}$$

Therefore, the total present value is:

$$\mathbf{\$1,683.36 + 917.43 = \$2,600.79}$$

To see why \$2,600.79 is the right answer, we can check to see that after the \$2,000 is paid out in two years, there is no money left. If we invest \$2,600.79 for one year at

9 percent, we will have:

$$\mathbf{\$2,600.79 \times 1.09 = \$2,834.86}$$

We take out \$1,000, leaving \$1,834.86. This amount earns 9 percent for another year, leaving us with:

$$\mathbf{\$1,834.86 \times 1.09 = \$2,000}$$

This is just as we planned. As this example illustrates, the present value of a series of future cash flows is simply the amount that you would need today in order to exactly duplicate those future cash flows (for a given discount rate).

An alternative way of calculating present values for multiple future cash flows is to discount back to the present one period at a time. To illustrate, suppose we had an investment that was going to pay \$1,000 at the end of every year for the next five years. To find the present value, we could discount each \$1,000 back to the present separately and then add the results up. Figure 5.5 illustrates this approach for a 6 percent discount rate. As shown, the answer is **\$4,212.37** (ignoring a small rounding error).

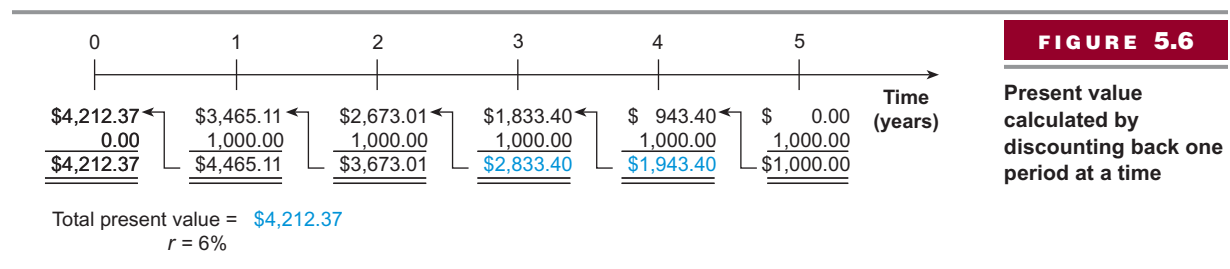

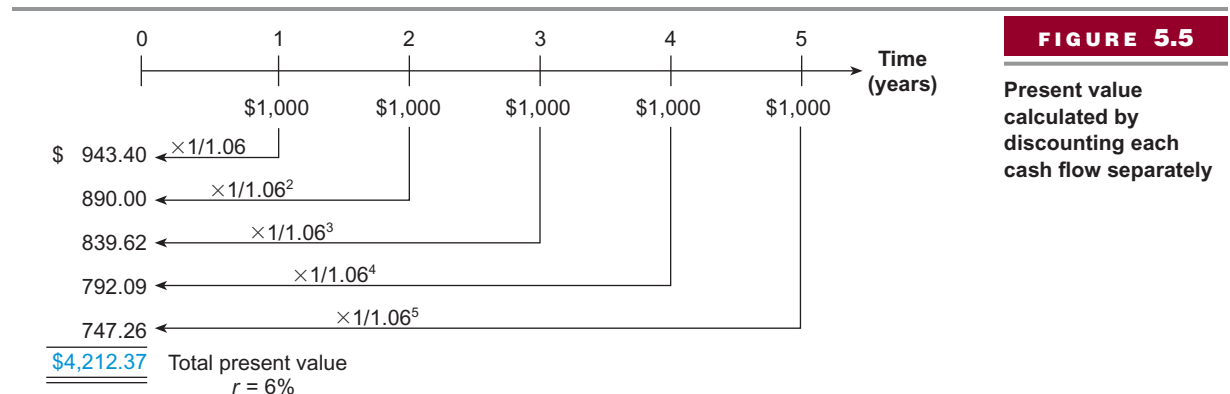

Alternatively, we could discount the last cash flow back one period and add it to the next-to-the-last cash flow:

$$\mathbf{\$1,000/1.06 + 1,000 = \$943.40 + 1,000 = \$1,943.40}$$

We could then discount this amount back one period and add it to the Year 3 cash flow:

$$\mathbf{\$1,943.40/1.06 + 1,000 = \$1,833.40 + 1,000 = \$2,833.40}$$

This process could be repeated as necessary. Figure 5.6 illustrates this approach and the remaining calculations.

Jackpot!

If you, or someone you know, is a regular lottery player, you probably already understand that you are 20 times more likely to be killed by a lightning bolt than to win a big lottery jackpot. How bad are the odds? Nearby you will find a table comparing your chances of winning the Mega Millions Lottery to other events.

Big Game: Is It Worth the Gamble?	
Odds of winning Mega Millions jackpot	1:135,145,920*
Odds of being killed by a venomous spider	1:57,018,763
Odds of being killed by a dog bite	1:11,403,753
Odds of being killed by lightning	1:6,479,405
Odds of being killed by drowning	1:690,300
Odds of being killed by falling from a bed or other furniture	1:388,411
Odds of being killed in a car crash	1:6,029

*Source: Virginia Lottery Web site. All other odds from the National Safety Council.

Sweepstakes may have different odds than lotteries, but the odds may not be much better. Probably the largest advertised grand prize ever was Pepsi's "Play for a Billion," which, you guessed it, had a \$1 billion (*billion!*) prize. Not bad for a day's work, but you still have to read the fine print. It turns out that the winner would be paid \$5 million per year for the next 20 years, \$10 million per year for years 21 to 39, and a lump sum of \$710 million in 40 years. From what you have learned, you

know the value of the sweepstakes wasn't even close to \$1 billion. In fact, at an interest rate of 10 percent, the present value was about \$70.7 million.

Lottery jackpots are often paid out over 20 or more years, but the winner can usually choose to take a lump sum cash payment instead. For example, in 2009, a group of lottery players from Ohio won the \$163.2 million Powerball lottery. The group had the option of a single cash payment of \$97.97 million or payments over the next 30 years, which is what the group chose to accept.

Some lotteries make your decision a little tougher. The Ontario Lottery will pay you either \$2,000 a week for the rest of your life or \$1.3 million now. (That's in Canadian dollars, by the way.) Of course, there is the chance you might die in the near future, so the lottery guarantees that your heirs will collect the \$2,000 weekly payments until the 20th anniversary of the first payment, or until you would have turned 91, whichever comes first. This payout scheme complicates your decision quite a bit. If you live for only the 20-year minimum, the break-even interest rate between the two options is about 5.13 percent per year, compounded weekly. If you expect to live longer than the 20-year minimum, you might be better off accepting \$2,000 per week for life. Of course, if you manage to invest the \$1.3 million lump sum at a rate of return of about 8 percent per year (compounded weekly), you can have your cake and eat it too since the investment will return \$2,000 at the end of each week forever! Taxes complicate the decision in this case because the lottery payments are all on an aftertax basis. Thus, the rates of return in this example would have to be aftertax as well.

As the accompanying *Reality Bytes* box shows, calculating present values is a vital step in comparing alternative cash flows. We will have much more to say on this subject in subsequent chapters.

EXAMPLE 5.3

How Much Is It Worth?

You are offered an investment that will pay you \$200 in one year, \$400 the next year, \$600 the next year, and \$800 at the end of the next year. You can earn 12 percent on very similar investments. What is the most you should pay for this one?

We need to calculate the present value of these cash flows at 12 percent. Taking them one at a time gives:

$$\begin{aligned}
 \$200 \times 1/1.12^1 &= \$200/1.1200 = \$178.57 \\
 \$400 \times 1/1.12^2 &= \$400/1.2544 = 318.88 \\
 \$600 \times 1/1.12^3 &= \$600/1.4049 = 427.07 \\
 +\$800 \times 1/1.12^4 &= \$800/1.5735 = 508.41 \\
 \text{Total present value} &= \underline{\underline{\$1,432.93}}
 \end{aligned}$$

(continued)

If you can earn 12 percent on your money, then you can duplicate this investment's cash flows for \$1,432.93, so this is the most you should be willing to pay.

How Much Is It Worth? Part 2

EXAMPLE 5.4

You are offered an investment that will make three \$5,000 payments. The first payment will occur four years from today. The second will occur in five years, and the third will follow in six years. If you can earn 11 percent, what is the most this investment is worth today? What is the future value of the cash flows?

We will answer the questions in reverse order to illustrate a point. The future value of the cash flows in six years is:

$$\begin{aligned} \$5,000 \times 1.11^2 + \$5,000 \times 1.11 + \$5,000 &= \$6,160.50 + 5,550 + 5,000 \\ &= \$16,710.50 \end{aligned}$$

The present value must be:

$$\$16,710.50 / 1.11^6 = \$8,934.12$$

Let's check this. Taking them one at a time, the PVs of the cash flows are:

$$\begin{aligned} \$5,000 \times 1/1.11^6 &= \$5,000/1.8704 = \$2,673.20 \\ \$5,000 \times 1/1.11^5 &= \$5,000/1.6851 = 2,967.26 \\ + \$5,000 \times 1/1.11^4 &= \$5,000/1.5181 = \underline{3,293.65} \\ \text{Total present value} &= \underline{\underline{\$8,934.12}} \end{aligned}$$

This is as we previously calculated. The point we want to make is that we can calculate present and future values in any order and convert between them using whatever way seems most convenient. The answers will always be the same as long as we stick with the same discount rate and are careful to keep track of the right number of periods.

How to Calculate Present Values with Multiple Future Cash Flows Using a Financial Calculator

CALCULATOR HINTS

To calculate the present value of multiple cash flows with a financial calculator, we will simply discount the individual cash flows one at a time using the same technique we used in our previous chapter, so this is not really new. There is a shortcut, however, that we can show you. We will use the numbers in Example 5.3 to illustrate.

To begin, of course, we first remember to clear out the calculator! Next, from Example 5.3, the first cash flow is \$200 to be received in one year and the discount rate is 12 percent, so we do the following:

Enter	1	12		200
	N	I/Y	PMT	FV
Solve for			PV	
			-178.57	

Now, you can write down this answer to save it, but that's inefficient. All calculators have a memory where you can store numbers. Why not just save it there? Doing so cuts way down on mistakes because you don't have to write down and/or rekey numbers, and it's much faster.

Next, we value the second cash flow. We need to change N to 2 and FV to 400. As long as we haven't changed anything else, we don't have to reenter I/Y or clear out the calculator, so we have:

Enter

2

400

N

I/Y

PMT

PV

FV

Solve for

-318.88

You save this number by adding it to the one you saved in our first calculation, and so on for the remaining two calculations.

As we will see in a later chapter, some financial calculators will let you enter all of the future cash flows at once, but we'll discuss that subject when we get to it.

A Note on Cash Flow Timing

In working present and future value problems, cash flow timing is critically important. In almost all such calculations, it is implicitly assumed that the cash flows occur at the end of each period. In fact, all the formulas we have discussed, all the numbers in a standard present value or future value table, and, very importantly, all the preset (or default) settings on a financial calculator or spreadsheet assume that cash flows occur at the end of each period. Unless you are very explicitly told otherwise, you should always assume that this is what is meant.

As a quick illustration of this point, suppose you are told that a three-year investment has a first-year cash flow of \$100, a second-year cash flow of \$200, and a third-year cash flow of \$300. You are asked to draw a time line. Without further information, you should always assume that the time line looks like this:

On our time line, notice how the first cash flow occurs at the end of the first period, the second at the end of the second period, and the third at the end of the third period.

We will close out this section by answering the question we posed at the beginning of the chapter concerning baseball player Mark Teixeira's contract. Remember that the contract called for a signing bonus of \$5 million to be paid immediately, plus a salary of \$175 million to be distributed as \$20 million per year in 2009 and 2010 and \$22.5 million per year for 2011 through 2016. If 12 percent is the appropriate discount rate, what kind of deal did the New York Yankee's first baseman field?

To answer, we can calculate the present value by discounting each year's salary back to the present as follows (notice we assumed the future salaries will be paid at the end of the year):

Year 0:	\$5,000,000	= \$5,000,000
Year 1:	$20,000,000 \times 1/1.12$	= \$17,857,142.86
Year 2:	$20,000,000 \times 1/1.12^2$	= \$15,943,877.55
.	.	.
.	.	.
.	.	.
Year 8:	$22,500,000 \times 1/1.12^8$	= \$9,087,372.63

If you fill in the missing rows and then add (do it for practice), you will see that Teixeira's contract had a present value of about \$112.55 million, or only about 63 percent of the \$180 million reported value, but still pretty good.

How to Calculate Present Values with Multiple Future Cash Flows Using a Spreadsheet

SPREADSHEET STRATEGIES

Just as we did in our previous chapter, we can set up a basic spreadsheet to calculate the present values of the individual cash flows as follows. Notice that we have simply calculated the present values one at a time and added them up.

	A	B	C	D	E	F
1						
2	Using a spreadsheet to value multiple cash flows					
3						
4	What is the present value of \$200 in one year, \$400 the next year, \$600 the next year, and					
5	\$800 the last year if the discount rate is 12 percent?					
6						
7	Rate:	.12				
8						
9	Year	Cash flows	Present values	Formula used		
10	1	\$200	\$178.57	=PV(\$B\$7,A10,0,-B10)		
11	2	\$400	\$318.88	=PV(\$B\$7,A11,0,-B11)		
12	3	\$600	\$427.07	=PV(\$B\$7,A12,0,-B12)		
13	4	\$800	\$508.41	=PV(\$B\$7,A13,0,-B13)		
14						
15		Total PV:	\$1,432.93	=SUM(C10:C13)		
16						
17	Notice the negative signs inserted in the PV formulas. These just make the present values have					
18	positive signs. Also, the discount rate in cell B7 is entered as \$B\$7 (an "absolute" reference)					
19	because it is used over and over. We could have just entered ".12" instead, but our approach is					
20	more flexible.					
21						
22						

CONCEPT QUESTIONS

- 5.1a** Describe how to calculate the future value of a series of cash flows.
- 5.1b** Describe how to calculate the present value of a series of cash flows.
- 5.1c** Unless we are explicitly told otherwise, what do we always assume about the timing of cash flows in present and future value problems?

5.2

VALUING LEVEL CASH FLOWS: ANNUITIES AND PERPETUITIES

We will frequently encounter situations where we have multiple cash flows that are all the same amount. For example, a very common type of loan repayment plan calls for the borrower to repay the loan by making a series of equal payments for some length of time. Almost all consumer loans (such as car loans) and home mortgages feature equal payments, usually made each month.

More generally, a series of constant, or level, cash flows that occur at the end of each period for some fixed number of periods is called an ordinary **annuity**; or, more correctly, the cash flows are said to be in ordinary annuity form. Annuities appear very frequently in financial arrangements, and there are some useful shortcuts for determining their values. We consider these next.

annuity

A level stream of cash flows for a fixed period of time.

Present Value for Annuity Cash Flows

Suppose we were examining an asset that promised to pay \$500 at the end of each of the next three years. The cash flows from this asset are in the form of a three-year, \$500 ordinary annuity. If we wanted to earn 10 percent on our money, how much would we offer for this annuity?

From the previous section, we know that we can discount each of these \$500 payments back to the present at 10 percent to determine the total present value:

$$\begin{aligned}
 \text{Present value} &= \$500/1.1^1 + 500/1.1^2 + 500/1.1^3 \\
 &= \$500/1.10 + 500/1.21 + 500/1.331 \\
 &= \$454.55 + 413.22 + 375.66 \\
 &= \$1,243.43
 \end{aligned}$$

This approach works just fine. However, we will often encounter situations where the number of cash flows is quite large. For example, a typical home mortgage calls for monthly payments over 30 years, for a total of 360 payments. If we were trying to determine the present value of those payments, it would be useful to have a shortcut.

Since the cash flows on an annuity are all the same, we can come up with a very useful variation on the basic present value equation. It turns out that the present value of an annuity of C dollars per period for t periods when the rate of return, or interest rate, is r is given by:

$$\begin{aligned}
 \text{Annuity present value} &= C \times \left(\frac{1 - \text{Present value factor}}{r} \right) \\
 &= C \times \left\{ \frac{1 - [1/(1 + r)^t]}{r} \right\}
 \end{aligned} \tag{5.1}$$

The term in parentheses on the first line is sometimes called the present value interest factor for annuities and abbreviated PVIFA(r, t).

The expression for the annuity present value may look a little complicated, but it isn't difficult to use. Notice that the term in square brackets on the second line, $1/(1 + r)^t$, is the same present value factor we've been calculating. In our example just above, the interest rate is 10 percent and there are three years involved. The usual present value factor is thus:

$$\text{Present value factor} = 1/1.1^3 = 1/1.331 = .75131$$

Number of Periods	Interest Rates			
	5%	10%	15%	20%
1	.9524	.9091	.8696	.8333
2	1.8594	1.7355	1.6257	1.5278
3	2.7232	2.4869	2.2832	2.1065
4	3.5460	3.1699	2.8550	2.5887
5	4.3295	3.7908	3.3522	2.9906

TABLE 5.1**Annuity present value
interest factors**

To calculate the annuity present value factor, we just plug this in:

$$\begin{aligned}
 \text{Annuity present value factor} &= (1 - \text{Present value factor})/r \\
 &= (1 - .75131)/.10 \\
 &= .248685/.10 = 2.48685
 \end{aligned}$$

Just as we calculated before, the present value of our \$500 annuity is then:

$$\text{Annuity present value} = \$500 \times 2.48685 = \$1,243.43$$

How Much Can You Afford?

EXAMPLE 5.5

After carefully going over your budget, you have determined you can afford to pay \$632 per month toward a new sports car. You call up your local bank and find out that the going rate is 1 percent per month for 48 months. How much can you borrow?

To determine how much you can borrow, we need to calculate the present value of \$632 per month for 48 months at 1 percent per month. The loan payments are in ordinary annuity form, so the annuity present value factor is:

$$\begin{aligned}
 \text{Annuity PV factor} &= (1 - \text{Present value factor})/r \\
 &= [1 - (1/1.01^{48})]/.01 \\
 &= (1 - .6203)/.01 = 37.9740
 \end{aligned}$$

With this factor, we can calculate the present value of the 48 payments of \$632 each as:

$$\text{Present value} = \$632 \times 37.9740 = \$24,000$$

Therefore, \$24,000 is what you can afford to borrow and repay.

Annuity Tables Just as there are tables for ordinary present value factors, there are tables for annuity factors as well. Table 5.1 contains a few such factors; Table A.3 in Appendix A contains a larger set. To find the annuity present value factor we just calculated, look for the row corresponding to three periods and then find the column for 10 percent. The number you see at that intersection should be 2.4869 (rounded to four decimal places), as we calculated. Once again, try calculating a few of these factors yourself and compare your answers to the ones in the table to make sure you know how to do it. If you are using a financial calculator, just enter \$1 as the payment and calculate the present value; the result should be the annuity present value factor.

In this case, we know that the present value is \$100,000. The interest rate is 18 percent, and there are five years to make payments. The payments are all equal, so we need to find the relevant annuity factor and solve for the unknown cash flow:

$$\begin{aligned}\text{Annuity present value} &= \$100,000 = C \times (1 - \text{Present value factor})/r \\ \$100,000 &= C \times (1 - 1/1.18^5)/.18 \\ &= C \times (1 - .4371)/.18 \\ &= C \times 3.1272 \\ C &= \$100,000/3.1272 = \$31,978\end{aligned}$$

Therefore, you'll make five payments of just under \$32,000 each.

Annuity Payments

Finding annuity payments is easy with a financial calculator. In our example just above, the PV is \$100,000, the interest rate is 18 percent, and there are five years. We find the payment as follows:

CALCULATOR HINTS

Enter	5	18	100,000		
	N	I/Y	PMT	PV	FV
Solve for			-31,978		

Here we get a negative sign on the payment because the payment is an outflow for us.

Annuity Payments

Using a spreadsheet to work the same problem goes like this:

SPREADSHEET STRATEGIES

[illegible]

EXAMPLE 5.6**Finding the Number of Payments**

You ran a little short on your spring break vacation, so you put \$1,000 on your credit card. You can only afford to make the minimum payment of \$20 per month. The interest rate on the credit card is 1.5 percent per month. How long will you need to pay off the \$1,000?

What we have here is an annuity of \$20 per month at 1.5 percent per month for some unknown length of time. The present value is \$1,000 (the amount you owe today). We need to do a little algebra (or else use a financial calculator):

$$\begin{aligned} \$1,000 &= \$20 \times (1 - \text{Present value factor})/.015 \\ (\$1,000/20) \times .015 &= 1 - \text{Present value factor} \\ \text{Present value factor} &= .25 = 1/(1 + r)^t \\ 1.015^t &= 1/.25 = 4 \end{aligned}$$

At this point, the problem boils down to asking the following question: How long does it take for your money to quadruple at 1.5 percent per month? Based on our previous chapter, the answer is about 93 months:

$$1.015^{93} = 3.99 \approx 4$$

It will take you about $93/12 = 7.75$ years at this rate.

CALCULATOR HINTS**Finding the Number of Payments**

To solve this one on a financial calculator, do the following:

Enter	1.5	-20	1,000	
	N	I/Y	PMT	PV
Solve for	93.11			

Notice that we put a negative sign on the payment you must make, and we have solved for the number of months. You still have to divide by 12 to get our answer. Also, some financial calculators won't report a fractional value for N; they automatically (without telling you) round up to the next whole period (not to the nearest value). With a spreadsheet, use the function = NPER(rate,pmt,pv,fv); be sure to put in a zero for fv and to enter -20 as the payment.

Finding the Rate The last question we might want to ask concerns the interest rate implicit in an annuity. For example, an insurance company offers to pay you \$1,000 per year for 10 years if you pay \$6,710 up front. What rate is implicit in this 10-year annuity?

In this case, we know the present value (\$6,710), we know the cash flows (\$1,000 per year), and we know the life of the investment (10 years). What we don't know is the discount rate:

$$\begin{aligned} \$6,710 &= \$1,000 \times (1 - \text{Present value factor})/r \\ \$6,710/1,000 &= 6.71 = \{1 - [1/(1 + r)^{10}]\}/r \end{aligned}$$

So, the annuity factor for 10 periods is equal to 6.71, and we need to solve this equation for the unknown value of r . Unfortunately, this is mathematically impossible to do directly. The only way to do it is to use a table or trial and error to find a value for r .

If you look across the row corresponding to 10 periods in Table A.3, you will see a factor of 6.7101 for 8 percent, so we see right away that the insurance company is offering just about 8 percent. Alternatively, we could just start trying different values until we got very close to the answer. Using this trial-and-error approach can be a little tedious, but, fortunately, machines are good at that sort of thing.¹

To illustrate how to find the answer by trial and error, suppose a relative of yours wants to borrow \$3,000. She offers to repay you \$1,000 every year for four years. What interest rate are you being offered?

The cash flows here have the form of a four-year, \$1,000 annuity. The present value is \$3,000. We need to find the discount rate, r . Our goal in doing so is primarily to give you a feel for the relationship between annuity values and discount rates.

We need to start somewhere, and 10 percent is probably as good a place as any to begin. At 10 percent, the annuity factor is:

$$\text{Annuity present value factor} = (1 - 1/1.10^4)/.10 = 3.1699$$

The present value of the cash flows at 10 percent is thus:

$$\text{Present value} = \$1,000 \times 3.1699 = \$3,169.90$$

You can see that we're already in the right ballpark.

Is 10 percent too high or too low? Recall that present values and discount rates move in opposite directions: Increasing the discount rate lowers the PV and vice versa. Our present value here is too high, so the discount rate is too low. If we try 12 percent:

$$\text{Present value} = \$1,000 \times (1 - 1/1.12^4)/.12 = \$3,037.35$$

Now we're almost there. We are still a little low on the discount rate (because the PV is a little high), so we'll try 13 percent:

$$\text{Present value} = \$1,000 \times (1 - 1/1.13^4)/.13 = \$2,974.47$$

This is less than \$3,000, so we now know that the answer is between 12 percent and 13 percent, and it looks to be about 12.5 percent. For practice, work at it for a while longer and see if you find that the answer is about 12.59 percent.

Finding the Rate

Alternatively, you could use a financial calculator to do the following:

Enter	4	1,000	-3,000		
	N	I/Y	PMT	PV	FV
Solve for		12.59			

Notice that we put a negative sign on the present value (why?). With a spreadsheet, use the function $\text{=RATE}(\text{nper}, \text{pmt}, \text{pv}, \text{fv})$; be sure to put in a zero for fv and to enter 1,000 as the payment and -3,000 as the present value.

**CALCULATOR
HINTS**

¹ Financial calculators rely on trial and error to find the answer. That's why they sometimes appear to be "thinking" before coming up with the answer. Actually, it is possible to directly solve for r if there are fewer than five periods, but it's usually not worth the trouble.

Future Value for Annuities

On occasion, it's also handy to know a shortcut for calculating the future value of an annuity. As you might guess, there are future value factors for annuities as well as present value factors. In general, the future value factor for an annuity is given by:

$$\begin{aligned}\text{Annuity FV factor} &= (\text{Future value factor} - 1)/r \\ &= [(1 + r)^t - 1]/r\end{aligned}\quad [5.2]$$

To see how we use annuity future value factors, suppose you plan to contribute \$2,000 every year into a retirement account paying 8 percent. If you retire in 30 years, how much will you have?

The number of years here, t , is 30, and the interest rate, r , is 8 percent, so we can calculate the annuity future value factor as:

$$\begin{aligned}\text{Annuity FV factor} &= (\text{Future value factor} - 1)/r \\ &= (1.08^{30} - 1)/.08 \\ &= (10.0627 - 1)/.08 \\ &= 113.2832\end{aligned}$$

The future value of this 30-year, \$2,000 annuity is thus:

$$\begin{aligned}\text{Annuity future value} &= \$2,000 \times 113.2832 \\ &= \$226,566.4\end{aligned}$$

CALCULATOR HINTS

Future Values of Annuities

Of course, you could solve this problem using a financial calculator by doing the following:

Enter	30	8	-2,000		
	N	I/Y	PMT	PV	FV
Solve for					226,566.42

Notice that we put a negative sign on the payment (why?). With a spreadsheet, use the function $=FV(\text{rate}, \text{nper}, \text{pmt}, \text{pv})$; be sure to put in a zero for pv and to enter $-2,000$ as the payment.

A Note on Annuities Due

So far, we have only discussed ordinary annuities. These are the most important, but there is a variation that is fairly common. Remember that with an ordinary annuity, the cash flows occur at the end of each period. When you take out a loan with monthly payments, for example, the first loan payment normally occurs one month after you get the loan. However, when you lease an apartment, the first lease payment is usually due immediately. The second payment is due at the beginning of the second month, and so on. A lease is an example of an **annuity due**. An annuity due is an annuity for which the cash flows occur at the beginning of each period. Almost any type of arrangement in which we have to prepay the same amount each period is an annuity due.

annuity due

An annuity for which the cash flows occur at the beginning of the period.

There are several different ways to calculate the value of an annuity due. With a financial calculator, you simply switch it into “due” or “beginning” mode. It is very important to remember to switch it back when you are finished! Another way to calculate the present value of an annuity due can be illustrated with a time line. Suppose an annuity due has five payments of \$400 each, and the relevant discount rate is 10 percent. The time line looks like this:

Notice how the cash flows here are the same as those for a *four*-year ordinary annuity, except that there is an extra \$400 at Time 0. For practice, verify that the present value of a four-year \$400 ordinary annuity at 10 percent is \$1,267.95. If we add on the extra \$400, we get \$1,667.95, which is the present value of this annuity due.

There is an even easier way to calculate the present or future value of an annuity due. If we assume that cash flows occur at the end of each period when they really occur at the beginning, then we discount each one by one period too many. We could fix this by simply multiplying our answer by $(1 + r)$, where r is the discount rate. In fact, the relationship between the value of an annuity due and an ordinary annuity with the same number of payments is just:

$$\text{Annuity due value} = \text{Ordinary annuity value} \times (1 + r) \quad [5.3]$$

This works for both present and future values, so calculating the value of an annuity due involves two steps: (1) calculate the present or future value as though it were an ordinary annuity and (2) multiply your answer by $(1 + r)$.

Perpetuities

We've seen that a series of level cash flows can be valued by treating those cash flows as an annuity. An important special case of an annuity arises when the level stream of cash flows continues forever. Such an asset is called a **perpetuity** since the cash flows are perpetual. Perpetuities are also called **consols**, particularly in Canada and the United Kingdom. See Example 5.7 for an important example of a perpetuity.

Since a perpetuity has an infinite number of cash flows, we obviously can't compute its value by discounting each one. Fortunately, valuing a perpetuity turns out to be the easiest possible case. The present value of a perpetuity is simply:

$$\text{PV for a perpetuity} = C/r \quad [5.4]$$

For example, an investment offers a perpetual cash flow of \$500 every year. The return you require on such an investment is 8 percent. What is the value of this investment? The value of this perpetuity is:

$$\text{Perpetuity PV} = C/r = \$500/.08 = \$6,250$$

This concludes our discussion of valuing investments with multiple cash flows. For future reference, Table 5.2 contains a summary of the annuity and perpetuity basic calculations we described. By now, you probably think that you'll just use online calculators to handle annuity problems. Before you do, see our nearby *Work the Web* box.

Time value applications abound on the Web. See, for example, www.collegeboard.com and personal.fidelity.com.

perpetuity

An annuity in which the cash flows continue forever.

consol

A type of perpetuity.

TABLE 5.2

Summary of annuity and perpetuity calculations

I. Symbols

PV = Present value, what future cash flows are worth today

FV_t = Future value, what cash flows are worth in the future at time t

r = Interest rate, rate of return, or discount rate per period—typically, but not always, one year

t = Number of periods—typically, but not always, the number of years

C = Cash amount

II. Future value of C invested per period for t periods at r percent per period

$$FV_t = C \times [(1 + r)^t - 1]/r$$

A series of identical cash flows paid for a set number of periods is called an annuity, and the term $[(1 + r)^t - 1]/r$ is called the *annuity future value factor*.

III. Present value of C per period for t periods at r percent per period

$$PV = C \times \{1 - [1/(1 + r)^t]\}/r$$

The term $\{1 - [1/(1 + r)^t]\}/r$ is called the *annuity present value factor*.

IV. Present value of a perpetuity of C per period

$$PV = C/r$$

A perpetuity has the same cash flow every period forever.

WORK THE WEB

As we discussed in our previous chapter, many Web sites have financial calculators. One of these sites is Calculatoredge, which is located at www.calculatoredge.com. Suppose you retire with \$1,500,000 and want to withdraw an equal amount each year for the next 30 years. If you can earn a 10 percent return, how much can you withdraw each year? Here is what Calculatoredge says:

Enter your values:

Currency:	US Dollars	
Starting Principal:	1500000	US Dollars
Annual Interest Rate:	10	%
Repayment Period:	30	Years

Calculate Clear

Results:

Annuity Payment: 144653.52 US Dollars / Year

According to the Calculatoredge calculator, the answer is \$144,653.52. How important is it to understand what you are doing? Calculate this one for yourself, and you should get \$159,118.87. Which one is right? You are, of course! What's going on is that Calculatoredge assumes (but tells you on a different page) that the annuity is in the form of an annuity due, not an ordinary annuity. Recall that with an annuity due the payments occur at the beginning of the period rather than at the end of the period. The moral of the story is clear: *Caveat calculator*.

Questions

1. Go to the calculator at www.calculatoredge.com and find out how much the Web site says you could withdraw each year if you have \$2,500,000, earn an 8 percent interest rate, and make annual withdrawals for 35 years. How much more are the withdrawals if they are in the form of an ordinary annuity?
2. Suppose you have \$500,000 and want to make withdrawals each month for the next 10 years. The first withdrawal is today and the appropriate interest rate is 9 percent compounded monthly. Using this Web site, how much are your withdrawals?

Preferred Stock

EXAMPLE 5.7

Preferred stock (or preference stock) is an important example of a perpetuity. When a corporation sells preferred stock, the buyer is promised a fixed cash dividend every period (usually every quarter) forever. This dividend must be paid before any dividend can be paid to regular stockholders, hence the term *preferred*.

Suppose the Fellini Co. wants to sell preferred stock at \$100 per share. A very similar issue of preferred stock already outstanding has a price of \$40 per share and offers a dividend of \$1 every quarter. What dividend will Fellini have to offer if the preferred stock is going to sell?

The issue that is already out has a present value of \$40 and a cash flow of \$1 every quarter forever. Since this is a perpetuity:

$$\text{Present value} = \$40 = \$1 \times (1/r)$$

$$r = 2.5\%$$

To be competitive, the new Fellini issue will also have to offer 2.5 percent *per quarter*; so, if the present value is to be \$100, the dividend must be such that:

$$\text{Present value} = \$100 = C \times (1/.025)$$

$$C = \$2.5 \text{ (per quarter)}$$

CONCEPT QUESTIONS

- 5.2a** In general, what is the present value of an annuity of C dollars per period at a discount rate of r per period? The future value?
- 5.2b** In general, what is the present value of a perpetuity?

COMPARING RATES: THE EFFECT OF COMPOUNDING PERIODS

5.3

The last issue we need to discuss has to do with the way interest rates are quoted. This subject causes a fair amount of confusion because rates are quoted in many different ways. Sometimes the way a rate is quoted is the result of tradition, and sometimes it's the result of legislation. Unfortunately, at times, rates are quoted in deliberately deceptive ways to mislead borrowers and investors. We will discuss these topics in this section.

Effective Annual Rates and Compounding

If a rate is quoted as 10 percent compounded semiannually, then what this means is that the investment actually pays 5 percent every six months. A natural question then arises: Is 5 percent every six months the same thing as 10 percent per year? It's easy to see that it is not. If you invest \$1 at 10 percent per year, you will have \$1.10 at the end of the year. If you invest at 5 percent every six months, then you'll have the future value of \$1 at 5 percent for two periods, or:

$$\$1 \times 1.05^2 = \$1.1025$$

This is \$.0025 more. The reason is very simple. What has occurred is that your account was credited with $\$1 \times .05 = 5$ cents in interest after six months. In the following six months, you earned 5 percent on that nickel, for an extra $.05 \times .05 = .0025 = .25$ cents.

stated interest rate

The interest rate expressed in terms of the interest payment made each period. Also, quoted interest rate.

effective annual rate (EAR)

The interest rate expressed as if it were compounded once per year.

As our example illustrates, 10 percent compounded semiannually is actually equivalent to 10.25 percent per year. Put another way, we would be indifferent between 10 percent compounded semiannually and 10.25 percent compounded annually. Anytime we have compounding during the year, we need to be concerned about what the rate really is.

In our example, the 10 percent is called a **stated**, or **quoted, interest rate**. Other names are used as well. The 10.25 percent, which is actually the rate that you will earn, is called the **effective annual rate (EAR)**. To compare different investments or interest rates, we will always need to convert to effective rates. Some general procedures for doing this are discussed next.

Calculating and Comparing Effective Annual Rates

To see why it is important to work only with effective rates, suppose you've shopped around and come up with the following three rates:

Bank A: 15 percent, compounded daily

Bank B: 15.5 percent, compounded quarterly

Bank C: 16 percent, compounded annually

Which of these is the best if you are thinking of opening a savings account? Which of these is best if they represent loan rates?

To begin, Bank C is offering 16 percent per year. Since there is no compounding during the year, this is the effective rate. Bank B is actually paying $.155/4 = .03875$, or 3.875 percent, per quarter. At this rate, an investment of \$1 for four quarters would grow to:

$$\text{\$1} \times 1.03875^4 = \text{\$1.1642}$$

The EAR, therefore, is 16.42 percent. For a saver, this is much better than the 16 percent rate Bank C is offering; for a borrower, it's worse.

Bank A is compounding every day. This may seem a little extreme, but it is very common to calculate interest daily. In this case, the daily interest rate is actually:

$$.15/365 = .000411$$

This is .0411 percent per day. At this rate, an investment of \$1 for 365 periods would grow to:

$$\text{\$1} \times 1.000411^{365} = \text{\$1.1618}$$

The EAR is 16.18 percent. This is not as good as Bank B's 16.42 percent for a saver, and not as good as Bank C's 16 percent for a borrower.

This example illustrates two things. First, the highest quoted rate is not necessarily the best. Second, compounding during the year can lead to a significant difference between the quoted rate and the effective rate. Remember that the effective rate is what you get or what you pay.

If you look at our examples, you see that we computed the EARs in three steps. We first divided the quoted rate by the number of times that the interest is compounded. We then added 1 to the result and raised it to the power of the number of times the interest is compounded. Finally, we subtracted the 1. If we let m be the number of times the interest is compounded during the year, these steps can be summarized simply as:

$$\text{EAR} = (1 + \text{Quoted rate}/m)^m - 1 \quad [5.5]$$

For example, suppose you were offered 12 percent compounded monthly. In this case, the interest is compounded 12 times a year, so m is 12. You can calculate the effective rate as:

$$\begin{aligned}\text{EAR} &= (1 + \text{Quoted rate}/m)^m - 1 \\ &= (1 + .12/12)^{12} - 1 \\ &= 1.01^{12} - 1 \\ &= 1.126825 - 1 \\ &= 12.6825\%\end{aligned}$$

What's the EAR?

EXAMPLE 5.8

A bank is offering 12 percent compounded quarterly. If you put \$100 in an account, how much will you have at the end of one year? What's the EAR? How much will you have at the end of two years?

The bank is effectively offering $12\%/4 = 3\%$ every quarter. If you invest \$100 for four periods at 3 percent per period, the future value is:

$$\begin{aligned}\text{Future value} &= \$100 \times 1.03^4 \\ &= \$100 \times 1.1255 \\ &= \$112.55\end{aligned}$$

The EAR is 12.55 percent: $\$100 \times (1 + .1255) = \112.55 .

We can determine what you would have at the end of two years in two different ways. One way is to recognize that two years is the same as eight quarters. At 3 percent per quarter, after eight quarters, you would have:

$$\$100 \times 1.03^8 = \$100 \times 1.2668 = \$126.68$$

Alternatively, we could determine the value after two years by using an EAR of 12.55 percent; so after two years you would have:

$$\$100 \times 1.1255^2 = \$100 \times 1.2668 = \$126.68$$

Thus, the two calculations produce the same answer. This illustrates an important point. Anytime we do a present or future value calculation, the rate we use must be an actual or effective rate. In this case, the actual rate is 3 percent per quarter. The effective annual rate is 12.55 percent. It doesn't matter which one we use once we know the EAR.

Quoting a Rate

EXAMPLE 5.9

Now that you know how to convert a quoted rate to an EAR, consider going the other way. As a lender, you know you want to actually earn 18 percent on a particular loan. You want to quote a rate that features monthly compounding. What rate do you quote?

In this case, we know that the EAR is 18 percent, and we know that this is the result of monthly compounding. Let q stand for the quoted rate. We thus have:

$$\begin{aligned}\text{EAR} &= (1 + \text{Quoted rate}/m)^m - 1 \\ .18 &= (1 + q/12)^{12} - 1 \\ 1.18 &= (1 + q/12)^{12}\end{aligned}$$

We need to solve this equation for the quoted rate. This calculation is the same as the ones we did to find an unknown interest rate in Chapter 4:

$$\begin{aligned}1.18^{(1/12)} &= 1 + q/12 \\ 1.18^{.08333} &= 1 + q/12\end{aligned}$$

(continued)

$$\begin{aligned}
 1.0139 &= 1 + q/12 \\
 q &= .0139 \times 12 \\
 &= 16.68\%
 \end{aligned}$$

Therefore, the rate you would quote is 16.68 percent, compounded monthly.

annual percentage rate (APR)

The interest rate charged per period multiplied by the number of periods per year.

EARs and APRs

Sometimes it's not altogether clear whether a rate is an effective annual rate or not. A case in point concerns what is called the **annual percentage rate (APR)** on a loan. Truth-in-lending laws in the United States require that lenders disclose an APR on virtually all consumer loans. This rate must be displayed on a loan document in a prominent and unambiguous way.

Given that an APR must be calculated and displayed, an obvious question arises: Is an APR an effective annual rate? Put another way: If a bank quotes a car loan at 12 percent APR, is the consumer actually paying 12 percent interest? Surprisingly, the answer is no. There is some confusion over this point, which we discuss next.

The confusion over APRs arises because lenders are required by law to compute the APR in a particular way. By law, the APR is simply equal to the interest rate per period multiplied by the number of periods in a year. For example, if a bank is charging 1.2 percent per month on car loans, then the APR that must be reported is $1.2\% \times 12 = 14.4\%$. So, an APR is in fact a quoted, or stated, rate in the sense we've been discussing. For example, an APR of 12 percent on a loan calling for monthly payments is really 1 percent per month. The EAR on such a loan is thus:

$$\begin{aligned}
 \text{EAR} &= (1 + \text{APR}/12)^{12} - 1 \\
 &= 1.01^{12} - 1 = 12.6825\%
 \end{aligned}$$

EXAMPLE 5.10

What Rate Are You Paying?

A typical credit card agreement quotes an interest rate of 18 percent APR. Monthly payments are required. What is the actual interest rate you pay on such a credit card?

Based on our discussion, an APR of 18 percent with monthly payments is really $.18/12 = .015$, or 1.5 percent, per month. The EAR is thus:

$$\begin{aligned}
 \text{EAR} &= (1 + .18/12)^{12} - 1 \\
 &= 1.015^{12} - 1 \\
 &= 1.1956 - 1 \\
 &= 19.56\%
 \end{aligned}$$

This is the rate you actually pay.

The difference between an APR and an EAR probably won't be all that great (as long as the rates are relatively low), but it is somewhat ironic that truth-in-lending laws sometimes require lenders to be *untruthful* about the actual rate on a loan.

There can be a huge difference between the APR and EAR when interest rates are large. For example, consider “payday loans.” Payday loans are short-term loans made to consumers, often for less than two weeks, and are offered by companies such as AmeriCash Advance and National Payday. The loans work like this: You write a check today that is postdated (i.e., the date on the check is in the future) and give it to the company. They give you some cash. When the check date arrives, you either go to the store and pay the cash amount of the check, or the company cashes it (or else automatically renews the loan).

For example, as of 2009, AmeriCash Advance allows you to write a check for \$120 dated 18 days in the future, for which they give you \$100 today (in most states). So, what are the APR and EAR of this arrangement? First, we need to find the interest rate, which we can find by the FV equation as:

$$\begin{aligned}\text{FV} &= \text{PV} \times (1 + r)^t \\ \$120 &= \$100 \times (1 + r)^1 \\ 1.20 &= (1 + r) \\ r &= .20 \text{ or } 20\%\end{aligned}$$

That doesn’t seem too bad until you remember this is the interest rate for *18 days*! The APR of the loan is:

$$\begin{aligned}\text{APR} &= .20 \times 365/18 \\ \text{APR} &= 4.0556 \text{ or } 405.56\%\end{aligned}$$

And the EAR for this loan is:

$$\begin{aligned}\text{EAR} &= (1 + \text{Quoted rate}/m)^m - 1 \\ \text{EAR} &= (1 + .20)^{365/18} - 1 \\ \text{EAR} &= 39.3292 \text{ or } 3,932.92\%\end{aligned}$$

Now that’s an interest rate! Just to see what a difference a day (or two) makes, let’s look at National Payday’s terms. This company charges a 25 percent fee for 16 days. Check for yourself that the APR of this arrangement is 570.31 percent and the EAR is 16,146.49 percent. Not a loan we would like to take out!

EARs, APRs, Financial Calculators, and Spreadsheets

A financial calculator will convert a quoted rate (or an APR) to an EAR and back. Unfortunately, the specific procedures are too different from calculator to calculator for us to illustrate in general terms; you’ll have to consult Appendix D or your calculator’s operating manual. Typically, however, what we have called EAR is labeled “EFF” (for *effective*) on a calculator. More troublesome is the fact that what we have called a quoted rate (or an APR) is labeled “NOM” (for *nominal*). Unfortunately, the term *nominal rate* has come to have a different meaning that we will see in our next chapter. So, just remember that *nominal* in this context means quoted or APR.

With a spreadsheet, we can easily do these conversions. To convert a quoted rate (or an APR) to an effective rate in Excel, for example, use the formula `EFFECT(nominal_rate, npery)`, where `nominal_rate` is the quoted rate or APR and `npery` is the number of compounding periods per year. Similarly, to convert an EAR to a quoted rate, use `NOMINAL(effect_rate, npery)`, where `effect_rate` is the EAR.

CONCEPT QUESTIONS

- 5.3a** If an interest rate is given as 12 percent, compounded daily, what do we call this rate?
- 5.3b** What is an APR? What is an EAR? Are they the same thing?
- 5.3c** In general, what is the relationship between a stated interest rate and an effective interest rate? Which is more relevant for financial decisions?

5.4

LOAN TYPES AND LOAN AMORTIZATION

Whenever a lender extends a loan, some provision will be made for repayment of the principal (the original loan amount). A loan might be repaid in equal installments, for example, or it might be repaid in a single lump sum. Because the way that the principal and interest are paid is up to the parties involved, there are actually an unlimited number of possibilities.

In this section, we describe a few forms of repayment that come up quite often; more complicated forms can usually be built up from these. The three basic types of loans are pure discount loans, interest-only loans, and amortized loans. Working with these loans is a very straightforward application of the present value principles that we have already developed.

Pure Discount Loans

The pure discount loan is the simplest form of loan. With such a loan, the borrower receives money today and repays a single lump sum at some time in the future. A one-year, 10 percent pure discount loan, for example, would require the borrower to repay \$1.1 in one year for every dollar borrowed today.

Because a pure discount loan is so simple, we already know how to value one. Suppose a borrower was able to repay \$25,000 in five years. If we, acting as the lender, wanted a 12 percent interest rate on the loan, how much would we be willing to lend? Put another way, what value would we assign today to that \$25,000 to be repaid in five years? Based on our work in Chapter 4, we know that the answer is just the present value of \$25,000 at 12 percent for five years:

$$\begin{aligned}
 \text{Present value} &= \$25,000/1.12^5 \\
 &= \$25,000/1.7623 \\
 &= \$14,186
 \end{aligned}$$

Pure discount loans are very common when the loan term is short, say, a year or less. In recent years, they have become increasingly common for much longer periods.

EXAMPLE 5.11

Treasury Bills

When the U.S. government borrows money on a short-term basis (a year or less), it does so by selling what are called *Treasury bills*, or *T-bills* for short. A T-bill is a promise by the government to repay a fixed amount at some time in the future, for example, 3 months or 12 months.

Treasury bills are pure discount loans. If a T-bill promises to repay \$10,000 in 12 months, and the market interest rate is 7 percent, how much will the bill sell for in the market?

Since the going rate is 7 percent, the T-bill will sell for the present value of \$10,000 to be paid in one year at 7 percent, or:

$$\text{Present value} = \$10,000/1.07 = \$9,345.79$$

Interest-Only Loans

A second type of loan has a repayment plan that calls for the borrower to pay interest each period and to repay the entire principal (the original loan amount) at some point in the future. Such loans are called *interest-only loans*. Notice that if there is just one period, a pure discount loan and an interest-only loan are the same thing.

For example, with a three-year, 10 percent, interest-only loan of \$1,000, the borrower would pay $\$1,000 \times .10 = \100 in interest at the end of the first and second years. At the end of the third year, the borrower would return the \$1,000 along with another \$100 in interest for that year. Similarly, a 50-year interest-only loan would call for the borrower to pay interest every year for the next 50 years and then repay the principal. In the extreme, the borrower pays the interest every period forever and never repays any principal. As we discussed earlier in the chapter, the result is a perpetuity.

Most corporate bonds have the general form of an interest-only loan. Because we will be considering bonds in some detail in the next chapter, we will defer a further discussion of them for now.

Amortized Loans

With a pure discount or interest-only loan, the principal is repaid all at once. An alternative is an *amortized loan*, with which the lender may require the borrower to repay parts of the loan amount over time. The process of paying off a loan by making regular principal reductions is called *amortizing* the loan.

A simple way of amortizing a loan is to have the borrower pay the interest each period plus some fixed amount. This approach is common with medium-term business loans. For example, suppose a business takes out a \$5,000, five-year loan at 9 percent. The loan agreement calls for the borrower to pay the interest on the loan balance each year and to reduce the loan balance each year by \$1,000. Since the loan amount declines by \$1,000 each year, it is fully paid in five years.

In the case we are considering, notice that the total payment will decline each year. The reason is that the loan balance goes down, resulting in a lower interest charge each year, while the \$1,000 principal reduction is constant. For example, the interest in the first year will be $\$5,000 \times .09 = \450 . The total payment will be $\$1,000 + \$450 = \$1,450$. In the second year, the loan balance is \$4,000, so the interest is $\$4,000 \times .09 = \360 , and the total payment is \$1,360. We can calculate the total payment in each of the remaining years by preparing a simple *amortization schedule* as follows:

Year	Beginning Balance	Total Payment	Interest Paid	Principal Paid	Ending Balance
1	\$5,000	\$1,450	\$ 450	\$1,000	\$4,000
2	4,000	1,360	360	1,000	3,000
3	3,000	1,270	270	1,000	2,000
4	2,000	1,180	180	1,000	1,000
5	1,000	1,090	90	1,000	0
Totals		\$6,350	\$1,350	\$5,000	

Notice that, in each year, the interest paid is just given by the beginning balance multiplied by the interest rate. Also, notice that the beginning balance is given by the ending balance from the previous year.

Probably the most common way of amortizing a loan is to have the borrower make a single, fixed payment every period. Almost all consumer loans (such as car loans) and mortgages work this way. For example, suppose our five-year, 9 percent, \$5,000 loan was amortized this way. How would the amortization schedule look?

We first need to determine the payment. From our discussion earlier in the chapter, we know that this loan's cash flows are in the form of an ordinary annuity. In this case, we can solve for the payment as follows:

$$\begin{aligned}\$5,000 &= C \times (1 - 1/1.09^5)/.09 \\ &= C \times (1 - .6499)/.09\end{aligned}$$

This gives us:

$$\begin{aligned}C &= \$5,000/3.8897 \\ &= \$1,285.46\end{aligned}$$

The borrower will therefore make five equal payments of \$1,285.46. Will this pay off the loan? We will check by filling in an amortization schedule.

In our previous example, we knew the principal reduction each year. We then calculated the interest owed to get the total payment. In this example, we know the total payment. We will thus calculate the interest and then subtract it from the total payment to get the principal portion in each payment.

In the first year, the interest is \$450, as we calculated before. Since the total payment is \$1,285.46, the principal paid in the first year must be:

$$\text{Principal paid} = \$1,285.46 - 450 = \$835.46$$

The ending loan balance is thus:

$$\text{Ending balance} = \$5,000 - 835.46 = \$4,164.54$$

The interest in the second year is $\$4,164.54 \times .09 = \374.81 , and the loan balance declines by $\$1,285.46 - 374.81 = \910.65 . We can summarize all of the relevant calculations in the following schedule:

Year	Beginning Balance	Total Payment	Interest Paid	Principal Paid	Ending Balance
1	\$5,000.00	\$1,285.46	\$ 450.00	\$ 835.46	\$4,164.54
2	4,164.54	1,285.46	374.81	910.65	3,253.88
3	3,253.88	1,285.46	292.85	992.61	2,261.27
4	2,261.27	1,285.46	203.51	1,081.95	1,179.32
5	1,179.32	1,285.46	106.14	1,179.32	.00
Totals		\$6,427.31	\$1,427.31	\$5,000.00	

You can find a good loan amortization schedule online at www.mymortizationchart.com.

Since the loan balance declines to zero, the five equal payments do pay off the loan. Notice that the interest paid declines each period. This isn't surprising since the loan balance is going down. Given that the total payment is fixed, the principal paid must be rising each period.

If you compare the two loan amortizations in this section, you will see that the total interest is greater for the equal total payment case, \$1,427.31 versus \$1,350. The reason for

this is that the loan is repaid more slowly early on, so the interest is somewhat higher. This doesn't mean that one loan is better than the other; it simply means that one is effectively paid off faster than the other. For example, the principal reduction in the first year is \$835.46 in the equal total payment case compared to \$1,000 in the first case. Many Web sites offer loan amortization schedules. See our nearby *Work the Web* box for an example.

Loan Amortization Using a Spreadsheet

SPREADSHEET STRATEGIES

Loan amortization is a very common spreadsheet application. To illustrate, we will set up the problem that we have just examined, a five-year, \$5,000, 9 percent loan with constant payments. Our spreadsheet looks like this:

	A	B	C	D	E	F	G	H
1								
2	Using a spreadsheet to amortize a loan							
3								
4			Loan amount:	\$5,000				
5			Interest rate:	.09				
6			Loan term:	5				
7			Loan payment:	\$1,285.46				
8			Note: payment is calculated using PMT(rate,nper,-pv,fv).					
9			Amortization table:					
10								
11		Year	Beginning	Total	Interest	Principal	Ending	
12			Balance	Payment	Paid	Paid	Balance	
13		1	\$5,000.00	\$1,285.46	\$450.00	\$835.46	\$4,164.54	
14		2	4,164.54	1,285.46	374.81	910.65	3,253.88	
15		3	3,253.88	1,285.46	292.85	992.61	2,261.27	
16		4	2,261.27	1,285.46	203.51	1,081.95	1,179.32	
17		5	1,179.32	1,285.46	106.14	1,179.32	.00	
18		Totals		\$6,427.31	\$1,427.31	\$5,000.00		
19								
20			Formulas in the amortization table:					
21								
22		Year	Beginning	Total	Interest	Principal	Ending	
23			Balance	Payment	Paid	Paid	Balance	
24		1	=+D4	=D\$7	=+D\$5*C13	=+D13-E13	=+C13-F13	
25		2	=+G13	=D\$7	=+D\$5*C14	=+D14-E14	=+C14-F14	
26		3	=+G14	=D\$7	=+D\$5*C15	=+D15-E15	=+C15-F15	
27		4	=+G15	=D\$7	=+D\$5*C16	=+D16-E16	=+C16-F16	
28		5	=+G16	=D\$7	=+D\$5*C17	=+D17-E17	=+C17-F17	
29								
30			Note: totals in the amortization table are calculated using the SUM formula.					
31								

We close out this discussion by noting that one type of loan may be particularly important to you. Student loans are an important source of financing for many college students, helping to cover the cost of tuition, books, new cars, condominiums, and many other

WORK THE WEB

Preparing an amortization table is one of the more tedious time value of money applications. Using a spreadsheet makes it relatively easy, but there are also Web sites available that will prepare an amortization very quickly and simply. One such site is Bankrate.com. The Web site at www.bankrate.com has a mortgage calculator for home loans, but the same calculations apply to most other types of loans such as car loans and student loans. Suppose you graduate with a student loan of \$35,000 and plan to repay the loan over the next 15 years at 8.25 percent, the maximum rate for Stafford loans. What are your monthly payments? Using the calculator, for the first year, we get:

Amortization Table for \$35000.00 borrowed on Nov 30, 2010												
Month Year	12 2010	1 2011	2 2011	3 2011	4 2011	5 2011	6 2011	7 2011	8 2011	9 2011	10 2011	11 2011
Payment (\$)	339.55	339.55	339.55	339.55	339.55	339.55	339.55	339.55	339.55	339.55	339.55	339.55
Principal Paid (\$)	98.92	99.60	100.29	100.98	101.67	102.37	103.08	103.78	104.50	105.22	105.94	106.67
Interest Paid (\$)	240.63	239.94	239.26	238.57	237.88	237.18	236.47	235.76	235.05	234.33	233.61	232.88
Total Interest (\$)	240.63	480.57	719.83	958.40	1196.28	1433.45	1669.93	1905.69	2140.74	2375.08	2608.69	2841.57
Balance (\$)	34901.08	34801.47	34701.18	34600.20	34498.53	34396.16	34293.08	34189.30	34084.80	33979.59	33873.65	33766.98

As you can see, the monthly payment will be \$339.55. The first payment will consist of \$98.92 in principal and \$240.63 in interest. Over the life of the loan you will pay a total of \$26,118.84 in interest.

Questions

1. Suppose you take out a 30-year mortgage for \$250,000 at an interest rate of 6.8 percent. Use this Web site to construct an amortization table for the loan. What are the interest payment and principal amounts in the 110th payment? How much in total interest will you pay over the life of the loan?
2. You take out a 30-year mortgage for \$275,000 at an interest rate of 7.3 percent. How much will you pay in interest over the life of this loan? Now assume you pay an extra \$100 per month on this loan. How much is your total interest now? How much sooner will the mortgage be paid off?

things. Sometimes students do not seem to fully realize that such loans have a serious drawback: They must be repaid. See our nearby *Reality Bytes* box for a discussion.

CONCEPT QUESTIONS

- 5.4a What is a pure discount loan?
- 5.4b What does it mean to amortize a loan?

An Unwelcome Christmas Present

If you are reading this, we can assume that you are a college student. While you will receive an education in college, and studies show that college graduates earn higher salaries on average than nongraduates, you might receive an unwelcome Christmas present if you graduate in May: student loan payments. About one-half of all college students graduate with student loans, and over 90 percent of the loans are Stafford loans. Stafford loans are available through lenders such as Sallie Mae, online lenders, or, in some cases, your college. Stafford loans must be paid off in 10 years, but there is a six-month grace period from the time you graduate until the first payment must be made. The interest rate on unsubsidized Stafford loans made after July 1, 2006, is 6.8 percent.

If you have student loans, you went through an introductory program. Just in case you forgot, here are several of the repayment options. First, you can make equal monthly payments like most other loans. A second option is to pay only the interest on the loan for up to four years, and then begin making principal and interest payments. This means your payments at the end of the loan are higher than the equal payment option. A third option is to make payments based on a percentage of your salary. A fourth option is a graduated payment option that increases your monthly payments on a predetermined schedule. Finally, you can consolidate your loans one time. If the loan balance is high enough, you may be able to extend your payment for up to 30 years.

So how do student loans work in practice? A recent graduate from the University of Maryland with a master's degree in creative writing graduated with \$40,000 in student loans. Her

loan payments were \$442 a month, a payment that was difficult to make on her salary as a fundraiser. She considered the percentage of salary option, which would have lowered her monthly payments to about \$200 per month. However, she realized that this was just putting off the inevitable, so she took a second job to make up the difference.

A recent master's graduate from law school took a different route. His student loans totaled \$109,000 and required monthly payments of \$1,200 per month for 10 years. The option chosen by this lawyer was to consolidate his loans and extend his payments to 30 years. This reduced his monthly payments to about \$640 per month.

A Chicago couple is using a third solution. Both the husband and wife are doctors. The wife is out of her residency and employed full time, while the husband is finishing his last year of residency. What is most unusual about this couple is the amount of student loan debt. The wife's student loan balance is \$234,000, the husband's student loan balance is \$310,000, and the couple has a \$156,000 mortgage! The wife's student loan repayments have already started and amount to \$1,750 per month. So how is the couple handling this? They are paying a total of \$2,250 per month towards the wife's student loans. This will reduce the repayment period from 22 years to 13 years. The couple is also paying an additional \$100 per month on their \$1,500 mortgage payment. Fortunately, when the husband's residency ends, he expects his salary to triple. The couple will need it. His loan payments will be \$2,349 per month. And you thought your student loan was high! Maybe MD stands for "mucho debt"!

SUMMARY AND CONCLUSIONS

This chapter rounds out your understanding of fundamental concepts related to the time value of money and discounted cash flow valuation. Several important topics were covered, including:

1. There are two ways of calculating present and future values when there are multiple cash flows. Both approaches are straightforward extensions of our earlier analysis of single cash flows.
2. A series of constant cash flows that arrive or are paid at the end of each period is called an ordinary annuity, and we described some useful shortcuts for determining the present and future values of annuities.
3. Interest rates can be quoted in a variety of ways. For financial decisions, it is important that any rates being compared be first converted to effective rates. The

relationship between a quoted rate, such as an annual percentage rate, or APR, and an effective annual rate, or EAR, is given by:

$$\text{EAR} = (1 + \text{Quoted rate}/m)^m - 1$$

where m is the number of times during the year the money is compounded, or, equivalently, the number of payments during the year.

4. Many loans are annuities. The process of paying off a loan gradually is called amortizing the loan, and we discussed how amortization schedules are prepared and interpreted.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

- 5.1 Present Values with Multiple Cash Flows.** A first-round draft choice quarterback has been signed to a three-year, \$10 million contract. The details provide for an immediate cash bonus of \$1 million. The player is to receive \$2 million in salary at the end of the first year, \$3 million the next, and \$4 million at the end of the last year. Assuming a 10 percent discount rate, is this package worth \$10 million? How much is it worth?
- 5.2 Future Value with Multiple Cash Flows.** You plan to make a series of deposits in an interest-bearing account. You will deposit \$1,000 today, \$2,000 in two years, and \$8,000 in five years. If you withdraw \$3,000 in three years and \$5,000 in seven years, how much will you have after eight years if the interest rate is 9 percent? What is the present value of these cash flows?
- 5.3 Annuity Present Value.** You are looking into an investment that will pay you \$12,000 per year for the next 10 years. If you require a 15 percent return, what is the most you would pay for this investment?
- 5.4 APR versus EAR.** The going rate on student loans is quoted as 9 percent APR. The terms of the loan call for monthly payments. What is the effective annual rate, or EAR, on such a student loan?
- 5.5 It's the Principal That Matters.** Suppose you borrow \$10,000. You are going to repay the loan by making equal annual payments for five years. The interest rate on the loan is 14 percent per year. Prepare an amortization schedule for the loan. How much interest will you pay over the life of the loan?
- 5.6 Just a Little Bit Each Month.** You've recently finished your MBA at the Darnit School. Naturally, you must purchase a new BMW immediately. The car costs about \$42,000. The bank quotes an interest rate of 15 percent APR for a 72-month loan with a 10 percent down payment. What will your monthly payment be? What is the effective interest rate on the loan?

Answers to Chapter Review and Self-Test Problems

- 5.1** Obviously, the package is not worth \$10 million because the payments are spread out over three years. The bonus is paid today, so it's worth \$1 million. The present values for the three subsequent salary payments are:

$$\begin{aligned} \$2/1.1 + 3/1.1^2 + 4/1.1^3 &= \$2/1.1 + 3/1.21 + 4/1.331 \\ &= \$7.3028 \end{aligned}$$

The package is worth a total of **\$8.3028 million**.

- 5.2** We will calculate the future value for each of the cash flows separately and then add the results up. Notice that we treat the withdrawals as negative cash flows:

$$\begin{aligned}
 \$1,000 \times 1.09^8 &= \$1,000 \times 1.9926 = \$1,992.60 \\
 \$2,000 \times 1.09^6 &= \$2,000 \times 1.6771 = 3,354.20 \\
 -\$3,000 \times 1.09^5 &= -\$3,000 \times 1.5386 = -4,615.87 \\
 \$8,000 \times 1.09^3 &= \$8,000 \times 1.2950 = 10,360.23 \\
 -\$5,000 \times 1.09^1 &= -\$5,000 \times 1.0900 = -5,450.00 \\
 \text{Total future value} &= \underline{\underline{\$5,641.12}}
 \end{aligned}$$

This value includes a small rounding error.

To calculate the present value, we could discount each cash flow back to the present or we could discount back a single year at a time. However, since we already know that the future value in eight years is \$5,641.12, the easy way to get the PV is just to discount this amount back eight years:

$$\begin{aligned}
 \text{Present value} &= \$5,641.12/1.09^8 \\
 &= \$5,641.12/1.9926 \\
 &= \$2,831.03
 \end{aligned}$$

We again ignore a small rounding error. For practice, you can verify that this is what you get if you discount each cash flow back separately.

- 5.3** The most you would be willing to pay is the present value of \$12,000 per year for 10 years at a 15 percent discount rate. The cash flows here are in ordinary annuity form, so the relevant present value factor is:

$$\begin{aligned}
 \text{Annuity present value factor} &= [1 - (1/1.15^{10})]/.15 \\
 &= (1 - .2472)/.15 \\
 &= 5.0188
 \end{aligned}$$

The present value of the 10 cash flows is thus:

$$\begin{aligned}
 \text{Present value} &= \$12,000 \times 5.0188 \\
 &= \$60,225
 \end{aligned}$$

This is the most you would pay.

- 5.4** A rate of 9 percent with monthly payments is actually $9\%/12 = .75\%$ per month. The EAR is thus:

$$\text{EAR} = (1 + .09/12)^{12} - 1 = 9.38\%$$

- 5.5** We first need to calculate the annual payment. With a present value of \$10,000, an interest rate of 14 percent, and a term of five years, the payment can be determined from:

$$\begin{aligned}
 \$10,000 &= \text{Payment} \times (1 - 1/1.14^5)/.14 \\
 &= \text{Payment} \times 3.4331
 \end{aligned}$$

Therefore, the payment is $\$10,000/3.4331 = \$2,912.84$ (actually, it's \$2,912.8355; this will create some small rounding errors in the schedule below).

We can now prepare the amortization schedule as follows:

Year	Beginning Balance	Total Payment	Interest Paid	Principal Paid	Ending Balance
1	\$10,000.00	\$ 2,912.84	\$1,400.00	\$ 1,512.84	\$8,487.16
2	8,487.16	2,912.84	1,188.20	1,724.63	6,762.53
3	6,762.53	2,912.84	946.75	1,966.08	4,796.45
4	4,796.45	2,912.84	671.50	2,241.33	2,555.12
5	2,555.12	2,912.84	357.72	2,555.12	.00
Totals		\$14,564.17	\$4,564.17	\$10,000.00	

- 5.6** The cash flows on the car loan are in annuity form, so we only need to find the payment. The interest rate is $15\%/12 = 1.25\%$ per month, and there are 72 months. The first thing we need is the annuity factor for 72 periods at 1.25 percent per period:

$$\begin{aligned}
 \text{Annuity present value factor} &= (1 - \text{Present value factor})/r \\
 &= [1 - (1/1.0125^{72})]/.0125 \\
 &= [1 - (1/2.4459)]/.0125 \\
 &= (1 - .4088)/.0125 \\
 &= 47.2925
 \end{aligned}$$

The present value is the amount we finance. With a 10 percent down payment, we will be borrowing 90 percent of \$42,000, or **\$37,800**.

So, to find the payment, we need to solve for C in the following:

$$\begin{aligned}
 \$37,800 &= C \times \text{Annuity present value factor} \\
 &= C \times 47.2925
 \end{aligned}$$

Rearranging things a bit, we have:

$$\begin{aligned}
 C &= \$37,800 \times (1/47.2925) \\
 &= \$37,800 \times .02115 \\
 &= \$799.28
 \end{aligned}$$

Your payment is just under \$800 per month.

The actual interest rate on this loan is 1.25 percent per month. Based on our work in the chapter, we can calculate the effective annual rate as:

$$\text{EAR} = 1.0125^{12} - 1 = 16.08\%$$

The effective rate is about one point higher than the quoted rate.

CRITICAL THINKING AND CONCEPTS REVIEW

- L0 1 5.1 Annuity Period.** As you increase the length of time involved, what happens to the present value of an annuity? What happens to the future value?
- L0 1 5.2 Interest Rates.** What happens to the future value of an annuity if you increase the rate, r ? What happens to the present value?

- L01** 5.3 **Annuity Present Values.** Tri-State Megabucks Lottery advertises a \$10 million grand prize. The winner receives \$500,000 today and 19 annual payments of \$500,000. A lump sum option of \$5 million payable immediately is also available. Is this deceptive advertising?
- L02**
- L01** 5.4 **Annuity Present Values.** Suppose you won the Tri-State Megabucks Lottery in the previous question. What factors should you take into account in deciding whether you should take the annuity option or the lump sum option?
- L01** 5.5 **Present Value.** If you were an athlete negotiating a contract, would you want a big signing bonus payable immediately and smaller payments in the future, or vice versa? How about looking at it from the team's perspective?
- L01** 5.6 **Present Value.** Suppose two athletes sign 10-year contracts for \$80 million. In one case, we're told that the \$80 million will be paid in 10 equal installments. In the other case, we're told that the \$80 million will be paid in 10 installments, but the installments will increase by 5 percent per year. Who got the better deal?
- L04** 5.7 **APR and EAR.** Should lending laws be changed to require lenders to report EARs instead of APRs? Why or why not?
- L03** 5.8 **Time Value.** On subsidized Stafford loans, a common source of financial aid for college students, interest does not begin to accrue until repayment begins. Who receives a bigger subsidy, a freshman or a senior? Explain.
- L03** 5.9 **Time Value.** In words, how would you go about valuing the subsidy on a subsidized Stafford loan?
- L03** 5.10 **Time Value.** Eligibility for a subsidized Stafford loan is based on current financial need. However, both subsidized and unsubsidized Stafford loans are repaid out of future income. Given this, do you see a possible objection to having two types?

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

- L01** 1. **Present Value and Multiple Cash Flows.** Zevon Co. has identified an investment project with the following cash flows. If the discount rate is 10 percent, what is the present value of these cash flows? What is the present value at 18 percent? At 24 percent?

Basic

(Questions 1–28)

Year	Cash Flow
1	\$ 950
2	730
3	1,420
4	1,780

- L01** 2. **Present Value and Multiple Cash Flows.** Investment X offers to pay you \$4,300 per year for 9 years, whereas Investment Y offers to pay you \$6,100 per year for 5 years. Which of these cash flow streams has the higher present value if the discount rate is 6 percent? If the discount rate is 22 percent?

L0 1

3. **Future Value and Multiple Cash Flows.** Havana, Inc., has identified an investment project with the following cash flows. If the discount rate is 8 percent, what is the future value of these cash flows in Year 4? What is the future value at an interest rate of 11 percent? At 24 percent?

Year	Cash Flow
1	\$ 910
2	1,140
3	1,360
4	2,100

L0 1

4. **Calculating Annuity Present Values.** An investment offers \$8,500 per year for 15 years, with the first payment occurring 1 year from now. If the required return is 9 percent, what is the value of the investment? What would the value be if the payments occurred for 40 years? For 75 years? Forever?

L0 1

5. **Calculating Annuity Cash Flows.** If you put up \$25,000 today in exchange for a 7.9 percent, 12-year annuity, what will the annual cash flow be?

L0 1

6. **Calculating Annuity Values.** Your company will generate \$45,000 in cash flow each year for the next nine years from a new information database. The computer system needed to set up the database costs \$260,000. If you can borrow the money to buy the computer system at 8.25 percent annual interest, can you afford the new system?

L0 1

7. **Calculating Annuity Values.** If you deposit \$4,000 at the end of each of the next 20 years into an account paying 9.5 percent interest, how much money will you have in the account in 20 years? How much will you have if you make deposits for 40 years?

L0 1

8. **Calculating Annuity Values.** You want to have \$25,000 in your savings account eight years from now, and you're prepared to make equal annual deposits into the account at the end of each year. If the account pays 4.75 percent interest, what amount must you deposit each year?

L0 1

9. **Calculating Annuity Values.** Bath's Bank offers you a \$60,000, seven-year term loan at 9 percent annual interest. What will your annual loan payment be?

L0 1

10. **Calculating Perpetuity Values.** Curly's Life Insurance Co. is trying to sell you an investment policy that will pay you and your heirs \$35,000 per year forever. If the required return on this investment is 6 percent, how much will you pay for the policy?

L0 1

11. **Calculating Perpetuity Values.** In the previous problem, suppose Curly's told you the policy costs \$600,000. At what interest rate would this be a fair deal?

L0 4

12. **Calculating EAR.** Find the EAR in each of the following cases:

Stated Rate (APR)	Number of Times Compounded	Effective Rate (EAR)
8%	Quarterly	
18	Monthly	
14	Daily	
10	Semiannually	

- L0 4** 13. **Calculating APR.** Find the APR, or stated rate, in each of the following cases:

Stated Rate (APR)	Number of Times Compounded	Effective Rate (EAR)
	Semiannually	12%
	Monthly	8
	Weekly	13
	Daily	11

- L0 4** 14. **Calculating EAR.** First National Bank charges 10.1 percent compounded monthly on its business loans. First United Bank charges 10.3 percent compounded semiannually. As a potential borrower, which bank would you go to for a new loan?
- L0 4** 15. **Calculating APR.** Magnus Credit Corp. wants to earn an effective annual return on its consumer loans of 16 percent per year. The bank uses daily compounding on its loans. What interest rate is the bank required by law to report to potential borrowers? Explain why this rate is misleading to an uninformed borrower.
- L0 4** 16. **Calculating Future Values.** What is the future value of \$1,560 in 13 years assuming an interest rate of 9 percent compounded semiannually?
- L0 4** 17. **Calculating Future Values.** Bucher Credit Bank is offering 5.3 percent compounded daily on its savings accounts. If you deposit \$5,000 today, how much will you have in the account in five years? In 10 years? In 20 years?
- L0 4** 18. **Calculating Present Values.** An investment will pay you \$80,000 in six years. If the appropriate discount rate is 6 percent compounded daily, what is the present value?
- L0 4** 19. **EAR versus APR.** Ricky Ripov's Pawn Shop charges an interest rate of 15 percent per month on loans to its customers. Like all lenders, Ricky must report an APR to consumers. What rate should the shop report? What is the effective annual rate?
- L0 2** 20. **Calculating Loan Payments.** You want to buy a new sports coupe for \$73,800, and the finance office at the dealership has quoted you a 6.2 percent APR loan for 60 months to buy the car. What will your monthly payments be? What is the effective annual rate on this loan?
- L0 2** 21. **Calculating Number of Periods.** One of your customers is delinquent on his accounts payable balance. You've mutually agreed to a repayment schedule of \$500 per month. You will charge 0.9 percent per month interest on the overdue balance. If the current balance is \$14,720, how long will it take for the account to be paid off?
- L0 4** 22. **Calculating EAR.** Friendly's Quick Loans, Inc., offers you "Six for four, or I knock on your door." This means you get \$4 today and repay \$6 when you get your paycheck in one week (or else). What's the effective annual return Friendly's earns on this lending business? If you were brave enough to ask, what APR would Friendly's say you were paying?
- L0 1** 23. **Valuing Perpetuities.** Maybepay Life Insurance Co. is selling a perpetual annuity contract that pays \$3,100 monthly. The contract currently sells for \$325,000. What is the monthly return on this investment vehicle? What is the APR? The effective annual return?

- L0 1** 24. **Calculating Annuity Future Values.** You are to make monthly deposits of \$400 into a retirement account that pays 10.5 percent interest compounded monthly. If your first deposit will be made one month from now, how large will your retirement account be in 30 years?
- L0 1** 25. **Calculating Annuity Future Values.** In the previous problem, suppose you make \$4,800 annual deposits into the same retirement account. How large will your account balance be in 30 years?
- L0 1** 26. **Calculating Annuity Present Values.** Beginning three months from now, you want to be able to withdraw \$2,500 each quarter from your bank account to cover college expenses over the next four years. If the account pays .65 percent interest per quarter, how much do you need to have in your bank account today to meet your expense needs over the next four years?
- L0 1** 27. **Discounted Cash Flow Analysis.** If the appropriate discount rate for the following cash flows is 8.4 percent, what is the present value of the cash flows?

Year	Cash Flow
1	\$1,200
2	1,100
3	800
4	600

- L0 1** 28. **Discounted Cash Flow Analysis.** If the appropriate discount rate for the following cash flows is 9.29 percent per year, what is the present value of the cash flows?

Year	Cash Flow
1	\$1,900
2	2,300
3	4,500
4	5,100

- L0 4** 29. **Simple Interest versus Compound Interest.** First Simple Bank pays 8 percent simple interest on its investment accounts. If First Complex Bank pays interest on its accounts compounded annually, what rate should the bank set if it wants to match First Simple Bank over an investment horizon of 10 years?

Intermediate
(Questions 29–56)

- L0 2** 30. **Calculating Annuities Due.** You want to buy a new sports car from Muscle Motors for \$43,000. The contract is in the form of a 60-month annuity due at a 6.25 percent APR. What will your monthly payment be?

- L0 4** 31. **Calculating Interest Expense.** You receive a credit card application from Shady Banks Savings and Loan offering an introductory rate of 2.1 percent per year, compounded monthly for the first six months, increasing thereafter to 17 percent compounded monthly. Assuming you transfer the \$10,000 balance from your existing credit card and make no subsequent payments, how much interest will you owe at the end of the first year?

- L0 4** 32. **Calculating the Number of Periods.** You are saving to buy a \$175,000 house. There are two competing banks in your area, both offering certificates of deposit yielding 6 percent. How long will it take your initial \$92,000 investment to reach the desired level at First Bank, which pays simple interest? How long at Second Bank, which compounds interest monthly?

- L0 4** 33. **Calculating Future Values.** You have an investment that will pay you 1.27 percent per month. How much will you have per dollar invested in one year? In two years?
- L0 4** 34. **Calculating Annuity Interest Rates.** Although you may know William Shakespeare from his classic literature, what is not well-known is that he was an astute investor. In 1604, when he was 40 and writing *King Lear*, Shakespeare grew worried about his eventual retirement. Afraid that he would become like King Lear in his retirement and beg hospitality from his children, he purchased grain “tithes,” or shares in farm output, for 440 pounds. The tithes paid him 60 pounds per year for 31 years. Even though he died at the age of 52, his children received the remaining payments. What interest rate did the Bard of Avon receive on this investment?
- L0 1** 35. **Comparing Cash Flow Streams.** You’ve just joined the investment banking firm of Dewey, Cheatum, and Howe. They’ve offered you two different salary arrangements. You can have \$6,800 per month for the next two years, or you can have \$5,500 per month for the next two years, along with a \$30,000 signing bonus today. If the interest rate is 7 percent compounded monthly, which do you prefer?
- L0 1** 36. **Calculating Present Value of Annuities.** Peter Lynchpin wants to sell you an investment contract that pays equal \$12,000 amounts at the end of each of the next 20 years. If you require an effective annual return of 9 percent on this investment, how much will you pay for the contract today?
- L0 4** 37. **Calculating Rates of Return.** You’re trying to choose between two different investments, both of which have up-front costs of \$85,000. Investment G returns \$150,000 in six years. Investment H returns \$270,000 in 13 years. Which of these investments has the higher return?
- L0 1** 38. **Present Value and Interest Rates.** What is the relationship between the value of an annuity and the level of interest rates? Suppose you just bought a 10-year annuity of \$15,000 per year at the current interest rate of 10 percent per year. What happens to the value of your investment if interest rates suddenly drop to 5 percent? What if interest rates suddenly rise to 15 percent?
- L0 1** 39. **Calculating the Number of Payments.** You’re prepared to make monthly payments of \$175, beginning at the end of this month, into an account that pays 10 percent interest compounded monthly. How many payments will you have made when your account balance reaches \$50,000?
- L0 2** 40. **Calculating Annuity Present Values.** You want to borrow \$58,000 from your local bank to buy a new sailboat. You can afford to make monthly payments of \$1,200, but no more. Assuming monthly compounding, what is the highest rate you can afford on a 60-month APR loan?
- L0 1** 41. **Calculating Present Values.** In 2007, baseball player Alex Rodriguez signed a contract reported to be worth \$275 million. The contract called for \$2 million immediately and \$27 million in 2008. The remaining \$246 million was to be paid as \$33 million in 2009, \$33 million in 2010, \$32 million in 2011, \$30 million in 2012, \$32 million in 2013, \$25 million in 2014, \$21 million in 2015, and \$20 million in 2016 and 2017. If the appropriate interest rate is 11 percent, what kind of deal did the infielder snag? Assume all payments other than the first \$2 million are paid at the end of the year.
- L0 1** 42. **Calculating Present Values.** 2007 was also a good year to be an NFL quarterback. Tony Romo of the Dallas Cowboys signed a contract reportedly worth \$67.5 million. The contract called for \$16 million immediately, \$6.5 million in 2008, \$7 million in 2009, \$8.5 million in 2010, \$9 million in 2011 and 2012, and \$11.5 million in 2013. If the appropriate interest rate is 11 percent, what is the present value of the deal? Assume all payments other than the first \$16 million are paid at the end of the year.

- L0 4** 43. **EAR versus APR.** You have just purchased a new warehouse. To finance the purchase, you've arranged for a 30-year mortgage loan for 80 percent of the \$3,200,000 purchase price. The monthly payment on this loan will be \$15,300. What is the APR on this loan? The EAR?
- L0 1** 44. **Annuity Values.** You are planning your retirement in 10 years. You currently have \$160,000 in a bond account and \$600,000 in a stock account. You plan to add \$8,000 per year at the end of each of the next 10 years to your bond account. The stock account will earn a 10.5 percent return and the bond account will earn a 7 percent return. When you retire, you plan to withdraw an equal amount for each of the next 25 years at the end of each year and have nothing left. Additionally, when you retire you will transfer your money to an account that earns 6.25 percent. How much can you withdraw each year?
- L0 4** 45. **Calculating Annuities Due Interest Rates.** You have arranged for a loan on your new car that will require the first payment today. The loan is for \$34,000, and the monthly payments are \$645. If the loan will be paid off over the next 60 months, what is the APR of the loan?
- L0 1** 46. **Calculating Annuities Due.** Suppose you are going to receive \$12,000 per year for five years. The appropriate interest rate is 9 percent.
- What is the present value of the payments if they are in the form of an ordinary annuity? What is the present value if the payments are an annuity due?
 - Suppose you plan to invest the payments for five years. What is the future value if the payments are an ordinary annuity? What if the payments are an annuity due?
 - Which has the higher present value, the ordinary annuity or annuity due? Which has the higher future value? Will this always be true?
- L0 1** 47. **Annuity and Perpetuity Values.** Mary is going to receive a 30-year annuity of \$8,500. Nancy is going to receive a perpetuity of \$8,500. If the appropriate interest rate is 8 percent, how much more is Nancy's cash flow worth?
- L0 1** 48. **Calculating Present Values.** A 5-year annuity of 10 \$7,800 semiannual payments will begin 9 years from now, with the first payment coming 9.5 years from now. If the discount rate is 9 percent compounded semiannually, what is the value of this annuity five years from now? What is the value three years from now? What is the current value of the annuity?
- L0 1** 49. **Present Value and Multiple Cash Flows.** What is the present value of \$1,625 per year, at a discount rate of 7 percent, if the first payment is received 6 years from now and the last payment is received 20 years from now?
- L0 1** 50. **Variable Interest Rates.** A 10-year annuity pays \$2,500 per month, and payments are made at the end of each month. If the interest rate is 9 percent compounded monthly for the first four years, and 7 percent compounded monthly thereafter, what is the present value of the annuity?
- L0 1** 51. **Comparing Cash Flow Streams.** You have your choice of two investment accounts. Investment A is a 10-year annuity that features end-of-month \$1,680 payments and has an interest rate of 8 percent compounded monthly. Investment B is a 10 percent annually compounded lump-sum investment, also good for 10 years. How much money would you need to invest in B today for it to be worth as much as Investment A 10 years from now?
- L0 1** 52. **Calculating Present Value of a Perpetuity.** Given an interest rate of 6.35 percent per year, what is the value at year $t = 7$ of a perpetual stream of \$3,100 payments that begin at year $t = 20$?

- L0 4** 53. **Calculating EAR.** A local finance company quotes a 17 percent interest rate on one-year loans. So, if you borrow \$20,000, the interest for the year will be \$3,400. Because you must repay a total of \$23,400 in one year, the finance company requires you to pay $\$23,400/12$, or \$1,950 per month over the next 12 months. Is this a 17 percent loan? What rate would legally have to be quoted? What is the effective annual rate?
- L0 1** 54. **Calculating Future Values.** If today is Year 0, what is the future value of the following cash flows five years from now? What is the future value 10 years from now? Assume an interest rate of 7.8 percent per year.

Year	Cash Flow
2	\$21,000
3	39,000
5	57,000

- L0 3** 55. **Amortization with Equal Payments.** Prepare an amortization schedule for a three-year loan of \$60,000. The interest rate is 9 percent per year, and the loan calls for equal annual payments. How much interest is paid in the third year? How much total interest is paid over the life of the loan?
- L0 3** 56. **Amortization with Equal Principal Payments.** Rework Problem 55 assuming that the loan agreement calls for a principal reduction of \$20,000 every year instead of equal annual payments.
- L0 4** 57. **Discount Interest Loans.** This question illustrates what is known as *discount interest*. Imagine you are discussing a loan with a somewhat unscrupulous lender. You want to borrow \$15,000 for one year. The interest rate is 16 percent. You and the lender agree that the interest on the loan will be $.16 \times \$15,000 = \$2,400$. So, the lender deducts this interest amount from the loan up front and gives you \$12,600. In this case, we say that the discount is \$2,400. What's wrong here?
- L0 1** 58. **Calculating Annuity Values.** You are serving on a jury. A plaintiff is suing the city for injuries sustained after a freak street sweeper accident. In the trial, doctors testified that it will be five years before the plaintiff is able to return to work. The jury has already decided in favor of the plaintiff. You are the foreperson of the jury and propose that the jury give the plaintiff an award to cover the following: (a) The present value of two years' back pay. The plaintiff's annual salary for the last two years would have been \$47,000 and \$50,000, respectively. (b) The present value of five years' future salary. You assume the salary will be \$54,000 per year. (c) \$150,000 for pain and suffering. (d) \$20,000 for court costs. Assume that the salary payments are equal amounts paid at the end of each month. If the interest rate you choose is a 9 percent EAR, what is the size of the settlement? If you were the plaintiff, would you like to see a higher or lower interest rate?
- L0 4** 59. **Calculating EAR with Points.** You are looking at a one-year loan of \$10,000. The interest rate is quoted as 10 percent plus two points. A *point* on a loan is simply 1 percent (one percentage point) of the loan amount. Quotes similar to this one are common with home mortgages. The interest rate quotation in this example requires the borrower to pay two points to the lender up front and repay the loan later with 10 percent interest. What rate would you actually be paying here?
- L0 1** 60. **Future Value and Multiple Cash Flows.** An insurance company is offering a new policy to its customers. Typically, the policy is bought by a parent or grandparent

Challenge
(Questions 57–60)

for a child at the child's birth. The details of the policy are as follows: The purchaser (say, the parent) makes the following six payments to the insurance company:

First birthday:	\$750
Second birthday:	\$750
Third birthday:	\$850
Fourth birthday:	\$850
Fifth birthday:	\$950
Sixth birthday:	\$950

After the child's sixth birthday, no more payments are made. When the child reaches age 65, he or she receives \$350,000. If the relevant interest rate is 11 percent for the first six years and 7 percent for all subsequent years, is the policy worth buying?

WHAT'S ON THE WEB?

- 5.1 Annuity Future Value.** The St. Louis Federal Reserve Board has files listing historical interest rates on their Web site www.stlouisfed.org. Find the link for "FRED®" (Federal Reserve Economic Data). You will find listings for Moody's Seasoned Aaa Corporate Bond Yield and Moody's Seasoned Baa Corporate Bond Yield. (These rates are discussed in the next chapter.) If you invest \$2,000 per year for the next 40 years at the most recent Aaa yield, how much will you have? What if you invest the same amount at the Baa yield?
- 5.2 Loan Payments.** Finding the time necessary until you pay off a loan is simple if you make equal payments each month. However, when paying off credit cards many individuals only make the minimum monthly payment, which is generally \$10 or 2 percent to 3 percent of the balance, whichever is greater. You can find a credit card calculator at www.fincalc.com. You currently owe \$10,000 on a credit card with a 17 percent interest rate and a minimum payment of \$10 or 2 percent of your balance, whichever is greater. How soon will you pay off this debt if you make the minimum payment each month? How much total interest will you pay?
- 5.3 Annuity Payments.** Find the retirement calculator at www.moneychimp.com to answer the following question: Suppose you have \$1,500,000 when you retire and want to withdraw an equal amount each year for the next 30 years. How much can you withdraw each year if you earn 7 percent? What if you can earn 9 percent?
- 5.4 Annuity Payments.** The St. Louis Federal Reserve Board has files listing historical interest rates on their Web site www.stlouisfed.org. Find the link for "FRED®" (Federal Reserve Economic Data). You will find a listing for the Bank Prime Loan Rate. The file lists the monthly prime rates since January 1949 (1949.01). What is the most recent prime rate? What is the highest prime rate over this period? If you buy a house for \$150,000 at the current prime rate on a 30-year mortgage with monthly payments, how much are your payments? If you had purchased the house at the same price when the prime rate was at its highest, what would your monthly payments have been?
- 5.5 Loan Amortization.** Bankrate.com, located at www.bankrate.com, has a financial calculator that will prepare an amortization table based on your inputs. First, find the APR quoted on the Web site for a 30-year fixed rate mortgage. You want to buy a home for \$200,000 on a 30-year mortgage with monthly payments at the rate quoted on the site. What percentage of your first month's payment is principal? What percentage of your last month's payment is principal? What is the total interest paid on the loan?

CHAPTER CASE

S&S AIR'S MORTGAGE

Mark Sexton and Todd Story, the owners of S&S Air, Inc., were impressed by the work Chris had done on financial planning. Using Chris's analysis, and looking at the demand for light aircraft, they have decided that their existing fabrication equipment is sufficient, but it is time to acquire a bigger manufacturing facility. Mark and Todd have identified a suitable structure that is currently for sale, and they believe they can buy and refurbish it for about \$22 million. Mark, Todd, and Chris are now ready to meet with Christie Vaughan, the loan officer for First United National Bank. The meeting is to discuss the mortgage options available to the company to finance the new facility.

Christie begins the meeting by discussing a 30-year mortgage. The loan would be repaid in equal monthly installments. Because of the previous relationship between S&S Air and the bank, there would be no closing costs for the loan. Christie states that the APR of the loan would be 6.1 percent. Todd asks if a shorter mortgage loan is available. Christie says that the bank does have a 20-year mortgage available at the same APR.

Mark decides to ask Christie about a "smart loan" he discussed with a mortgage broker when he was refinancing his home loan. A smart loan works as follows: Every two weeks a mortgage payment is made that is exactly one-half of the traditional monthly mortgage payment. Christie informs him that the bank does have smart loans. The APR of the smart loan would be the same as the APR of the traditional loan. Mark nods his head. He then states this is the best mortgage option available to the company since it saves interest payments.

Christie agrees with Mark, but then suggests that a bullet loan, or balloon payment, would result in the

greatest interest savings. At Todd's prompting, she goes on to explain a bullet loan. The monthly payments of a bullet loan would be calculated using a 30-year traditional mortgage. In this case, there would be a 5-year bullet. This would mean that the company would make the mortgage payments for the traditional 30-year mortgage for the first five years, but immediately after the company makes the 60th payment, the bullet payment would be due. The bullet payment is the remaining principal of the loan. Chris then asks how the bullet payment is calculated. Christie tells him that the remaining principal can be calculated using an amortization table, but it is also the present value of the remaining 25 years of mortgage payments for the 30-year mortgage.

Todd has also heard of an interest-only loan and asks if this loan is available and what the terms would be. Christie says that the bank offers an interest-only loan with a term of 10 years and an APR of 3.5 percent. She goes on to further explain the terms. The company would be responsible for making interest payments each month on the amount borrowed. No principal payments are required. At the end of the 10-year term, the company would repay the \$22 million. However, the company can make principal payments at any time. The principal payments would work just like those on a traditional mortgage. Principal payments would reduce the principal of the loan and reduce the interest due on the next payment.

Mark and Todd are satisfied with Christie's answers, but they are still unsure of which loan they should choose. They have asked Chris to answer the following questions to help them choose the correct mortgage. ■

QUESTIONS

1. What are the monthly payments for a 30-year traditional mortgage? What are the payments for a 20-year traditional mortgage?
2. Prepare an amortization table for the first six months of the traditional 30-year mortgage. How much of the first payment goes toward principal?
3. How long would it take for S&S Air to pay off the smart loan assuming 30-year traditional mortgage payments? Why is this shorter than the time needed to pay off the traditional mortgage? How much interest would the company save?
4. Assume S&S Air takes out a bullet loan under the terms described. What are the payments on the loan?
5. What are the payments for the interest-only loan?
6. Which mortgage is the best for the company? Are there any potential risks in this action?

Interest Rates and Bond Valuation

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Identify important bond features and types of bonds.
- LO 2** Describe bond values and why they fluctuate.
- LO 3** Discuss bond ratings and what they mean.
- LO 4** Evaluate the impact of inflation on interest rates.
- LO 5** Explain the bond structure of interest rates and the determinants of bond yields.

In its most basic form, a bond is a pretty simple thing. You lend a company some money, say \$1,000. The company pays you interest regularly, and it repays the original loan amount of \$1,000 at some point in the future. But bonds also can have complex features, and, in 2008, a type of bond known as a mortgage-backed security, or MBS, was causing havoc in the global financial system.

An MBS, as the name suggests, is a bond that is backed by a pool of home mortgages. The bondholders receive payments derived from payments on the underlying mortgages, and these payments can be divided up in various ways to create different classes of

bonds. Defaults on the underlying mortgages lead to losses to MBS bondholders, particularly those in the riskier classes, and as the U.S. housing crunch hit in 2007–2008, defaults increased sharply. Losses to investors continue to pile up, so the total damage still isn't known, but estimates range from \$250 billion to \$500 billion or more, colossal sums by any measure.

This chapter takes what we have learned about the time value of money and shows how it can be used to value one of the most common of all financial assets, a bond. It then discusses bond features, bond types, and the operation of the bond market.

What we will see is that bond prices depend critically on interest rates, so we will go on to discuss some very fundamental issues regarding interest rates. Clearly, interest rates are important to everybody because they underlie what businesses of all types—small and large—must pay to borrow money.

Visit us at www.mhhe.com/rwj

Our goal in this chapter is to introduce you to bonds. We begin by showing how the techniques we developed in Chapters 4 and 5 can be applied to bond valuation. From there, we go on to discuss bond features and how bonds are bought and sold. One important thing we learn is that bond values depend, in large part, on interest rates. We therefore close out the chapter with an examination of interest rates and their behavior.

BONDS AND BOND VALUATION

6.1

When a corporation (or government) wishes to borrow money from the public on a long-term basis, it usually does so by issuing, or selling, debt securities that are generically called bonds. In this section, we describe the various features of corporate bonds and some of the terminology associated with bonds. We then discuss the cash flows associated with a bond and how bonds can be valued using our discounted cash flow procedure.

Bond Features and Prices

As we mentioned in our previous chapter, a bond is normally an interest-only loan, meaning that the borrower will pay the interest every period, but none of the principal will be repaid until the end of the loan. For example, suppose the Beck Corporation wants to borrow \$1,000 for 30 years. The interest rate on similar debt issued by similar corporations is 12 percent. Beck will thus pay $.12 \times \$1,000 = \120 in interest every year for 30 years. At the end of 30 years, Beck will repay the \$1,000. As this example suggests, a bond is a fairly simple financing arrangement. There is, however, a rich jargon associated with bonds, so we will use this example to define some of the more important terms.

In our example, the \$120 regular interest payments that Beck promises to make are called the bond's **coupons**. Because the coupon is constant and paid every year, the type of bond we are describing is sometimes called a *level coupon bond*. The amount that will be repaid at the end of the loan is called the bond's **face value** or **par value**. As in our example, this par value is usually \$1,000 for corporate bonds, and a bond that sells for its par value is called a *par value bond*. Government bonds frequently have much larger face, or par, values. Finally, the annual coupon divided by the face value is called the **coupon rate** on the bond; in this case, because $\$120/\$1,000 = 12\%$, the bond has a 12 percent coupon rate.

The number of years until the face value is paid is called the bond's time to **maturity**. A corporate bond will frequently have a maturity of 30 years when it is originally issued, but this varies. Once the bond has been issued, the number of years to maturity declines as time goes by.

Bond Values and Yields

As time passes, interest rates change in the marketplace. The cash flows from a bond, however, stay the same. As a result, the value of the bond will fluctuate. When interest rates rise, the present value of the bond's remaining cash flows declines, and the bond is worth less. When interest rates fall, the bond is worth more.

To determine the value of a bond at a particular point in time, we need to know the number of periods remaining until maturity, the face value, the coupon, and the market interest rate for bonds with similar features. This interest rate required in the market on a bond is called the bond's **yield to maturity (YTM)**. This rate is sometimes called the bond's *yield* for short. Given all this information, we can calculate the present value of the cash flows as an estimate of the bond's current market value.

coupon

Stated interest payment made on a bond.

face value

The principal amount of a bond that is repaid at the end of the term. Also, par value.

coupon rate

The annual coupon divided by the face value of a bond.

maturity

Date on which the principal amount of a bond is paid.

yield to maturity (YTM)

The rate required in the market on a bond.

FIGURE 6.1**Cash flows for Xanth Co. bond***Cash flows*

Year	0	1	2	3	4	5	6	7	8	9	10
Coupon		\$80	\$80	\$80	\$80	\$80	\$80	\$80	\$80	\$80	\$ 80
Face Value											1,000
		<u>\$80</u>	<u>\$80</u>	<u>\$80</u>	<u>\$80</u>	<u>\$80</u>	<u>\$80</u>	<u>\$80</u>	<u>\$80</u>	<u>\$80</u>	<u>\$1,080</u>

As shown, the Xanth bond has an annual coupon of \$80 and a face, or par, value of \$1,000 paid at maturity in 10 years.

For example, suppose the Xanth (pronounced “zanth”) Co. were to issue a bond with 10 years to maturity. The Xanth bond has an annual coupon of \$80. Similar bonds have a yield to maturity of 8 percent. Based on our preceding discussion, the Xanth bond will pay \$80 per year for the next 10 years in coupon interest. In 10 years, Xanth will pay \$1,000 to the owner of the bond. The cash flows from the bond are shown in Figure 6.1. What would this bond sell for?

As illustrated in Figure 6.1, the Xanth bond’s cash flows have an annuity component (the coupons) and a lump sum (the face value paid at maturity). We thus estimate the market value of the bond by calculating the present value of these two components separately and adding the results together. First, at the going rate of 8 percent, the present value of the \$1,000 paid in 10 years is:

$$\text{Present value} = \$1,000/1.08^{10} = \$1,000/2.1589 = \$463.19$$

Second, the bond offers \$80 per year for 10 years; the present value of this annuity stream is:

$$\begin{aligned}\text{Annuity present value} &= \$80 \times (1 - 1/1.08^{10})/.08 \\ &= \$80 \times (1 - 1/2.1589)/.08 \\ &= \$80 \times 6.7101 \\ &= \$536.81\end{aligned}$$

We can now add the values for the two parts together to get the bond’s value:

$$\text{Total bond value} = \$463.19 + \$536.81 = \$1,000$$

This bond sells for exactly its face value. This is not a coincidence. The going interest rate in the market is 8 percent. Considered as an interest-only loan, what interest rate does this bond have? With an \$80 coupon, this bond pays exactly 8 percent interest only when it sells for \$1,000.

To illustrate what happens as interest rates change, suppose that a year has gone by. The Xanth bond now has nine years to maturity. If the interest rate in the market has risen to 10 percent, what will the bond be worth? To find out, we repeat the present value calculations with 9 years instead of 10, and a 10 percent yield instead of an 8 percent yield. First, the present value of the \$1,000 paid in nine years at 10 percent is:

$$\text{Present value} = \$1,000/1.10^9 = \$1,000/2.3579 = \$424.10$$

Second, the bond now offers \$80 per year for nine years; the present value of this annuity stream at 10 percent is:

$$\begin{aligned}\text{Annuity present value} &= \$80 \times (1 - 1/1.10^9)/.10 \\ &= \$80 \times (1 - 1/2.3579)/.10 \\ &= \$80 \times 5.7590 \\ &= \$460.72\end{aligned}$$

We can now add the values for the two parts together to get the bond's value:

$$\text{Total bond value} = \$424.10 + 460.72 = \$884.82$$

Therefore, the bond should sell for about \$885. In the vernacular, we say that this bond, with its 8 percent coupon, is priced to yield 10 percent at \$885.

The Xanth Co. bond now sells for less than its \$1,000 face value. Why? The market interest rate is 10 percent. Considered as an interest-only loan of \$1,000, this bond only pays 8 percent, its coupon rate. Because this bond pays less than the going rate, investors are only willing to lend something less than the \$1,000 promised repayment. Because the bond sells for less than face value, it is said to be a *discount bond*.

The only way to get the interest rate up to 10 percent is to lower the price to less than \$1,000 so that the purchaser, in effect, has a built-in gain. For the Xanth bond, the price of \$885 is \$115 less than the face value, so an investor who purchased and kept the bond would get \$80 per year and would have a \$115 gain at maturity as well. This gain compensates the lender for the below-market coupon rate.

Another way to see why the bond is discounted by \$115 is to note that the \$80 coupon is \$20 below the coupon on a newly issued par value bond, based on current market conditions. The bond would be worth \$1,000 only if it had a coupon of \$100 per year. In a sense, an investor who buys and keeps the bond gives up \$20 per year for nine years. At 10 percent, this annuity stream is worth:

$$\begin{aligned}\text{Annuity present value} &= \$20 \times (1 - 1/1.10^9)/.10 \\ &= \$20 \times 5.7590 \\ &= \$115.18\end{aligned}$$

This is just the amount of the discount.

What would the Xanth bond sell for if interest rates had dropped by 2 percent instead of rising by 2 percent? As you might guess, the bond would sell for more than \$1,000. Such a bond is said to sell at a *premium* and is called a *premium bond*.

This case is just the opposite of that of a discount bond. The Xanth bond now has a coupon rate of 8 percent when the market rate is only 6 percent. Investors are willing to pay a premium to get this extra coupon amount. In this case, the relevant discount rate is 6 percent, and there are nine years remaining. The present value of the \$1,000 face amount is:

$$\text{Present value} = \$1,000/1.06^9 = \$1,000/1.6895 = \$591.89$$

The present value of the coupon stream is:

$$\begin{aligned}\text{Annuity present value} &= \$80 \times (1 - 1/1.06^9)/.06 \\ &= \$80 \times (1 - 1/1.6895)/.06 \\ &= \$80 \times 6.8017 \\ &= \$544.14\end{aligned}$$

We can now add the values for the two parts together to get the bond's value:

$$\text{Total bond value} = \$591.89 + 544.14 = \$1,136.03$$

Total bond value is therefore about \$136 in excess of par value. Once again, we can verify this amount by noting that the coupon is now \$20 too high, based on current market conditions. The present value of \$20 per year for nine years at 6 percent is:

$$\begin{aligned}\text{Annuity present value} &= \$20 \times (1 - 1/1.06^9)/.06 \\ &= \$20 \times 6.8017 \\ &= \$136.03\end{aligned}$$

This is just as we calculated.

A good bond site to visit is bonds.yahoo.com, which has loads of useful information.

Based on our examples, we can now write the general expression for the value of a bond. If a bond has (1) a face value of F paid at maturity, (2) a coupon of C paid per period, (3) t periods to maturity, and (4) a yield of r per period, its value is:

$$\begin{aligned} \text{Bond value} &= C \times [1 - 1/(1 + r)^t]/r + F/(1 + r)^t \\ \text{Bond value} &= \text{Present value of the coupons} + \text{Present value of the face amount} \end{aligned} \quad [6.1]$$

EXAMPLE 6.1

Semiannual Coupons

In practice, bonds issued in the United States usually make coupon payments twice a year. So, if an ordinary bond has a coupon rate of 14 percent, then the owner will get a total of \$140 per year, but this \$140 will come in two payments of \$70 each. Suppose we are examining such a bond. The yield to maturity is quoted at 16 percent.

Bond yields are quoted like APRs; the quoted rate is equal to the actual rate per period multiplied by the number of periods. In this case, with a 16 percent quoted yield and semiannual payments, the true yield is 8 percent per six months. The bond matures in seven years. What is the bond's price? What is the effective annual yield on this bond?

Based on our discussion, we know that the bond will sell at a discount because it has a coupon rate of 7 percent every six months when the market requires 8 percent every six months. So, if our answer exceeds \$1,000, we know that we have made a mistake.

To get the exact price, we first calculate the present value of the bond's face value of \$1,000 paid in seven years. This seven-year period has 14 periods of six months each. At 8 percent per period, the value is:

$$\text{Present value} = \$1,000/1.08^{14} = \$1,000/2.9372 = \$340.46$$

The coupons can be viewed as a 14-period annuity of \$70 per period. At an 8 percent discount rate, the present value of such an annuity is:

$$\begin{aligned} \text{Annuity present value} &= \$70 \times (1 - 1/1.08^{14})/.08 \\ &= \$70 \times (1 - .3405)/.08 \\ &= \$70 \times 8.2442 \\ &= \$577.10 \end{aligned}$$

The total present value gives us what the bond should sell for:

$$\text{Total present value} = \$340.46 + \$577.10 = \$917.56$$

To calculate the effective yield on this bond, note that 8 percent every six months is equivalent to:

$$\text{Effective annual rate} = (1 + .08)^2 - 1 = 16.64\%$$

The effective yield, therefore, is 16.64 percent.

Online bond calculators are available at personal.fidelity.com; interest rate information is available at money.cnn.com/markets/bondcenter/ and www.bankrate.com.

As we have illustrated in this section, bond prices and interest rates always move in opposite directions. When interest rates rise, a bond's value, like any other present value, will decline. Similarly, when interest rates fall, bond values rise. Even if we are considering a bond that is riskless in the sense that the borrower is certain to make all the payments, there is still risk in owning a bond. We discuss this next.

Interest Rate Risk

The risk that arises for bond owners from fluctuating interest rates is called *interest rate risk*. How much interest rate risk a bond has depends on how sensitive its price is to interest rate changes. This sensitivity directly depends on two things: the time to maturity and the

**FIGURE 6.2**

Interest rate risk and
time to maturity

Value of a Bond with a 10 Percent Coupon Rate for Different Interest Rates and Maturities

Interest Rate	Time to Maturity	
	1 Year	30 Years
5%	\$1,047.62	\$1,768.62
10	1,000.00	1,000.00
15	956.52	671.70
20	916.67	502.11

coupon rate. As we will see momentarily, you should keep the following in mind when looking at a bond:

1. All other things being equal, the longer the time to maturity, the greater the interest rate risk.
2. All other things being equal, the lower the coupon rate, the greater the interest rate risk.

We illustrate the first of these two points in Figure 6.2. As shown, we compute and plot prices under different interest rate scenarios for 10 percent coupon bonds with maturities of 1 year and 30 years. Notice how the slope of the line connecting the prices is much steeper for the 30-year maturity bond than it is for the 1-year maturity bond. This steepness tells us that a relatively small change in interest rates will lead to a substantial change in the bond's value. In comparison, the one-year bond's price is relatively insensitive to interest rate changes.

Intuitively, we can see that the reason that longer-term bonds have greater interest rate sensitivity is that a large portion of a bond's value comes from the \$1,000 face amount. The present value of this amount isn't greatly affected by a small change in interest rates if the amount is to be received in one year. Even a small change in the interest rate, however, once it is compounded for 30 years, can have a significant effect on the present value. As a result, the present value of the face amount will be much more volatile with a longer-term bond.

The other thing to know about interest rate risk is that, like most things in finance and economics, it increases at a decreasing rate. In other words, if we compared a 10-year bond to a 1-year bond, we would see that the 10-year bond has much greater interest rate risk. However, if you were to compare a 20-year bond to a 30-year bond, you would find that the 30-year bond has somewhat greater interest rate risk because it has a longer maturity, but the difference in the risk would be fairly small.

The reason that bonds with lower coupons have greater interest rate risk is easy to understand. As we discussed earlier, the value of a bond depends on the present value of its

to learn more about
bonds.

coupons and the present value of the face amount. If two bonds with different coupon rates have the same maturity, then the value of the one with the lower coupon is proportionately more dependent on the face amount to be received at maturity. As a result, all other things being equal, its value will fluctuate more as interest rates change. Put another way, the bond with the higher coupon has a larger cash flow early in its life, so its value is less sensitive to changes in the discount rate.

Bonds are usually not issued with maturities longer than 30 years. However, low interest rates in recent years have led to the issuance of bonds with much longer maturities. In the 1990s, Walt Disney issued “Sleeping Beauty” bonds with a 100-year maturity. Similarly, BellSouth (now known as AT&T), Coca-Cola, and Dutch banking giant ABN Amro all issued bonds with 100-year maturities. These companies wanted to lock in the historical low interest rates for a *long* time. The current record holder for corporations appears to be Republic National Bank, which sold bonds with 1,000 years to maturity. Before these fairly recent issues, it appears the last time 100-year bonds were issued was in May 1954 by the Chicago and Eastern Railroad. Just in case you are wondering when the next 100-year bonds will be issued, you might have a long wait on your hands. The IRS has warned companies about issuing such long-term bonds, threatening to disallow the interest payment tax deduction.

We can illustrate the effect of interest rate risk using the 100-year BellSouth issue. The following table provides some basic information on this issue, along with its prices on December 31, 1995, January 14, 2005, and March 6, 2009.

Maturity	Coupon Rate	Price on 12/31/95	Price on 01/14/05	Percentage Change in Price 1995–2005	Price on 03/06/09	Percentage Change in Price 2005–2009
2095	7.00%	\$1,000.00	\$1,150.20	+15.02%	\$803.43	–30.15%

Several things emerge from this table. First, interest rates apparently fell between December 31, 1995, and January 14, 2005 (why?). After that, however, they rose (why?). The bond’s price first gained 15 percent and then lost 30.2 percent. These swings illustrate that longer-term bonds have significant interest rate risk.

Finding the Yield to Maturity: More Trial and Error

Frequently, we will know a bond’s price, coupon rate, and maturity date, but not its yield to maturity. For example, suppose we are interested in a six-year, 8 percent coupon bond. A broker quotes a price of \$955.14. What is the yield on this bond?

We’ve seen that the price of a bond can be written as the sum of its annuity and lump-sum components. Knowing that there is an \$80 coupon for six years and a \$1,000 face value, we can say that the price is:

$$\text{\$955.14} = \text{\$80} \times [1 - 1/(1 + r)^6]/r + 1,000/(1 + r)^6$$

where r is the unknown discount rate, or yield to maturity. We have one equation here and one unknown, but we cannot solve for r explicitly. The only way to find the answer is to use trial and error.

This problem is essentially identical to the one we examined in the last chapter when we tried to find the unknown interest rate on an annuity. However, finding the rate (or yield) on a bond is even more complicated because of the \$1,000 face amount.

We can speed up the trial-and-error process by using what we know about bond prices and yields. In this case, the bond has an \$80 coupon and is selling at a discount. We thus know that the yield is greater than 8 percent. If we compute the price at 10 percent:

$$\begin{aligned}\text{Bond value} &= \$80 \times (1 - 1/1.10^6)/.10 + 1,000/1.10^6 \\ &= \$80 \times 4.3553 + 1,000/1.7716 \\ &= \$912.89\end{aligned}$$

At 10 percent, the value we calculate is lower than the actual price, so 10 percent is too high. The true yield must be somewhere between 8 and 10 percent. At this point, it's "plug and chug" to find the answer. You would probably want to try 9 percent next. If you did, you would see that this is in fact the bond's yield to maturity.

A bond's yield to maturity should not be confused with its **current yield**, which is simply a bond's annual coupon divided by its price. In the example we just worked, the bond's annual coupon was \$80, and its price was \$955.14. Given these numbers, we see that the current yield is $\$80/\$955.14 = 8.38$ percent, which is less than the yield to maturity of 9 percent. The reason the current yield is too low is that it only considers the coupon portion of your return; it doesn't consider the built-in gain from the price discount. For a premium bond, the reverse is true, meaning that current yield would be higher because it ignores the built-in loss.

Our discussion of bond valuation is summarized in Table 6.1.

Current market rates are available at www.bankrate.com.

current yield

A bond's annual coupon divided by its price.

Current Events

EXAMPLE 6.2

A bond has a quoted price of \$1,080.42. It has a face value of \$1,000, a semiannual coupon of \$30, and a maturity of five years. What is its current yield? What is its yield to maturity? Which is bigger? Why?

Notice that this bond makes semiannual payments of \$30, so the annual payment is \$60. The current yield is thus $\$60/\$1,080.42 = 5.55$ percent. To calculate the yield to maturity, refer back to Example 6.1. Now, in this case, the bond pays \$30 every six months and it has 10 six-month periods until maturity. So, we need to find r as follows:

$$\$1,080.42 = \$30 \times [1 - 1/(1 + r)^{10}]/r + 1,000/(1 + r)^{10}$$

After some trial and error, we find that r is equal to 2.1 percent. But, the tricky part is that this 2.1 percent is the yield per *six months*. We have to double it to get the yield to maturity, so the yield to maturity is 4.2 percent, which is less than the current yield. The reason is that the current yield ignores the built-in loss of the premium between now and maturity.

I. Finding the value of a bond

$$\text{Bond value} = C \times [1 - 1/(1 + r)^t]/r + F/(1 + r)^t$$

where

C = Coupon paid each period

r = Rate per period

t = Number of periods

F = Bond's face value

II. Finding the yield on a bond

Given a bond value, coupon, time to maturity, and face value, it is possible to find the implicit discount rate, or yield to maturity, by trial and error only. To do this, try different discount rates in the formula above until the calculated bond value equals the given bond value. Remember that increasing the rate *decreases* the bond value.

TABLE 6.1

Summary of bond valuation

EXAMPLE 6.3**Bond Yields**

You're looking at two bonds identical in every way except for their coupons and, of course, their prices. Both have 12 years to maturity. The first bond has a 10 percent coupon rate and sells for \$935.08. The second has a 12 percent coupon rate. What do you think it would sell for?

Because the two bonds are very similar, they will be priced to yield about the same rate. We first need to calculate the yield on the 10 percent coupon bond. Proceeding as before, we know that the yield must be greater than 10 percent because the bond is selling at a discount. The bond has a fairly long maturity of 12 years. We've seen that long-term bond prices are relatively sensitive to interest rate changes, so the yield is probably close to 10 percent. A little trial and error reveals that the yield is actually 11 percent:

$$\begin{aligned}\text{Bond value} &= \$100 \times (1 - 1/1.11^{12})/.11 + 1,000/1.11^{12} \\ &= \$100 \times 6.4924 + 1,000/3.4985 \\ &= \$649.24 + 285.84 \\ &= \$935.08\end{aligned}$$

With an 11 percent yield, the second bond will sell at a premium because of its \$120 coupon. Its value is:

$$\begin{aligned}\text{Bond value} &= \$120 \times (1 - 1/1.11^{12})/.11 + 1,000/1.11^{12} \\ &= \$120 \times 6.4924 + 1,000/3.4985 \\ &= \$779.08 + 285.84 \\ &= \$1,064.92\end{aligned}$$

CALCULATOR HINTS**How to Calculate Bond Prices and Yields Using a Financial Calculator**

Many financial calculators have fairly sophisticated built-in bond valuation routines. However, these vary quite a lot in implementation, and not all financial calculators have them. As a result, we will illustrate a simple way to handle bond problems that will work on just about any financial calculator.

To begin, of course, we first remember to clear out the calculator! Next, for Example 6.3, we have two bonds to consider, both with 12 years to maturity. The first one sells for \$935.08 and has a 10 percent coupon rate. To find its yield, we can do the following:

Enter	12	100	-935.08	1,000
	N	I/Y	PMT	PV
Solve for		11		

Notice that here we have entered both a future value of \$1,000, representing the bond's face value, and a payment of 10 percent of \$1,000, or \$100, per year, representing the bond's annual coupon. Also notice that we have a negative sign on the bond's price, which we have entered as the present value.

For the second bond, we now know that the relevant yield is 11 percent. It has a 12 percent coupon and 12 years to maturity, so what's the price? To answer, we just enter the relevant values and solve for the present value of the bond's cash flows:

Enter	12	11	120	1,000
	N	I/Y	PMT	PV
Solve for				-1,064.92

(continued)

There is an important detail that comes up here. Suppose we have a bond with a price of \$902.29, 10 years to maturity, and a coupon rate of 6 percent. As we mentioned earlier, most bonds actually make semiannual payments. Assuming that this is the case for the bond here, what's the bond's yield? To answer, we need to enter the relevant numbers like this:

Enter	20	30	-902.29	1,000
	N	I/Y	PMT	PV
Solve for		3.7		

Notice that we entered \$30 as the payment because the bond actually makes payments of \$30 every six months. Similarly, we entered 20 for N because there are actually 20 six-month periods. When we solve for the yield, we get 3.7 percent, but the tricky thing to remember is that this is the yield *per six months*, so we have to double it to get the right answer: $2 \times 3.7 = 7.4$ percent, which would be the bond's reported yield.

How to Calculate Bond Prices and Yields Using a Spreadsheet

SPREADSHEET STRATEGIES

Like financial calculators, most spreadsheets have fairly elaborate routines available for calculating bond values and yields; many of these routines involve details that we have not discussed. However, setting up a simple spreadsheet to calculate prices or yields is straightforward, as our next two spreadsheets show:

	A	B	C	D	E	F	G	H
1								
2	Using a spreadsheet to calculate bond values							
3								
4	Suppose we have a bond with 22 years to maturity, a coupon rate of 8 percent, and a price of							
5	\$960.17. If the bond makes semiannual payments, what is its yield to maturity?							
6								
7	Settlement date:	1/1/00						
8	Maturity date:	1/1/22						
9	Annual coupon rate:	.08						
10	Bond price (% of par):	96.017						
11	Face value (% of par):	100						
12	Coupons per year:	2						
13	Yield to maturity:	.084						
14								
15	The formula entered in cell B13 is =YIELD(B7,B8,B9,B10,B11,B12); notice that face value and bond							
16	price are entered as a percentage of face value.							
17								

(continued)

	A	B	C	D	E	F	G	H
1								
2	Using a spreadsheet to calculate bond values							
3								
4	Suppose we have a bond with 22 years to maturity, a coupon rate of 8 percent, and a yield to							
5	maturity of 9 percent. If the bond makes semiannual payments, what is its price today?							
6								
7	Settlement date:	1/1/00						
8	Maturity date:	1/1/22						
9	Annual coupon rate:	.08						
10	Yield to maturity:	.09						
11	Face value (% of par):	100						
12	Coupons per year:	2						
13	Bond price (% of par):	90.49						
14								
15	The formula entered in cell B13 is =PRICE(B7,B8,B9,B10,B11,B12); notice that face value and bond							
16	price are entered as a percentage of face value.							
17								

In our spreadsheets, notice that we had to enter two dates, a settlement date and a maturity date. The settlement date is just the date you actually pay for the bond, and the maturity date is the day the bond actually matures. In most of our problems, we don't explicitly have these dates, so we have to make them up. For example, since our bond has 22 years to maturity, we just picked 1/1/2000 (January 1, 2000) as the settlement date and 1/1/2022 (January 1, 2022) as the maturity date. Any two dates would do as long as they were exactly 22 years apart, but these are particularly easy to work with. Finally, notice that we had to enter the coupon rate and yield to maturity in annual terms and then explicitly provide the number of coupon payments per year.

CONCEPT QUESTIONS

- 6.1a** What are the cash flows associated with a bond?
- 6.1b** What is the general expression for the value of a bond?
- 6.1c** Is it true that the only risk associated with owning a bond is that the issuer will not make all the payments? Explain.

6.2

MORE ON BOND FEATURES

In this section, we continue our discussion of corporate debt by describing in some detail the basic terms and features that make up a typical long-term corporate bond. We discuss additional issues associated with long-term debt in subsequent sections.

Securities issued by corporations may be classified roughly as *equity securities* and *debt securities*. At the crudest level, a debt represents something that must be repaid; it is the result of borrowing money. When corporations borrow, they generally promise to make regularly scheduled interest payments and to repay the original amount borrowed (that is, the principal). The person or firm making the loan is called the *creditor*, or *lender*. The corporation borrowing the money is called the *debtor*, or *borrower*.

From a financial point of view, the main differences between debt and equity are the following:

1. Debt is not an ownership interest in the firm. Creditors generally do not have voting power.
2. The corporation's payment of interest on debt is considered a cost of doing business and is fully tax deductible. Dividends paid to stockholders are *not* tax deductible.
3. Unpaid debt is a liability of the firm. If it is not paid, the creditors can legally claim the assets of the firm. This action can result in liquidation or reorganization, two of the possible consequences of bankruptcy. Thus, one of the costs of issuing debt is the possibility of financial failure. This possibility does not arise when equity is issued.

Information for bond investors can be found at www.investinginbonds.com.

Is It Debt or Equity?

Sometimes it is not clear if a particular security is debt or equity. For example, suppose a corporation issues a perpetual bond with interest payable solely from corporate income if and only if earned. Whether or not this is really a debt is hard to say and is primarily a legal and semantic issue. Courts and taxing authorities would have the final say.

Corporations are very adept at creating exotic, hybrid securities that have many features of equity but are treated as debt. Obviously, the distinction between debt and equity is very important for tax purposes. So, one reason that corporations try to create a debt security that is really equity is to obtain the tax benefits of debt and the bankruptcy benefits of equity.

As a general rule, equity represents an ownership interest, and it is a residual claim. This means that equity holders are paid after debt holders. As a result of this, the risks and benefits associated with owning debt and equity are different. To give just one example, note that the maximum reward for owning a debt security is ultimately fixed by the amount of the loan, whereas there is no upper limit to the potential reward from owning an equity interest.

Long-Term Debt: The Basics

Ultimately, all long-term debt securities are promises made by the issuing firm to pay principal when due and to make timely interest payments on the unpaid balance. Beyond this, there are a number of features that distinguish these securities from one another. We discuss some of these features next.

The maturity of a long-term debt instrument is the length of time the debt remains outstanding with some unpaid balance. Debt securities can be short term (with maturities of one year or less) or long term (with maturities of more than one year).¹ Short-term debt is sometimes referred to as *unfunded debt*.²

Debt securities are typically called *notes*, *debentures*, or *bonds*. Strictly speaking, a bond is a secured debt. However, in common usage, the word *bond* refers to all kinds of secured and unsecured debt. We will therefore continue to use the term generically to refer to long-term debt.

The two major forms of long-term debt are public issue and privately placed. We concentrate on public-issue bonds. Most of what we say about them holds true for private-issue, long-term debt as well. The main difference between public-issue and privately placed debt

¹ There is no universally agreed-upon distinction between short-term and long-term debt. In addition, people often refer to intermediate-term debt, which has a maturity of more than 1 year and less than 3 to 5, or even 10, years.

² The word *funding* is part of the jargon of finance. It generally refers to the long term. Thus, a firm planning to “fund” its debt requirements may be replacing short-term debt with long-term debt.

Information on individual bonds can be found at www.bondsonline.com.

is that the latter is directly placed with a lender and not offered to the public. Because this is a private transaction, the specific terms are up to the parties involved.

There are many other dimensions to long-term debt, including such things as security, call features, sinking funds, ratings, and protective covenants. The following table illustrates these features for a bond issued by ConocoPhillips on February 1, 2009. If some of these terms are unfamiliar, have no fear. We will discuss them all presently.

Features of a ConocoPhillips Bond		
Term		Explanation
Amount of issue	\$2.25 billion	The company issued \$2.25 billion worth of bonds.
Date of issue	02/01/2009	The bonds were sold on 02/01/2009.
Maturity	02/01/2039	The bonds mature on 02/01/2039.
Face value	\$2,000	The denomination of the bonds is \$2,000.
Annual coupon	6.50%	Each bondholder will receive \$130.00 per bond per year (6.5% of face value).
Offer price	98.560	The offer price will be 98.560% of the \$2,000 face value, or \$1,971.20, per bond.
Coupon payment dates	2/01, 8/01	Coupons of $\$130.00/2 = \65.00 will be paid on these dates.
Security	None	The bonds are not secured by specific assets.
Sinking fund	None	The bonds have no sinking fund.
Call provision	At any time	The bonds do not have a deferred call.
Call price	Treasury rate plus 0.50%	The bonds have a “make whole” call feature.
Rating	Moody's A1 S&P A	The bonds are in the middle of the investment grade rating.

Many of these features will be detailed in the bond indenture, so we discuss this first.

The Indenture

indenture

The written agreement between the corporation and the lender detailing the terms of the debt issue.

The **indenture** is the written agreement between the corporation (the borrower) and its creditors. It is sometimes referred to as the *deed of trust*.³ Usually, a trustee (a bank, perhaps) is appointed by the corporation to represent the bondholders. The trust company must (1) make sure the terms of the indenture are obeyed, (2) manage the sinking fund (described in the following pages), and (3) represent the bondholders in default, that is, if the company defaults on its payments to them.

The bond indenture is a legal document. It can run several hundred pages and generally makes for very tedious reading. It is an important document, however, because it generally includes the following provisions:

1. The basic terms of the bonds.
2. The total amount of bonds issued.
3. A description of property used as security.
4. The repayment arrangements.
5. The call provisions.
6. Details of the protective covenants.

We discuss these features next.

³ The term *loan agreement* or *loan contract* is usually used for privately placed debt and term loans.

Terms of a Bond Corporate bonds usually have a face value (that is, a denomination) of \$1,000 (\$2,000 has also become fairly common). This is called the *principal value*, and it is stated on the bond certificate. So, if a corporation wanted to borrow \$1 million, 1,000 bonds would have to be sold. The par value (that is, initial accounting value) of a bond is almost always the same as the face value, and the terms are used interchangeably in practice.

Corporate bonds are usually in **registered form**. For example, the indenture might read as follows:

Interest is payable semiannually on July 1 and January 1 of each year to the person in whose name the bond is registered at the close of business on June 15 or December 15, respectively.

This means that the company has a registrar who will record the ownership of each bond and record any changes in ownership. The company will pay the interest and principal by check mailed directly to the address of the owner of record. Long ago, corporate bonds (and other types) had attached “coupons.” To obtain an interest payment, the owner had to separate a coupon from the bond certificate and send it to the company registrar (the paying agent).

Alternatively, the bond could be in **bearer form**. This means that the certificate is the basic evidence of ownership, and the corporation will “pay the bearer.” Ownership is not otherwise recorded, and, as with a registered bond with attached coupons, the holder of the bond certificate detaches the coupons and sends them to the company to receive payment.

There are two drawbacks to bearer bonds. First, they are difficult to recover if they are lost or stolen. Second, because the company does not know who owns its bonds, it cannot notify bondholders of important events. Bearer bonds were once the dominant type, but they are now much less common (in the United States) than registered bonds.

Security Debt securities are classified according to the collateral and mortgages used to protect the bondholder.

Collateral is a general term that frequently means securities (for example, bonds and stocks) that are pledged as security for payment of debt. For example, collateral trust bonds often involve a pledge of common stock held by the corporation. However, the term *collateral* is commonly used to refer to any asset pledged on a debt.

Mortgage securities are secured by a mortgage on the real property of the borrower. The property involved is usually real estate, for example, land or buildings. The legal document that describes the mortgage is called a *mortgage trust indenture* or *trust deed*. A “blanket” mortgage pledges all the real property owned by the company.⁴

Bonds frequently represent unsecured obligations of the company. A **debenture** is an unsecured bond, for which no specific pledge of property is made. The term **note** is generally used for such instruments if the maturity of the unsecured bond is less than 10 or so years when the bond is originally issued. Debenture holders only have a claim on property not otherwise pledged, in other words, the property that remains after mortgages and collateral trusts are taken into account.

The terminology that we use here and elsewhere in this chapter is standard in the United States. Outside the United States, these same terms can have different meanings.

registered form

The form of bond issue in which the registrar of the company records ownership of each bond; payment is made directly to the owner of record.

bearer form

The form of bond issue in which the bond is issued without record of the owner's name; payment is made to whomever holds the bond.

debenture

An unsecured debt, usually with a maturity of 10 years or more.

note

An unsecured debt, usually with a maturity under 10 years.

⁴ Real property includes land and things “affixed thereto.” It does not include cash or inventories.

For example, bonds issued by the British government (“gilts”) are called treasury “stock.” Also, in the United Kingdom, a debenture is a *secured* obligation.

At the current time, almost all public bonds issued in the United States by industrial and financial companies are debentures. However, most utility and railroad bonds are secured by a pledge of assets.

Seniority In general terms, *seniority* indicates preference in position over other lenders, and debts are sometimes labeled as *senior* or *junior* to indicate seniority. Some debt is *subordinated*, as in, for example, a subordinated debenture.

In the event of default, holders of subordinated debt must give preference to other specified creditors. Usually, this means that the subordinated lenders will be paid off only after the specified creditors have been compensated. However, debt cannot be subordinated to equity.

Repayment Bonds can be repaid at maturity, at which time the bondholder will receive the stated, or face, value of the bond, or they may be repaid in part or in entirety before maturity. Early repayment in some form is more typical and is often handled through a sinking fund.

A **sinking fund** is an account managed by the bond trustee for the purpose of repaying the bonds. The company makes annual payments to the trustee, who then uses the funds to retire a portion of the debt. The trustee does this by either buying up some of the bonds in the market or calling in a fraction of the outstanding bonds. This second option is discussed in the next section.

There are many different kinds of sinking fund arrangements, and the details would be spelled out in the indenture. For example:

1. Some sinking funds start about 10 years after the initial issuance.
2. Some sinking funds establish equal payments over the life of the bond.
3. Some high-quality bond issues establish payments to the sinking fund that are not sufficient to redeem the entire issue. As a consequence, there is the possibility of a large “balloon payment” at maturity.

The Call Provision A **call provision** allows the company to repurchase, or “call,” part or all of the bond issue at stated prices over a specific period. Corporate bonds are usually callable.

Generally, the call price is above the bond’s stated value (that is, the par value). The difference between the call price and the stated value is the **call premium**. The amount of the call premium usually becomes smaller over time. One arrangement is to initially set the call premium equal to the annual coupon payment and then make it decline to zero as the call date moves closer to the time of maturity.

Call provisions are not usually operative during the first part of a bond’s life. This makes the call provision less of a worry for bondholders in the bond’s early years. For example, a company might be prohibited from calling its bonds for the first 10 years. This is a **deferred call provision**. During this period of prohibition, the bond is said to be **call protected**.

In just the last few years, use of a new type of call provision, a “make-whole” call, has become very widespread in the corporate bond market. With such a feature, bondholders receive exactly what the bonds are worth if they are called. When bondholders don’t suffer a loss in the event of a call, they are made whole.

To determine the make-whole call price, we calculate the present value of the remaining interest and principal payments at a rate specified in the indenture. For example,

The Securities Industry
and Financial Markets
Association (SIFMA)
Web site is
www.sifma.org.

sinking fund

An account managed by the bond trustee for early bond redemption.

call provision

An agreement giving the corporation the option to repurchase the bond at a specific price prior to maturity.

call premium

The amount by which the call price exceeds the par value of the bond.

deferred call provision

A call provision prohibiting the company from redeeming the bond prior to a certain date.

call protected bond

A bond that currently cannot be redeemed by the issuer.

looking at our ConocoPhillips issue, we see that the discount rate is “Treasury rate plus 0.50%.” What this means is that we determine the discount rate by first finding a U.S. Treasury issue with the same maturity. We calculate the yield to maturity on the Treasury issue and then add on an additional 0.50 percent to get the discount rate we use.

Notice that, with a make-whole call provision, the call price is higher when interest rates are lower and vice versa (why?). Also notice that, as is common with a make-whole call, the ConocoPhillips issue does not have a deferred call feature. Why might investors not be too concerned about the absence of this feature?

Protective Covenants A **protective covenant** is that part of the indenture or loan agreement that limits certain actions a company might otherwise wish to take during the term of the loan. Protective covenants can be classified into two types: negative covenants and positive (or affirmative) covenants.

A *negative covenant* is a “thou shalt not” type of covenant. It limits or prohibits actions that the company might take. Here are some typical examples:

1. The firm must limit the amount of dividends it pays according to some formula.
2. The firm cannot pledge any assets to other lenders.
3. The firm cannot merge with another firm.
4. The firm cannot sell or lease any major assets without approval by the lender.
5. The firm cannot issue additional long-term debt.

A *positive covenant* is a “thou shalt” type of covenant. It specifies an action that the company agrees to take or a condition the company must abide by. Here are some examples:

1. The company must maintain its working capital at or above some specified minimum level.
2. The company must periodically furnish audited financial statements to the lender.
3. The firm must maintain any collateral or security in good condition.

This is only a partial list of covenants; a particular indenture may feature many different ones.

protective covenant

A part of the indenture limiting certain actions that might be taken during the term of the loan, usually to protect the lender.

Want detailed information on the amount and terms of the debt issued by a particular firm? Check out the firm's latest financial statements by searching SEC filings at www.sec.gov.

CONCEPT QUESTIONS

- 6.2a** What are the distinguishing features of debt as compared to equity?
- 6.2b** What is the indenture? What are protective covenants? Give some examples.
- 6.2c** What is a sinking fund?

BOND RATINGS

6.3

Firms frequently pay to have their debt rated. The two leading bond-rating firms are Moody's and Standard and Poor's (S&P). The debt ratings are an assessment of the creditworthiness of the corporate issuer. The definitions of creditworthiness used by Moody's and S&P are based on how likely the firm is to default and the protection creditors have in the event of a default.

It is important to recognize that bond ratings are concerned *only* with the possibility of default. Earlier, we discussed interest rate risk, which we defined as the risk of a change in

the value of a bond resulting from a change in interest rates. Bond ratings do not address this issue. As a result, the price of a highly rated bond can still be quite volatile.

Bond ratings are constructed from information supplied by the corporation. The rating classes and some information concerning them are shown in the following table.

Investment-Quality Bond Ratings					Low-Quality, Speculative, and/or “Junk” Bond Ratings						
		High Grade		Medium Grade		Low Grade		Very Low Grade			
Standard & Poor’s		AAA	AA	A	BBB	BB	B	CCC	CC	C	D
Moody’s		Aaa	Aa	A	Baa	Ba	B	Caa	Ca	C	

Moody’s	S&P	
Aaa	AAA	Debt rated Aaa and AAA has the highest rating. Capacity to pay interest and principal is extremely strong.
Aa	AA	Debt rated Aa and AA has a very strong capacity to pay interest and repay principal. Together with the highest rating, this group comprises the high-grade bond class.
A	A	Debt rated A has a strong capacity to pay interest and repay principal, although it is somewhat more susceptible to the adverse effects of changes in circumstances and economic conditions than debt in higher-rated categories.
Baa	BBB	Debt rated Baa and BBB is regarded as having an adequate capacity to pay interest and repay principal. Whereas it normally exhibits adequate protection parameters, adverse economic conditions or changing circumstances are more likely to lead to a weakened capacity to pay interest and repay principal for debt in this category than in higher-rated categories. These bonds are medium-grade obligations.
Ba; B	BB; B	Debt rated in these categories is regarded, on balance, as predominantly speculative with respect to capacity to pay interest and repay principal in accordance with the terms of the obligation. BB and Ba indicate the lowest degree of speculation, and Ca, CC, and C the highest degree of speculation. Although such debt is likely to have some quality and protective characteristics, these are outweighed by large uncertainties or major risk exposures to adverse conditions. Issues rated C by Moody’s are typically in default.
Caa	CCC	
Ca	CC	
C	C	
	D	Debt rated D is in default, and payment of interest and/or repayment of principal is in arrears.

Note: At times, both Moody’s and S&P use adjustments (called notches) to these ratings. S&P uses plus and minus signs: A+ is the strongest A rating and A– the weakest. Moody’s uses a 1, 2, or 3 designation, with 1 being the highest.

Want to know what criteria are commonly used to rate corporate and municipal bonds? Go to www.standardandpoors.com, www.moodys.com, or www.fitchinv.com.

The highest rating a firm’s debt can have is AAA or Aaa, and such debt is judged to be the best quality and to have the lowest degree of default risk. For example, the 100-year BellSouth issue we discussed earlier was rated AAA. This rating is not awarded very often: As of 2009, only five non-financial U.S. companies had AAA ratings. AA or Aa ratings indicate very good quality debt and are much more common. The lowest rating is D, for debt that is in default.

Beginning in the 1980s, a growing part of corporate borrowing has taken the form of low-grade, or “junk,” bonds. If these low-grade corporate bonds are rated at all, they are rated below investment grade by the major rating agencies. Investment-grade bonds are bonds rated at least BBB by S&P or Baa by Moody’s.

Some bonds are called “crossover” or “5B” bonds. The reason is that they are rated triple-B (or Baa) by one rating agency and double-B (or Ba) by another, a “split rating.” For example, in January 2009, Tennessee Gas Pipeline, a subsidiary of the more well-known natural gas company El Paso Corporation, issued \$250 million worth of seven-year notes that were rated Baa3 by Moody’s and BB by S&P.

A bond’s credit rating can change as the issuer’s financial strength improves or deteriorates. For example, in December 2008, S&P downgraded Starwood Hotels & Resorts

Worldwide, operator of brands such as Sheraton, W Hotels, and Westin, from investment grade to junk bond status. Bonds that drop into junk territory from above are called “fallen angels.” Why was Starwood downgraded? The reasons given by S&P included a drop in revenue per room and slumping worldwide demand for hotel stays.

Of course, Starwood was not alone. During 2008, 55 companies worldwide had debt downgraded from investment grade to junk status, the third highest number of fallen angels since S&P began tracking this number in 1987. The value of the debt affected by these downgrades amounted to \$226.4 billion. And 2009 was off to a bad start. At the beginning of the year, there were 65 companies that were rated one notch above junk territory and had a negative credit outlook, meaning they were likely to be downgraded.

Credit ratings are important because defaults really do occur, and, when they do, investors can lose heavily. For example, in 2000, AmeriServe Food Distribution, Inc., which supplied restaurants such as Burger King with everything from burgers to giveaway toys, defaulted on \$200 million in junk bonds. After the default, the bonds traded at just 18 cents on the dollar, leaving investors with a loss of more than \$160 million.

Even worse in AmeriServe’s case, the bonds had been issued only four months earlier, thereby making AmeriServe an NCAA champion. While that might be a good thing for a college basketball team such as the University of Kentucky Wildcats, in the bond market it means “No Coupon At All,” and it’s not a good thing for investors.

CONCEPT QUESTIONS

6.3a What is a junk bond?

6.3b What does a bond rating say about the risk of fluctuations in a bond’s value resulting from interest rate changes?

SOME DIFFERENT TYPES OF BONDS

6.4

Thus far, we have considered only “plain vanilla” corporate bonds. In this section, we briefly look at bonds issued by governments and also at bonds with unusual features.

Government Bonds

The biggest borrower in the world—by a wide margin—is everybody’s favorite family member, Uncle Sam. In early 2009, the total debt of the U.S. government was approaching \$11 *trillion*, or about \$36,000 per U.S. citizen (and growing rapidly). When the government wishes to borrow money for more than one year, it sells what are known as Treasury notes and bonds to the public (in fact, it does so every month). Currently, Treasury notes and bonds have original maturities ranging from 2 to 30 years.

Most U.S. Treasury issues are just ordinary coupon bonds. Some older issues are callable, and a very few have some unusual features. There are two important things to keep in mind, however. First, U.S. Treasury issues, unlike essentially all other bonds, have no default risk because (we hope) the Treasury can always come up with the money to make the payments. Second, Treasury issues are exempt from state income taxes (though not federal income taxes). In other words, the coupons you receive on a Treasury note or bond are only taxed at the federal level.

If you’re nervous about the level of debt piled up by the U.S. government, don’t go to www.publicdebt.treas.gov or to www.brillig.com/debt_clock! Learn all about government bonds at www.ny.frb.org.

State and local governments also borrow money by selling notes and bonds. Such issues are called *municipal* notes and bonds, or just “munis.” Unlike Treasury issues, munis have varying degrees of default risk, and, in fact, they are rated much like corporate issues. Also, they are almost always callable. The most intriguing thing about munis is that their coupons are exempt from federal income taxes (and state income taxes in some cases), which makes them very attractive to high-income, high-tax bracket investors.

Because of the enormous tax break they receive, the yields on municipal bonds are much lower than the yields on taxable bonds. For example, in early 2009, long-term, high-quality corporate bonds were yielding about 6.3 percent. At the same time, long-term, high-quality munis were yielding about 4.8 percent. Suppose an investor was in a 30 percent tax bracket. All else being the same, would this investor prefer an Aa corporate bond or an Aa municipal bond?

To answer, we need to compare the *aftertax* yields on the two bonds. Ignoring state and local taxes, the muni pays 4.8 percent on both a pretax and an aftertax basis. The corporate issue pays 6.3 percent before taxes, but it only pays $.063 \times (1 - .30) = .044$, or 4.4 percent, once we account for the 30 percent tax bite. Given this, the muni has a better yield.

EXAMPLE 6.4

Taxable versus Municipal Bonds

Suppose taxable bonds are currently yielding 8 percent, while at the same time, munis of comparable risk and maturity are yielding 6 percent. Which is more attractive to an investor in a 40 percent tax bracket? What is the break-even tax rate? How do you interpret this rate?

For an investor in a 40 percent tax bracket, a taxable bond yields $8 \times (1 - .40) = 4.8$ percent after taxes, so the muni is much more attractive. The break-even tax rate is the tax rate at which an investor would be indifferent between a taxable and a nontaxable issue. If we let t^* stand for the break-even tax rate, then we can solve for it as follows:

$$\begin{aligned} .08 \times (1 - t^*) &= .06 \\ 1 - t^* &= .06/.08 = .75 \\ t^* &= .25 \end{aligned}$$

Thus, an investor in a 25 percent tax bracket would make 6 percent after taxes from either bond.

Zero Coupon Bonds

zero coupon bond

A bond that makes no coupon payments and thus is initially priced at a deep discount.

A bond that pays no coupons at all must be offered at a price that is much lower than its stated value. Such bonds are called **zero coupon bonds**, or just *zeroes*.⁵

Suppose the Eight-Inch Nails (EIN) Company issues a \$1,000 face value, five-year zero coupon bond. The initial price is set at \$508.35. Even though no interest payments are made on the bond, zero coupon bond calculations use semiannual periods to be consistent with coupon bond calculations. Using semiannual periods, it is straightforward to verify that, at this price, the bond yields 14 percent to maturity. The total interest paid over the life of the bond is $\$1,000 - \$508.35 = \$491.65$.

For tax purposes, the issuer of a zero coupon bond deducts interest every year even though no interest is actually paid. Similarly, the owner must pay taxes on interest accrued every year, even though no interest is actually received.

⁵ A bond issued with a very low coupon rate (as opposed to a zero coupon rate) is an original-issue discount (OID) bond.

Year	Beginning Value	Ending Value	Implicit Interest Expense	Straight-line Interest Expense
1	\$508.35	\$ 582.01	\$ 73.66	\$ 98.33
2	582.01	666.34	84.33	98.33
3	666.34	762.90	96.56	98.33
4	762.90	873.44	110.54	98.33
5	873.44	1,000.00	126.56	98.33
Total			\$491.65	\$491.65

TABLE 6.2

Interest expense for EIN's zeroes

The way in which the yearly interest on a zero coupon bond is calculated is governed by tax law. Before 1982, corporations could calculate the interest deduction on a straight-line basis. For EIN, the annual interest deduction would have been $\$491.65/5 = \98.33 per year.

Under current tax law, the implicit interest is determined by amortizing the loan. We do this by first calculating the bond's value at the beginning of each year. For example, after one year, the bond will have four years until maturity, so it will be worth $\$1,000/1.07^8 = \582.01 ; the value in two years will be $\$1,000/1.07^6 = \666.34 ; and so on. The implicit interest each year is simply the change in the bond's value for the year. The values and interest expenses for the EIN bond are listed in Table 6.2.

Notice that under the old rules, zero coupon bonds were more attractive for corporations because the deductions for interest expense were larger in the early years (compare the implicit interest expense with the straight-line expense).

Under current tax law, EIN could deduct \$73.66 in interest paid the first year, and the owner of the bond would pay taxes on \$73.66 of taxable income (even though no interest was actually received). This second tax feature makes taxable zero coupon bonds less attractive to individuals. However, they are still a very attractive investment for tax-exempt investors with long-term dollar-denominated liabilities, such as pension funds, because the future dollar value is known with relative certainty.

Some bonds are zero coupon bonds for only part of their lives. For example, at one time, General Motors had a debenture outstanding that matured on March 15, 2036. For the first 20 years, no coupon payments were scheduled, but 20 years into the bond's life, it was to begin paying coupons at a rate of 7.75 percent per year, payable semiannually.

Floating-Rate Bonds

The conventional bonds we have talked about in this chapter have fixed-dollar obligations because the coupon rate is set as a fixed percentage of the par value. Similarly, the principal is set equal to the par value. Under these circumstances, the coupon payment and principal are completely fixed.

With *floating-rate bonds* (*floaters*), the coupon payments are adjustable. The adjustments are tied to an interest rate index such as the Treasury bill interest rate or the 30-year Treasury bond rate. For example, U.S. Government EE Savings Bonds pay interest at a rate that is adjusted every six months. The rate is set equal to 90 percent of the average yield on ordinary five-year Treasury notes over the previous six months.

The value of a floating-rate bond depends on exactly how the coupon payment adjustments are defined. In most cases, the coupon adjusts with a lag to some base rate.

Another good bond market site is money.cnn.com.

For example, suppose a coupon rate adjustment is made on June 1. The adjustment might be based on the simple average of Treasury bond yields during the previous three months. In addition, the majority of floaters have the following features:

1. The holder has the right to redeem the note at par on the coupon payment date after some specified amount of time. This is called a *put* provision, and it is discussed in the following section.
2. The coupon rate has a floor and a ceiling, meaning that the coupon is subject to a minimum and a maximum. In this case, the coupon rate is said to be “capped,” and the upper and lower rates are sometimes called the *collar*.

Official information on U.S. inflation-indexed bonds is at

www.treasurydirect.gov.

A particularly interesting type of floating-rate bond is an *inflation-linked* bond. Such bonds have coupons that are adjusted according to the rate of inflation (the principal amount may be adjusted as well). The U.S. Treasury began issuing such bonds in January of 1997. The issues are sometimes called “TIPS,” or Treasury Inflation Protection Securities. Other countries, including Canada, Israel, and Britain, have issued similar securities.

Other Types of Bonds

Many bonds have unusual, or exotic, features. Unfortunately, there are far too many variations for us to cover in detail here. We therefore focus on only a few of the more common types.

Income bonds are similar to conventional bonds, except that coupon payments are dependent on company income. Specifically, coupons are paid to bondholders only if the firm’s income is sufficient. This would appear to be an attractive feature, but income bonds are not very common.

A *convertible bond* can be swapped for a fixed number of shares of stock anytime before maturity at the holder’s option. Convertibles are relatively common, but the number has been decreasing in recent years.

A *put bond* allows the *holder* to force the issuer to buy the bond back at a stated price. The put feature is therefore just the reverse of the call provision and is a relatively new development.

A given bond may have many unusual features. For example, two recent types of exotic bonds include CoCo bonds, which have a coupon payment, and NoNo bonds, which are zero coupon bonds. CoCo and NoNo bonds are contingent convertible, puttable, callable, subordinated bonds. The contingent convertible clause is similar to the normal conversion feature, except the contingency feature must be met. For example, a contingency feature may require that the company stock trade at 110 percent of the conversion price for 20 out of 30 days. Valuing a bond of this sort can be quite complex, and the yield to maturity calculation is often meaningless. The nearby *Reality Bytes* box provides some more examples of exotic bonds.

CONCEPT QUESTIONS

- 6.4a** Why might an income bond be attractive to a corporation with volatile cash flows? Can you think of a reason why income bonds are not more popular?
- 6.4b** What do you think would be the effect of a put feature on a bond’s coupon? How about a convertibility feature? Why?
-
-

Exotic Bonds

Bonds come in many flavors. The unusual types are called “exotics” and can range from the fairly simple to the truly esoteric. Take the case of mortgage-backed securities (MBSs) that we discussed in the chapter opening. MBSs are a type of securitized financial instrument. In securitization, cash flows from financial assets are pooled together into securities, and the securities are sold to investors. Securitization has grown to the point that about \$11 trillion of securitized securities were outstanding in the United States during 2008. With an MBS, banks or mortgage brokers who originate mortgages sell the mortgages to a trust. The trust pools the mortgages and sells bonds to investors. Bondholders receive payments based on the mortgage payments made by homeowners. During 2008, problems with MBSs skyrocketed due to the precipitous drop in real estate values and the sharply increased default rates on the underlying mortgages.

on major stock exchanges, rather than the typical \$1,000 par value in the OTC bond market. This gives PETS more liquidity. Once you know the ticker symbol, you can get quotes for PETS on any stock quote service. Nearby is a quote on a General Electric Capital PETS (GEC) that we found on finance.yahoo.com. As you can see, 250,631 PETS traded on this day, so this bond is quite liquid.

CAT bonds are issued to cover insurance companies against natural catastrophes. The type of natural catastrophe is outlined in the bond. For example, about 30 percent of all CAT bonds protect against a North Atlantic hurricane. The way these issues are structured is that the borrowers can suspend payment temporarily (or even permanently) if they have significant hurricane-related losses. These CAT bonds may seem like pretty risky investments, but, to date, only one such CAT bond

Other exotic bonds sport acronyms like PETS, CATS, MIDS, PINES, and CORTS. The acronym PETS stands for “preferred equity traded security.” PETS are actually several different types of bonds that have one thing in common: They trade like preferred stocks. Why is this important? As we mentioned, the bond market is relatively illiquid. This is due in large part to the fact that institutional investors such as banks, pension funds, mutual funds, and insurance companies are the dominant players. These large institutions generally trade in large blocks of \$500,000 or more.

PETS, on the other hand, are essentially preferred stock with a twist. First, they trade in \$25 par value denominations

has not made its scheduled payments, courtesy of the massive destruction caused by Hurricane Katrina.

Perhaps the most unusual bond (and certainly the most ghoulish) is the “death bond.” Companies such as Stone Street Financial purchase life insurance policies from individuals who are expected to die within the next 10 years. They then sell bonds that are paid off from the life insurance proceeds received when the policyholders die. The return on the bonds to investors depends on how long the policyholders live. A major risk is that if medical treatment advances quickly, it will raise the life expectancy of the policyholders, thereby decreasing the return to the bondholder.

BOND MARKETS

6.5

Bonds are bought and sold in enormous quantities every day. You may be surprised to learn that the trading volume in bonds on a typical day is many, many times larger than the trading volume in stocks (by trading volume, we simply mean the amount of money that

changes hands). Here is a finance trivia question: What is the largest securities market in the world? Most people would guess the New York Stock Exchange. In fact, the largest securities market in the world in terms of trading volume is the U.S. Treasury market.

How Bonds Are Bought and Sold

As we mentioned all the way back in Chapter 1, most trading in bonds takes place over the counter, or OTC. Recall that this means that there is no particular place where buying and selling occur. Instead, dealers around the country (and around the world) stand ready to buy and sell. The various dealers are connected electronically.

One reason the bond markets are so big is that the number of bond issues far exceeds the number of stock issues. There are two reasons for this. First, a corporation would typically have only one common stock issue outstanding (there are exceptions to this that we discuss in our next chapter). However, a single large corporation could easily have a dozen or more note and bond issues outstanding. Beyond this, federal, state, and local borrowing is simply enormous. For example, even a small city would usually have a wide variety of notes and bonds outstanding, representing money borrowed to pay for things like roads, sewers, and schools. When you think about how many small cities there are in the United States, you begin to get the picture!

Because the bond market is almost entirely OTC, it has historically had little or no *transparency*. A financial market is transparent if it is possible to easily observe its prices and trading volume. On the New York Stock Exchange, for example, it is possible to see the price and quantity for every single transaction. In contrast, in the bond market, it is usually not possible to observe either. Transactions are privately negotiated between parties, and there is little or no centralized reporting of transactions.

Although the total volume of trading in bonds far exceeds that in stocks, only a very small fraction of the total bond issues that exist actually trade on a given day. This fact, combined with the lack of transparency in the bond market, means that getting up-to-date prices on individual bonds is often difficult or impossible, particularly for smaller corporate or municipal issues. Instead, a variety of sources of estimated prices exist and are very commonly used.

Bond Price Reporting

In 2002, transparency in the corporate bond market began to improve dramatically. Under new regulations, corporate bond dealers are now required to report trade information through what is known as the Transactions Report and Compliance Engine (TRACE). By 2009, transaction and price data were reported on more than 29,000 corporate bonds, which is essentially all publicly traded corporate bonds. More bonds will be added over time. A nearby *Work the Web* box shows how to get TRACE prices.

As we mentioned before, the U.S. Treasury market is the largest securities market in the world. As with bond markets in general, it is an OTC market, so there is limited transparency. However, unlike the situation with bond markets in general, trading in Treasury issues, particularly recently issued ones, is very heavy. Each day, representative prices for outstanding Treasury issues are reported.

Figure 6.3 shows a portion of the daily Treasury note and bond listings from *The Wall Street Journal* online. The only difference between a Treasury note and a Treasury bond is that notes have 10 years or less to maturity at the time of issuance. The entry that begins “2020 Feb 15” is highlighted. Reading from left to right, the “2020 Feb 15” tells us that the bond’s maturity is February 15, 2020. The 8.500 is the bond’s coupon rate. Treasury bonds all make semiannual payments and have a face value of \$1,000, so this bond will pay \$42.50 per six months until it matures.

To learn more about TRACE, visit www.finra.org.

To purchase newly issued corporate bonds, go to www.internotes.com.

WORK THE WEB

Bond quotes have become more available with the rise of the Web. One site where you can find current bond prices (from TRACE) is cxa.marketwatch.com/finra/BondCenter. We went to the site and entered “Dell” for the well-known computer manufacturer. We found a total of four bond issues outstanding. Below you will see the information we pulled up.

Include in Watchlist	Bond Symbol	Issuer Name	Coupon	Maturity	Callable	Ratings			Last Sale	
						Moody's	S&P	Fitch	Price	Yield
<input type="checkbox"/>	DELL.GF	DELL INCORPORATED	4.70	04/15/2013	Yes	A2	NR	A	99.660	4.791
<input type="checkbox"/>	DELL.GG	DELL INCORPORATED	5.65	04/15/2018	Yes	A2	NR	A	96.111	6.215
<input type="checkbox"/>	DELL.GB	DELL INCORPORATED	7.10	04/15/2028	Yes	A2	A-	A	99.536	7.143
<input type="checkbox"/>	DELL.GH	DELL INCORPORATED	6.50	04/15/2038	Yes	A2	A-	A	79.740	8.365

Most of the information is self-explanatory. The price and yield columns show the price and yield to maturity of the issues based on their most recent sales. If you need more information about a particular issue, clicking on it will give you more details such as coupon dates and call dates.

Questions

1. Go to this Web site and find the last bond shown above. When was this bond issued? What was the size of the bond issue? What were the yield to maturity and price when the bond was issued?
2. When you search for Chevron bonds (CVX), you will find bonds for several companies listed. Why do you think Chevron has bonds issued with different corporate names?

The next two pieces of information are the **bid** and **asked prices**. In general, in any OTC or dealer market, the bid price represents what a dealer is willing to pay for a security, and the asked price (or just “ask” price) is what a dealer is willing to take for it. The difference between the two prices is called the **bid-ask spread** (or just “spread”), and it represents the dealer’s profit.

For historical reasons, Treasury prices are quoted in 32nds. Thus, the bid price on the 2020 Feb 15 bond, 145:12, actually translates into $145\frac{12}{32}$, or 145.375 percent of face value. With a \$1,000 face value, this represents \$1,453.75. Because prices are quoted in 32nds, the smallest possible price change is $\frac{1}{32}$. This is called the “tick” size.

The next number quoted is the change in the asked price from the previous day, measured in ticks (i.e., in 32nds), so this issue’s asked price rose by $\frac{64}{32}$ of 1 percent, or 2.0 percent, of face value from the previous day. Finally, the last number reported is the yield to maturity, based on the asked price. Notice that this is a premium bond because it sells for more than its face value. Not surprisingly, its yield to maturity (3.473 percent) is less than its coupon rate (8.5 percent).

bid price

The price a dealer is willing to pay for a security.

asked price

The price a dealer is willing to take for a security.

bid-ask spread

The difference between the bid price and the asked price.

U.S. Treasury Quotes TREASURY NOTES & BONDS

Treasury note and bond data are representative over-the-counter quotations as of 3 p.m. Eastern time. Figures after colons in bid and ask quotes represent 32nds; 101:26 means 101 26/32, or 101.8125% of face value; 99:01 means 99 1/32, or 99.03125% of face value. For notes and bonds callable prior to maturity, yields are computed to the earliest call date for issues quoted above par and to the maturity date for issues below par.

Maturity	Coupon	Bid	Asked	Chg	Asked Yield

Source: www.wsj.com, 03/06/2009, from Thomson Reuters.

Current and historical Treasury yield information is available at www.treasurydirect.gov.

The very last ordinary bond listed, in this case the 2039 Feb 15, is often called the “bellwether” bond. This bond’s yield is the one that is usually reported in the evening news. So, for example, when you hear that long-term interest rates rose, what is really being said is that the yield on this bond went up (and its price went down).

If you examine the yields on the various issues in Figure 6.3, you will clearly see that they vary by maturity. Why this occurs and what it might mean is one of the things we discuss in our next section.

Treasury Quotes

EXAMPLE 6.5

Locate the Treasury issue in Figure 6.3 maturing in February 2015. What is its coupon rate? What is its bid price? What was the *previous day's* asked price?

The bond listed as 2015 Feb 15 is the one we seek. Its coupon rate is 11.25 percent of face value. The bid price is 148:31, or 148.96875 percent of face value. The ask price is 149:00, which is up by 28 ticks from the previous day. This means that the ask price on the previous day was equal to $149 - \frac{28}{32} = 148.125 = 148:04$.

A Note on Bond Price Quotes If you buy a bond between coupon payment dates, the price you pay is usually more than the price you are quoted. The reason is that standard convention in the bond market is to quote prices net of “accrued interest,” meaning that accrued interest is deducted to arrive at the quoted price. This quoted price is called the **clean price**. The price you actually pay, however, includes the accrued interest. This price is the **dirty price**, also known as the “full” or “invoice” price.

An example is the easiest way to understand these issues. Suppose you buy a bond with a 12 percent annual coupon, payable semiannually. You actually pay \$1,080 for this bond, so \$1,080 is the dirty, or invoice, price. Further, on the day you buy it, the next coupon is due in four months, so you are between coupon dates. Notice that the next coupon will be \$60.

The accrued interest on a bond is calculated by taking the fraction of the coupon period that has passed, in this case two months out of six, and multiplying this fraction by the next coupon, \$60. So, the accrued interest in this example is $\frac{2}{6} \times \$60 = \20 . The bond's quoted price (i.e., its clean price) would be $\$1,080 - 20 = \$1,060$.

clean price

The price of a bond net of accrued interest; this is the price that is typically quoted.

dirty price

The price of a bond including accrued interest, also known as the *full* or *invoice price*. This is the price the buyer actually pays.

CONCEPT QUESTIONS

- 6.5a** Why do we say bond markets may have little or no transparency?
- 6.5b** In general, what are bid and ask prices?
- 6.5c** What is the difference between a bond's clean price and dirty price?

INFLATION AND INTEREST RATES

6.6

So far, we haven't considered the role of inflation in our various discussions of interest rates, yields, and returns. Because this is an important consideration, we consider the impact of inflation next.

real rates

Interest rates or rates of return that have been adjusted for inflation.

nominal rates

Interest rates or rates of return that have not been adjusted for inflation.

Real versus Nominal Rates

In examining interest rates, or any other financial market rates such as discount rates, bond yields, rates of return, and required returns, it is often necessary to distinguish between **real rates** and **nominal rates**. Nominal rates are called “nominal” because they have not been adjusted for inflation. Real rates are rates that have been adjusted for inflation.

To see the effect of inflation, suppose prices are currently rising by 5 percent per year. In other words, the rate of inflation is 5 percent. An investment is available that will be worth \$115.50 in one year. It costs \$100 today. Notice that with a present value of \$100 and a future value in one year of \$115.50, this investment has a 15.5 percent rate of return. In calculating this 15.5 percent return, we did not consider the effect of inflation, however, so this is the nominal return.

What is the impact of inflation here? To answer, suppose pizzas cost \$5 apiece at the beginning of the year. With \$100, we can buy 20 pizzas. Because the inflation rate is 5 percent, pizzas will cost 5 percent more, or \$5.25, at the end of the year. If we take the investment, how many pizzas can we buy at the end of the year? Measured in pizzas, what is the rate of return on this investment?

Our \$115.50 from the investment will buy us $\$115.50 / \$5.25 = 22$ pizzas. This is up from 20 pizzas, so our pizza rate of return is 10 percent. What this illustrates is that even though the nominal return on our investment is 15.5 percent, our buying power goes up by only 10 percent because of inflation. Put another way, we are really only 10 percent richer. In this case, we say that the real return is 10 percent.

Alternatively, we can say that with 5 percent inflation, each of the \$115.50 nominal dollars we get is worth 5 percent less in real terms, so the real dollar value of our investment in a year is:

$$\$115.50 / 1.05 = \$110$$

What we have done is to *deflate* the \$115.50 by 5 percent. Because we give up \$100 in current buying power to get the equivalent of \$110, our real return is again 10 percent. Now that we have removed the effect of future inflation, this \$110 is said to be measured in current dollars.

The difference between nominal and real rates is important and bears repeating:

The nominal rate on an investment is the percentage change in the number of dollars you have.

The real rate on an investment is the percentage change in how much you can buy with your dollars, in other words, the percentage change in your buying power.

The Fisher Effect

Fisher effect

The relationship between nominal returns, real returns, and inflation.

Our discussion of real and nominal returns illustrates a relationship often called the **Fisher effect** (after the great economist Irving Fisher). Because investors are ultimately concerned with what they can buy with their money, they require compensation for inflation. Let R stand for the nominal rate and r stand for the real rate. The Fisher effect tells us that the relationship between nominal rates, real rates, and inflation can be written as:

$$1 + R = (1 + r) \times (1 + h) \quad [6.2]$$

where h is the inflation rate.

In the preceding example, the nominal rate was 15.50 percent, and the inflation rate was 5 percent. What was the real rate? We can determine it by plugging in these numbers:

$$\begin{aligned} 1 + .1550 &= (1 + r) \times (1 + .05) \\ 1 + r &= 1.1550 / 1.05 = 1.10 \\ r &= 10\% \end{aligned}$$

This real rate is the same as we had before. If we take another look at the Fisher effect, we can rearrange things a little as follows:

$$\begin{aligned} 1 + R &= (1 + r) \times (1 + h) \\ R &= r + h + r \times h \end{aligned} \quad [6.3]$$

What this tells us is that the nominal rate has three components. First, there is the real rate on the investment, r . Next, there is the compensation for the decrease in the value of the money originally invested because of inflation, h . The third component represents compensation for the fact that the dollars earned on the investment are also worth less because of the inflation.

This third component is usually small, so it is often dropped. The nominal rate is then approximately equal to the real rate plus the inflation rate:

$$R \approx r + h \quad [6.4]$$

The Fisher Effect

EXAMPLE 6.6

If investors require a 10 percent real rate of return, and the inflation rate is 8 percent, what must the approximate nominal rate be? The exact nominal rate?

First of all, the nominal rate is approximately equal to the sum of the real rate and the inflation rate: $10\% + 8\% = 18\%$. From the Fisher effect, we have:

$$\begin{aligned} 1 + R &= (1 + r) \times (1 + h) \\ &= 1.10 \times 1.08 \\ &= 1.1880 \end{aligned}$$

Therefore, the nominal rate will actually be closer to 19 percent.

It is important to note that financial rates, such as interest rates, discount rates, and rates of return, are almost always quoted in nominal terms. To remind you of this, we will henceforth use the symbol R instead of r in most of our discussions about such rates.

CONCEPT QUESTIONS

- 6.6a** What is the difference between a nominal and a real return? Which is more important to a typical investor?
- 6.6b** What is the Fisher effect?

DETERMINANTS OF BOND YIELDS

6.7

We are now in a position to discuss the determinants of a bond's yield. As we will see, the yield on any particular bond is a reflection of a variety of factors, some common to all bonds and some specific to the issue under consideration.

The Term Structure of Interest Rates

At any point in time, short-term and long-term interest rates will generally be different. Sometimes short-term rates are higher, sometimes lower. Figure 6.4 gives us a long-range perspective on this by showing over two centuries of short- and long-term interest rates.

FIGURE 6.4

U.S. interest rates: 1800–2008

Source: Adapted from Jeremy J. Siegel, *Stocks for the Long Run*, 3rd ed., © McGraw-Hill, 2004, as updated by the authors.

term structure of interest rates

The relationship between nominal interest rates on default-free, pure discount securities and time to maturity; that is, the pure time value of money.

As shown, through time, the difference between short- and long-term rates has ranged from essentially zero to up to several percentage points, both positive and negative.

The relationship between short- and long-term interest rates is known as the **term structure of interest rates**. To be a little more precise, the term structure of interest rates tells us what *nominal* interest rates are on *default-free, pure discount* bonds of all maturities. These rates are, in essence, “pure” interest rates because they involve no risk of default and a single, lump-sum future payment. In other words, the term structure tells us the pure time value of money for different lengths of time.

When long-term rates are higher than short-term rates, we say that the term structure is upward sloping, and when short-term rates are higher, we say it is downward sloping. The term structure can also be “humped.” When this occurs, it is usually because rates increase at first, but then begin to decline as we look at longer- and longer-term rates. The most common shape of the term structure, particularly in modern times, is upward sloping, but the degree of steepness has varied quite a bit.

What determines the shape of the term structure? There are three basic components. The first two are the ones we discussed in our previous section: the real rate of interest and the rate of inflation. The real rate of interest is the compensation investors demand for forgoing the use of their money. You can think of it as the pure time value of money after adjusting for the effects of inflation.

The real rate of interest is the basic component underlying every interest rate, regardless of the time to maturity. When the real rate is high, all interest rates will tend to be higher, and vice versa. Thus, the real rate doesn't really determine the shape of the term structure; instead, it mostly influences the overall level of interest rates.

In contrast, the prospect of future inflation very strongly influences the shape of the term structure. Investors thinking about loaning money for various lengths of time recognize that future inflation erodes the value of the dollars that will be returned. As a result, investors demand compensation for this loss in the form of higher nominal rates. This extra compensation is called the **inflation premium**.

If investors believe that the rate of inflation will be higher in the future, then long-term nominal interest rates will tend to be higher than short-term rates. Thus, an upward-sloping term structure may be a reflection of anticipated increases in inflation. Similarly, a downward-sloping term structure probably reflects the belief that inflation will be falling in the future.

The third, and last, component of the term structure has to do with interest rate risk. As we discussed earlier in the chapter, longer-term bonds have much greater risk of loss resulting from changes in interest rates than do shorter-term bonds. Investors recognize this risk, and they demand extra compensation in the form of higher rates for bearing it. This extra compensation is called the **interest rate risk premium**. The longer the term to maturity, the greater is the interest rate risk, so the interest rate risk premium increases with maturity. However, as we discussed earlier, interest rate risk increases at a decreasing rate, so the interest rate risk premium does as well.⁶

Putting the pieces together, we see that the term structure reflects the combined effect of the real rate of interest, the inflation premium, and the interest rate risk premium. Figure 6.5 shows how these can interact to produce an upward-sloping term structure (in the top part of Figure 6.5) or a downward-sloping term structure (in the bottom part).

In the top part of Figure 6.5, notice how the rate of inflation is expected to rise gradually. At the same time, the interest rate risk premium increases at a decreasing rate, so the combined effect is to produce a pronounced upward-sloping term structure. In the bottom part of Figure 6.5, the rate of inflation is expected to fall in the future, and the expected decline is enough to offset the interest rate risk premium and produce a downward-sloping term structure. Notice that if the rate of inflation was expected to decline by only a small amount, we could still get an upward-sloping term structure because of the interest rate risk premium.

We assumed in drawing Figure 6.5 that the real rate would remain the same. Actually, expected future real rates could be larger or smaller than the current real rate. Also, for simplicity, we used straight lines to show expected future inflation rates as rising or declining, but they do not necessarily have to look like this. They could, for example, rise and then fall, leading to a humped yield curve.

Bond Yields and the Yield Curve: Putting It All Together

Going back to Figure 6.3, recall that we saw that the yields on Treasury notes and bonds of different maturities are not the same. Each day, in addition to the Treasury prices and yields shown in Figure 6.3, *The Wall Street Journal* provides a plot of Treasury yields relative to maturity. This plot is called the **Treasury yield curve** (or just the yield curve). Figure 6.6 shows the yield curve drawn from the yields in Figure 6.3.

inflation premium

The portion of a nominal interest rate that represents compensation for expected future inflation.

interest rate risk premium

The compensation investors demand for bearing interest rate risk.

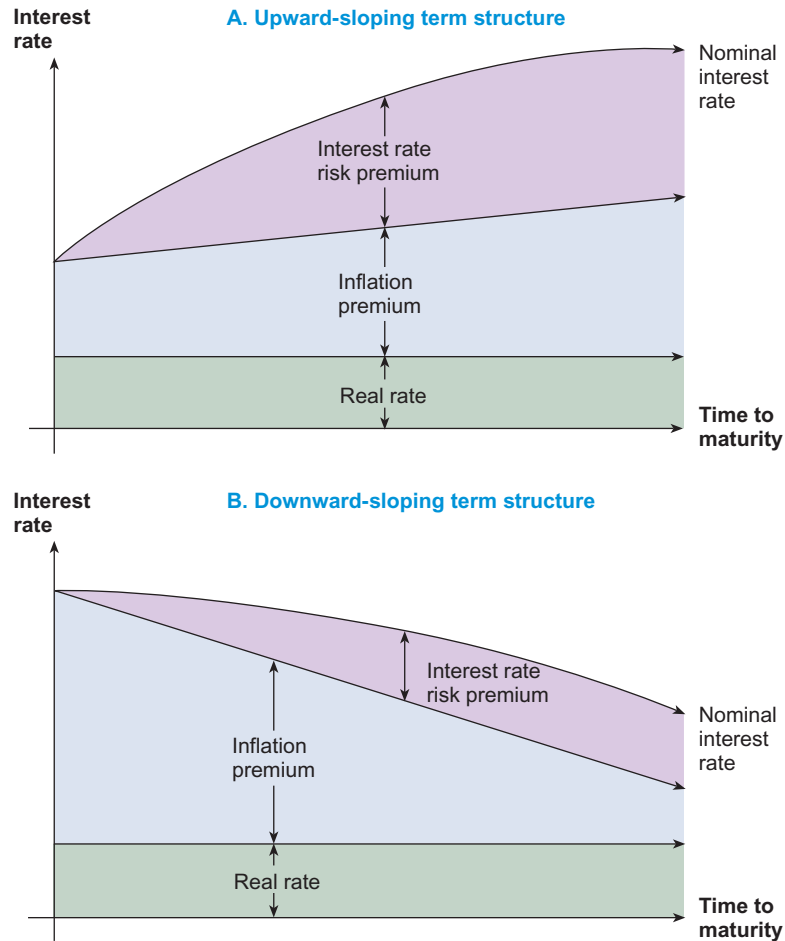

Treasury yield curve

A plot of the yields on Treasury notes and bonds relative to maturity.

⁶ In days of old, the interest rate risk premium was called a “liquidity” premium. Today, the term *liquidity premium* has an altogether different meaning, which we explore in our next section. Also, the interest rate risk premium is sometimes called a maturity risk premium. Our terminology is consistent with the modern view of the term structure.

FIGURE 6.5

The term structure of interest rates

As you probably now suspect, the shape of the yield curve is a reflection of the term structure of interest rates. In fact, the Treasury yield curve and the term structure of interest rates are almost the same thing. The only difference is that the term structure is based on pure discount bonds, whereas the yield curve is based on coupon bond yields. As a result, Treasury yields depend on the three components that underlie the term structure: the real rate, expected future inflation, and the interest rate risk premium.

Treasury notes and bonds have three important features that we need to remind you of: They are default-free, they are taxable, and they are highly liquid. This is not true of bonds in general, so we need to examine what additional factors come into play when we look at bonds issued by corporations or municipalities.

The first thing to consider is credit risk, that is, the possibility of default. Investors recognize that issuers other than the Treasury may or may not make all the promised payments on a bond, so they demand a higher yield as compensation for this risk. This extra compensation is called the **default risk premium**. Earlier in the chapter, we saw how bonds were rated based on their credit risk. What you will find if you start looking at bonds of different ratings is that lower-rated bonds have higher yields.

An important thing to recognize about a bond's yield is that it is calculated assuming that all the promised payments will be made. As a result, it is really a promised yield, and it may or may not be what you will earn. In particular, if the issuer defaults, your actual yield will be lower,

default risk premium

The portion of a nominal interest rate or bond yield that represents compensation for the possibility of default.

**FIGURE 6.6****The Treasury yield curve**

Treasury Yield Curve

probably much lower. This fact is particularly important when it comes to junk bonds. Thanks to a clever bit of marketing, such bonds are now commonly called high-yield bonds, which has a much nicer ring to it; but now you recognize that these are really high-*promised* yield bonds.

Next, recall that we discussed earlier how municipal bonds are free from most taxes and, as a result, have much lower yields than taxable bonds. Investors demand the extra yield on a taxable bond as compensation for the unfavorable tax treatment. This extra compensation is the **taxability premium**.

Finally, bonds have varying degrees of liquidity. As we discussed earlier, there are an enormous number of bond issues, most of which do not trade on a regular basis. As a result, if you wanted to sell quickly, you would probably not get as good a price as you could otherwise. Investors prefer liquid assets to illiquid ones, so they demand a **liquidity premium** on top of all the other premiums we have discussed. As a result, all else being the same, less liquid bonds will have higher yields than more liquid bonds.

Conclusion

If we combine all of the things we have discussed regarding bond yields, we find that bond yields represent the combined effect of no fewer than six things. The first is the real rate of interest. On top of the real rate are five premiums representing compensation for (1) expected future inflation, (2) interest rate risk, (3) default risk, (4) taxability, and (5) lack of liquidity. As a result, determining the appropriate yield on a bond requires careful analysis of each of these effects.

Check out the “living yield curve” at www.smartmoney.com.

taxability premium

The portion of a nominal interest rate or bond yield that represents compensation for unfavorable tax status.

liquidity premium

The portion of a nominal interest rate or bond yield that represents compensation for lack of liquidity.

CONCEPT QUESTIONS

- 6.7a** What is the term structure of interest rates? What determines its shape?
- 6.7b** What is the Treasury yield curve?
- 6.7c** What are the six components that make up a bond’s yield?

SUMMARY AND CONCLUSIONS

This chapter has explored bonds and bond yields. We saw that:

1. Determining bond prices and yields is an application of basic discounted cash flow principles.
2. Bond values move in the direction opposite that of interest rates, leading to potential gains or losses for bond investors.
3. Bonds have a variety of features spelled out in a document called the indenture.
4. Bonds are rated based on their default risk. Some bonds, such as Treasury bonds, have no risk of default, whereas so-called junk bonds have substantial default risk.
5. A wide variety of bonds exist, many of which contain exotic, or unusual, features.
6. Almost all bond trading is OTC, with little or no market transparency. As a result, bond price and volume information can be difficult to find.
7. Bond yields reflect the effect of six different things: the real rate and five premiums that investors demand as compensation for inflation, interest rate risk, default risk, taxability, and lack of liquidity.

In closing, we note that bonds are a vital source of financing to governments and corporations of all types. Bond prices and yields are a rich subject, and our one chapter, necessarily, touches on only the most important concepts and ideas. There is a great deal more we could say, but, instead, we will move on to stocks in our next chapter.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

- 6.1 Bond Values.** A Microgates Industries bond has a 10 percent coupon rate and a \$1,000 face value. Interest is paid semiannually, and the bond has 20 years to maturity. If investors require a 12 percent yield, what is the bond's value? What is the effective annual yield on the bond?
- 6.2 Yields.** A Macrohard Corp. bond carries an 8 percent coupon, paid semiannually. The par value is \$1,000, and the bond matures in six years. If the bond currently sells for \$911.37, what is its yield to maturity? What is the effective annual yield?

■ Answers to Chapter Review and Self-Test Problems

- 6.1** Because the bond has a 10 percent coupon yield and investors require a 12 percent return, we know that the bond must sell at a discount. Notice that, because the bond pays interest semiannually, the coupons amount to $\$100/2 = \50 every six months. The required yield is $12\%/2 = 6\%$ every six months. Finally, the bond matures in 20 years, so there are a total of 40 six-month periods.

The bond's value is thus equal to the present value of \$50 every six months for the next 40 six-month periods plus the present value of the \$1,000 face amount:

$$\begin{aligned}\text{Bond value} &= \$50 \times (1 - 1/1.06^{40})/.06 + 1,000/1.06^{40} \\ &= \$50 \times 15.04630 + 1,000/10.2857 \\ &= \$849.54\end{aligned}$$

Notice that we discounted the \$1,000 back 40 periods at 6 percent per period, rather than 20 years at 12 percent. The reason is that the effective annual yield

on the bond is $1.06^2 - 1 = 12.36\%$, not 12 percent. We thus could have used 12.36 percent per year for 20 years when we calculated the present value of the \$1,000 face amount, and the answer would have been the same.

- 6.2** The present value of the bond's cash flows is its current price, \$911.37. The coupon is \$40 every six months for 12 periods. The face value is \$1,000. So, the bond's yield is the unknown discount rate in the following:

$$\$911.37 = \$40 \times [1 - 1/(1 + r)^{12}]/r + 1,000/(1 + r)^{12}$$

The bond sells at a discount. Because the coupon rate is 8 percent, the yield must be something in excess of that.

If we were to solve this by trial and error, we might try 12 percent (or 6 percent per six months):

$$\begin{aligned}\text{Bond value} &= \$40 \times (1 - 1/1.06^{12})/.06 + 1,000/1.06^{12} \\ &= \$832.32\end{aligned}$$

This is less than the actual value, so our discount rate is too high. We now know that the yield is somewhere between 8 and 12 percent. With further trial and error (or a little machine assistance), the yield works out to be 10 percent, or 5 percent every six months.

By convention, the bond's yield to maturity would be quoted as $2 \times 5\% = 10\%$. The effective yield is thus $1.05^2 - 1 = 10.25\%$.

CRITICAL THINKING AND CONCEPTS REVIEW

- L0 1** **6.1 Treasury Bonds.** Is it true that a U.S. Treasury security is risk-free?
- L0 2** **6.2 Interest Rate Risk.** Which has greater interest rate risk, a 30-year Treasury bond or a 30-year BB corporate bond?
- L0 1** **6.3 Treasury Pricing.** With regard to bid and ask prices on a Treasury bond, is it possible for the bid price to be higher? Why or why not?
- L0 2** **6.4 Yield to Maturity.** Treasury bid and ask quotes are sometimes given in terms of yields, so there would be a bid yield and an ask yield. Which do you think would be larger? Explain.
- L0 1** **6.5 Call Provisions.** A company is contemplating a long-term bond issue. It is debating whether or not to include a call provision. What are the benefits to the company from including a call provision? What are the costs? How do these answers change for a put provision?
- L0 1** **6.6 Coupon Rate.** How does a bond issuer decide on the appropriate coupon rate to set on its bonds? Explain the difference between the coupon rate and the required return on a bond.
- L0 4** **6.7 Real and Nominal Returns.** Are there any circumstances under which an investor might be more concerned about the nominal return on an investment than the real return?
- L0 3** **6.8 Bond Ratings.** Companies pay rating agencies such as Moody's and S&P to rate their bonds, and the costs can be substantial. However, companies are not required to have their bonds rated in the first place; doing so is strictly voluntary. Why do you think they do it?

- L0 3** 6.9 **Bond Ratings.** U.S. Treasury bonds are not rated. Why? Often, junk bonds are not rated. Why?
- L0 3** 6.10 **Crossover Bonds.** Looking back at the crossover bonds we discussed in the chapter, why do you think split ratings such as these occur?
- L0 1** 6.11 **Municipal Bonds.** Why is it that municipal bonds are not taxed at the federal level, but are taxable across state lines? Why is it that U.S. Treasury bonds are not taxable at the state level? (You may need to dust off the history books for this one.)
- L0 1** 6.12 **Treasury Market.** All Treasury bonds are relatively liquid, but some are more liquid than others. Take a look back at Figure 6.3. Which issues appear to be the most liquid? The least liquid?
- L0 3** 6.13 **Rating Agencies.** Several years ago, a controversy erupted regarding bond-rating agencies when some agencies began to provide unsolicited bond ratings. Why do you think this is controversial?
- L0 1** 6.14 **Bonds as Equity.** The 100-year bonds we discussed in the chapter have something in common with junk bonds. Critics charge that, in both cases, the issuers are really selling equity in disguise. What are the issues here? Why would a company want to sell “equity in disguise”?
- L0 2** 6.15 **Bond Prices versus Yields.**
- What is the relationship between the price of a bond and its YTM?
 - Explain why some bonds sell at a premium over par value while other bonds sell at a discount. What do you know about the relationship between the coupon rate and the YTM for premium bonds? What about for discount bonds? For bonds selling at par value?
 - What is the relationship between the current yield and YTM for premium bonds? For discount bonds? For bonds selling at par value?

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

Basic

(Questions 1–14)

- L0 2** 1. **Interpreting Bond Yields.** Is the yield to maturity on a bond the same thing as the required return? Is YTM the same thing as the coupon rate? Suppose today a 10 percent coupon bond sells at par. Two years from now, the required return on the same bond is 8 percent. What is the coupon rate on the bond now? The YTM?
- L0 2** 2. **Interpreting Bond Yields.** Suppose you buy a 7 percent coupon, 20-year bond today when it's first issued. If interest rates suddenly rise to 15 percent, what happens to the value of your bond? Why?
- L0 2** 3. **Bond Prices.** Lycan, Inc., has 7 percent coupon bonds on the market that have 8 years left to maturity. The bonds make annual payments. If the YTM on these bonds is 9 percent, what is the current bond price?
- L0 2** 4. **Bond Yields.** The Timberlake-Jackson Wardrobe Co. has 10 percent coupon bonds on the market with nine years left to maturity. The bonds make annual payments. If the bond currently sells for \$1,145.70, what is its YTM?
- L0 2** 5. **Coupon Rates.** Merton Enterprises has bonds on the market making annual payments, with 16 years to maturity, and selling for \$963. At this price, the bonds yield 7.5 percent. What must the coupon rate be on Merton's bonds?
- L0 2** 6. **Bond Prices.** App Store Co. issued 15-year bonds one year ago at a coupon rate of 6.1 percent. The bonds make semiannual payments. If the YTM on these bonds is 5.3 percent, what is the current bond price?

- L0 2** 7. **Bond Yields.** Night Hawk Co. issued 15-year bonds two years ago at a coupon rate of 8.4 percent. The bonds make semiannual payments. If these bonds currently sell for 108 percent of par value, what is the YTM?
- L0 2** 8. **Coupon Rates.** Osbourne Corporation has bonds on the market with 10.5 years to maturity, a YTM of 9.4 percent, and a current price of \$945. The bonds make semiannual payments. What must the coupon rate be on the bonds?
- L0 4** 9. **Calculating Real Rates of Return.** If Treasury bills are currently paying 5.7 percent and the inflation rate is 2.9 percent, what is the approximate real rate of interest? The exact real rate?
- L0 4** 10. **Inflation and Nominal Returns.** Suppose the real rate is 3.2 percent and the inflation rate is 2.6 percent. What rate would you expect to see on a Treasury bill?
- L0 4** 11. **Nominal and Real Returns.** An investment offers a 13 percent total return over the coming year. Bill Bernanke thinks the total real return on this investment will be only 7 percent. What does Bill believe the inflation rate will be over the next year?
- L0 4** 12. **Nominal versus Real Returns.** Say you own an asset that had a total return last year of 17 percent. If the inflation rate last year was 3.2 percent, what was your real return?
- L0 2** 13. **Using Treasury Quotes.** Locate the Treasury issue in Figure 6.3 maturing in August 2023. What is its coupon rate? What is its bid price? What was the *previous day's* asked price?
- L0 2** 14. **Using Treasury Quotes.** Locate the Treasury bond in Figure 6.3 maturing in February 2027. Is this a premium or a discount bond? What is its current yield? What is its yield to maturity? What is the bid-ask spread?
- L0 2** 15. **Bond Price Movements.** Bond X is a premium bond making annual payments. The bond pays an 8 percent coupon, has a YTM of 6 percent, and has 13 years to maturity. Bond Y is a discount bond making annual payments. This bond pays a 6 percent coupon, has a YTM of 8 percent, and also has 13 years to maturity. What are the prices of these bonds today? If interest rates remain unchanged, what do you expect the prices of these bonds to be in one year? In three years? In eight years? In 12 years? In 13 years? What's going on here? Illustrate your answers by graphing bond prices versus time to maturity.
- L0 2** 16. **Interest Rate Risk.** Both Bond Bill and Bond Ted have 9 percent coupons, make semiannual payments, and are priced at par value. Bond Bill has 3 years to maturity, whereas Bond Ted has 20 years to maturity. If interest rates suddenly rise by 2 percent, what is the percentage change in the price of Bond Bill? Of Bond Ted? If rates were to suddenly fall by 2 percent instead, what would the percentage change in the price of Bond Bill be then? Of Bond Ted? Illustrate your answers by graphing bond prices versus YTM. What does this problem tell you about the interest rate risk of longer-term bonds?
- L0 2** 17. **Interest Rate Risk.** Bond J is a 4 percent coupon bond. Bond S is a 14 percent coupon bond. Both bonds have eight years to maturity, make semiannual payments, and have a YTM of 9 percent. If interest rates suddenly rise by 2 percent, what is the percentage price change of these bonds? What if rates suddenly fall by 2 percent instead? What does this problem tell you about the interest rate risk of lower-coupon bonds?
- L0 2** 18. **Bond Yields.** PK Software has 7.5 percent coupon bonds on the market with 22 years to maturity. The bonds make semiannual payments and currently sell

Intermediate
(Questions 15–30)

for 108 percent of par. What is the current yield on PK's bonds? The YTM? The effective annual yield?

- L0 2** 19. **Bond Yields.** BDJ Co. wants to issue new 20-year bonds for some much-needed expansion projects. The company currently has 8.5 percent coupon bonds on the market that sell for \$1,125, make semiannual payments, and mature in 20 years. What coupon rate should the company set on its new bonds if it wants them to sell at par?
- L0 2** 20. **Accrued Interest.** You purchase a bond with an invoice price of \$1,060. The bond has a coupon rate of 9.2 percent, semiannual coupons, and there are five months to the next coupon date. What is the clean price of the bond?
- L0 2** 21. **Accrued Interest.** You purchase a bond with a coupon rate of 7.5 percent, semiannual coupons, and a clean price of \$915. If the next coupon payment is due in two months, what is the invoice price?
- L0 2** 22. **Using Bond Quotes.** Suppose the following bond quote for IOU Corporation appears in the financial page of today's newspaper. Assume the bond has a face value of \$1,000, and the current date is April 15, 2010. What is the yield to maturity of the bond? What is the current yield?

Company (Ticker)	Coupon	Maturity	Last Price	Last Yield	EST Vol (000s)
IOU (IOU)	9.75	Apr 15, 2022	91.535	??	1,827

- L0 2** 23. **Zero Coupon Bonds.** Suppose your company needs to raise \$45 million and you want to issue 20-year bonds for this purpose. Assume the required return on your bond issue will be 7.5 percent, and you're evaluating two issue alternatives: a 7.5 percent annual coupon bond and a zero coupon bond. Your company's tax rate is 35 percent.
- How many of the coupon bonds would you need to issue to raise the \$45 million? How many of the zeroes would you need to issue?
 - In 20 years, what will your company's repayment be if you issue the coupon bonds? What if you issue the zeroes?
 - Based on your answers in (a) and (b), why would you ever want to issue the zeroes? To answer, calculate the firm's aftertax cash outflows for the first year under the two different scenarios. Assume that the IRS amortization rules apply for the zero coupon bonds.
- L0 2** 24. **Finding the Maturity.** You've just found a 10 percent coupon bond on the market that sells for par value. What is the maturity on this bond (Warning: possible trick question)?

Use the following Treasury bond quotes to answer Questions 25–27. To calculate the number of years until maturity, assume that it is currently May 2010.

Rate	Maturity Mo/Yr	Bid	Asked	Chg	Ask Yld
??	May 15	106:13	106:17	+2	4.96
6.450	May 23	108:12	108:14	+4	??
5.375	May 33	??	??	+3	6.48

- L0 2** 25. **Bond Yields.** In the table, find the Treasury bond that matures in May 2023. What is your yield to maturity if you buy this bond?
- L0 2** 26. **Bond Prices.** In the table, find the Treasury bond that matures in May 2033. What is the asked price of this bond in dollars? If the bid-ask spread for this bond is two ticks, what is the bid price in dollars?
- L0 2** 27. **Coupon Rates.** Find the Treasury bond that matures in May 2015. What is the coupon rate for this bond?
- Use the following corporate bond quotes to answer Questions 28–30. To calculate the number of years until maturity, assume that it is currently January 15, 2010.

Company (Ticker)	Coupon	Maturity	Last Price	Last Yield	EST \$ Vol (000's)
Xenon, Inc. (XIC)	5.400	Jan 15, 2020	94.183	??	57,362
Kenny Corp. (KCC)	7.125	Jan 15, 2017	??	6.02	48,941
Williams Co. (WICO)	??	Jan 15, 2026	94.735	6.85	43,802

- L0 2** 28. **Bond Yields.** What is the yield to maturity for the bond issued by Xenon, Inc.?
- L0 2** 29. **Bond Prices.** What price would you expect to pay for the Kenny Corp. bond? What is the bond's current yield?
- L0 2** 30. **Coupon Rates.** What is the coupon rate for the Williams Co. bond?
- L0 2** 31. **Components of Bond Returns.** Bond P is a premium bond with an 8 percent coupon. Bond D is a 4 percent coupon bond currently selling at a discount. Both bonds make annual payments, have a YTM of 6 percent, and have five years to maturity. What is the current yield for bond P? For bond D? If interest rates remain unchanged, what is the expected capital gains yield over the next year for bond P? For bond D? Explain your answers and the interrelationships among the various types of yields.
- L0 2** 32. **Holding Period Yield.** The YTM on a bond is the interest rate you earn on your investment if interest rates don't change. If you actually sell the bond before it matures, your realized return is known as the *holding period yield* (HPY).
- Suppose that today you buy an 8 percent annual coupon bond for \$875. The bond has 10 years to maturity. What rate of return do you expect to earn on your investment?
 - Two years from now, the YTM on your bond has declined by 1 percent, and you decide to sell. What price will your bond sell for? What is the HPY on your investment? Compare this yield to the YTM when you first bought the bond. Why are they different?

Challenge

(Questions 31–32)

- 6.1 Bond Quotes.** You can find current bond prices at www.finra.org. You want to find the bond prices and yields for bonds issued by Georgia Pacific. Enter the ticker symbol "GP" to do a search. What is the shortest maturity bond issued by Georgia Pacific that is outstanding? What is the longest maturity bond? What is the credit rating for Georgia Pacific's bonds? Do all of the bonds have the same credit rating? Why do you think this is?

**WHAT'S ON
THE WEB?**

- 6.2 Yield Curves.** You can find information regarding the most current bond yields at money.cnn.com. Go there and graph the yield curve for U.S. Treasury bonds. What is the general shape of the yield curve? What does this imply about expected future inflation? Now graph the yield curve for AAA-, AA-, and A-rated corporate bonds. Is the corporate yield curve the same shape as the Treasury yield curve? Why or why not?
- 6.3 Default Premiums.** The St. Louis Federal Reserve Board has files listing historical interest rates on their Web site www.stlouisfed.org. Find your way to the “FRED” data, then “Interest Rates.” You will find listings for Moody’s Seasoned Aaa Corporate Bond Yield and Moody’s Seasoned Baa Corporate Bond Yield. A default premium can be calculated as the difference between the Aaa bond yield and the Baa bond yield. Calculate the default premium using these two bond indices for the most recent 36 months. Is the default premium the same for every month? Why do you think this is?

CHAPTER CASE

FINANCING S&S AIR'S EXPANSION PLANS WITH A BOND ISSUE

Mark Sexton and Todd Story, the owners of S&S Air, have decided to expand their operations. They instructed their newly hired financial analyst, Chris Guthrie, to enlist an underwriter to help sell \$20 million in new 10-year bonds to finance construction. Chris has entered into discussions with Renata Harper, an underwriter from the firm of Crowe & Mallard, about which bond features S&S Air should consider and what coupon rate the issue will likely have.

Although Chris is aware of the bond features, he is uncertain as to the costs and benefits of some features, so he isn't clear on how each feature would affect the coupon rate of the bond issue. You are Renata's assistant, and she has asked you to prepare a memo to Chris describing the effect of each of the following bond features on the coupon rate of the bond. She would also like you to list any advantages or disadvantages of each feature. ■

QUESTIONS

1. The security of the bond, that is, whether the bond has collateral.
2. The seniority of the bond.
3. The presence of a sinking fund.
4. A call provision with specified call dates and call prices.
5. A deferred call accompanying the above call provision.
6. A make-whole call provision.
7. Any positive covenants. Also, discuss several possible positive covenants S&S Air might consider.
8. Any negative covenants. Also, discuss several possible negative covenants S&S Air might consider.
9. A conversion feature (note that S&S Air is not a publicly traded company).
10. A floating rate coupon.

Equity Markets and Stock Valuation

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Assess how stock prices depend on future dividends and dividend growth.
- LO 2** Identify the different ways corporate directors are elected to office.
- LO 3** Explain how the stock markets work.

When the stock market closed on March 4, 2009, the common stock of McGraw-Hill, publisher of fine-quality college textbooks, was going for \$18.83 per share. On that same day, commercial property and casualty insurance company Loews Corporation closed at \$19.82, while Alaska Air Group closed at \$18.18. Since the stock prices of these three companies were so similar, you might expect that they would be offering similar dividends to their stock-

holders, but you would be wrong. In fact, McGraw-Hill's annual dividend was \$0.90, Loews' was \$0.25 per share, and Alaska Air Group was paying no dividend at all!

As we will see in this chapter, the dividends currently being paid are one of the primary factors we look at when we attempt to value common stocks. However, it is obvious from looking at Alaska Air Group that current dividends are not the end of the story, so this chapter explores dividends, stock values, and the connection between the two.

Going back to Chapter 1, we saw that the goal of financial management is to maximize stock prices, so an understanding of what determines share values is obviously a key concern. When a corporation has publicly held stock, its shares will often be bought and sold on one or more of the major stock exchanges, so we will examine how stocks are traded. We will also see that the shareholders in a corporation have certain rights, and that just how these rights are allocated can have a significant impact on corporate control and governance.

Visit us at www.mhhe.com/rwj

In our previous chapter, we introduced you to bonds and bond valuation. In this chapter, we turn to the other major source of financing for corporations, common and preferred stock. We first describe the cash flows associated with a share of stock and then go on to develop a very famous result, the dividend growth model. From there, we move on to examine various important features of common and preferred stock, focusing on shareholder rights. We close out the chapter with a discussion of how shares of stock are traded and how stock prices and other important information are reported in the financial press.

COMMON STOCK VALUATION

7.1

A share of common stock is more difficult to value in practice than a bond, for at least three reasons. First, with common stock, not even the promised cash flows are known in advance. Second, the life of the investment is essentially forever, since common stock has no maturity. Third, there is no way to easily observe the rate of return that the market requires. Nonetheless, as we will see, there are cases in which we can come up with the present value of the future cash flows for a share of stock and thus determine its value.

Cash Flows

Imagine that you are considering buying a share of stock today. You plan to sell the stock in one year. You somehow know that the stock will be worth \$70 at that time. You predict that the stock will also pay a \$10 per share dividend at the end of the year. If you require a 25 percent return on your investment, what is the most you would pay for the stock? In other words, what is the present value of the \$10 dividend along with the \$70 ending value at 25 percent?

If you buy the stock today and sell it at the end of the year, you will have a total of \$80 in cash. At 25 percent:

$$\text{Present value} = (\$10 + \$70)/1.25 = \$64$$

Therefore, \$64 is the value you would assign to the stock today.

More generally, let P_0 be the current price of the stock, and assign P_1 to be the price in one period. If D_1 is the cash dividend paid at the end of the period, then:

$$P_0 = (D_1 + P_1)/(1 + R) \quad [7.1]$$

where R is the required return in the market on this investment.

Notice that we really haven't said much so far. If we wanted to determine the value of a share of stock today (P_0), we would first have to come up with the value in one year (P_1). This is even harder to do, so we've only made the problem more complicated.

What is the price in one period, P_1 ? We don't know in general. Instead, suppose we somehow knew the price in two periods, P_2 . Given a predicted dividend in two periods, D_2 , the stock price in one period would be:

$$P_1 = (D_2 + P_2)/(1 + R)$$

If we were to substitute this expression for P_1 into our expression for P_0 , we would have:

$$\begin{aligned} P_0 &= \frac{D_1 + P_1}{1 + R} = \frac{D_1 + \frac{D_2 + P_2}{1 + R}}{1 + R} \\ &= \frac{D_1}{(1 + R)^1} + \frac{D_2}{(1 + R)^2} + \frac{P_2}{(1 + R)^2} \end{aligned}$$

Now we need to get a price in two periods. We don't know this either, so we can procrastinate again and write:

$$P_2 = (D_3 + P_3)/(1 + R)$$

If we substitute this back in for P_2 , we have:

$$\begin{aligned} P_0 &= \frac{D_1}{(1 + R)^1} + \frac{D_2}{(1 + R)^2} + \frac{P_2}{(1 + R)^2} \\ &= \frac{D_1}{(1 + R)^1} + \frac{D_2}{(1 + R)^2} + \frac{D_3 + P_3}{(1 + R)^2} \\ &= \frac{D_1}{(1 + R)^1} + \frac{D_2}{(1 + R)^2} + \frac{D_3}{(1 + R)^3} + \frac{P_3}{(1 + R)^3} \end{aligned}$$

You should start to notice that we can push the problem of coming up with the stock price off into the future forever. It is important to note that no matter what the stock price is, the present value is essentially zero if we push the sale of the stock far enough away. What we are eventually left with is the result that the current price of the stock can be written as the present value of the dividends beginning in one period and extending out forever:

$$P_0 = \frac{D_1}{(1 + R)^1} + \frac{D_2}{(1 + R)^2} + \frac{D_3}{(1 + R)^3} + \frac{D_4}{(1 + R)^4} + \frac{D_5}{(1 + R)^5} + \dots$$

We have illustrated here that the price of the stock today is equal to the present value of all of the future dividends. How many future dividends are there? In principle, there can be an infinite number. This means that we still can't compute a value for the stock because we would have to forecast an infinite number of dividends and then discount them all. In the next section, we consider some special cases in which we can get around this problem.

EXAMPLE 7.1

Growth Stocks

You might be wondering about shares of stock in companies such as eBay that currently pay no dividends. Small, growing companies frequently plow back everything and thus pay no dividends. Are such shares worth nothing? It depends. When we say that the value of the stock is equal to the present value of the future dividends, we don't rule out the possibility that some number of those dividends are zero. They just can't *all* be zero.

Imagine a company that has a provision in its corporate charter that prohibits the paying of dividends now or ever. The corporation never borrows any money, never pays out any money to stockholders in any form whatsoever, and never sells any assets. Such a corporation couldn't really exist because the IRS wouldn't like it, and the stockholders could always vote to amend the charter if they wanted to. If it did exist, however, what would the stock be worth?

The stock would be worth absolutely nothing. Such a company is a financial "black hole." Money goes in, but nothing valuable ever comes out. Because nobody would ever get any return on this investment, the investment has no value. This example is a little absurd, but it illustrates that when we speak of companies that don't pay dividends, what we really mean is that they are not *currently* paying dividends.

Some Special Cases

There are a few very useful special circumstances under which we can come up with a value for the stock. What we have to do is make some simplifying assumptions about the

pattern of future dividends. The two cases we consider are the following: (1) the dividend has a zero growth rate and (2) the dividend grows at a constant rate. We consider each of these separately.

Zero Growth The case of zero growth is one we've already seen. A share of common stock in a company with a constant dividend is much like a share of preferred stock. From Chapter 5 (Example 5.7), we know that the dividend on a share of preferred stock has zero growth and thus is constant through time. For a zero-growth share of common stock, this implies that:

$$D_1 = D_2 = D_3 = D = \text{constant}$$

So, the value of the stock is:

$$P_0 = \frac{D}{(1+R)^1} + \frac{D}{(1+R)^2} + \frac{D}{(1+R)^3} + \frac{D}{(1+R)^4} + \frac{D}{(1+R)^5} + \dots$$

Because the dividend is always the same, the stock can be viewed as an ordinary perpetuity with a cash flow equal to D every period. The per-share value is thus given by:

$$P_0 = D/R \quad [7.2]$$

where R is the required return.

For example, suppose the Paradise Prototyping Company has a policy of paying a \$10 per-share dividend every year. If this policy is to be continued indefinitely, what is the value of a share of stock if the required return is 20 percent? The stock in this case amounts to an ordinary perpetuity, so the stock is worth $\$10/.20 = \50 per share.

Constant Growth Suppose we know that the dividend for some company always grows at a steady rate. Call this growth rate g . If we let D_0 be the dividend just paid, then the next dividend, D_1 , is:

$$D_1 = D_0 \times (1 + g)$$

The dividend in two periods is:

$$\begin{aligned} D_2 &= D_1 \times (1 + g) \\ &= [D_0 \times (1 + g)] \times (1 + g) \\ &= D_0 \times (1 + g)^2 \end{aligned}$$

We could repeat this process to come up with the dividend at any point in the future. In general, from our discussion of compound growth in Chapter 4, we know that the dividend t periods into the future, D_t , is given by:

$$D_t = D_0 \times (1 + g)^t$$

An asset with cash flows that grow at a constant rate forever is called a *growing perpetuity*. As we will see momentarily, there is a simple expression for determining the value of such an asset.

The assumption of steady dividend growth might strike you as peculiar. Why would the dividend grow at a constant rate? The reason is that, for many companies, steady growth in dividends is an explicit goal. This subject falls under the general heading of dividend policy, so we will defer further discussion of it to a later chapter.

Students who are interested in equity valuation techniques should check out the Motley Fool at www.fool.com/School/Earnings-BasedValuations.htm.

EXAMPLE 7.2**Dividend Growth**

The Hedless Corporation has just paid a dividend of \$3 per share. The dividend of this company grows at a steady rate of 8 percent per year. Based on this information, what will the dividend be in five years?

Here we have a \$3 current amount that grows at 8 percent per year for five years. The future amount is thus:

$$\$3 \times 1.08^5 = \$3 \times 1.4693 = \$4.41$$

The dividend will therefore increase by \$1.41 over the coming five years.

If the dividend grows at a steady rate, then we have replaced the problem of forecasting an infinite number of future dividends with the problem of coming up with a single growth rate, a considerable simplification. In this case, if we take D_0 to be the dividend just paid and g to be the constant growth rate, the value of a share of stock can be written as:

$$\begin{aligned} P_0 &= \frac{D_1}{(1+R)^1} + \frac{D_2}{(1+R)^2} + \frac{D_3}{(1+R)^3} + \dots \\ &= \frac{D_0(1+g)^1}{(1+R)^1} + \frac{D_0(1+g)^2}{(1+R)^2} + \frac{D_0(1+g)^3}{(1+R)^3} + \dots \end{aligned}$$

As long as the growth rate, g , is less than the discount rate, R , the present value of this series of cash flows can be written very simply as:

$$P_0 = \frac{D_0 \times (1+g)}{R-g} = \frac{D_1}{R-g} \quad [7.3]$$

dividend growth model

A model that determines the current price of a stock as its dividend next period divided by the discounted rate less the dividend growth rate.

This elegant result goes by a lot of different names. We will call it the **dividend growth model**. By any name, it is very easy to use. To illustrate, suppose D_0 is \$2.30, R is 13 percent, and g is 5 percent. The price per share in this case is:

$$\begin{aligned} P_0 &= D_0 \times (1+g)/(R-g) \\ &= \$2.30 \times 1.05/ (.13 - .05) \\ &= \$2.415/.08 \\ &= \$30.19 \end{aligned}$$

We can actually use the dividend growth model to get the stock price at any point in time, not just today. In general, the price of the stock as of time t is:

$$P_t = \frac{D_t \times (1+g)}{R-g} = \frac{D_{t+1}}{R-g} \quad [7.4]$$

In our example, suppose we are interested in the price of the stock in five years, P_5 . We first need the dividend at Time 5, D_5 . Because the dividend just paid is \$2.30 and the growth rate is 5 percent per year, D_5 is:

$$D_5 = \$2.30 \times 1.05^5 = \$2.30 \times 1.2763 = \$2.935$$

From the dividend growth model, we get that the price of the stock in five years is:

$$P_5 = \frac{D_5 \times (1+g)}{R-g} = \frac{\$2.935 \times 1.05}{.13 - .05} = \frac{\$3.0822}{.08} = \$38.53$$

Gordon Growth Company

EXAMPLE 7.3

The next dividend for the Gordon Growth Company will be \$4 per share. Investors require a 16 percent return on companies such as Gordon. Gordon's dividend increases by 6 percent every year. Based on the dividend growth model, what is the value of Gordon's stock today? What is the value in four years?

The only tricky thing here is that the next dividend, D_1 , is given as \$4, so we won't multiply this by $(1 + g)$. With this in mind, the price per share is given by:

$$\begin{aligned} P_0 &= D_1 / (R - g) \\ &= \$4 / (.16 - .06) \\ &= \$4 / .10 \\ &= \$40 \end{aligned}$$

Because we already have the dividend in one year, we know that the dividend in four years is equal to $D_1 \times (1 + g)^3 = \$4 \times 1.06^3 = \4.764 . The price in four years is therefore:

$$\begin{aligned} P_4 &= D_4 \times (1 + g) / (R - g) \\ &= \$4.764 \times 1.06 / (.16 - .06) \\ &= \$5.05 / .10 \\ &= \$50.50 \end{aligned}$$

Notice in this example that P_4 is equal to $P_0 \times (1 + g)^4$

$$P_4 = \$50.50 = \$40 \times 1.06^4 = P_0 \times (1 + g)^4$$

To see why this is so, notice first that:

$$P_4 = D_5 / (R - g)$$

However, D_5 is just equal to $D_1 \times (1 + g)^4$, so we can write P_4 as:

$$\begin{aligned} P_4 &= D_1 \times (1 + g)^4 / (R - g) \\ &= [D_1 / (R - g)] \times (1 + g)^4 \\ &= P_0 \times (1 + g)^4 \end{aligned}$$

This last example illustrates that the dividend growth model makes the implicit assumption that the stock price will grow at the same constant rate as the dividend. This really isn't too surprising. What it tells us is that if the cash flows on an investment grow at a constant rate through time, so does the value of that investment.

You might wonder what would happen with the dividend growth model if the growth rate, g , were greater than the discount rate, R . It looks like we would get a negative stock price because $R - g$ would be less than zero. This is not what would happen.

Instead, if the constant growth rate exceeds the discount rate, then the stock price is infinitely large. Why? If the growth rate is bigger than the discount rate, then the present value of the dividends keeps on getting bigger and bigger. Essentially, the same is true if the growth rate and the discount rate are equal. In both cases, the simplification that allows us to replace the infinite stream of dividends with the dividend growth model is "illegal," so the answers we get from the dividend growth model are nonsense unless the growth rate is less than the discount rate.

Finally, the expression we came up with for the constant growth case will work for any growing perpetuity, not just dividends on common stock. If C_1 is the next cash flow on a growing perpetuity, then the present value of the cash flows is given by:

$$\text{Present value} = C_1/(R - g) = C_0(1 + g)/(R - g)$$

Notice that this expression looks like the result for an ordinary perpetuity except that we have $R - g$ on the bottom instead of just R .

Nonconstant Growth The last case we consider is nonconstant growth. The main reason to consider this case is to allow for “supernormal” growth rates over some finite length of time. As we discussed earlier, the growth rate cannot exceed the required return indefinitely, but it certainly could do so for some number of years. To avoid the problem of having to forecast and discount an infinite number of dividends, we will require that the dividends start growing at a constant rate sometime in the future.

For a simple example of nonconstant growth, consider the case of a company that is currently not paying dividends. You predict that, in five years, the company will pay a dividend for the first time. The dividend will be \$.50 per share. You expect that this dividend will then grow at a rate of 10 percent per year indefinitely. The required return on companies such as this one is 20 percent. What is the price of the stock today?

To see what the stock is worth today, we first find out what it will be worth once dividends are paid. We can then calculate the present value of that future price to get today’s price. The first dividend will be paid in five years, and the dividend will grow steadily from then on. Using the dividend growth model, we can say that the price in four years will be:

$$\begin{aligned} P_4 &= D_4 \times (1 + g)/(R - g) \\ &= D_5/(R - g) \\ &= \$.50/(.20 - .10) \\ &= \$5 \end{aligned}$$

If the stock will be worth \$5 in four years, then we can get the current value by discounting this price back four years at 20 percent:

$$P_0 = \$5/1.20^4 = \$5/2.0736 = \$2.41$$

The stock is therefore worth \$2.41 today.

The problem of nonconstant growth is only slightly more complicated if the dividends are not zero for the first several years. For example, suppose that you have come up with the following dividend forecasts for the next three years:

Year	Expected Dividend
1	\$1.00
2	\$2.00
3	\$2.50

After the third year, the dividend will grow at a constant rate of 5 percent per year. The required return is 10 percent. What is the value of the stock today?

In dealing with nonconstant growth, a time line can be very helpful. Figure 7.1 illustrates one for this problem. The important thing to notice is when constant growth starts. As we’ve shown, for this problem, constant growth starts at Time 3. This means that we can use our constant growth model to determine the stock price at Time 3, P_3 . By far the most

common mistake in this situation is to incorrectly identify the start of the constant growth phase and, as a result, calculate the future stock price at the wrong time.

As always, the value of the stock is the present value of all the future dividends. To calculate this present value, we first have to compute the present value of the stock price three years down the road, just as we did before. We then have to add in the present value of the dividends that will be paid between now and then. So, the price in three years is:

$$\begin{aligned} P_3 &= D_3 \times (1 + g)/(R - g) \\ &= \$2.50 \times 1.05/(\.10 - .05) \\ &= \$52.50 \end{aligned}$$

We can now calculate the total value of the stock as the present value of the first three dividends plus the present value of the price at time 3, P_3 .

$$\begin{aligned} P_0 &= \frac{D_1}{(1 + R)^1} + \frac{D_2}{(1 + R)^2} + \frac{D_3}{(1 + R)^3} + \frac{P_3}{(1 + R)^3} \\ &= \frac{\$1}{1.10} + \frac{2}{1.10^2} + \frac{2.50}{1.10^3} + \frac{52.50}{1.10^3} \\ &= \$.91 + 1.65 + 1.88 + 39.44 \\ &= \$43.88 \end{aligned}$$

The value of the stock today is thus \$43.88.

Supernormal Growth

EXAMPLE 7.4

Chain Reaction, Inc., has been growing at a phenomenal rate of 30 percent per year because of its rapid expansion and explosive sales. You believe that this growth rate will last for three more years and that the rate will then drop to 10 percent per year. If the growth rate then remains at 10 percent indefinitely, what is the total value of the stock? Total dividends just paid were \$5 million, and the required return is 20 percent.

Chain Reaction's situation is an example of supernormal growth. It is unlikely that a 30 percent growth rate can be sustained for any extended length of time. To value the equity in this company, we first need to calculate the total dividends over the supernormal growth period:

Year	Total Dividends (in millions)
1	$\$5.00 \times 1.3 = \$ 6.500$
2	$6.50 \times 1.3 = 8.450$
3	$8.45 \times 1.3 = 10.985$

The price at Time 3 can be calculated as:

$$P_3 = D_3 \times (1 + g)/(R - g)$$

(continued)

where g is the long-run growth rate. So we have:

$$P_3 = \$10.985 \times 1.10 / (.20 - .10) = \$120.835$$

To determine the value today, we need the present value of this amount plus the present value of the total dividends:

$$\begin{aligned} P_0 &= \frac{D_1}{(1+R)^1} + \frac{D_2}{(1+R)^2} + \frac{D_3}{(1+R)^3} + \frac{P_3}{(1+R)^3} \\ &= \frac{\$6.50}{1.20} + \frac{8.45}{1.20^2} + \frac{10.985}{1.20^3} + \frac{120.835}{1.20^3} \\ &= \$5.42 + 5.87 + 6.36 + 69.93 \\ &= \$87.58 \end{aligned}$$

The total value of the stock today is thus \$87.58 million. If there were, for example, 20 million shares, then the stock would be worth $\$87.58/20 = \4.38 per share.

Components of the Required Return

Thus far, we have taken the required return, or discount rate, R , as given. We will have quite a bit to say on this subject in Chapters 10 and 11. For now, we want to examine the implications of the dividend growth model for this required return. Earlier, we calculated P_0 as:

$$P_0 = D_1 / (R - g)$$

If we rearrange this to solve for R , we get:

$$\begin{aligned} R - g &= D_1 / P_0 \\ R &= D_1 / P_0 + g \end{aligned} \quad [7.5]$$

This tells us that the total return, R , has two components. The first of these, D_1/P_0 , is called the **dividend yield**. Because this is calculated as the expected cash dividend divided by the current price, it is conceptually similar to the current yield on a bond.

The second part of the total return is the growth rate, g . We know that the dividend growth rate is also the rate at which the stock price grows (see Example 7.3). Thus, this growth rate can be interpreted as the **capital gains yield**, that is, the rate at which the value of the investment grows.¹

To illustrate the components of the required return, suppose we observe a stock selling for \$20 per share. The next dividend will be \$1 per share. You think that the dividend will grow by 10 percent per year more or less indefinitely. What return does this stock offer you if this is correct?

The dividend growth model calculates the total return as:

$$\begin{aligned} R &= \text{Dividend yield} + \text{Capital gains yield} \\ R &= D_1/P_0 + g \end{aligned}$$

In this case, the total return works out to be:

$$\begin{aligned} R &= \$1/20 + 10\% \\ &= 5\% + 10\% \\ &= 15\% \end{aligned}$$

This stock, therefore, has a required return of 15 percent.

¹ Here and elsewhere, we use the term *capital gains* a little loosely. For the record, a capital gain (or loss) is, strictly speaking, something defined by the IRS. For our purposes, it would be more accurate (but less common) to use the term *price appreciation* instead of *capital gain*.

dividend yield

A stock's expected cash dividend divided by its current price.

capital gains yield

The dividend growth rate, or the rate at which the value of an investment grows.

I. The general case

In general, the price today of a share of stock, P_0 , is the present value of all of its future dividends, D_1, D_2, D_3, \dots :

$$P_0 = \frac{D_1}{(1+R)^1} + \frac{D_2}{(1+R)^2} + \frac{D_3}{(1+R)^3} + \dots$$

where R is the required return.

II. Constant growth case

If the dividend is constant and equal to D , then the price can be written as:

$$P_0 = \frac{D}{R}$$

If the dividend grows at a steady rate, g , then the price can be written as:

$$P_0 = \frac{D_1}{R - g}$$

This result is called the *dividend growth model*.

III. The required return, R , can be written as the sum of two things:

$$R = D_1/P_0 + g$$

where D_1/P_0 is the *dividend yield* and g is the *capital gains yield* (which is the same thing as the growth rate in dividends for the steady growth case).

TABLE 7.1

Summary of stock valuation

We can verify this answer by calculating the price in one year, P_1 , using 15 percent as the required return. Based on the dividend growth model, this price is:

$$\begin{aligned} P_1 &= D_1 \times (1 + g) / (R - g) \\ &= \$1 \times 1.10 / (.15 - .10) \\ &= \$1.10 / .05 \\ &= \$22 \end{aligned}$$

Notice that this \$22 is $\$20 \times 1.1$, so the stock price has grown by 10 percent, as it should. If you pay \$20 for the stock today, you will get a \$1 dividend at the end of the year, and you will have a $\$22 - \$20 = \$2$ gain. Your dividend yield is thus $\$1/\$20 = 5\%$. Your capital gains yield is $\$2/\$20 = 10\%$, so your total return would be $5\% + 10\% = 15\%$.

To get a feel for actual numbers in this context, consider that, according to the 2009 Value Line *Investment Survey*, Hershey Food's dividends were expected to grow by 4.5 percent over the next 5 or so years, compared to an historical growth rate of 12.5 percent over the preceding 10 years. In 2009, the projected dividend for the coming year was given as \$1.19. The stock price at that time was about \$34 per share. What is the return investors require on Hershey? Here, the dividend yield is about 3.5 percent and the capital gains yield is 4.5 percent, giving a total required return of 8 percent on Hershey stock.

Our discussion of stock valuation is summarized in Table 7.1.

CONCEPT QUESTIONS

- 7.1a** What are the relevant cash flows for valuing a share of common stock?
- 7.1b** Does the value of a share of stock depend on how long you expect to keep it?
- 7.1c** What is the value of a share of stock when the dividend grows at a constant rate?

7.2

SOME FEATURES OF COMMON AND PREFERRED STOCK

In discussing common stock features, we focus on shareholder rights and dividend payments. For preferred stock, we explain what “preferred” means, and we also debate whether preferred stock is really debt or equity.

Common Stock Features

common stock

Equity without priority for dividends or in bankruptcy.

The term **common stock** means different things to different people, but it is usually applied to stock that has no special preference either in paying dividends or in bankruptcy.

Shareholder Rights The conceptual structure of the corporation assumes that shareholders elect directors who, in turn, hire management to carry out their directives. Shareholders, therefore, control the corporation through the right to elect the directors. Generally, only shareholders have this right.

Directors are elected each year at an annual meeting. Although there are exceptions (discussed in a moment), the general idea is “one share, one vote” (*not* one shareholder, one vote). Corporate democracy is thus very different from our political democracy. With corporate democracy, the “golden rule” prevails absolutely.²

Directors are elected at an annual shareholders’ meeting by a vote of the holders of a majority of shares who are present and entitled to vote. However, the exact mechanism for electing directors differs across companies. The most important difference is whether shares must be voted cumulatively or voted straight.

To illustrate the two different voting procedures, imagine that a corporation has two shareholders: Smith with 20 shares and Jones with 80 shares. Both want to be a director. Jones does not want Smith, however. We assume that there are a total of four directors to be elected.

cumulative voting

A procedure in which a shareholder may cast all votes for one member of the board of directors.

The effect of **cumulative voting** is to permit minority participation.³ If cumulative voting is permitted, the total number of votes that each shareholder may cast is determined first. This is usually calculated as the number of shares (owned or controlled) multiplied by the number of directors to be elected.

With cumulative voting, the directors are elected all at once. In our example, this means that the top four vote-getters will be the new directors. Individual shareholders can distribute votes however they wish.

Will Smith get a seat on the board? If we ignore the possibility of a five-way tie, then the answer is yes. Smith will cast $20 \times 4 = 80$ votes, and Jones will cast $80 \times 4 = 320$ votes. If Smith gives all his votes to himself, he is assured of a directorship. The reason is that Jones can’t divide 320 votes among four candidates in such a way as to give all of them more than 80 votes, so Smith will finish fourth at worst.

In general, if there are N directors up for election, then $1/(N + 1)$ percent of the stock plus one share will guarantee you a seat. In our current example, this is $1/(4 + 1) = 20\%$ (plus one share). So, the more seats that are up for election at one time, the easier (and cheaper) it is to win one.

straight voting

A procedure in which a shareholder may cast all votes for each member of the board of directors.

With **straight voting** the directors are elected one at a time. Each time, Smith can cast 20 votes and Jones can cast 80. As a consequence, Jones will elect all of the candidates. The only way to guarantee a seat is to own 50 percent plus one share. This also guarantees that you will win every seat, so it’s really all or nothing.

² The golden rule: Whoever has the gold makes the rules.

³ By minority participation, we mean participation by shareholders with relatively small amounts of stock.

Buying the Election

EXAMPLE 7.5

Stock in JRJ Corporation sells for \$20 per share and features cumulative voting. There are 10,000 shares outstanding. If three directors are up for election, how much does it cost to ensure yourself a seat on the board?

The question here is how many shares of stock it will take to get a seat. The answer is 2,501, so the cost is $2,501 \times \$20 = \$50,020$. Why 2,501? Because there is no way the remaining 7,499 votes can be divided among three people to give all of them more than 2,501 votes. For example, suppose two people receive 2,502 votes and the first two seats. A third person can receive at most $10,000 - 2,502 - 2,502 = 2,495$, so the third seat is yours. Verify that we arrived at 2,501 using the formula described earlier.

As we've illustrated, straight voting can "freeze out" minority shareholders; that is the reason many states have mandatory cumulative voting. In states where cumulative voting is mandatory, devices have been worked out to minimize its impact.

One such device is to stagger the voting for the board of directors. With staggered elections, only a fraction of the directorships are up for election at a particular time. Thus, if only two directors are up for election at any one time, it will take $1/(2 + 1) = 33.33\%$ of the stock plus one share to guarantee a seat.

Overall, staggering has two basic effects:

1. Staggering makes it more difficult for a minority to elect a director when there is cumulative voting because there are fewer directors to be elected at one time.
2. Staggering makes takeover attempts less likely to be successful because it makes it more difficult to vote in a majority of new directors.

We should note that staggering may serve a beneficial purpose. It provides "institutional memory," that is, continuity on the board of directors. This may be important for corporations with significant long-range plans and projects.

Proxy Voting A **proxy** is the grant of authority by a shareholder to someone else to vote the shareholder's shares. For convenience, much of the voting in large public corporations is actually done by proxy.

As we have seen, with straight voting, each share of stock has one vote. The owner of 10,000 shares has 10,000 votes. Large companies have hundreds of thousands or even millions of shareholders. Shareholders can come to the annual meeting and vote in person, or they can transfer their right to vote to another party.

Obviously, management always tries to get as many proxies as possible transferred to it. However, if shareholders are not satisfied with management, an "outside" group of shareholders can try to obtain votes via proxy. They can vote by proxy in an attempt to replace management by electing enough directors. The resulting battle is called a *proxy fight*.

Classes of Stock Some firms have more than one class of common stock. Often, the classes are created with unequal voting rights. The Ford Motor Company, for example, has Class B common stock, which is not publicly traded (it is held by Ford family interests and trusts). This class has about 40 percent of the voting power, even though it represents less than 10 percent of the total number of shares outstanding.

There are many other cases of corporations with different classes of stock. For example, Google, the Web search company, has two classes of common stock, A and B. The Class A shares are held by the public, and each share has one vote. The Class B shares are held by company insiders, and each Class B share has 10 votes. As a result, Google's founders and managers control the company. The CEO of cable TV giant Comcast, Brian Roberts,

proxy

A grant of authority by a shareholder allowing another individual to vote that shareholder's shares.

owns about .4 percent of the company's equity, but he has a third of all the votes thanks to the creation of a special class of stock.

In principle, the New York Stock Exchange does not allow companies to create classes of publicly traded common stock with unequal voting rights. Exceptions (e.g., Ford) appear to have been made. In addition, many non-NYSE companies have dual classes of common stock.

A primary reason for creating dual or multiple classes of stock has to do with control of the firm. If such stock exists, management of a firm can raise equity capital by issuing nonvoting or limited-voting stock while maintaining control.

The subject of unequal voting rights is controversial in the United States, and the idea of one share, one vote has a strong following and a long history. Interestingly, however, shares with unequal voting rights are quite common in the United Kingdom and elsewhere around the world.

Other Rights The value of a share of common stock in a corporation is directly related to the general rights of shareholders. In addition to the right to vote for directors, shareholders usually have the following rights:

1. The right to share proportionally in dividends paid.
2. The right to share proportionally in assets remaining after liabilities have been paid in a liquidation.
3. The right to vote on stockholder matters of great importance, such as a merger. Voting is usually done at the annual meeting or a special meeting.

In addition, shareholders sometimes have the right to share proportionally in any new stock sold. This is called the *preemptive right*.

Essentially, a preemptive right means that a company that wishes to sell stock must first offer it to the existing stockholders before offering it to the general public. The purpose is to give stockholders the opportunity to protect their proportionate ownership in the corporation.

Dividends A distinctive feature of corporations is that they have shares of stock on which they are authorized by law to pay dividends to their shareholders. **Dividends** paid to shareholders represent a return on the capital directly or indirectly contributed to the corporation by the shareholders. The payment of dividends is at the discretion of the board of directors.

Some important characteristics of dividends include the following:

1. Unless a dividend is declared by the board of directors of a corporation, it is not a liability of the corporation. A corporation cannot default on an undeclared dividend. As a consequence, corporations cannot become bankrupt because of nonpayment of dividends. The amount of the dividend and even whether it is paid are decisions based on the business judgment of the board of directors.
2. The payment of dividends by the corporation is not a business expense. Dividends are not deductible for corporate tax purposes. In short, dividends are paid out of the corporation's aftertax profits.
3. Dividends received by individual shareholders are taxable. However, corporations that own stock in other corporations are permitted to exclude 70 percent of the dividend amounts they receive and are taxed only on the remaining 30 percent.⁴

⁴ For the record, the 70 percent exclusion applies when the recipient owns less than 20 percent of the outstanding stock in a corporation. If a corporation owns more than 20 percent but less than 80 percent, the exclusion is 80 percent. If more than 80 percent is owned, the corporation can file a single "consolidated" return, and the exclusion is effectively 100 percent.

dividends

Payments by a corporation to shareholders, made in either cash or stock.

Preferred Stock Features

Preferred stock differs from common stock because it has preference over common stock in the payment of dividends and in the distribution of corporation assets in the event of liquidation. *Preference* means only that the holders of the preferred shares must receive a dividend (in the case of an ongoing firm) before holders of common shares are entitled to anything.

Preferred stock is a form of equity from a legal and tax standpoint. It is important to note, however, that holders of preferred stock sometimes have no voting privileges.

Stated Value Preferred shares have a stated liquidating value, usually \$100 per share. The cash dividend is described in terms of dollars per share. For example, General Motors “\$5 preferred” easily translates into a dividend yield of 5 percent of stated value.

Cumulative and Noncumulative Dividends A preferred dividend is *not* like interest on a bond. The board of directors may decide not to pay the dividends on preferred shares, and their decision may have nothing to do with the current net income of the corporation.

Dividends payable on preferred stock are either *cumulative* or *noncumulative*; most are cumulative. If preferred dividends are cumulative and are not paid in a particular year, they will be carried forward as an *arrearage*. Usually, both the accumulated (past) preferred dividends and the current preferred dividends must be paid before the common shareholders can receive anything.

Unpaid preferred dividends are *not* debts of the firm. Directors elected by the common shareholders can defer preferred dividends indefinitely. However, in such cases, common shareholders must also forgo dividends. In addition, holders of preferred shares are often granted voting and other rights if preferred dividends have not been paid for some time. For example, at one point, US Airways had failed to pay dividends on one of its preferred stock issues for six quarters. As a consequence, the holders of the shares were allowed to nominate two people to represent their interests on the airline’s board. Because preferred stockholders receive no interest on the accumulated dividends, some have argued that firms have an incentive to delay paying preferred dividends, but, as we have seen, this may mean sharing control with preferred stockholders.

Is Preferred Stock Really Debt? A good case can be made that preferred stock is really debt in disguise, a kind of equity bond. Preferred shareholders are only entitled to receive a stated dividend, and, if the corporation is liquidated, preferred shareholders are only entitled to the stated value of their preferred shares. Often, preferred stocks carry credit ratings much like those of bonds. Furthermore, preferred stock is sometimes convertible into common stock, and preferred stocks are often callable.

In addition, in recent years, many new issues of preferred stock have had obligatory sinking funds. The existence of such a sinking fund effectively creates a final maturity because it means that the entire issue will ultimately be retired. For these reasons, preferred stock seems to be a lot like debt. However, for tax purposes, preferred dividends are treated like common stock dividends.

preferred stock

Stock with dividend priority over common stock, normally with a fixed dividend rate, sometimes without voting rights.

CONCEPT QUESTIONS

- 7.2a** What is a proxy?
- 7.2b** What rights do stockholders have?
- 7.2c** Why is preferred stock called preferred?

7.3

THE STOCK MARKETS

primary market

The market in which new securities are originally sold to investors.

secondary market

The market in which previously issued securities are traded among investors.

dealer

An agent who buys and sells securities from inventory.

broker

An agent who arranges security transactions among investors.

Back in Chapter 1, we very briefly mentioned that shares of stock are bought and sold on various stock exchanges, the two most important of which are the New York Stock Exchange and the NASDAQ. From our earlier discussion, recall that the stock market consists of a **primary market** and a **secondary market**. In the primary, or new-issue, market, shares of stock are first brought to the market and sold to investors. In the secondary market, existing shares are traded among investors.

In the primary market, companies sell securities to raise money. We will discuss this process in detail in a later chapter. We therefore focus mainly on secondary-market activity in this section. We conclude with a discussion of how stock prices are quoted in the financial press.

Dealers and Brokers

Because most securities transactions involve dealers and brokers, it is important to understand exactly what is meant by the terms *dealer* and *broker*. A **dealer** maintains an inventory and stands ready to buy and sell at any time. In contrast, a **broker** brings buyers and sellers together, but does not maintain an inventory. Thus, when we speak of used car dealers and real estate brokers, we recognize that the used car dealer maintains an inventory, whereas the real estate broker does not.

In the securities markets, a dealer stands ready to buy securities from investors wishing to sell them and sell securities to investors wishing to buy them. Recall from our previous chapter that the price the dealer is willing to pay is called the bid price. The price at which the dealer will sell is called the ask price (sometimes called the asked, offered, or offering price). The difference between the bid and ask prices is called the spread, and it is the basic source of dealer profits.

Dealers exist in all areas of the economy, not just the stock markets. For example, your local college bookstore is probably both a primary- and a secondary-market textbook dealer. If you buy a new book, this is a primary-market transaction. If you buy a used book, this is a secondary-market transaction, and you pay the store's ask price. If you sell the book back, you receive the store's bid price, often half of the ask price. The bookstore's spread is the difference between the two prices.

In contrast, a securities broker arranges transactions between investors, matching investors wishing to buy securities with investors wishing to sell securities. The distinctive characteristic of security brokers is that they do not buy or sell securities for their own accounts. Facilitating trades by others is their business.

Organization of the NYSE

The New York Stock Exchange, or NYSE, popularly known as the Big Board, recently celebrated its bicentennial. It has occupied its current location on Wall Street since the turn of the twentieth century. Measured in terms of dollar volume of activity and the total value of shares listed, it is the largest stock market in the world.

member

As of 2006, a member is the owner of a trading license on the NYSE.

Members Historically, the NYSE had 1,366 exchange **members**. Prior to 2006, the exchange members were said to own "seats" on the exchange, and, collectively, the members of the exchange were also the owners. For this and other reasons, seats were valuable and were bought and sold fairly regularly. Seat prices reached a record \$4 million in 2005.

In 2006, all of this changed when the NYSE became a publicly owned corporation called NYSE Group, Inc. Naturally, its stock is listed on the NYSE. Now, instead of purchasing seats, exchange members must purchase trading licenses, the number of which is limited to 1,500. In 2009, a license would set you back a cool \$44,000—per year. Having a license entitles you to buy and sell securities on the floor of the exchange. Different members play different roles in this regard.

In April 2007, the NYSE completed a merger with Euronext to form the NYSE Euronext. The Euronext exchange was formed in 2000 and included markets in Belgium, France, Ireland, the Netherlands, Luxembourg, Portugal, and the United Kingdom. With the merger completed, the NYSE Euronext became the world's first global exchange, with trading occurring over 21 hours each business day.

The largest number of NYSE members are registered as **commission brokers**. The business of a commission broker is to execute customer orders to buy and sell stocks. A commission broker's primary responsibility to customers is to get the best possible prices for their orders. The exact number varies, but, usually, about 500 NYSE members are commission brokers. NYSE commission brokers typically are employees of brokerage companies such as Merrill Lynch.

Second in number of NYSE members are **specialists**, so named because each of them acts as an assigned dealer for a small set of securities. With a few exceptions, each security listed for trading on the NYSE is assigned to a single specialist. Specialists are also called "market makers" because they are obligated to maintain a fair, orderly market for the securities assigned to them.

Specialists post bid prices and ask prices for securities assigned to them. Specialists make a market by standing ready to buy at bid prices and sell at asked prices when there is a temporary disparity between the flow of buy orders and that of sell orders for a security. In this capacity, they act as dealers for their own accounts.

Third in number of exchange members are **floor brokers**. Floor brokers are used by commission brokers who are too busy to handle certain orders themselves. Such commission brokers will delegate some orders to floor brokers for execution. Floor brokers are sometimes called \$2 brokers, a name earned at a time when the standard fee for their service was only \$2.

In recent years, floor brokers have become less important on the exchange floor because of the efficient **SuperDOT system** (the *DOT* stands for Designated Order Turnaround), which allows orders to be transmitted electronically directly to the specialist. SuperDOT trading now accounts for a substantial percentage of all trading on the NYSE, particularly on smaller orders.

Finally, a small number of NYSE members are **floor traders** who independently trade for their own accounts. Floor traders try to anticipate temporary price fluctuations and profit from them by buying low and selling high. In recent decades, the number of floor traders has declined substantially, suggesting that it has become increasingly difficult to profit from short-term trading on the exchange floor.

Operations Now that we have a basic idea of how the NYSE is organized and who the major players are, we turn to the question of how trading actually takes place. Fundamentally, the business of the NYSE is to attract and process **order flow**. The term *order flow* means the flow of customer orders to buy and sell stocks. The customers of the NYSE are the millions of individual investors and tens of thousands of institutional investors who place their orders to buy and sell shares in NYSE-listed companies. The NYSE has been quite successful in attracting order flow. Currently, it is common for more than one billion shares to change hands in a single day.

commission brokers

NYSE members who execute customer orders to buy and sell stock transmitted to the exchange floor.

specialist

An NYSE member acting as a dealer in a small number of securities on the exchange floor; often called a market maker.

floor brokers

NYSE members who execute orders for commission brokers on a fee basis; sometimes called \$2 brokers.

SuperDOT system

An electronic NYSE system allowing orders to be transmitted directly to the specialist.

floor traders

NYSE members who trade for their own accounts, trying to anticipate temporary price fluctuations.

order flow

The flow of customer orders to buy and sell securities.

Floor Activity It is quite likely that you have seen footage of the NYSE trading floor on television, or you may have visited the NYSE and viewed exchange floor activity from the visitors' gallery (it's worth the trip). Either way, you would have seen a big room, about the size of a basketball gym. This big room is called, technically, "the Big Room." There are a couple of other, smaller rooms that you normally don't see, one of which is called "the Garage" because that is literally what it was before it was taken over for trading.

On the floor of the exchange are a number of stations, each with a roughly figure-eight shape. These stations have multiple counters with numerous terminal screens above and on the sides. People operate behind and in front of the counters in relatively stationary positions.

Other people move around on the exchange floor, frequently returning to the many telephones positioned along the exchange walls. In all, you may be reminded of worker ants moving around an ant colony. It is natural to wonder, What are all those people doing down there (and why are so many wearing funny-looking coats)?

As an overview of exchange floor activity, here is a quick look at what goes on. Each of the counters at a figure-eight-shaped station is a **specialist's post**. Specialists normally operate in front of their posts to monitor and manage trading in the stocks assigned to them. Clerical employees working for the specialists operate behind the counter. Moving from the many telephones lining the walls of the exchange out to the exchange floor and back again are swarms of commission brokers, receiving telephoned customer orders, walking out to specialists' posts where the orders can be executed, and returning to confirm order executions and receive new customer orders.

To better understand activity on the NYSE trading floor, imagine yourself as a commission broker. Your phone clerk has just handed you an order to sell 2,000 shares of Walmart for a customer of the brokerage company that employs you. The customer wants to sell the stock at the best possible price as soon as possible. You immediately walk (running violates exchange rules) to the specialist's post where Walmart stock is traded.

As you approach the specialist's post where Walmart is traded, you check the terminal screen for information on the current market price. The screen reveals that the last executed trade was at \$25.63, and that the specialist is bidding \$25.50 per share. You could immediately sell to the specialist at \$25.50, but that would be too easy.

Instead, as the customer's representative, you are obligated to get the best possible price. It is your job to "work" the order, and your job depends on providing satisfactory order execution service. So, you look around for another broker who represents a customer who wants to buy Walmart stock. Luckily, you quickly find another broker at the specialist's post with an order to buy 2,000 shares. Noticing that the dealer is asking \$25.76 per share, you both agree to execute your orders with each other at a price of \$25.63. This price is about halfway between the specialist's bid and ask prices, and it saves each of your customers $\$.13 \times 2,000 = \260 as compared to dealing at the posted prices.

For a very actively traded stock, there may be many buyers and sellers around the specialist's post, and most of the trading will be done directly between brokers. This is called trading in the "crowd." In such cases, the specialist's responsibility is to maintain order and to make sure that all buyers and sellers receive a fair price. In other words, the specialist essentially functions as a referee.

More often, however, there will be no crowd at the specialist's post. Going back to our Walmart example, suppose you are unable to quickly find another broker with an order to buy 2,000 shares. Because you have an order to sell immediately, you may have no choice but to sell to the specialist at the bid price of \$25.50. In this case, the need to execute an order quickly takes priority, and the specialist provides the liquidity necessary to allow immediate order execution.

Finally, note that colored coats are worn by many of the people on the floor of the exchange. The color of the coat indicates the person's job or position. Clerks, runners,

specialist's post

A fixed place on the exchange floor where the specialist operates.

Take a virtual field trip to the New York Stock Exchange at www.nyse.com.

visitors, exchange officials, and so on wear particular colors to identify themselves. Also, things can get a little hectic on a busy day, with the result that good clothing doesn't last long; the cheap coats offer some protection.

NASDAQ Operations

In terms of the number of companies listed and, on many days, the number of shares traded, the NASDAQ is even bigger than the NYSE. As we mentioned in Chapter 1, the somewhat odd name is derived from the acronym *NASDAQ*, which stood for National Association of Securities Dealers Automated Quotations system; but NASDAQ is now a name in its own right.

Introduced in 1971, the NASDAQ market is a computer network of securities dealers who disseminate timely security price quotes to NASDAQ subscribers. These dealers act as market makers for securities listed on the NASDAQ. As market makers, NASDAQ dealers post bid and asked prices at which they accept sell and buy orders, respectively. With each price quote, they also post the number of stock shares that they obligate themselves to trade at their quoted prices.

Not to be outdone by the NYSE, the NASDAQ completed a merger in May 2007 when it finalized its deal to buy the OMX, which controlled seven Nordic and Baltic stock exchanges. Since the merger, the NASDAQ is officially the NASDAQ OMX Group, although it is still often referred to as simply NASDAQ.

Unlike the NYSE specialist system, NASDAQ relies on multiple market makers for actively traded stocks. Thus, there are two key differences between the NYSE and NASDAQ: (1) NASDAQ is a computer network and has no physical location where trading takes place and (2) NASDAQ has a multiple market maker system rather than a specialist system. Notice that there is no direct trading in the crowd as there may be on the NYSE.

About 3,200 companies are listed on the NASDAQ system, with an average of about a dozen market makers for each security. Traditionally, shares of stock in smaller companies were listed on the NASDAQ, and there was a tendency for companies to move from the NASDAQ to the NYSE once they became large enough. Today, however, giant companies such as Amazon, Microsoft, and Intel have chosen to remain on the NASDAQ.

The NASDAQ network operates with three levels of information access. Level 1 is designed to provide a timely, accurate source of price quotations. These prices are freely available over the Internet.

Level 2 allows users to view price quotes from all NASDAQ market makers. In particular, this level allows access to **inside quotes**. Inside quotes are the highest bid quotes and the lowest asked quotes for a NASDAQ-listed security. Level 2 is now available on the Web, usually for a small fee. Level 3 is for the use of market makers only. This access level allows NASDAQ dealers to enter or change their price quote information.

The NASDAQ is actually made up of three separate markets: the NASDAQ Global Select Market, the NASDAQ Global Market, and the NASDAQ Capital Market. As the market for NASDAQ's larger and more actively traded securities, the Global Select Market lists about 1,200 companies (as of early 2009), including some of the best-known companies in the world, such as Microsoft and Intel. The Global Market companies are somewhat smaller in size, and NASDAQ lists about 1,450 of these companies. Finally, the smallest companies listed on NASDAQ are in the NASDAQ Capital Market; about 550 are currently listed. Of course, as Capital Market companies become more established, they may move up to the Global Market or Global Select Market.

ECNs In a very important development in the late 1990s, the NASDAQ system was opened to so-called **electronic communications networks (ECNs)**. ECNs are basically Web sites that

How big is the bid-ask spread on your favorite NASDAQ stock? Check out the latest quotes at money.cnn.com!

NASDAQ
(www.nasdaq.com)
has a *great* Web site; check it out!

inside quotes

The highest bid quotes and the lowest ask quotes for a security.

electronic communications networks (ECNs)

Web sites that allow investors to trade directly with one another.

allow investors to trade directly with one another. Investor buy and sell orders placed on ECNs are transmitted to the NASDAQ and displayed along with market maker bid and ask prices. As a result, the ECNs open up the NASDAQ by essentially allowing individual investors, not just market makers, to enter orders. As a result, the ECNs act to increase liquidity and competition. Our nearby *Work the Web* box describes one ECN, BATS Trading (www.batstrading.com), and contains important information about ECN “order books.” Be sure to read it.

Of course, the NYSE and NASDAQ are not the only places stocks are traded. See our nearby *Reality Bytes* box for a discussion of somewhat wilder markets.

Stock Market Reporting

Like so many other things, stock price reporting has largely migrated to the Web. You can get up-to-the-minute prices on stocks from many online servers, along with plenty of information about a stock. Below you will see a stock quote from moneycentral.msn.com for famed motorcycle manufacturer Harley-Davidson (HOG) from May 13, 2009.

You can get real-time stock quotes on the Web. See finance.yahoo.com for details.

In the upper left, we have a recent trade price of \$17.18. Based on that price, the stock had fallen by \$1.42 during the day, or 7.63 percent. In the box below, more information is provided. For example, the “Previous Close” is the closing price from the previous trading day, and “Open” is the first price of the current day. The high price for this day so far was \$18.07, and the low price was \$17.12. About 3.86 million shares of Harley-Davidson had traded, relative to an average volume over the last 13 weeks of 6.66 million shares. As always, the bid and ask are the highest price someone was willing to pay and the lowest price someone was willing to take. You can also see the number of shares at the bid and ask. Finally, the 52-week high and low give the highest and lowest stock prices over the past 52 weeks.

The column on the right has more information. The first number given, “Beta” is an important number. We will have lots more to say about it in a later chapter. Because Harley-Davidson, like most dividend-paying companies, actually pays dividends quarterly, the dividend shown of \$0.40 is actually the last quarterly dividend multiplied by four. The dividend yield is the annual dividend divided by the stock price. Harley-Davidson’s EPS for the past year was \$2.50. Notice there is a PE ratio and a “forward” PE ratio. If you remember our discussion of the PE ratio in an earlier chapter, it is calculated as the stock price divided by the EPS. However, what we would really like to know is the price per share divided by the future EPS. The forward PE is exactly that. It is calculated as the current stock price divided by the estimated EPS for the next year. Notice the forward PE ratio is higher than the regular PE ratio, an indication that earnings next year are expected to be lower than the current year’s earnings. Finally, we are shown the “Market Cap.” (market capitalization), the return on equity (ROE), and the total number of shares outstanding.

The Wild, Wild West of Stock Trading

Where do companies go when they can't (or don't want to) meet the listing requirements of the larger stock markets? Two options are the Over-the-Counter Bulletin Board (OTCBB) and the Pink Sheets. These two electronic markets are part of the Wild, Wild West of stock trading. The somewhat odd names have simple explanations. The OTCBB began as an electronic bulletin board that was created to facilitate OTC trading in nonlisted stocks. The name "Pink Sheets" just reflects the fact that, at one time, prices for such stocks were quoted on pink sheets of paper.

The well-known markets such as the NASDAQ and the NYSE have relatively strict listing requirements. If a company fails to meet these requirements, it can be delisted. The OTCBB and the Pink Sheets, on the other hand, have no listing

volumes when they do trade, but the dollar amount is quite a bit lower than larger exchanges. For example, by the end of this same trading day, General Electric (GE) was the most active stock on NYSE, trading about 753 million shares. Remote Dynamics traded about 155 million shares. If we assume the average price was \$0.0002 per share, then the total dollar volume for the day was a whopping \$31,000 or so. In contrast, about \$5.1 billion worth of GE stock was traded.

The Pink Sheets (www.pinksheets.com) is operated by a privately owned company. To be listed on the Pink Sheets, a company just has to find a market maker willing to trade in the company's stock. Companies list on the Pink Sheets for various reasons. Small companies that do not wish to meet listing requirements are one type. Foreign companies often list

requirements. The OTCBB does require that companies file financial statements with the SEC (or other relevant agency), but the Pink Sheets does not.

Stocks traded on these markets often have very low prices and are frequently referred to as "penny stocks," "microcaps," or even "nanocaps." Relatively few brokers do any research on these companies, so information is often spread through word of mouth or the Internet, not the most reliable of sources. In fact, for many stocks, these markets often look like big electronic rumor mills and gossip factories. To get a feel for what trading looks like, we captured a typical screen from the OTCBB Web site (www.OTCBB.com) above.

First, let's look at the returns. Remote Dynamics had a return on this day of *negative* 50 percent! Of course, the loss occurred because the stock price dropped by \$0.0001. The stock price of Phoenix Interests doubled as its price increased by \$0.0001. Stocks on the OTCBB tend to have large trading

on the Pink Sheets because they do not prepare their financial statements according to GAAP, a requirement for listing on U.S. stock exchanges. There are many companies that were formerly listed on bigger stock markets that were either delisted involuntarily or chose to "go dark" for various reasons, including, as we discussed in Chapter 1, the costs associated with Sarbox compliance.

All in all, the OTCBB and Pink Sheets can be pretty wild places to trade. Low stock prices allow huge percentage returns on small stock price movements. Be advised, however, that attempts at manipulation and fraud are commonplace. Also, stocks on these markets are often very thinly traded, meaning there is little volume. It is not unusual for a stock listed on either market to have no trades on a given day. Even two or three days in a row without a trade in a particular stock is not uncommon.

CONCEPT QUESTIONS

- 7.3a** What is the difference between a securities broker and a securities dealer?
- 7.3b** Which is bigger, the bid price or the ask price? Why?
- 7.3c** What are the four types of members of the New York Stock Exchange, or NYSE?
- 7.3d** How does NASDAQ differ from the NYSE?

SUMMARY AND CONCLUSIONS

This chapter has covered the basics of stocks and stock valuation. The key points include:

1. The cash flows from owning a share of stock come in the form of future dividends. We saw that in certain special cases it is possible to calculate the present value of all the future dividends and thus come up with a value for the stock.
2. As the owner of shares of common stock in a corporation, you have various rights, including the right to vote to elect corporate directors. Voting in corporate elections can be either cumulative or straight. Most voting is actually done by proxy, and a proxy battle breaks out when competing sides try to gain enough votes to have their candidates for the board elected.
3. In addition to common stock, some corporations have issued preferred stock. The name stems from the fact that preferred stockholders must be paid first, before common stockholders can receive anything. Preferred stock has a fixed dividend.
4. The two biggest stock markets in the United States are the NYSE and the NASDAQ. We discussed the organization and operation of these two markets, and we saw how stock price information is reported in the financial press.

This chapter completes Part 4 of our book. By now, you should have a good grasp of what we mean by present value. You should also be familiar with how to calculate present values, loan payments, and so on. In Part 5, we cover capital budgeting decisions. As you will see, the techniques you have learned in Chapters 4–7 form the basis for our approach to evaluating business investment decisions.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

- 7.1 Dividend Growth and Stock Valuation.** The Brigapenski Co. has just paid a cash dividend of \$2 per share. Investors require a 16 percent return from investments such as this. If the dividend is expected to grow at a steady 8 percent per year, what is the current value of the stock? What will the stock be worth in five years?
- 7.2 Required Returns.** Suppose we observe a stock selling for \$40 per share. The next dividend will be \$1 per share, and you think the dividend will grow at 12 percent per year forever. What is the dividend yield in this case? The capital gains yield? The total required return?

Answers to Chapter Review and Self-Test Problems

- 7.1** The last dividend, D_0 , was \$2. The dividend is expected to grow steadily at 8 percent. The required return is 16 percent. Based on the dividend growth model, we can say that the current price is:

$$\begin{aligned} P_0 &= D_1 / (R - g) \\ &= D_0 \times (1 + g) / (R - g) \\ &= \$2 \times 1.08 / (.16 - .08) \\ &= \$2.16 / .08 \\ &= \$27 \end{aligned}$$

We could calculate the price in five years by calculating the dividend in five years and then using the growth model again. Alternatively, we could recognize that the stock price will increase by 8 percent per year and calculate the future price directly. We'll do both. First, the dividend in five years will be:

$$\begin{aligned} D_5 &= D_0 \times (1 + g)^5 \\ &= \$2 \times 1.08^5 \\ &= \$2.9387 \end{aligned}$$

The price in five years would therefore be:

$$\begin{aligned} P_5 &= D_5 \times (1 + g) / (R - g) \\ &= \$2.9387 \times 1.08 / .08 \\ &= \$3.1738 / .08 \\ &= \$39.67 \end{aligned}$$

Once we understand the dividend model, however, it's easier to notice that:

$$\begin{aligned} P_5 &= P_0 \times (1 + g)^5 \\ &= \$27 \times 1.08^5 \\ &= \$27 \times 1.4693 \\ &= \$39.67 \end{aligned}$$

Notice that both approaches yield the same price in five years.

- 7.2** The dividend yield is the next dividend, D_1 , divided by the current price, P_0 , or $\$1/40 = 2.5\%$. The capital gains yield is the same as the dividend growth rate, 12 percent. The total required return is the sum of the two, $2.5\% + 12\% = 14.5\%$.

CRITICAL THINKING AND CONCEPTS REVIEW

- | | |
|-------------|--|
| L0 1 | 7.1 Stock Valuation. Why does the value of a share of stock depend on dividends? |
| L0 1 | 7.2 Stock Valuation. A substantial percentage of the companies listed on the NYSE and the NASDAQ don't pay dividends, but investors are nonetheless willing to buy shares in them. How is this possible given your answer to the previous question? |
| L0 1 | 7.3 Dividend Policy. Referring to the previous questions, under what circumstances might a company choose not to pay dividends? |

- L01 7.4 Dividend Growth Model.** Under what two assumptions can we use the dividend growth model presented in the chapter to determine the value of a share of stock? Comment on the reasonableness of these assumptions.
- L01 7.5 Common versus Preferred Stock.** Suppose a company has a preferred stock issue and a common stock issue. Both have just paid a \$2 dividend. Which do you think will have a higher price, a share of the preferred or a share of the common?
- L01 7.6 Dividend Growth Model.** Based on the dividend growth model, what are the two components of the total return on a share of stock? Which do you think is typically larger?
- L01 7.7 Growth Rate.** In the context of the dividend growth model, is it true that the growth rate in dividends and the growth rate in the price of the stock are identical?
- L01 7.8 Dividends and Earnings.** Is it possible for a company to pay dividends when it has a negative net income for the year? Could this happen for longer periods?
- L02 7.9 Corporate Ethics.** Is it unfair or unethical for corporations to create classes of stock with unequal voting rights?
- L02 7.10 Voting Rights.** Some companies, such as Google, have created classes of stock with little or no voting rights at all. Why would investors buy such stock?
- L02 7.11 Stock Valuation.** Evaluate the following statement: Managers should not focus on the current stock value because doing so will lead to an overemphasis on short-term profits at the expense of long-term profits.
- L01 7.12 Constant Dividend Growth Model.** In the constant dividend growth model, what is the highest reasonable growth rate for a stock's dividend?

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

- L01 1. Stock Values.** Patience, Inc., just paid a dividend of \$2.35 per share on its stock. The dividends are expected to grow at a constant rate of 4.5 percent per year, indefinitely. If investors require an 11 percent return on this stock, what is the current price? What will the price be in three years? In 15 years?
- L01 2. Stock Values.** The next dividend payment by Mosby, Inc., will be \$2.45 per share. The dividends are anticipated to maintain a 5.5 percent growth rate, forever. If the stock currently sells for \$48.50 per share, what is the required return?
- L01 3. Stock Values.** For the company in the previous problem, what is the dividend yield? What is the expected capital gains yield?
- L01 4. Stock Values.** Ziggs Corporation will pay a \$3.85 per share dividend next year. The company pledges to increase its dividend by 4.75 percent per year, indefinitely. If you require a 12 percent return on your investment, how much will you pay for the company's stock today?
- L01 5. Stock Valuation.** Bruer, Inc., is expected to maintain a constant 5.8 percent growth rate in its dividends, indefinitely. If the company has a dividend yield of 4.3 percent, what is the required return on the company's stock?
- L01 6. Stock Valuation.** Suppose you know that a company's stock currently sells for \$65 per share and the required return on the stock is 11 percent. You also know that the total return on the stock is evenly divided between capital gains yield and

Basic
(Questions 1–12)

dividend yield. If it's the company's policy to always maintain a constant growth rate in its dividends, what is the current dividend per share?

L0 1

7. **Stock Valuation.** Bowman Corp. pays a constant \$13 dividend on its stock. The company will maintain this dividend for the next eight years and will then cease paying dividends forever. If the required return on this stock is 9 percent, what is the current share price?

L0 1

8. **Valuing Preferred Stock.** Gesto, Inc., has an issue of preferred stock outstanding that pays a \$4.50 dividend every year, in perpetuity. If this issue currently sells for \$79.85 per share, what is the required return?

L0 2

9. **Voting Rights.** After successfully completing your corporate finance class, you feel the next challenge ahead is to serve on the board of directors of Schenkel Enterprises. Unfortunately, you will be the only individual voting for you. If Schenkel has 400,000 shares outstanding and the stock currently sells for \$48, how much will it cost you to buy a seat if the company uses straight voting? Assume that Schenkel uses cumulative voting and there are four seats in the current election; how much will it cost you to buy a seat now?

L0 1

10. **Growth Rates.** The stock price of Jenkins Co. is \$53. Investors require a 12 percent rate of return on similar stocks. If the company plans to pay a dividend of \$3.15 next year, what growth rate is expected for the company's stock price?

L0 1

11. **Valuing Preferred Stock.** E-Eyes.com has a new issue of preferred stock it calls 20/20 preferred. The stock will pay a \$20 dividend per year, but the first dividend will not be paid until 20 years from today. If you require a 7 percent return on this stock, how much should you pay today?

L0 1

12. **Stock Valuation.** Alexander Corp. will pay a dividend of \$2.60 next year. The company has stated that it will maintain a constant growth rate of 4.5 percent a year forever. If you want a 15 percent rate of return, how much will you pay for the stock? What if you want a 10 percent rate of return? What does this tell you about the relationship between the required return and the stock price?

L0 1

13. **Nonconstant Growth.** Metallica Bearings, Inc., is a young start-up company. No dividends will be paid on the stock over the next nine years, because the firm needs to plow back its earnings to fuel growth. The company will then pay a \$12 per share dividend in year 10 and will increase the dividend by 5 percent per year thereafter. If the required return on this stock is 13 percent, what is the current share price?

L0 1

14. **Nonconstant Dividends.** Hot Wings, Inc., has an odd dividend policy. The company has just paid a dividend of \$8 per share and has announced that it will increase the dividend by \$6 per share for each of the next four years, and then never pay another dividend. If you require a 14 percent return on the company's stock, how much will you pay for a share today?

L0 1

15. **Nonconstant Dividends.** Apocalyptica Corporation is expected to pay the following dividends over the next four years: \$5, \$16, \$21, and \$2.80. Afterwards, the company pledges to maintain a constant 5 percent growth rate in dividends, forever. If the required return on the stock is 11 percent, what is the current share price?

L0 1

16. **Supernormal Growth.** Taylor Corp. is growing quickly. Dividends are expected to grow at a 30 percent rate for the next three years, with the growth rate falling off to a constant 6 percent thereafter. If the required return is 13 percent and the company just paid a \$2.75 dividend, what is the current share price? Hint: Calculate the first four dividends.

Intermediate
(Questions 13–23)

- L0 1** 17. **Negative Growth.** Antiques ‘R’ Us is a mature manufacturing firm. The company just paid a \$10.50 dividend, but management expects to reduce the payout by 4.5 percent per year, indefinitely. If you require a 10 percent return on this stock, what will you pay for a share today?
- L0 1** 18. **Finding the Dividend.** Gontier Corporation stock currently sells for \$64.13 per share. The market requires an 11 percent return on the firm’s stock. If the company maintains a constant 5.5 percent growth rate in dividends, what was the most recent dividend per share paid on the stock?
- You’ve collected the following information from your favorite financial Web site. Use it to answer Questions 19–23 (the 52-week Hi and Lo are the highest and lowest stock prices over the previous 52 weeks).

52-Week Price		Stock (Div)	Div Yld %	PE Ratio	Close Price	Net Chg
Hi	Lo					
77.40	10.43	ArchCoal 0.36	2.5	6	13.90	−0.24
55.81	33.42	LacledeGrp 1.54	3.7	10	40.43	−0.01
130.93	69.50	IBM 2.00	2.3	10	88.97	3.07
50.24	13.95	JCPenney 0.80	5.2	6	15.43	−0.26
35.00	20.74	TootsieRoll 0.32	1.5	28	??	0.18

- L0 3** 19. **Dividend Yield.** Find the quote for the Laclede Group. Assume that the dividend is constant. What was the highest dividend yield over the past year? What was the lowest dividend yield over the past year?
- L0 1** 20. **Stock Valuation.** According to the 2009 Value Line *Investment Survey*, the growth rate in dividends for IBM for the next five years is expected to be 19.5 percent. Suppose IBM meets this growth rate in dividends for the next five years and then the dividend growth rate falls to 5 percent indefinitely. Assume investors require an 11 percent return on IBM stock. Is the stock priced correctly? What factors could affect your answer?
- L0 1** 21. **Stock Valuation.** According to the 2009 Value Line *Investment Survey*, the growth rate in dividends for ArchCoal for the previous 10 years has been 3.5 percent. If investors feel this growth rate will continue, what is the required return for ArchCoal stock?
- L0 1** 22. **Negative Growth.** According to the 2009 Value Line *Investment Survey*, the growth rate in dividends for JCPenney for the previous 10 years has been −11 percent. If investors feel this growth rate will continue, what is the required return for JCPenney stock? Does this number make sense? What are some of the potential reasons for the negative growth in dividends?
- L0 1** 23. **Stock Quotes.** Using the dividend yield, calculate the closing price for Tootsie Roll on this day. The actual closing 2009 price for Tootsie Roll was \$21.02. Why is your closing price different? The Value Line *Investment Survey* projects a 4 percent dividend growth rate for Tootsie Roll. What is the required return for the stock using the dividend discount model and the actual stock price?
- L0 1** 24. **Capital Gains versus Income.** Consider four different stocks, all of which have a required return of 18 percent and a most recent dividend of \$2.80 per share. Stocks W, X, and Y are expected to maintain constant growth rates in dividends for the foreseeable future of 10 percent, 0 percent, and −5 percent per

Challenge
(Questions 24–25)

year, respectively. Stock Z is a growth stock that will increase its dividend by 20 percent for the next two years and then maintain a constant 12 percent growth rate, thereafter. What is the dividend yield for each of these four stocks? What is the expected capital gains yield? Discuss the relationship among the various returns that you find for each of these stocks.

L01

- 25. Stock Valuation.** Most corporations pay quarterly dividends on their common stock rather than annual dividends. Barring any unusual circumstances during the year, the board raises, lowers, or maintains the current dividend once a year and then pays this dividend out in equal quarterly installments to its shareholders.
- Suppose a company currently pays a \$2.80 annual dividend on its common stock in a single annual installment, and management plans on raising this dividend by 6 percent per year indefinitely. If the required return on this stock is 12 percent, what is the current share price?
 - Now suppose the company in (a) actually pays its annual dividend in equal quarterly installments; thus, the company has just paid a \$.70 dividend per share, as it has for the previous three quarters. What is your value for the current share price now? (*Hint:* Find the equivalent annual end-of-year dividend for each year.) Comment on whether you think this model of stock valuation is appropriate.

WHAT'S ON THE WEB?

- 7.1 Dividend Discount Model.** According to the June 2009 Value Line *Investment Survey*, the dividend growth rate for ExxonMobil (XOM) is 7 percent. Find the current stock price quote and dividend information at finance.yahoo.com. If this dividend growth rate is correct, what is the required return for ExxonMobil? Does this number make sense to you?
- 7.2 Stock Quotes.** What is the most expensive publicly traded stock in the United States? Go to finance.yahoo.com and enter BRKA (for Berkshire Hathaway Class A). What is the current price per share? What is the 52-week high and low? How many shares trade on an average day? How many shares have traded today?
- 7.3 Supernormal Growth.** You are interested in buying stock in Coca-Cola (KO). You believe that the dividends will grow at 15 percent for the next four years and level off at 6 percent thereafter. Using the most recent dividend on finance.yahoo.com, if you want a 12 percent return, how much should you be willing to pay for a share of stock?
- 7.4 Market Operations.** How does a stock trade take place? Go to www.nyse.com to find out. Describe the process of a trade on the NYSE.

CHAPTER CASE

STOCK VALUATION AT RAGAN, INC.

Ragan, Inc., was founded nine years ago by brother and sister Carrington and Genevieve Ragan. The company manufactures and installs commercial heating, ventilation, and cooling (HVAC) units. Ragan, Inc., has experienced rapid growth because of a proprietary technology that increases the energy efficiency of its units. The company is equally owned by Carrington and Genevieve. The original partnership agreement between the siblings gave each 50,000 shares of stock. In the event either wished to sell stock, the shares first had to be offered to the other at a discounted price.

Although neither sibling wants to sell, they have decided they should value their holdings in the company. To get started, they have gathered the following information about their main competitors:

Expert HVAC Corporation's negative earnings per share were the result of an accounting write-off last year. Without the write-off, earnings per share for the company would have been \$0.49.

Last year, Ragan, Inc., had an EPS of \$5.32 and paid a dividend to Carrington and Genevieve of \$70,000 each. The company also had a return on equity of 18 percent. The siblings believe that $R = 15$ percent is an appropriate required return for the company. ■

Ragan, Inc. — Competitors					
	EPS	Div.	Stock Price	ROE	R
Arctic Cooling, Inc.	\$0.79	\$0.31	\$17.83	16.00%	11.00%
National Heating & Cooling	1.27	0.45	19.23	14.00	14.00
Expert HVAC Corp.	(0.44)	0.39	18.14	15.00	13.00
Industry Average	\$0.54	\$0.38	\$18.40	15.00%	12.67%

QUESTIONS

1. Assuming the company continues its current growth rate, what is the value per share of the company's stock?
2. To verify their calculations, Carrington and Genevieve have hired Josh Schlessman as a consultant. Josh was previously an equity analyst and covered the HVAC industry. Josh has examined the company's financial statements, as well as those of its competitors. Although Ragan, Inc., currently has a technological advantage, his research indicates that other companies are

investigating methods to improve efficiency. Given this, Josh believes that the company's technological advantage will last only for the next five years. After that period, the company's growth will likely slow to the industry growth average. Additionally, Josh believes that the required return used by the company is too high. He believes the industry average required return is more appropriate. Under this growth rate assumption, what is your estimate of the stock price?

Net Present Value and Other Investment Criteria

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Summarize the payback rule and some of its shortcomings.
- LO 2** Discuss accounting rates of return and some of the problems with them.
- LO 3** Explain the internal rate of return criterion and its associated strengths and weaknesses.
- LO 4** Evaluate proposed investments by using the net present value criterion.
- LO 5** Apply the modified internal rate of return.
- LO 6** Calculate the profitability index and understand its relation to net present value.

Is there green in green? General Electric (GE) thinks so. Through its “Ecomagination” program, the company planned to double research and development spending on green products, from \$700 million in 2004 to \$1.5 billion in 2010. By 2008, the company had nearly reached its goal, spending about \$1.4 billion in green initiatives. With products such as a hybrid railroad locomotive (described as a 200-ton, 6,000-horsepower “Prius on rails”), GE’s green initiative seems to be paying off. Revenue from green products increased by 21 percent to \$17 billion in 2008, with a target of \$25 billion in 2010. The company’s internal commitment to reduced energy consumption saved it more than \$100 million from

2004 to 2008, and it was on target to reduce its water consumption by 20 percent by 2012, another considerable cost savings.

While GE was in part motivated by the desire to go green, from a financial perspective the decision only makes sense if the company *makes* some green. Given that GE plans to spend about \$1.5 billion per year on such undertakings, it is obviously a major financial decision, and the risks and rewards must be carefully weighed. In this chapter, we discuss the basic tools used in making such decisions.

This chapter introduces you to the practice of capital budgeting. Back in Chapter 1, we saw that increasing the value of the stock in a company is the goal of financial management. Thus, what we need to learn is how to tell whether a particular investment will achieve that or not. This chapter considers a variety of techniques that are actually used in practice. More importantly, it shows how many of these techniques can be misleading, and it explains why the net present value approach is the right one.

Visit us at www.mhhe.com/rwj

In Chapter 1, we identified the three key areas of concern to the financial manager. The first of these was the following: What long-term investments should we make? We called this the *capital budgeting decision*. In this chapter, we begin to deal with the issues that arise in answering this question.

The process of allocating, or budgeting, capital is usually more involved than just deciding whether or not to buy a particular fixed asset. We will frequently face broader issues like whether or not we should launch a new product or enter a new market. Decisions such as these will determine the nature of a firm's operations and products for years to come, primarily because fixed asset investments are generally long-lived and not easily reversed once they are made.

For these reasons, the capital budgeting question is probably the most important issue in corporate finance. How a firm chooses to finance its operations (the capital structure question) and how a firm manages its short-term operating activities (the working capital question) are certainly issues of concern, but it is the fixed assets that define the business of the firm. Airlines, for example, are airlines because they operate airplanes, regardless of how they finance them.

Any firm possesses a huge number of possible investments. Each possible investment is an option available to the firm. Some options are valuable and some are not. The essence of successful financial management, of course, is learning to identify which are which. With this in mind, our goal in this chapter is to introduce you to the techniques used to analyze potential business ventures to decide which are worth undertaking.

We present and compare several different procedures used in practice. Our primary goal is to acquaint you with the advantages and disadvantages of the various approaches. As we shall see, the most important concept in this area is the idea of net present value. We consider this next.

NET PRESENT VALUE

8.1

In Chapter 1, we argued that the goal of financial management is to create value for the stockholders. The financial manager must therefore examine a potential investment in light of its likely effect on the price of the firm's shares. In this section, we describe a widely used procedure for doing this, the net present value approach.

The Basic Idea

An investment is worth undertaking if it creates value for its owners. In the most general sense, we create value by identifying an investment worth more in the marketplace than it costs us to acquire. How can something be worth more than it costs? It's a case of the whole being worth more than the cost of the parts.

For example, suppose you buy a run-down house for \$25,000 and spend another \$25,000 on painters, plumbers, and so on to get it fixed up. Your total investment is \$50,000. When the work is completed, you place the house back on the market and find that it's worth \$60,000. The market value (\$60,000) exceeds the cost (\$50,000) by \$10,000. What you have done here is to act as a manager and bring together some fixed assets (a house), some labor (plumbers, carpenters, and others), and some materials (carpeting, paint, and so on). The net result is that you have created \$10,000 in value. Put another way, this \$10,000 is the *value added* by management.

With our house example, it turned out *after the fact* that \$10,000 in value was created. Things thus worked out very nicely. The real challenge, of course, would have been to somehow

net present value (NPV)

The difference between an investment's market value and its cost.

identify *ahead of time* whether or not investing the necessary \$50,000 was a good idea in the first place. This is what capital budgeting is all about, namely, trying to determine whether a proposed investment or project will be worth more than it costs once it is in place.

For reasons that will be obvious in a moment, the difference between an investment's market value and its cost is called the **net present value** of the investment, abbreviated **NPV**. In other words, net present value is a measure of how much value is created or added today by undertaking an investment. Given our goal of creating value for the stockholders, the capital budgeting process can be viewed as a search for investments with positive net present values.

With our run-down house, you can probably imagine how we would go about making the capital budgeting decision. We would first look at what comparable, fixed-up properties were selling for in the market. We would then get estimates of the cost of buying a particular property, fixing it up, and bringing it to market. At this point, we have an estimated total cost and an estimated market value. If the difference is positive, then this investment is worth undertaking because it has a positive estimated net present value. There is risk, of course, because there is no guarantee that our estimates will turn out to be correct.

As our example illustrates, investment decisions are greatly simplified when there is a market for assets similar to the investment we are considering. Capital budgeting becomes much more difficult when we cannot observe the market price for at least roughly comparable investments. The reason is that we are then faced with the problem of estimating the value of an investment using only indirect market information. Unfortunately, this is precisely the situation the financial manager usually encounters. We examine this issue next.

Estimating Net Present Value

Imagine we are thinking of starting a business to produce and sell a new product, say, organic fertilizer. We can estimate the start-up costs with reasonable accuracy because we know what we will need to buy to begin production. Would this be a good investment? Based on our discussion, you know that the answer depends on whether or not the value of the new business exceeds the cost of starting it. In other words, does this investment have a positive NPV?

This problem is much more difficult than our “fixer-upper” house example, because entire fertilizer companies are not routinely bought and sold in the marketplace; so it is essentially impossible to observe the market value of a similar investment. As a result, we must somehow estimate this value by other means.

Based on our work in Chapters 4 and 5, you may be able to guess how we will go about estimating the value of our fertilizer business. We will first try to estimate the future cash flows we expect the new business to produce. We will then apply our basic discounted cash flow procedure to estimate the present value of those cash flows. Once we have this estimate, we then estimate NPV as the difference between the present value of the future cash flows and the cost of the investment. As we mentioned in Chapter 5, this procedure is often called **discounted cash flow**, or **DCF, valuation**.

discounted cash flow (DCF) valuation

The process of valuing an investment by discounting its future cash flows.

To see how we might go about estimating NPV, suppose we believe the cash revenues from our fertilizer business will be \$20,000 per year, assuming everything goes as expected. Cash costs (including taxes) will be \$14,000 per year. We will wind down the business in eight years. The plant, property, and equipment will be worth \$2,000 as salvage at that time. The project costs \$30,000 to launch. We use a 15 percent discount rate on new projects such as this one. Is this a good investment? If there are 1,000 shares of stock outstanding, what will be the effect on the price per share from taking the investment?

From a purely mechanical perspective, we need to calculate the present value of the future cash flows at 15 percent. The net cash inflow will be \$20,000 cash income less \$14,000 in costs per year for eight years. These cash flows are illustrated in Figure 8.1.

Time (years)	0	1	2	3	4	5	6	7	8
Initial cost	-\$30								
Inflows		\$20	\$20	\$20	\$20	\$20	\$20	\$20	\$20
Outflows		- 14	- 14	- 14	- 14	- 14	- 14	- 14	- 14
Net inflow		\$ 6	\$ 6	\$ 6	\$ 6	\$ 6	\$ 6	\$ 6	\$ 6
Salvage									2
Net cash flow	-\$30	\$ 6	\$ 6	\$ 6	\$ 6	\$ 6	\$ 6	\$ 6	\$ 8

FIGURE 8.1

Project cash flows (\$000)

As Figure 8.1 suggests, we effectively have an eight-year annuity of $\$20,000 - 14,000 = \$6,000$ per year along with a single lump-sum inflow of $\$2,000$ in eight years. Calculating the present value of the future cash flows thus comes down to the same type of problem we considered in Chapter 5. The total present value is:

$$\begin{aligned}
 \text{Present value} &= \$6,000 \times (1 - 1/1.15^8)/.15 + 2,000/1.15^8 \\
 &= \$6,000 \times 4.4873 + 2,000/3.0590 \\
 &= \$26,924 + 654 \\
 &= \$27,578
 \end{aligned}$$

When we compare this to the $\$30,000$ estimated cost, the NPV is:

$$\text{NPV} = -\$30,000 + 27,578 = -\$2,422$$

Therefore, this is *not* a good investment. Based on our estimates, taking it would *decrease* the total value of the stock by $\$2,422$. With 1,000 shares outstanding, our best estimate of the impact of taking this project is a loss of value of $\$2,422/1,000 = \2.422 per share.

Our fertilizer example illustrates how NPV estimates can be used to determine whether or not an investment is desirable. From our example, notice that if the NPV is negative, the effect on share value will be unfavorable. If the NPV were positive, the effect would be favorable. As a consequence, all we need to know about a particular proposal for the purpose of making an accept-reject decision is whether the NPV is positive or negative.

Given that the goal of financial management is to increase share value, our discussion in this section leads us to the *net present value rule*:

An investment should be accepted if the net present value is positive and rejected if it is negative.

In the unlikely event that the net present value turned out to be exactly zero, we would be indifferent between taking the investment and not taking it.

Two comments about our example are in order. First and foremost, it is not the rather mechanical process of discounting the cash flows that is important. Once we have the cash flows and the appropriate discount rate, the required calculations are fairly straightforward. The task of coming up with the cash flows and the discount rate in the first place is much more challenging. We will have much more to say about this in our next chapter. For the remainder of this chapter, we take it as given that we have estimates of the cash revenues and costs and, where needed, an appropriate discount rate.

The second thing to keep in mind about our example is that the $-\$2,422$ NPV is an estimate. Like any estimate, it can be high or low. The only way to find out the true NPV would be to place the investment up for sale and see what we could get for it. We generally won't be doing this, so it is important that our estimates be reliable. Once again, we will have more to say about this later. For the rest of this chapter, we will assume that the estimates are accurate.

As we have seen in this section, estimating NPV is one way of assessing the profitability of a proposed investment. It is certainly not the only way profitability is assessed, and we now turn to some alternatives. As we will see, when compared to NPV, each of the ways of assessing profitability that we examine is flawed in some key way; so, NPV is the preferred approach in principle, if not always in practice.

In our nearby *Spreadsheet Strategies* box, we rework Example 8.1. Notice that we have provided two answers. By comparing the answers to that found in Example 8.1, we see that the first answer is wrong even though we used the spreadsheet's NPV formula. What happened is that the "NPV" function in our spreadsheet is actually a PV function; unfortunately, one of the original spreadsheet programs many years ago got the definition wrong, and subsequent spreadsheets have copied it! Our second answer shows how to use the formula properly.

The example here illustrates the danger of blindly using calculators or computers without understanding what is going on; we shudder to think of how many capital budgeting decisions in the real world are based on incorrect use of this particular function. We will see another example of something that can go wrong with a spreadsheet later in the chapter.

CONCEPT QUESTIONS

8.1a What is the net present value rule?

8.1b If we say an investment has an NPV of \$1,000, what exactly do we mean?

THE PAYBACK RULE

8.2

It is very common in practice to talk of the payback on a proposed investment. Loosely, the *payback* is the length of time it takes to recover our initial investment, or "get our bait back." Because this idea is widely understood and used, we will examine it in some detail.

Defining the Rule

We can illustrate how to calculate a payback with an example. Figure 8.2 below shows the cash flows from a proposed investment. How many years do we have to wait until the accumulated cash flows from this investment equal or exceed the cost of the investment? As Figure 8.2 indicates, the initial investment is \$50,000. After the first year, the firm has recovered \$30,000, leaving \$20,000 outstanding. The cash flow in the second year is exactly \$20,000, so this investment "pays for itself" in exactly two years. Put another way, the **payback period** (or just payback) is two years. If we require a payback of, say, three years or less, then this investment is acceptable. This illustrates the *payback period rule*:

Based on the payback rule, an investment is acceptable if its calculated payback period is less than some prespecified number of years.

payback period

The amount of time required for an investment to generate cash flows sufficient to recover its initial cost.

FIGURE 8.2

Net project cash flows

In our example, the payback works out to be exactly two years. This won't usually happen, of course. When the numbers don't work out exactly, it is customary to work with fractional years. For example, suppose the initial investment is \$60,000, and the cash flows are \$20,000 in the first year and \$90,000 in the second. The cash flows over the first two years are \$110,000, so the project obviously pays back sometime in the second year. After the first year, the project has paid back \$20,000, leaving \$40,000 to be recovered. To figure out the fractional year, note that this \$40,000 is $\$40,000/\$90,000 = 4/9$ of the second year's cash flow. Assuming that the \$90,000 cash flow is paid uniformly throughout the year, the payback would thus be $1\frac{4}{9}$ years.

EXAMPLE 8.2

Calculating Payback

The projected cash flows from a proposed investment are:

Year	Cash Flow
1	\$100
2	200
3	500

This project costs \$500. What is the payback period for this investment?
The initial cost is \$500. After the first two years, the cash flows total \$300. After the third year, the total cash flow is \$800, so the project pays back sometime between the end of year 2 and the end of year 3. Since the accumulated cash flows for the first two years are \$300, we need to recover \$200 in the third year. The third-year cash flow is \$500, so we will have to wait $\$200/\$500 = .40$ years to do this. The payback period is thus 2.4 years, or about two years and five months.

Now that we know how to calculate the payback period on an investment, using the payback period rule for making decisions is straightforward. A particular cutoff time is selected, say, two years, and all investment projects that have payback periods of two years or less are accepted, and all of those that pay back in more than two years are rejected.

Table 8.1 illustrates cash flows for five different projects. The figures shown as the Year 0 cash flows are the cost of the investment. We examine these to indicate some peculiarities that can, in principle, arise with payback periods.

The payback for the first project, A, is easily calculated. The sum of the cash flows for the first two years is \$70, leaving us with $\$100 - \$70 = \$30$ to go. Since the cash flow in the third year is \$50, the payback occurs sometime in that year. When we compare the \$30 we need to the \$50 that will be coming in, we get $\$30/\$50 = .60$; so, payback will occur 60 percent of the way into the year. The payback period is thus 2.6 years.

TABLE 8.1	Year	A	B	C	D	E
Expected cash flows for projects A through E	0	−\$100	−\$200	−\$200	−\$200	−\$ 50
	1	30	40	40	100	100
	2	40	20	20	100	− 50,000,000
	3	50	10	10	− 200	
	4	60		130	200	

Project B's payback is also easy to calculate: It *never* pays back because the cash flows never total up to the original investment. Project C has a payback of exactly four years because it supplies the \$130 that B is missing in year 4. Project D is a little strange. Because of the negative cash flow in year 3, you can easily verify that it has two different payback periods, two years and four years. Which of these is correct? Both of them; the way the payback period is calculated doesn't guarantee a single answer. Finally, Project E is obviously unrealistic, but it does pay back in six months, thereby illustrating the point that a rapid payback does not guarantee a good investment.

Analyzing the Rule

When compared to the NPV rule, the payback period rule has some rather severe shortcomings. First, the payback period is calculated by simply adding up the future cash flows. There is no discounting involved, so the time value of money is completely ignored. The payback rule also fails to consider risk differences. The payback would be calculated the same way for both very risky and very safe projects.

Perhaps the biggest problem with the payback period rule is coming up with the right cutoff period, because we don't really have an objective basis for choosing a particular number. Put another way, there is no economic rationale for looking at payback in the first place, so we have no guide as to how to pick the cutoff. As a result, we end up using a number that is arbitrarily chosen.

Suppose we have somehow decided on an appropriate payback period, say two years or less. As we have seen, the payback period rule ignores the time value of money for the first two years. More seriously, cash flows after the second year are ignored entirely. To see this, consider the two investments, Long and Short, in Table 8.2. Both projects cost \$250. Based on our discussion, the payback on Long is $2 + \$50/100 = 2.5$ years, and the payback on Short is $1 + \$150/200 = 1.75$ years. With a cutoff of two years, Short is acceptable and Long is not.

Is the payback period rule giving us the right decisions? Maybe not. Suppose again that we require a 15 percent return on this type of investment. We can calculate the NPV for these two investments as:

$$\text{NPV(Short)} = -\$250 + 100/1.15 + 200/1.15^2 = -\$11.81$$

$$\text{NPV(Long)} = -\$250 + 100 \times (1 - 1/1.15^4)/.15 = \$35.50$$

Now we have a problem. The NPV of the shorter-term investment is actually negative, meaning that taking it diminishes the value of the shareholders' equity. The opposite is true for the longer-term investment—it increases share value.

Our example illustrates two primary shortcomings of the payback period rule. First, by ignoring time value, we may be led to take investments (like Short) that actually are worth less than they cost. Second, by ignoring cash flows beyond the cutoff, we may be led to reject profitable long-term investments (like Long). More generally, using a payback period rule will tend to bias us towards shorter-term investments.

Year	Long	Short
0	-\$250	-\$250
1	100	100
2	100	200
3	100	0
4	100	0

TABLE 8.2

Investment projected cash flows

Redeeming Qualities of the Rule

Despite its shortcomings, the payback period rule is often used by large and sophisticated companies when they are making relatively minor decisions. There are several reasons for this. The primary reason is that many decisions simply do not warrant detailed analysis because the cost of the analysis would exceed the possible loss from a mistake. As a practical matter, an investment that pays back rapidly and has benefits extending beyond the cutoff period probably has a positive NPV.

Small investment decisions are made by the hundreds every day in large organizations. Moreover, they are made at all levels. As a result, it would not be uncommon for a corporation to require, for example, a two-year payback on all investments of less than \$10,000. Investments larger than this are subjected to greater scrutiny. The requirement of a two-year payback is not perfect for reasons we have seen, but it does exercise some control over expenditures and thus has the effect of limiting possible losses.

In addition to its simplicity, the payback rule has two other positive features. First, because it is biased towards short-term projects, it is biased towards liquidity. In other words, a payback rule tends to favor investments that free up cash for other uses more quickly. This could be very important for a small business; it would be less so for a large corporation. Second, the cash flows that are expected to occur later in a project’s life are probably more uncertain. Arguably, a payback period rule adjusts for the extra riskiness of later cash flows, but it does so in a rather draconian fashion—by ignoring them altogether.

We should note here that some of the apparent simplicity of the payback rule is an illusion. The reason is that we still must come up with the cash flows first, and, as we discuss above, this is not at all easy to do. Thus, it would probably be more accurate to say that the *concept* of a payback period is both intuitive and easy to understand.

Summary of the Rule

To summarize, the payback period is a kind of “break-even” measure. Because time value is ignored, you can think of the payback period as the length of time it takes to break even in an accounting sense, but not in an economic sense. The biggest drawback to the payback period rule is that it doesn’t ask the right question. The relevant issue is the impact an investment will have on the value of our stock, not how long it takes to recover the initial investment.

Nevertheless, because it is so simple, companies often use it as a screen for dealing with the myriad of minor investment decisions they have to make. There is certainly nothing wrong with this practice. Like any simple rule of thumb, there will be some errors in using it, but it wouldn’t have survived all this time if it weren’t useful. Now that you understand the rule, you can be on the alert for those circumstances under which it might lead to problems. To help you remember, the following table lists the pros and cons of the payback period rule.

Advantages and Disadvantages of the Payback Period Rule	
Advantages	Disadvantages
1. Easy to understand.	1. Ignores the time value of money.
2. Adjusts for uncertainty of later cash flows.	2. Requires an arbitrary cutoff point.
3. Biased towards liquidity.	3. Ignores cash flows beyond the cutoff date.
	4. Biased against long-term projects, such as research and development, and new projects.

CONCEPT QUESTIONS

- 8.2a** In words, what is the payback period? The payback period rule?
- 8.2b** Why do we say that the payback period is, in a sense, an accounting break-even measure?

THE AVERAGE ACCOUNTING RETURN

8.3

Another attractive, but flawed, approach to making capital budgeting decisions involves the **average accounting return (AAR)**. There are many different definitions of the AAR. However, in one form or another, the AAR is always defined as:

$$\frac{\text{Some measure of average accounting profit}}{\text{Some measure of average accounting value}}$$

The specific definition we will use is:

$$\frac{\text{Average net income}}{\text{Average book value}}$$

average accounting return (AAR)

An investment's average net income divided by its average book value.

To see how we might calculate this number, suppose we are deciding whether or not to open a store in a new shopping mall. The required investment in improvements is \$500,000. The store would have a five-year life because everything reverts to the mall owners after that time. The required investment would be 100 percent depreciated (straight-line) over five years, so the depreciation would be $\$500,000/5 = \$100,000$ per year. The tax rate is 25 percent. Table 8.3 contains the projected revenues and expenses. Based on these figures, net income in each year is also shown.

To calculate the average book value for this investment, we note that we started out with a book value of \$500,000 (the initial cost) and ended up at \$0. The average book value during the life of the investment is thus $(\$500,000 + 0)/2 = \$250,000$. As long as we use straight-line depreciation and a zero salvage value, the average investment will always be one-half of the initial investment.¹

Looking at Table 8.3, we see that net income is \$100,000 in the first year, \$150,000 in the second year, \$50,000 in the third year, \$0 in year 4, and $-\$50,000$ in year 5. The average net income, then, is:

$$[\$100,000 + \$150,000 + \$50,000 + 0 + (-\$50,000)]/5 = \$50,000$$

The average accounting return is:

$$\text{AAR} = \frac{\text{Average net income}}{\text{Average book value}} = \frac{\$50,000}{\$250,000} = 20\%$$

If the firm has a target AAR less than 20 percent, then this investment is acceptable; otherwise, it is not. The *average accounting return rule* is thus:

Based on the average accounting return rule, a project is acceptable if its average accounting return exceeds a target average accounting return.

¹ We could, of course, calculate the average of the six book values directly. In thousands, we would have $(\$500 + 400 + 300 + 200 + 100 + 0)/6 = \250 .

TABLE 8.3		Year 1	Year 2	Year 3	Year 4	Year 5
Projected yearly revenues and costs for average accounting return	Revenue	\$433,333	\$450,000	\$266,667	\$200,000	\$133,333
	Expenses	<u>200,000</u>	<u>150,000</u>	<u>100,000</u>	<u>100,000</u>	<u>100,000</u>
	Earnings before depreciation	\$233,333	\$300,000	\$166,667	\$100,000	\$ 33,333
	Depreciation	<u>100,000</u>	<u>100,000</u>	<u>100,000</u>	<u>100,000</u>	<u>100,000</u>
	Earnings before taxes	\$133,333	\$200,000	\$ 66,667	\$ 0	−\$ 66,667
	Taxes (25%)	<u>33,333</u>	<u>50,000</u>	<u>16,667</u>	<u>0</u>	<u>− 16,667</u>
	Net income	<u>\$100,000</u>	<u>\$150,000</u>	<u>\$ 50,000</u>	<u>\$ 0</u>	<u>−\$ 50,000</u>
	Average net income = $\frac{(\$100,000 + \$150,000 + \$50,000 + 0 - 50,000)}{5} = \$50,000$					
	Average book value = $\frac{\$500,000 + 0}{2} = \$250,000$					

As we will see next, this rule has a number of problems.

You should recognize the chief drawback to the AAR immediately. Above all else, the AAR is not a rate of return in any meaningful economic sense. Instead, it is the ratio of two accounting numbers, and it is not comparable to the returns offered, for example, in financial markets.²

One of the reasons the AAR is not a true rate of return is that it ignores time value. When we average figures that occur at different times, we are treating the near future and the more distant future the same way. There was no discounting involved when we computed the average net income, for example.

The second problem with the AAR is similar to the problem we had with the payback period rule concerning the lack of an objective cutoff period. Since a calculated AAR is really not comparable to a market return, the target AAR must somehow be specified. There is no generally agreed-upon way to do this. One way of doing it is to calculate the AAR for the firm as a whole and use this as a benchmark, but there are lots of other ways as well.

The third, and perhaps worst, flaw in the AAR is that it doesn't even look at the right things. Instead of cash flow and market value, it uses net income and book value. These are both poor substitutes. As a result, an AAR doesn't tell us what the effect on share price will be from taking an investment, so it doesn't tell us what we really want to know.

Does the AAR have any redeeming features? About the only one is that it almost always can be computed. The reason is that accounting information will almost always be available, both for the project under consideration and for the firm as a whole. We hasten to add that once the accounting information is available, we can always convert it to cash flows, so even this is not a particularly important fact. The AAR is summarized in the table that follows.

Advantages and Disadvantages of the Average Accounting Return	
Advantages	Disadvantages
1. Easy to calculate.	1. Not a true rate of return; time value of money is ignored.
2. Needed information will usually be available.	2. Uses an arbitrary benchmark cutoff rate.
	3. Based on accounting net income and book values, not cash flows and market values.

² The AAR is closely related to the return on assets, or ROA, discussed in Chapter 3. In practice, the AAR is sometimes computed by first calculating the ROA for each year and then averaging the results. This produces a number that is similar, but not identical, to the one we computed.

CONCEPT QUESTIONS

8.3a What is an average accounting rate of return, or AAR?

8.3b What are the weaknesses of the AAR rule?

THE INTERNAL RATE OF RETURN

8.4

internal rate of return (IRR)

The discount rate that makes the NPV of an investment zero.

We now come to the most important alternative to NPV, the **internal rate of return**, universally known as the **IRR**. As we will see, the IRR is closely related to NPV. With the IRR, we try to find a single rate of return that summarizes the merits of a project. Furthermore, we want this rate to be an “internal” rate in the sense that it only depends on the cash flows of a particular investment, not on rates offered elsewhere.

To illustrate the idea behind the IRR, consider a project that costs \$100 today and pays \$110 in one year. Suppose you were asked, “What is the return on this investment?” What would you say? It seems both natural and obvious to say that the return is 10 percent because, for every dollar we put in, we get \$1.10 back. In fact, as we will see in a moment, 10 percent is the internal rate of return, or IRR, on this investment.

Is this project with its 10 percent IRR a good investment? Once again, it would seem apparent that this is a good investment only if our required return is less than 10 percent. This intuition is also correct and illustrates the *IRR rule*:

Based on the IRR rule, an investment is acceptable if the IRR exceeds the required return. It should be rejected otherwise.

Imagine that we wanted to calculate the NPV for our simple investment. At a discount rate of R , the NPV is:

$$\text{NPV} = -\$100 + 110/(1 + R)$$

Now, suppose we didn’t know the discount rate. This presents a problem, but we could still ask how high the discount rate would have to be before this project was unacceptable. We know that we are indifferent between taking and not taking this investment when its NPV is just equal to zero. In other words, this investment is *economically* a break-even proposition when the NPV is zero because value is neither created nor destroyed. To find the break-even discount rate, we set NPV equal to zero and solve for R :

$$\text{NPV} = 0 = -\$100 + 110/(1 + R)$$

$$\$100 = \$110/(1 + R)$$

$$1 + R = \$110/\$100 = 1.10$$

$$R = 10\%$$

This 10 percent is what we already have called the return on this investment. What we have now illustrated is that the internal rate of return on an investment (or just “return” for short) is the discount rate that makes the NPV equal to zero. This is an important observation, so it bears repeating:

The IRR on an investment is the required return that results in a zero NPV when it is used as the discount rate.

The fact that the IRR is simply the discount rate that makes the NPV equal to zero is important because it tells us how to calculate the returns on more complicated investments. As we have seen, finding the IRR turns out to be relatively easy for a single-period investment. However, suppose you were now looking at an investment with the cash flows shown in Figure 8.3. As illustrated, this investment costs \$100 and has a cash flow of \$60 per year for two years, so it’s only slightly more complicated than our single-period example. However, if you were asked for the return on this investment, what would you say? There doesn’t seem to be any obvious answer (at least to us). However, based on what we now know, we can set the NPV equal to zero and solve for the discount rate:

$$NPV = 0 = -\$100 + 60/(1 + IRR) + 60/(1 + IRR)^2$$

Unfortunately, the only way to find the IRR in general is by trial and error, either by hand or by calculator. This is precisely the same problem that came up in Chapter 5 when we found the unknown rate for an annuity and in Chapter 6 when we found the yield to maturity on a bond. In fact, we now see that, in both of those cases, we were finding an IRR.

In this particular case, the cash flows form a two-period, \$60 annuity. To find the unknown rate, we can try some different rates until we get the answer. If we were to start with a 0 percent rate, the NPV would obviously be $\$120 - 100 = \20 . At a 10 percent discount rate, we would have:

$$NPV = -\$100 + 60/1.1 + 60/1.1^2 = \$4.13$$

Now, we’re getting close. We can summarize these and some other possibilities as shown in Table 8.4. From our calculations, the NPV appears to be zero between 10 percent and 15 percent, so the IRR is somewhere in that range. With a little more effort, we can find that the IRR is about 13.1 percent. So, if our required return is less than 13.1 percent, we would take this investment. If our required return exceeds 13.1 percent, we would reject it.

By now, you have probably noticed that the IRR rule and the NPV rule appear to be quite similar. In fact, the IRR is sometimes simply called the *discounted cash flow*, or *DCF, return*. The easiest way to illustrate the relationship between NPV and IRR is to plot the numbers we calculated in Table 8.4. We put the different NPVs on the vertical axis, or *y-axis*, and the discount rates on the horizontal axis, or *x-axis*. If we had a very large number of points, the resulting picture would be a smooth curve called

	Discount Rate	NPV
NPV at different discount rates	0%	\$20.00
	5	11.56
	10	4.13
	15	− 2.46
	20	− 8.33

FIGURE 8.4

An NPV profile

a **net present value profile**. Figure 8.4 illustrates the NPV profile for this project. Beginning with a 0 percent discount rate, we have \$20 plotted directly on the y-axis. As the discount rate increases, the NPV declines smoothly. Where will the curve cut through the x-axis? This will occur where the NPV is just equal to zero, so it will happen right at the IRR of 13.1 percent.

In our example, the NPV rule and the IRR rule lead to identical accept-reject decisions. We will accept an investment using the IRR rule if the required return is less than 13.1 percent. As Figure 8.4 illustrates, however, the NPV is positive at any discount rate less than 13.1 percent, so we would accept the investment using the NPV rule as well. The two rules are equivalent in this case.

net present value profile

A graphical representation of the relationship between an investment's NPV and various discount rates.

Calculating the IRR

EXAMPLE 8.3

A project has a total up-front cost of \$435.44. The cash flows are \$100 in the first year, \$200 in the second year, and \$300 in the third year. What's the IRR? If we require an 18 percent return, should we take this investment?

We'll describe the NPV profile and find the IRR by calculating some NPVs at different discount rates. You should check our answers for practice. Beginning with 0 percent, we have:

Discount Rate	NPV
0%	\$164.56
5	100.36
10	46.15
15	.00
20	−39.61

The NPV is zero at 15 percent, so 15 percent is the IRR. If we require an 18 percent return, then we should not take the investment. The reason is that the NPV is negative at 18 percent (verify that it is −\$24.47). The IRR rule tells us the same thing in this case. We shouldn't take this investment because its 15 percent return is below our required 18 percent return.

At this point, you may be wondering whether the IRR and NPV rules always lead to identical decisions. The answer is yes as long as two very important conditions are met. First, the project’s cash flows must be *conventional*, meaning that the first cash flow (the initial investment) is negative and all the rest are positive. Second, the project must be *independent*, meaning that the decision to accept or reject this project does not affect the decision to accept or reject any other. The first of these conditions is typically met, but the second often is not. In any case, when one or both of these conditions are not met, problems can arise. We discuss some of these in a moment.

SPREADSHEET STRATEGIES

Calculating IRRs with a Spreadsheet

Because IRRs are so tedious to calculate by hand, financial calculators and, especially, spreadsheets are generally used. The procedures used by various financial calculators are too different for us to illustrate here, so we will focus on using a spreadsheet (financial calculators are covered in Appendix D). As the following example illustrates, using a spreadsheet is very easy:

	A	B	C	D	E	F	G	H
1								
2	Using a spreadsheet to calculate internal rates of return							
3								
4	Suppose we have a four-year project that costs \$500. The cash flows over the four-year life will be							
5	\$100, \$200, \$300, and \$400. What is the IRR?							
6								
7		Year	Cash flow					
8		0	–\$500					
9		1	100		IRR =	27.3%		
10		2	200					
11		3	300					
12		4	400					
13								
14								
15	The formula entered in cell F9 is = IRR(C8:C12). Notice that the Year 0 cash flow has a negative sign,							
16	representing the initial cost of the project.							
17								

Problems with the IRR

The problems with the IRR come about when the cash flows are not conventional or when we are trying to compare two or more investments to see which is best. In the first case, surprisingly, the simple question “What’s the return?” can become very difficult to answer. In the second case, the IRR can be a misleading guide.

Nonconventional Cash Flows Suppose we have a strip-mining project that requires a \$60 investment. Our cash flow in the first year will be \$155. In the second year, the mine is depleted, but we have to spend \$100 to restore the terrain. As Figure 8.5 illustrates, both the first and third cash flows are negative.

**FIGURE 8.5****Project cash flows**

To find the IRR on this project, we can calculate the NPV at various rates:

Discount Rate	NPV
0%	-\$5.00
10	-1.74
20	-.28
30	.06
40	-.31

The NPV appears to be behaving in a very peculiar fashion here. First, as the discount rate increases from 0 percent to 30 percent, the NPV starts out negative and becomes positive. This seems backward because the NPV is rising as the discount rate rises. It then starts getting smaller and becomes negative again. What's the IRR? To find out, we draw the NPV profile in Figure 8.6.

**FIGURE 8.6****NPV profile**

multiple rates of return

The possibility that more than one discount rate makes the NPV of an investment zero.

In Figure 8.6, notice that the NPV is zero when the discount rate is 25 percent, so this is the IRR. Or is it? The NPV is also zero at 33⅓ percent. Which of these is correct? The answer is both or neither; more precisely, there is no unambiguously correct answer. This is the **multiple rates of return** problem. Many computer spreadsheet packages aren't aware of this problem and just report the first IRR that is found. Others report only the smallest positive IRR, even though this answer is no better than any other. For example, if you enter this problem in our spreadsheet above, it will simply report that the IRR is 25 percent.

In our current example, the IRR rule breaks down completely. Suppose our required return was 10 percent. Should we take this investment? Both IRRs are greater than 10 percent, so, by the IRR rule, maybe we should. However, as Figure 8.6 shows, the NPV is negative at any discount rate less than 25 percent, so this is not a good investment. When should we take it? Looking at Figure 8.6 one last time, we see that the NPV is positive only if our required return is between **25 percent** and **33⅓ percent**.

The moral of the story is that when the cash flows aren't conventional, strange things can start to happen to the IRR. This is not anything to get upset about, however, because the NPV rule, as always, works just fine. This illustrates that, oddly enough, the obvious question "What's the rate of return?" may not always have a good answer.

EXAMPLE8.4

What's the IRR?

You are looking at an investment that requires you to invest \$51 today. You'll get \$100 in one year, but you must pay out \$50 in two years. What is the IRR on this investment?

You're on the alert now to the nonconventional cash flow problem, so you probably wouldn't be surprised to see more than one IRR. However, if you start looking for an IRR by trial and error, it will take you a long time. The reason is that there is no IRR. The NPV is negative at every discount rate, so we shouldn't take this investment under any circumstances. What's the return on this investment? Your guess is as good as ours.

mutually exclusive investment decisions

A situation where taking one investment prevents the taking of another.

Mutually Exclusive Investments Even if there is a single IRR, another problem can arise concerning **mutually exclusive investment decisions**. If two investments, X and Y, are mutually exclusive, then taking one of them means that we cannot take the other. Two projects that are not mutually exclusive are said to be independent. For example, if we own one corner lot, then we can build a gas station or an apartment building, but not both. These are mutually exclusive alternatives.

Thus far, we have asked whether or not a given investment is worth undertaking. There is a related question, however, that comes up very often: Given two or more mutually exclusive investments, which one is the best? The answer is simple enough: The best one is the one with the largest NPV. Can we also say that the best one has the highest return? As we show, the answer is no.

To illustrate the problem with the IRR rule and mutually exclusive investments, consider the cash flows from the following two mutually exclusive investments:

Year	Investment A	Investment B
0	-\$100	-\$100
1	50	20
2	40	40
3	40	50
4	30	60

The IRR for A is 24 percent, and the IRR for B is 21 percent. Since these investments are mutually exclusive, we can only take one of them. Simple intuition suggests that Investment A is better because of its higher return. Unfortunately, simple intuition is not always correct.

To see why Investment A is not necessarily the better of the two investments, we've calculated the NPV of these investments for different required returns:

Discount Rate	NPV (A)	NPV (B)
0%	\$60.00	\$70.00
5	43.13	47.88
10	29.06	29.79
15	17.18	14.82
20	7.06	2.31
25	-1.63	-8.22

The IRR for A (24 percent) is larger than the IRR for B (21 percent). However, if you compare the NPVs, you'll see that which investment has the higher NPV depends on our required return. B has greater total cash flow, but it pays back more slowly than A. As a result, it has a higher NPV at lower discount rates.

In our example, the NPV and IRR rankings conflict for some discount rates. If our required return is 10 percent, for instance, then B has the higher NPV and is thus the better of the two, even though A has the higher IRR. If our required return is 15 percent, then there is no ranking conflict: A is better.

The conflict between the IRR and NPV for mutually exclusive investments can be illustrated by plotting their NPV profiles as we have done in Figure 8.7. In Figure 8.7,

FIGURE 8.7

NPV profiles for mutually exclusive investments

notice that the NPV profiles cross at 11.1 percent. Notice also that at any discount rate less than 11.1 percent, the NPV for B is higher. In this range, taking B benefits us more than taking A, even though A's IRR is higher. At any rate greater than 11.1 percent, Investment A has the greater NPV.

This example illustrates that whenever we have mutually exclusive projects, we shouldn't rank them based on their returns. More generally, anytime we are comparing investments to determine which is best, IRRs can be misleading. Instead, we need to look at the relative NPVs to avoid the possibility of choosing incorrectly. Remember, we're ultimately interested in creating value for the shareholders, so the option with the higher NPV is preferred, regardless of the relative returns.

If this seems counterintuitive, think of it this way. Suppose you have two investments. One has a 10 percent return and makes you \$100 richer immediately. The other has a 20 percent return and makes you \$50 richer immediately. Which one do you like better? We would rather have \$100 than \$50, regardless of the returns, so we like the first one better.

As we saw from Figure 8.7, the crossover rate for Investment A and Investment B is 11.1 percent. You might be wondering how we got this number. Actually, the calculation is fairly easy. We begin by subtracting the cash flows from one project from the cash flows of the second project. In this case, we will subtract Investment B from Investment A. Doing so, we get:

Year	Investment A	Investment B	Cash Flow Difference (A – B)
0	–\$100	–\$100	\$ 0
1	50	20	30
2	40	40	0
3	40	50	–10
4	30	60	–30

Now all we have to do is calculate the IRR for these differential cash flows, which works out to be 11.1 percent. Verify for yourself that if you subtract Investment A's cash flows from Investment B's cash flows the crossover rate is still 11.1 percent, so it doesn't matter which one you subtract from which.

Redeeming Qualities of the IRR

Despite its flaws, the IRR is very popular in practice, more so than even the NPV. It probably survives because it fills a need that the NPV does not. In analyzing investments, people in general, and financial analysts in particular, seem to prefer talking about rates of return rather than dollar values.

In a similar vein, the IRR also appears to provide a simple way of communicating information about a proposal. One manager might say to another, "Remodeling the clerical wing has a 20 percent return." This may somehow be simpler than saying, "At a 10 percent discount rate, the net present value is \$4,000."

Finally, under certain circumstances, the IRR may have a practical advantage over the NPV. We can't estimate the NPV unless we know the appropriate discount rate, but we can still estimate the IRR. Suppose we didn't know the required return on an investment, but we found, for example, that it had a 40 percent return. We would probably be inclined to take it since it is very unlikely that the required return would be that high. The advantages and disadvantages of the IRR are summarized on the next page.

Advantages and Disadvantages of the Internal Rate of Return	
Advantages	Disadvantages
<ol style="list-style-type: none"> 1. Closely related to NPV, often leading to identical decisions. 2. Easy to understand and communicate. 	<ol style="list-style-type: none"> 1. May result in multiple answers with nonconventional cash flows. 2. May lead to incorrect decisions in comparisons of mutually exclusive investments.

The Modified Internal Rate of Return (MIRR)

To address some of the problems that can crop up with the standard IRR, it is often proposed that a modified version be used. As we will see, there are several different ways of calculating a modified IRR, or MIRR, but the idea is to modify the cash flows first and then calculate IRR using the modified cash flows.

To illustrate, let's go back to the cash flows in Figure 8.5: $-\$60$, $+\$155$, and $-\$100$. As we saw, there are two IRRs, 25 percent and $33\frac{1}{3}$ percent. We next illustrate three different MIRRs, all of which have the property that only one answer will result, thereby eliminating the multiple IRR problem.

Method 1: The Discounting Approach With the discounting approach, the idea is to discount all negative cash flows back to the present at the required return and add them to the initial cost. Then, calculate the IRR. Because only the first modified cash flow is negative, there will be only one IRR. The discount rate used might be the required return, or it might be some other externally supplied rate. We will use the project's required return.

If the required return on the project is 20 percent, then the modified cash flows look like this:

$$\begin{aligned}\text{Time 0: } & -\$60 + \frac{-\$100}{1.20^2} = -\$129.44 \\ \text{Time 1: } & +\$155 \\ \text{Time 2: } & +\$0\end{aligned}$$

If you calculate the MIRR now, you should get 19.74 percent.

Method 2: The Reinvestment Approach With the reinvestment approach, we compound *all* cash flows (positive and negative) except the first out to the end of the project's life and then calculate the IRR. In a sense, we are "reinvesting" the cash flows and not taking them out of the project until the very end. The rate we use could be the required return on the project, or it could be a separately specified "reinvestment rate." We will use the project's required return. When we do, here are the modified cash flows:

$$\begin{aligned}\text{Time 0: } & -\$60 \\ \text{Time 1: } & +0 \\ \text{Time 2: } & -\$100 + (\$155 \times 1.2) = \$86\end{aligned}$$

The MIRR on this set of cash flows is 19.72 percent, or a little lower than we got using the discounting approach.

Method 3: The Combination Approach As the name suggests, the combination approach blends our first two methods. Negative cash flows are discounted back to the present, and positive cash flows are compounded to the end of the project. In practice,

different discount or compounding rates might be used, but we will again stick with the project’s required return.

With the combination approach, the modified cash flows are as follows:

Time 0: $-\$60 + \frac{-\$100}{1.20^2} = -\$129.44$
Time 1: $+0$
Time 2: $\$155 \times 1.2 = \186

See if you don’t agree that the MIRR is 19.87, the highest of the three.

MIRR or IRR: Which Is Better? MIRRs are controversial. At one extreme are those who claim that MIRRs are superior to IRRs, period. For example, by design, they clearly don’t suffer from the multiple rate of return problem.

At the other end, detractors say that MIRR should stand for “meaningless internal rate of return.” As our example makes clear, one problem with MIRRs is that there are different ways of calculating them, and there is no clear reason to say one of our three methods is better than any other. The differences are small with our simple cash flows, but they could be much larger for a more complex project. Further, it’s not clear how to interpret an MIRR. It may look like a rate of return; but it’s a rate of return on a modified set of cash flows, not the project’s actual cash flows.

We’re not going to take sides. However, notice that calculating an MIRR requires discounting, compounding, or both, which leads to two obvious observations. First, if we have the relevant discount rate, why not calculate the NPV and be done with it? Second, because an MIRR depends on an externally supplied discount (or compounding) rate, the answer you get is not truly an “internal” rate of return, which, by definition, depends on only the project’s cash flows.

We will take a stand on one issue that frequently comes up in this context. The value of a project does not depend on what the firm does with the cash flows generated by that project. A firm might use a project’s cash flows to fund other projects, to pay dividends, or to buy an executive jet. It doesn’t matter: How the cash flows are spent in the future does not affect their value today. As a result, there is generally no need to consider reinvestment of interim cash flows.

CONCEPT QUESTIONS	
8.4a	Under what circumstances will the IRR and NPV rules lead to the same accept-reject decisions? When might they conflict?
8.4b	Is it generally true that an advantage of the IRR rule over the NPV rule is that we don’t need to know the required return to use the IRR rule?

8.5

THE PROFITABILITY INDEX

profitability index (PI)

The present value of an investment’s future cash flows divided by its initial cost. Also, benefit-cost ratio.

Another method used to evaluate projects involves the **profitability index (PI)**, or benefit-cost ratio. This index is defined as the present value of the future cash flows divided by the initial investment. So, if a project costs \$200 and the present value of its future cash flows is \$220, the profitability index value would be $\$220/\$200 = 1.10$. Notice that the NPV for this investment is \$20, so it is a desirable investment.

More generally, if a project has a positive NPV, then the present value of the future cash flows must be bigger than the initial investment. The profitability index would thus be bigger than 1.00 for a positive NPV investment and less than 1.00 for a negative NPV investment.

How do we interpret the profitability index? In our example, the PI was 1.10. This tells us that, per dollar invested, \$1.10 in value or \$.10 in NPV results. The profitability index thus measures “bang for the buck,” that is, the value created per dollar invested. For this reason, it is often proposed as a measure of performance for government or other not-for-profit investments. Also, when capital is scarce, it may make sense to allocate it to those projects with the highest PIs.

The PI is obviously very similar to the NPV. However, consider an investment that costs \$5 and has a \$10 present value and an investment that costs \$100 with a \$150 present value. The first of these investments has an NPV of \$5 and a PI of 2. The second has an NPV of \$50 and a PI of 1.50. If these are mutually exclusive investments, then the second one is preferred, even though it has a lower PI. This ranking problem is very similar to the IRR ranking problem we saw in the previous section. In all, there seems to be little reason to rely on the PI instead of the NPV. Our discussion of the PI is summarized below.

Advantages and Disadvantages of the Profitability Index	
Advantages	Disadvantages
<ol style="list-style-type: none"> 1. Closely related to NPV, generally leading to identical decisions. 2. Easy to understand and communicate. 3. May be useful when available investment funds are limited. 	<ol style="list-style-type: none"> 1. May lead to incorrect decisions in comparisons of mutually exclusive investments.

CONCEPT QUESTIONS

8.5a What does the profitability index measure?

8.5b How would you state the profitability index rule?

THE PRACTICE OF CAPITAL BUDGETING

8.6

Given that NPV seems to be telling us directly what we want to know, you might be wondering why there are so many other procedures and why alternative procedures are commonly used. Recall that we are trying to make an investment decision and that we are frequently operating under considerable uncertainty about the future. We can only *estimate* the NPV of an investment in this case. The resulting estimate can be very “soft,” meaning that the true NPV might be quite different.

Because the true NPV is unknown, the astute financial manager seeks clues to assess whether the estimated NPV is reliable. For this reason, firms would typically use multiple criteria for evaluating a proposal. For example, suppose we have an investment with a positive estimated NPV. Based on our experience with other projects, this one appears to have a short payback and a very high AAR. In this case, the different indicators seem to agree that it’s “all systems go.” Put another way, the payback and the AAR are consistent with the conclusion that the NPV is positive.

On the other hand, suppose we had a positive estimated NPV, a long payback, and a low AAR. This could still be a good investment, but it looks like we need to be much more careful in making the decision since we are getting conflicting signals. If the estimated NPV is based on projections in which we have little confidence, then further analysis is probably in order. We will consider how to go about this analysis in more detail in the next chapter.

Large firms often have huge capital budgets. For example, in 2009, ExxonMobil announced that it expected to have about \$29 billion in capital outlays during the year, up from \$26 billion in 2008. About the same time, competitor ChevronTexaco announced that it would maintain its capital budget in 2009 at \$22.8 billion, the same amount it had spent in 2008. Other companies with large capital spending budgets were General Motors, which projected capital spending of about \$4.8 billion for 2009, and semiconductor company Intel, which projected capital spending of about \$7 billion for 2009 and 2010 combined.

Large-scale capital spending is often an industrywide occurrence. For example, in 2008, capital spending in the semiconductor industry was expected to be \$30.3 billion. This represented a 34 percent decrease over 2007 and was in sharp contrast to the 18 percent increase from 2005 to 2006.

According to information released by the Census Bureau in 2008, capital investment for the economy as a whole was \$1.31 trillion in 2006, \$1.22 trillion in 2005, and \$1.05 trillion in 2004. The totals for the three years therefore exceeded \$3 trillion! Given the sums at stake, it is not too surprising that careful analysis of capital expenditures is something at which successful businesses seek to become adept.

There have been a number of surveys conducted asking firms what types of investment criteria they actually use. Table 8.5 summarizes the results of several of these. The first part of the table is a historical comparison looking at the primary capital budgeting techniques used by large firms through time. In 1959, only 19 percent of the firms surveyed used either IRR or NPV, and 68 percent used either payback periods or accounting returns. It is clear that, by the 1980s, IRR and NPV had become the dominant criteria.

TABLE 8.5 Capital budgeting techniques in practice

A. Historical Comparison of the Primary Use of Various Capital Budgeting Techniques							
	1959	1964	1970	1975	1977	1979	1981
Payback period	34%	24%	12%	15%	9%	10%	5.0%
Average accounting return (AAR)	34	30	26	10	25	14	10.7
Internal rate of return (IRR)	19	38	57	37	54	60	65.3
Net present value (NPV)	—	—	—	26	10	14	16.5
IRR or NPV	19	38	57	63	64	74	81.8

B. Percentage of CFOs Who Always or Almost Always Use a Given Technique in 1999				
Capital Budgeting Technique	Percentage Always or Almost Always Use	Overall	Average Score	
			Scale is 4 (always) to 0 (never)	
			Large Firms	Small Firms
Internal rate of return	76%	3.09	3.41	2.87
Net present value	75	3.08	3.42	2.83
Payback period	57	2.53	2.25	2.72
Accounting rate of return	20	1.34	1.25	1.41
Profitability index	12	0.83	0.75	0.88

Reichert, "An Analysis of the Financial Management Techniques Currently Employed by Large U.S. Corporations," *Journal of Business Finance and Accounting*, Winter 1983, pp. 623–45; M. T. Stanley and S. B. Block, "A Survey of Multinational Capital Budgeting," *The Financial Review*, March 1984, pp. 36–51.

Panel B of Table 8.5 summarizes the results of a 1999 survey of chief financial officers (CFOs) at both large and small firms in the United States. A total of 392 CFOs responded. What is shown is the percentage of CFOs who always or almost always use the various capital budgeting techniques we described in this chapter. Not surprisingly, IRR and NPV are the two most widely used techniques, particularly at larger firms. However, over half of the respondents always, or almost always, use the payback criterion as well. In fact, among smaller firms, payback is used just about as much as NPV and IRR. Less commonly used are accounting rates of return and the profitability index. For quick reference, these criteria are briefly summarized in Table 8.6.

CONCEPT QUESTIONS

- 8.6a** What are the most commonly used capital budgeting procedures?
- 8.6b** Since NPV is conceptually the best tool for capital budgeting, why do you think multiple measures are used in practice?

TABLE 8.6

Summary of investment criteria

I. Discounted cash flow criteria

- A. *Net present value (NPV)*. The NPV of an investment is the difference between its market value and its cost. The NPV rule is to take a project if its NPV is positive. NPV is frequently estimated by calculating the present value of the future cash flows (to estimate market value) and then subtracting the cost. NPV has no serious flaws; it is the preferred decision criterion.
- B. *Internal rate of return (IRR)*. The IRR is the discount rate that makes the estimated NPV of an investment equal to zero; it is sometimes called the *discounted cash flow (DCF) return*. The IRR rule is to take a project when its IRR exceeds the required return. IRR is closely related to NPV, and it leads to exactly the same decisions as NPV for conventional, independent projects. When project cash flows are not conventional, there may be no IRR or there may be more than one. More seriously, the IRR cannot be used to rank mutually exclusive projects; the project with the highest IRR is not necessarily the preferred investment.
- C. *Modified internal rate of return (MIRR)*. The MIRR is a modification to the IRR. A project's cash flows are modified by (1) discounting the negative cash flows back to the present; (2) compounding all cash flows to the end of the project's life; or (3) combining (1) and (2). An IRR is then computed on the modified cash flows. MIRRs are guaranteed to avoid the multiple rate of return problem. But, it is unclear how to interpret them, and they are not truly "internal" because they depend on externally supplied discounting or compounding rates.
- D. *Profitability index (PI)*. The PI, also called the *benefit-cost ratio*, is the ratio of present value to cost. The PI rule is to take an investment if the index exceeds 1. The PI measures the present value of an investment per dollar invested. It is quite similar to NPV, but, like IRR, it cannot be used to rank mutually exclusive projects. However, it is sometimes used to rank projects when a firm has more positive NPV investments than it can currently finance.

II. Payback criteria

- A. *Payback period*. The payback period is the length of time until the sum of an investment's cash flows equals its cost. The payback period rule is to take a project if its payback is *less* than some cutoff. The payback period is a flawed criterion primarily because it ignores risk, the time value of money, and cash flows beyond the cutoff point.

III. Accounting criteria

- A. *Average accounting return (AAR)*. The AAR is a measure of accounting profit relative to book value. It is *not* related to the IRR, but it is similar to the accounting return on assets (ROA) measure in Chapter 3. The AAR rule is to take an investment if its AAR exceeds a benchmark AAR. The AAR is seriously flawed for a variety of reasons, and it has little to recommend it.

SUMMARY AND CONCLUSIONS

This chapter has covered the different criteria used to evaluate proposed investments. The five criteria, in the order in which we discussed them, are:

1. Net present value (NPV)
2. Payback period
3. Average accounting return (AAR)
4. Internal rate of return (IRR)
5. Modified internal rate of return (MIRR)
6. Profitability index (PI)

We illustrated how to calculate each of these and discussed the interpretation of the results. We also described the advantages and disadvantages of each of them. Ultimately, a good capital budgeting criterion must tell us two things. First, is a particular project a good investment? Second, if we have more than one good project, but we can only take one of them, which one should we take? The main point of this chapter is that only the NPV criterion can always provide the correct answer to both questions.

For this reason, NPV is one of the two or three most important concepts in finance, and we will refer to it many times in the chapters ahead. When we do, keep two things in mind: (1) NPV is always just the difference between the market value of an asset or project and its cost and (2) the financial manager acts in the shareholders' best interests by identifying and taking positive NPV projects.

Finally, we noted that NPVs can't normally be observed in the market; instead, they must be estimated. Because there is always the possibility of a poor estimate, financial managers use multiple criteria for examining projects. These other criteria provide additional information about whether a project truly has a positive NPV.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

- 8.1 Investment Criteria.** This problem will give you some practice calculating NPVs and paybacks. A proposed overseas expansion has the following cash flows:

Year	Cash Flow
0	−\$100
1	50
2	40
3	40
4	15

Calculate the payback and NPV at a required return of 15 percent.

- 8.2 Mutually Exclusive Investments.** Consider the following two mutually exclusive investments. Calculate the IRR for each. Under what circumstances will the IRR and NPV criteria rank the two projects differently?

Year	Investment A	Investment B
0	−\$100	−\$100
1	50	70
2	70	75
3	40	10

- 8.3 Average Accounting Return.** You are looking at a three-year project with a projected net income of \$1,000 in year 1, \$2,000 in year 2, and \$4,000 in year 3. The cost is \$9,000, which will be depreciated straight-line to zero over the three-year life of the project. What is the average accounting return, or AAR?

■ Answers to Chapter Review and Self-Test Problems

- 8.1** In the table below, we have listed the cash flows and their discounted values (at 15 percent).

Year	Cash Flow	
	Undiscounted	Discounted (at 15%)
1	\$ 50	\$ 43.48
2	40	30.25
3	40	26.30
4	15	8.58
Total	<u>\$145</u>	<u>\$108.61</u>

Recall that the initial investment is \$100. Examining the undiscounted cash flows, we see that the payback occurs between Years 2 and 3. The cash flows for the first two years are \$90 total, so, going into the third year, we are short by \$10. The total cash flow in Year 3 is \$40, so the payback is $2 + \$10/40 = 2.25$ years.

Looking at the discounted cash flows, we see that the sum is \$108.61, so the NPV is \$8.61.

- 8.2** To calculate the IRR, we might try some guesses as in the following table:

Discount Rate	NPV(A)	NPV(B)
0%	\$60.00	\$55.00
10	33.36	33.13
20	13.43	16.20
30	− 1.91	2.78
40	−13.99	− 8.09

Several things are immediately apparent from our guesses. First, the IRR on A must be just a little less than 30 percent (why?). With some more effort, we find that it's 28.61 percent. For B, the IRR must be a little more than 30 percent (again,

why?); it works out to be 32.37 percent. Also, notice that at 10 percent, the NPVs are very close, indicating that the NPV profiles cross in that vicinity. Verify that the NPVs are the same at 10.61 percent.

Now, the IRR for B is always higher. As we've seen, A has the larger NPV for any discount rate less than 10.61 percent, so the NPV and IRR rankings will conflict in that range. Remember, if there's a conflict, we will go with the higher NPV. Our decision rule is thus very simple: Take A if the required return is less than 10.61 percent, take B if the required return is between 10.61 percent and 32.37 percent (the IRR on B), and take neither if the required return is more than 32.37 percent.

- 8.3** Here we need to calculate the ratio of average net income to average book value to get the AAR. Average net income is:

$$\begin{aligned}\text{Average net income} &= (\$1,000 + 2,000 + 4,000)/3 \\ &= \$2,333.33\end{aligned}$$

Average book value is:

$$\text{Average book value} = \$9,000/2 = \$4,500$$

So, the average accounting return is:

$$\text{AAR} = \$2,333.33/4,500 = 51.85\%$$

This is an impressive return. Remember, however, that it isn't really a rate of return like an interest rate or an IRR, so the size doesn't tell us a lot. In particular, our money is probably not going to grow at 51.85 percent per year, sorry to say.

CRITICAL THINKING AND CONCEPTS REVIEW

- L0 4** **L0 1** **8.1 Payback Period and Net Present Value.** If a project with conventional cash flows has a payback period less than its life, can you definitively state the algebraic sign of the NPV? Why or why not?
- L0 4** **8.2 Net Present Value.** Suppose a project has conventional cash flows and a positive NPV. What do you know about its payback? Its profitability index? Its IRR? Explain.
- L0 1** **8.3 Payback Period.** Concerning payback:
- Describe how the payback period is calculated and describe the information this measure provides about a sequence of cash flows. What is the payback criterion decision rule?
 - What are the problems associated with using the payback period as a means of evaluating cash flows?
 - What are the advantages of using the payback period to evaluate cash flows? Are there any circumstances under which using payback might be appropriate? Explain.
- L0 2** **8.4 Average Accounting Return.** Concerning AAR:
- Describe how the average accounting return is usually calculated and describe the information this measure provides about a sequence of cash flows. What is the AAR criterion decision rule?

- b. What are the problems associated with using the AAR as a means of evaluating a project's cash flows? What underlying feature of AAR is most troubling to you from a financial perspective? Does the AAR have any redeeming qualities?

L0 4 **8.5 Net Present Value.** Concerning NPV:

- a. Describe how NPV is calculated and describe the information this measure provides about a sequence of cash flows. What is the NPV criterion decision rule?
- b. Why is NPV considered to be a superior method of evaluating the cash flows from a project? Suppose the NPV for a project's cash flows is computed to be \$2,500. What does this number represent with respect to the firm's shareholders?

L0 3 **8.6 Internal Rate of Return.** Concerning IRR:

- a. Describe how the IRR is calculated, and describe the information this measure provides about a sequence of cash flows. What is the IRR criterion decision rule?
- b. What is the relationship between IRR and NPV? Are there any situations in which you might prefer one method over the other? Explain.
- c. Despite its shortcomings in some situations, why do most financial managers use IRR along with NPV when evaluating projects? Can you think of a situation in which IRR might be a more appropriate measure to use than NPV? Explain.

L0 6 **8.7 Profitability Index.** Concerning the profitability index:

- a. Describe how the profitability index is calculated and describe the information this measure provides about a sequence of cash flows. What is the profitability index decision rule?
- b. What is the relationship between the profitability index and the NPV? Are there any situations in which you might prefer one method over the other? Explain.

L0 1 **8.8 Payback and Internal Rate of Return.** A project has perpetual cash flows of C per period, a cost of I , and a required return of R . What is the relationship between the project's payback and its IRR? What implications does your answer have for long-lived projects with relatively constant cash flows?

L0 4 **8.9 International Investment Projects.** In January 2008, automobile manufacturer Volkswagen announced plans to build an automatic transmission and engine plant in South Carolina. Volkswagen apparently believed that it would be better able to compete and create value with U.S.-based facilities. Other companies such as Fuji Film and Swiss chemical company Lonza have reached similar conclusions and taken similar actions. What are some of the reasons that foreign manufacturers of products as diverse as automobiles, film, and chemicals might arrive at this same conclusion?

L0 4 **8.10 Capital Budgeting Problems.** What are some of the difficulties that might come up in actual applications of the various criteria we discussed in this chapter? Which one would be the easiest to implement in actual applications? The most difficult?

L0 4 **8.11 Capital Budgeting in Not-for-Profit Entities.** Are the capital budgeting criteria we discussed applicable to not-for-profit corporations? How should such entities make capital budgeting decisions? What about the U.S. government? Should it evaluate spending proposals using these techniques?

- L0 3** **8.12 Internal Rate of Return.** In a previous chapter, we discussed the yield to maturity (YTM) of a bond. In what ways are the IRR and the YTM similar? How are they different?
- L0 5** **8.13 Modified Internal Rate of Return.** One of the less flattering interpretations of the acronym MIRR is “meaningless internal rate of return.” Why do you think this term is applied to MIRR?
- L0 4** **8.14 Net Present Value.** It is sometimes stated that “the net present value approach assumes reinvestment of the intermediate cash flows at the required return.” Is this claim correct? To answer, suppose you calculate the NPV of a project in the usual way. Next, suppose you do the following:
- Calculate the future value (as of the end of the project) of all the cash flows other than the initial outlay assuming they are reinvested at the required return, producing a single future value figure for the project.
 - Calculate the NPV of the project using the single future value calculated in the previous step and the initial outlay. It is easy to verify that you will get the same NPV as in your original calculation only if you use the required return as the reinvestment rate in the previous step.
- L0 3** **8.15 Internal Rate of Return.** It is sometimes stated that “the internal rate of return approach assumes reinvestment of the intermediate cash flows at the internal rate of return.” Is this claim correct? To answer, suppose you calculate the IRR of a project in the usual way. Next, suppose you do the following:
- Calculate the future value (as of the end of the project) of all the cash flows other than the initial outlay assuming they are reinvested at the IRR, producing a single future value figure for the project.
 - Calculate the IRR of the project using the single future value calculated in the previous step and the initial outlay. It is easy to verify that you will get the same IRR as in your original calculation only if you use the IRR as the reinvestment rate in the previous step.

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

- L0 1** **1. Calculating Payback.** What is the payback period for the following set of cash flows?

Basic

(Questions 1–22)

Year	Cash Flow
0	–\$4,500
1	1,300
2	2,400
3	1,100
4	800

- L0 1** **2. Calculating Payback.** An investment project provides cash inflows of \$925 per year for eight years. What is the project payback period if the initial cost is \$3,400? What if the initial cost is \$4,450? What if it is \$8,400?

L0 1

3. **Calculating Payback.** Offshore Drilling Products, Inc., imposes a payback cutoff of three years for its international investment projects. If the company has the following two projects available, should it accept either of them?

Year	Cash Flow (A)	Cash Flow (B)
0	-\$45,000	-\$ 90,000
1	17,000	19,000
2	23,000	24,000
3	19,000	35,000
4	5,000	250,000

L0 2

4. **Calculating AAR.** You're trying to determine whether or not to expand your business by building a new manufacturing plant. The plant has an installation cost of \$17 million, which will be depreciated straight-line to zero over its four-year life. If the plant has projected net income of \$1,735,000, \$2,105,000, \$1,954,000, and \$1,286,000 over these four years, what is the project's average accounting return (AAR)?

L0 3

5. **Calculating IRR.** A firm evaluates all of its projects by applying the IRR rule. If the required return is 13 percent, should the firm accept the following project?

Year	Cash Flow
0	-\$145,000
1	71,000
2	68,000
3	52,000

L0 4

6. **Calculating NPV.** For the cash flows in the previous problem, suppose the firm uses the NPV decision rule. At a required return of 10 percent, should the firm accept this project? What if the required return was 21 percent?

L0 3

7. **Calculating NPV and IRR.** A project that provides annual cash flows of \$2,150 for nine years costs \$8,900 today. Is this a good project if the required return is 8 percent? What if it's 24 percent? At what discount rate would you be indifferent between accepting the project and rejecting it?

L0 4

L0 3

8. **Calculating IRR.** What is the IRR of the following set of cash flows?

Year	Cash Flow
0	-\$32,000
1	13,200
2	18,500
3	10,600

L0 4

9. **Calculating NPV.** For the cash flows in the previous problem, what is the NPV at a discount rate of zero percent? What if the discount rate is 10 percent? If it is 20 percent? If it is 30 percent?

LO 3

LO 4

10. **NPV versus IRR.** Framing Hanley, LLC, has identified the following two mutually exclusive projects:

Year	Cash Flow (A)	Cash Flow (B)
0	−\$50,000	−\$50,000
1	26,000	14,000
2	20,000	18,000
3	16,000	22,000
4	12,000	26,000

- What is the IRR for each of these projects? If you apply the IRR decision rule, which project should the company accept? Is this decision necessarily correct?
- If the required return is 11 percent, what is the NPV for each of these projects? Which project will you choose if you apply the NPV decision rule?
- Over what range of discount rates would you choose Project A? Project B? At what discount rate would you be indifferent between these two projects? Explain.

LO 3

LO 4

11. **NPV versus IRR.** Consider the following two mutually exclusive projects:

X

Year	Cash Flow (X)	Cash Flow (Y)
0	−\$15,000	−\$15,000
1	6,800	7,470
2	7,380	7,640
3	4,900	3,810

Sketch the NPV profiles for X and Y over a range of discount rates from zero to 25 percent. What is the crossover rate for these two projects?

LO 3

12. **Problems with IRR.** Howell Petroleum, Inc., is trying to evaluate a generation project with the following cash flows:

Year	Cash Flow
0	−\$35,000,000
1	52,000,000
2	−10,000,000

- If the company requires a 10 percent return on its investments, should it accept this project? Why?
- Compute the IRR for this project. How many IRRs are there? If you apply the IRR decision rule, should you accept the project or not? What's going on here?

- L0 6** 13. **Calculating Profitability Index.** What is the profitability index for the following set of cash flows if the relevant discount rate is 10 percent? What if the discount rate is 15 percent? If it is 22 percent?

Year	Cash Flow
0	−\$28,000
1	15,700
2	13,200
4	9,600

- L0 6** 14. **Problems with Profitability Index.** The Matterhorn Corporation is trying to choose between the following two mutually exclusive design projects:

Year	Cash Flow (I)	Cash Flow (II)
0	−\$72,000	−\$30,000
1	27,000	9,000
2	32,000	19,500
3	38,000	13,500

- If the required return is 11 percent and the company applies the profitability index decision rule, which project should the firm accept?
- If the company applies the NPV decision rule, which project should it take?
- Explain why your answers in (a) and (b) are different.

- L0 1** 15. **Comparing Investment Criteria.** Consider the following two mutually exclusive projects:

L0 3**L0 4****L0 6**

Year	Cash Flow (A)	Cash Flow (B)
0	−\$415,000	−\$35,000
1	49,000	19,400
2	57,000	14,300
3	74,000	13,600
4	530,000	10,400

Whichever project you choose, if any, you require a 13 percent return on your investment.

- If you apply the payback criterion, which investment will you choose? Why?
- If you apply the NPV criterion, which investment will you choose? Why?
- If you apply the IRR criterion, which investment will you choose? Why?
- If you apply the profitability index criterion, which investment will you choose? Why?
- Based on your answers in (a) through (d), which project will you finally choose? Why?

LO 3

LO 4

16. **NPV and IRR.** Higher Ground Company is presented with the following two mutually exclusive projects. The required return for both projects is 15 percent.

Year	Project M	Project N
0	−\$145,000	−\$350,000
1	63,000	155,000
2	81,000	175,000
3	72,000	140,000
4	58,000	105,000

- What is the IRR for each project?
- What is the NPV for each project?
- Which, if either, of the projects should the company accept?

LO 4

LO 6

17. **NPV and Profitability Index.** Dahlia Manufacturing has the following two possible projects. The required return is 12 percent.

Year	Project Y	Project Z
0	−\$27,000	−\$50,000
1	13,000	22,000
2	11,400	21,000
3	13,800	20,000
4	9,400	19,000

- What is the profitability index for each project?
- What is the NPV for each project?
- Which, if either, of the projects should the company accept?

LO 3

18. **Crossover Point.** J. Marcel Enterprises has gathered projected cash flows for two projects. At what interest rate would the company be indifferent between the two projects? Which project is better if the required return is above this interest rate? Why?

Year	Project I	Project J
0	−\$250,000	−\$250,000
1	115,000	85,000
2	103,000	99,000
3	87,000	101,000
4	76,000	108,000

LO 1

LO 3

19. **Payback Period and IRR.** Suppose you have a project with a payback period exactly equal to the life of the project. What do you know about the IRR of the project? Suppose that the payback period is never. What do you know about the IRR of the project now?

LO 4

20. **NPV and Discount Rates.** An investment has an installed cost of \$561,382. The cash flows over the four-year life of the investment are projected to be

\$190,584, \$234,318, \$182,674, and \$150,313. If the discount rate is zero, what is the NPV? If the discount rate is infinite, what is the NPV? At what discount rate is the NPV just equal to zero? Sketch the NPV profile for this investment based on these three points.

L0 1

21. **NPV and Payback Period.** Kaleb Konstruktion, Inc., has the following mutually exclusive projects available. The company has historically used a three-year cutoff for projects. The required return is 10 percent.

L0 4

Year	Project F	Project G
0	−\$125,000	−\$195,000
1	65,000	45,000
2	45,000	60,000
3	55,000	85,000
4	50,000	115,000
5	45,000	130,000

- Calculate the payback period for both projects.
- Calculate the NPV for both projects.
- Which project, if any, should the company accept?

L0 5

22. **MIRR.** Lifeline Corp. is evaluating a project with the following cash flows:

Year	Cash Flow
0	−\$15,000
1	6,100
2	7,300
3	6,900
4	5,700
5	−3,100

The company uses a 10 percent interest rate on all of its projects. Calculate the MIRR of the project using all three methods.

L0 5

23. **MIRR.** Suppose the company in the previous problem uses an 11 percent discount rate and an 8 percent reinvestment rate on all of its projects. Calculate the MIRR of the project using all three methods using these interest rates.

Intermediate
(Questions 23–27)

L0 4

24. **Crossover and NPV.** Seether, Inc., has the following two mutually exclusive projects available.

Year	Project R	Project S
0	−\$75,000	−\$96,000
1	26,000	24,000
2	25,000	24,000
3	23,000	39,000
4	17,000	34,000
5	12,000	13,000

What is the crossover rate for these two projects? What is the NPV of each project at the crossover rate?

L0 3

25. **Calculating IRR.** A project has the following cash flows:

Year	Cash Flow
0	\$65,000
1	−38,000
2	−34,000

What is the IRR for this project? If the required return is 6 percent, should the firm accept the project? What is the NPV of this project? What is the NPV of the project if the required return is 0 percent? 24 percent? What is going on here? Sketch the NPV profile to help you with your answer.

L0 4

L0 6

26. **NPV and the Profitability Index.** If we define the NPV index as the ratio of NPV to cost, what is the relationship between this index and the profitability index?

L0 1

L0 4

L0 6

27. **Cash Flow Intuition.** A project has an initial cost of I , has a required return of R , and pays C annually for N years.

- Find C in terms of I and N such that the project has a payback period just equal to its life.
- Find C in terms of I , N , and R such that this is a profitable project according to the NPV decision rule.
- Find C in terms of I , N , and R such that the project has a benefit-cost ratio of 2.

L0 4

28. **NPV Valuation.** The Yurdone Corporation wants to set up a private cemetery business. According to the CFO, Barry M. Deep, business is “looking up.” As a result, the cemetery project will provide a net cash inflow of \$112,000 for the firm during the first year, and the cash flows are projected to grow at a rate of 5.5 percent per year forever. The project requires an initial investment of \$1,350,000.

- If Yurdone requires a 13 percent return on such undertakings, should the cemetery business be started?
- The company is somewhat unsure about the assumption of a 5.5 percent growth rate in its cash flows. At what constant growth rate would the company just break even if it still required a 13 percent return on its investment?

L0 3

29. **Problems with IRR.** Ashwood Corp. has a project with the following cash flows:

Year	Cash Flow
0	\$35,000
1	−27,000
2	29,000

What is the IRR of the project? What is happening here?

Challenge

(Questions 28–30)

LO 3

- 30. NPV and IRR.** Anderson International Limited is evaluating a project in Erewhon. The project will create the following cash flows:

LO 4

Year	Cash Flow
0	−\$575,000
1	205,000
2	148,000
3	213,000
4	192,000

All cash flows will occur in Erewhon and are expressed in dollars. In an attempt to improve its economy, the Erewhonian government has declared that all cash flows created by a foreign company are “blocked” and must be reinvested with the government for one year. The reinvestment rate for these funds is 4 percent. If Anderson uses a 10 percent required return on this project, what are the NPV and IRR of the project? Is the IRR you calculated the MIRR of the project? Why or why not?

- 8.1 Net Present Value.** You have a project that has an initial cash outflow of −\$20,000 and cash inflows of \$6,000, \$5,000, \$4,000, and \$3,000, respectively, for the next four years. Go to www.datadynamica.com and follow the “Online NPV IRR Calculator” link. Enter the cash flows. If the required return is 12 percent, what is the IRR of the project? The NPV?
- 8.2 Internal Rate of Return.** Using the online calculator from the previous problem, find the IRR for a project with cash flows of −\$500, \$1,200, and −\$400. What is going on here?

**WHAT'S ON
THE WEB?**

CHAPTER CASE

BULLOCK GOLD MINING

Seth Bullock, the owner of Bullock Gold Mining, is evaluating a new gold mine in South Dakota. Dan Dority, the company's geologist, has just finished his analysis of the mine site. He has estimated that the mine would be productive for eight years, after which the gold would be completely mined. Dan has taken an estimate of the gold deposits to Alma Garrett, the company's financial officer. Alma has been asked by Seth to perform an analysis of the new mine and present her recommendation on whether the company should open the new mine.

Alma has used the estimates provided by Dan to determine the revenues that could be expected from the mine. She has also projected the expense of opening the mine and the annual operating expenses. If the company opens the mine, it will cost \$725 million today, and it will have a cash outflow of \$80 million nine years from today in costs associated with closing the mine and reclaiming the area surrounding it. The expected cash flows each year from the mine are shown in the table on this page. Bullock Mining has a 12 percent required return on all of its gold mines. ■

Year	Cash Flow
0	−\$725,000,000
1	90,000,000
2	135,000,000
3	180,000,000
4	245,000,000
5	232,000,000
6	170,000,000
7	120,000,000
8	95,000,000
9	−80,000,000

QUESTIONS

- Construct a spreadsheet to calculate the payback period, internal rate of return, modified internal rate of return, and net present value of the proposed mine.
- Based on your analysis, should the company open the mine?
- Bonus question: Most spreadsheets do not have a built-in formula to calculate the payback period. Write a VBA script that calculates the payback period for a project.

Making Capital Investment Decisions

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Determine the relevant cash flows for a proposed investment.
- LO 2** Analyze a project's projected cash flows.
- LO 3** Evaluate an estimated NPV.

In the summer of 2008, the movie *Speed Racer*, starring Emile Hirsch and Christina Ricci, spun its wheels at the box office. The *Speed Racer* slogan is “Go Speed Racer, Go!”, but critics said “Don’t go (see) *Speed Racer*, Don’t go!” One critic said “the races felt like a drag.” Others were even more harsh, saying the movie was “like spending two hours caroming through a pinball machine” and “a long, dreary, migraine-inducing slog.”

Looking at the numbers, Warner Brothers spent close to \$150 million making the movie, plus millions more for marketing and distribution. Unfortunately for Warner Brothers, *Speed Racer* crashed and burned, pulling in only \$90 million worldwide. In fact, about 4 of 10 movies lose money in theaters, though DVD sales often help the final tally. Of course, there are movies that do quite well. Also in 2008, the Paramount movie *Indiana Jones and the Kingdom of the Crystal Skull* raked in about \$780 million worldwide at a production cost of \$185 million.

Obviously, Warner Brothers didn’t *plan* to lose \$60 or so million on *Speed Racer*, but it happened. As the box office crash of *Speed Racer* shows, projects don’t always go as companies think they will. This chapter explores how this can happen and what companies can do to analyze and possibly avoid these situations.

In broader terms, this chapter follows up on our previous one by delving more deeply into capital budgeting. We have two main tasks. First, recall that in the last chapter, we saw that cash flow estimates are the critical input into a net present value analysis, but we didn’t say very much about where these cash flows come from; so, we will now examine this question in some detail. Our second goal is to learn how to critically examine NPV estimates and, in particular, how to evaluate the sensitivity of NPV estimates to assumptions made about the uncertain future.

So far, we've covered various parts of the capital budgeting decision. Our task in this chapter is to start bringing these pieces together. In particular, we will show you how to "spread the numbers" for a proposed investment or project and, based on those numbers, make an initial assessment about whether or not the project should be undertaken.

In the discussion that follows, we focus on the process of setting up a discounted cash flow analysis. From the last chapter, we know that the projected future cash flows are the key element in such an evaluation. Accordingly, we emphasize working with financial and accounting information to come up with these figures.

In evaluating a proposed investment, we pay special attention to deciding what information is relevant to the decision at hand and what information is not. As we shall see, it is easy to overlook important pieces of the capital budgeting puzzle. We also describe how to go about evaluating the results of our discounted cash flow analysis.

9.1

PROJECT CASH FLOWS: A FIRST LOOK

The effect of taking a project is to change the firm's overall cash flows today and in the future. To evaluate a proposed investment, we must consider these changes in the firm's cash flows and then decide whether or not they add value to the firm. The first (and most important) step, therefore, is to decide which cash flows are relevant and which are not.

Relevant Cash Flows

What is a relevant cash flow for a project? The general principle is simple enough: A relevant cash flow for a project is a change in the firm's overall future cash flow that comes about as a direct consequence of the decision to take that project. Because the relevant cash flows are defined in terms of changes in, or increments to, the firm's existing cash flow, they are called the **incremental cash flows** associated with the project.

The concept of incremental cash flow is central to our analysis, so we will state a general definition and refer back to it as needed:

The incremental cash flows for project evaluation consist of *any and all* changes in the firm's future cash flows that are a direct consequence of taking the project.

This definition of incremental cash flows has an obvious and important corollary: Any cash flow that exists regardless of whether or *not* a project is undertaken is *not* relevant.

The Stand-Alone Principle

In practice, it would be very cumbersome to actually calculate the future total cash flows to the firm with and without a project, especially for a large firm. Fortunately, it is not really necessary to do so. Once we identify the effect of undertaking the proposed project on the firm's cash flows, we need only focus on the project's resulting incremental cash flows. This is called the **stand-alone principle**.

What the stand-alone principle says is that, once we have determined the incremental cash flows from undertaking a project, we can view that project as a kind of "minifirm" with its own future revenues and costs, its own assets, and, of course, its own cash flows. We will then be primarily interested in comparing the cash flows from this minifirm to the cost of acquiring it. An important consequence of this approach is that we will be evaluating the proposed project purely on its own merits, in isolation from any other activities or projects.

incremental cash flows

The difference between a firm's future cash flows with a project and those without the project.

stand-alone principle

The assumption that evaluation of a project may be based on the project's incremental cash flows.

CONCEPT QUESTIONS

- 9.1a** What are the relevant incremental cash flows for project evaluation?
- 9.1b** What is the stand-alone principle?

INCREMENTAL CASH FLOWS

9.2

We are concerned here only with those cash flows that are incremental and that result from a project. Looking back at our general definition, it seems easy enough to decide whether a cash flow is incremental or not. Even so, there are a few situations where mistakes are easy to make. In this section, we describe some of these common pitfalls and how to avoid them.

Sunk Costs

A **sunk cost**, by definition, is a cost we have already paid or have already incurred the liability to pay. Such a cost cannot be changed by the decision today to accept or reject a project. Put another way, the firm will have to pay this cost no matter what. Based on our general definition of incremental cash flow, such a cost is clearly not relevant to the decision at hand. So, we will always be careful to exclude sunk costs from our analysis.

That a sunk cost is not relevant seems obvious given our discussion. Nonetheless, it's easy to fall prey to the sunk cost fallacy. For example, suppose General Milk Company hires a financial consultant to help evaluate whether or not a line of chocolate milk should be launched. When the consultant turns in the report, General Milk objects to the analysis because the consultant did not include the hefty consulting fee as a cost of the chocolate milk project.

Who is correct? By now, we know that the consulting fee is a sunk cost because the consulting fee must be paid whether or not the chocolate milk line is actually launched (this is an attractive feature of the consulting business).

Opportunity Costs

When we think of costs, we normally think of out-of-pocket costs, namely, those that require us to actually spend some amount of cash. An **opportunity cost** is slightly different; it requires us to give up a benefit. A common situation arises where a firm already owns some of the assets a proposed project will be using. For example, we might be thinking of converting an old rustic cotton mill we bought years ago for \$100,000 into “upmarket” condominiums.

If we undertake this project, there will be no direct cash outflow associated with buying the old mill since we already own it. For purposes of evaluating the condo project, should we then treat the mill as “free”? The answer is no. The mill is a valuable resource used by the project. If we didn't use it here, we could do something else with it. Like what? The obvious answer is that, at a minimum, we could sell it. Using the mill for the condo complex thus has an opportunity cost: We give up the valuable opportunity to do something else with it.¹

sunk cost

A cost that has already been incurred and cannot be recouped and therefore should not be considered in an investment decision.

opportunity cost

The most valuable alternative that is given up if a particular investment is undertaken.

¹ Economists sometimes use the acronym *TANSTAAFL*, which is short for “There ain't no such thing as a free lunch,” to describe the fact that only very rarely is something truly free.

There is another issue here. Once we agree that the use of the mill has an opportunity cost, how much should the condo project be charged? Given that we paid \$100,000, it might seem that we should charge this amount to the condo project. Is this correct? The answer is no, and the reason is based on our discussion concerning sunk costs.

The fact that we paid \$100,000 some years ago is irrelevant. That cost is sunk. At a minimum, the opportunity cost that we charge the project is what the mill would sell for today (net of any selling costs) because this is the amount that we give up by using it instead of selling it.

Side Effects

Remember that the incremental cash flows for a project include all the changes in the *firm's* future cash flows. It would not be unusual for a project to have side, or spillover, effects, both good and bad. For example, if the Innovative Motors Company (IMC) introduces a new car, some of the sales might come at the expense of other IMC cars. This is called **erosion**, and the same general problem could occur for any multiline consumer product producer or seller.² In this case, the cash flows from the new line should be adjusted downward to reflect lost profits on other lines.

In accounting for erosion, it is important to recognize that any sales lost as a result of our launching a new product might be lost anyway because of future competition. Erosion is only relevant when the sales would not otherwise be lost.

Net Working Capital

Normally, a project will require that the firm invest in net working capital in addition to long-term assets. For example, a project will generally need some amount of cash on hand to pay any expenses that arise. In addition, a project will need an initial investment in inventories and accounts receivable (to cover credit sales). Some of this financing will be in the form of amounts owed to suppliers (accounts payable), but the firm will have to supply the balance. This balance represents the investment in net working capital.

It's easy to overlook an important feature of net working capital in capital budgeting. As a project winds down, inventories are sold, receivables are collected, bills are paid, and cash balances can be drawn down. These activities free up the net working capital originally invested. So, the firm's investment in project net working capital closely resembles a loan. The firm supplies working capital at the beginning and recovers it towards the end.

Financing Costs

In analyzing a proposed investment, we will not include interest paid or any other financing costs such as dividends or principal repaid, because we are interested in the cash flow generated by the assets of the project. As we mentioned in Chapter 2, interest paid, for example, is a component of cash flow to creditors, not cash flow from assets.

More generally, our goal in project evaluation is to compare the cash flow from a project to the cost of acquiring that project in order to estimate NPV. The particular mixture of debt and equity a firm actually chooses to use in financing a project is a managerial variable and primarily determines how project cash flow is divided between owners and creditors. This is not to say that financing arrangements are unimportant. They are just something to be analyzed separately. We will cover this in later chapters.

erosion

The cash flows of a new project that come at the expense of a firm's existing projects.

² More colorfully, erosion is sometimes called *piracy* or *cannibalism*.

Other Issues

There are some other things to watch out for. First, we are only interested in measuring cash flow. Moreover, we are interested in measuring it when it actually occurs, not when it accrues in an accounting sense. Second, we are always interested in *aftertax* cash flow since taxes are definitely a cash outflow. In fact, whenever we write “incremental cash flows,” we mean aftertax incremental cash flows. Remember, however, that aftertax cash flow and accounting profit, or net income, are entirely different things.

CONCEPT QUESTIONS

- 9.2a** What is a sunk cost? An opportunity cost?
- 9.2b** Explain what erosion is and why it is relevant.
- 9.2c** Explain why interest paid is not a relevant cash flow for project evaluation.

PRO FORMA FINANCIAL STATEMENTS AND PROJECT CASH FLOWS

9.3

The first thing we need when we begin evaluating a proposed investment is a set of pro forma, or projected, financial statements. Given these, we can develop the projected cash flows from the project. Once we have the cash flows, we can estimate the value of the project using the techniques we described in the previous chapter.

Getting Started: Pro Forma Financial Statements

Pro forma financial statements are a convenient and easily understood means of summarizing much of the relevant information for a project. To prepare these statements, we will need estimates of quantities such as unit sales, the selling price per unit, the variable cost per unit, and total fixed costs. We will also need to know the total investment required, including any investment in net working capital.

To illustrate, suppose we think we can sell 50,000 cans of shark attractant per year at a price of \$4.00 per can. It costs us about \$2.50 per can to make the attractant, and a new product such as this one typically has only a three-year life (perhaps because the customer base dwindles rapidly). We require a 20 percent return on new products.

Fixed costs for the project, including such things as rent on the production facility, will run \$12,000 per year. Further, we will need to invest a total of \$90,000 in manufacturing equipment. For simplicity, we will assume that this \$90,000 will be 100 percent depreciated over the three-year life of the project. Furthermore, the cost of removing the equipment will roughly equal its actual value in three years, so it will be essentially worthless on a market value basis as well. Finally, the project will require an initial \$20,000 investment in net working capital. As usual, the tax rate is 34 percent.

In Table 9.1, we organize these initial projections by first preparing the pro forma income statement for each of the three years. Once again, notice that we have *not* deducted any interest expense. This will always be so. As we described earlier, interest paid is a financing expense, not a component of operating cash flow.

We can also prepare a series of abbreviated balance sheets that show the capital requirements for the project as we’ve done in Table 9.2. Here we have net working capital

pro forma financial statements

Financial statements projecting future years’ operations.

TABLE 9.1

Projected income statement, shark attractant project, years 1–3

Sales (50,000 units at \$4.00/unit)	\$200,000
Variable costs (\$2.50/unit)	125,000
Gross profit	\$ 75,000
Fixed costs	12,000
Depreciation (\$90,000/3)	30,000
EBIT	\$ 33,000
Taxes (34%)	11,220
Net income	<u>\$ 21,780</u>

TABLE 9.2

Projected capital requirements, shark attractant project

	Year			
	0	1	2	3
Net working capital	\$ 20,000	\$20,000	\$20,000	\$20,000
Net fixed assets	90,000	60,000	30,000	0
Total investment	<u>\$110,000</u>	<u>\$80,000</u>	<u>\$50,000</u>	<u>\$20,000</u>

of \$20,000 in each year. Fixed assets are \$90,000 at the start of the project's life (year 0), and they decline by the \$30,000 in depreciation each year, ending up at zero. Notice that the total investment given here for future years is the total book, or accounting, value, not market value.

At this point, we need to start converting this accounting information into cash flows. We consider how to do this next.

Project Cash Flows

To develop the cash flows from a project, we need to recall (from Chapter 2) that cash flow from assets has three components: operating cash flow, capital spending, and additions to net working capital. To evaluate a project, or minifirm, we need to arrive at estimates for each of these.

Once we have estimates of the components of cash flow, we will calculate cash flow for our minifirm just as we did in Chapter 2 for an entire firm:

$$\begin{aligned} \text{Project cash flow} &= \text{Project operating cash flow} \\ &\quad - \text{Project change in net working capital} \\ &\quad - \text{Project capital spending} \end{aligned}$$

We consider these components next.

Project Operating Cash Flow To determine the operating cash flow associated with a project, we first need to recall the definition of operating cash flow:

$$\begin{aligned} \text{Operating cash flow} &= \text{Earnings before interest and taxes} \\ &\quad + \text{Depreciation} \\ &\quad - \text{Taxes} \end{aligned}$$

To illustrate the calculation of operating cash flow, we will use the projected information from the shark attractant project. For ease of reference, Table 9.3 repeats the income statement.

Sales	\$200,000
Variable costs	125,000
Fixed costs	12,000
Depreciation	30,000
EBIT	\$ 33,000
Taxes (34%)	11,220
Net income	<u>\$ 21,780</u>

TABLE 9.3

Projected income statement, shark attractant project, years 1–3

EBIT	\$33,000
Depreciation	+ 30,000
Taxes	– 11,220
Operating cash flow	<u>\$51,780</u>

TABLE 9.4

Projected operating cash flow, shark attractant project

	Year			
	0	1	2	3
Operating cash flow		\$51,780	\$51,780	\$51,780
Change in NWC	–\$ 20,000			+20,000
Capital spending	–90,000			
Total project cash flow	<u>–\$110,000</u>	<u>\$51,780</u>	<u>\$51,780</u>	<u>\$71,780</u>

TABLE 9.5

Projected total cash flows, shark attractant project

Given the income statement in Table 9.3, calculating the operating cash flow is very straightforward. As we see in Table 9.4, projected operating cash flow for the shark attractant project is \$51,780.

Project Net Working Capital and Capital Spending We next need to take care of the fixed asset and net working capital requirements. Based on our balance sheets above, the firm must spend \$90,000 up front for fixed assets and invest an additional \$20,000 in net working capital. The immediate outflow is thus \$110,000. At the end of the project's life, the fixed assets will be worthless (the salvage value will be zero), but the firm will recover the \$20,000 that was tied up in working capital. This will lead to a \$20,000 cash *inflow* in the last year.

On a purely mechanical level, notice that whenever we have an investment in net working capital, that same investment has to be recovered; in other words, the same number needs to appear at some time in the future with the opposite sign.

Projected Total Cash Flow and Value

Given the information we've accumulated, we can finish the preliminary cash flow analysis as illustrated in Table 9.5.

Now that we have cash flow projections, we are ready to apply the various criteria we discussed in the last chapter. First, the NPV at the 20 percent required return is:

$$\begin{aligned}\text{NPV} &= -\$110,000 + \$51,780/1.2 + \$51,780/1.2^2 + \$71,780/1.2^3 \\ &= \$10,648\end{aligned}$$

So, based on these projections, the project creates over \$10,000 in value and should be accepted. Also, the return on this investment obviously exceeds 20 percent (since the NPV is positive at 20 percent). After some trial and error, we find that the IRR works out to be about 25.8 percent.

In addition, if required, we could go ahead and calculate the payback and the average accounting return, or AAR. Inspection of the cash flows shows that the payback on this project is just a little over two years (verify that it's about 2.1 years).

From the last chapter, we know that the AAR is average net income divided by average book value. The net income each year is \$21,780. The average (in thousands) of the four book values (from Table 9.2) for total investment is $(\$110 + 80 + 50 + 20)/4 = \65 , so the AAR is $\$21,780/\$65,000 = 33.51$ percent. We've already seen that the return on this investment (the IRR) is about 26 percent. The fact that the AAR is larger illustrates again why the AAR cannot be meaningfully interpreted as the return on a project.

The Tax Shield Approach

A useful variation on our basic definition of operating cash flow (OCF) is the *tax shield* approach. The tax shield definition of OCF is:

$$\text{OCF} = (\text{Sales} - \text{Costs}) \times (1 - T) + \text{Depreciation} \times T$$

where T is the corporate tax rate. Assuming that $T = 34\%$, the OCF works out to be:

$$\begin{aligned}\text{OCF} &= (\$200,000 - 137,000) \times .66 + 30,000 \times .34 \\ &= \$41,580 + 10,200 \\ &= \$51,780\end{aligned}$$

This is just as we had before.

This approach views OCF as having two components. The first part is what the project's cash flow would be if there were no depreciation expense. In this case, this would-have-been cash flow is \$41,580.

The second part of OCF in this approach is the depreciation deduction multiplied by the tax rate. This is called the **depreciation tax shield**. We know that depreciation is a noncash expense. The only cash flow effect of deducting depreciation is to reduce our taxes, a benefit to us. At the current 34 percent corporate tax rate, every dollar in depreciation expense saves us 34 cents in taxes. So, in our example, the \$30,000 depreciation deduction saves us $\$30,000 \times .34 = \$10,200$ in taxes.

The tax shield approach will always give the same answer as our basic approach, so you might wonder why we bother. The answer is that it is sometimes a little simpler to use, particularly for projects that involve cost-cutting.

depreciation tax shield

The tax saving that results from the depreciation deduction, calculated as depreciation multiplied by the corporate tax rate.

CONCEPT QUESTIONS

- 9.3a** What is the definition of project operating cash flow? How does this differ from net income?
- 9.3b** In the shark attractant project, why did we add back the firm's net working capital investment in the final year?
- 9.3c** What is the "depreciation tax shield"?

MORE ON PROJECT CASH FLOW

9.4

In this section, we take a closer look at some aspects of project cash flow. In particular, we discuss project net working capital in more detail. We then examine current tax laws regarding depreciation.

A Closer Look at Net Working Capital

In calculating operating cash flow, we did not explicitly consider the fact that some of our sales might be on credit. Also, we may not have actually paid some of the costs shown. In either case, the cash flow has not yet occurred. We show here that these possibilities are not a problem as long as we don't forget to include additions to net working capital in our analysis. This discussion thus emphasizes the importance and the effect of doing so.

Suppose during a particular year of a project we have the following simplified income statement:

Sales	\$500
Costs	<u>310</u>
Net income	<u>\$190</u>

Depreciation and taxes are zero. No fixed assets are purchased during the year. Also, to illustrate a point, we assume that the only components of net working capital are accounts receivable and payable. The beginning and ending amounts for these accounts are:

	Beginning of Year	End of Year	Change
Accounts receivable	\$880	\$910	+\$30
Accounts payable	<u>550</u>	<u>605</u>	+ 55
Net working capital	<u>\$330</u>	<u>\$305</u>	<u>-\$25</u>

Based on this information, what is total cash flow for the year? We can first just mechanically apply what we have been discussing to come up with the answer. Operating cash flow in this particular case is the same as EBIT since there are no taxes or depreciation and thus equals \$190. Also, notice that net working capital actually *declined* by \$25, so the change in net working capital is negative. This just means that \$25 was freed up during the year. There was no capital spending, so the total cash flow for the year is:

$$\begin{aligned}
 \text{Total cash flow} &= \text{Operating cash flow} - \text{Change in NWC} - \text{Capital spending} \\
 &= \$190 - (-\$25) - 0 \\
 &= \$215
 \end{aligned}$$

Now, we know that this \$215 total cash flow has to be “dollars in” less “dollars out” for the year. We could therefore ask a different question: What were cash revenues for the year? Also, what were cash costs?

To determine cash revenues, we need to look more closely at net working capital. During the year, we had sales of \$500. However, accounts receivable rose by \$30 over the same time period. What does this mean? The \$30 increase tells us that sales exceeded collections by \$30. In other words, we haven't yet received the cash from \$30 of the \$500 in sales. As a result, our cash inflow is $\$500 - \$30 = \$470$. In general, cash income is sales minus the increase in accounts receivable.

Cash outflows can be similarly determined. We show costs of \$310 on the income statement, but accounts payable increased by \$55 during the year. This means that we have not yet paid \$55 of the \$310, so cash costs for the period are just $\$310 - \$55 = \$255$. In other words, in this case, cash costs equal costs less the increase in accounts payable.

Putting this information together, cash inflows less cash outflows is $\$470 - \$255 = \$215$, just as we had before. Notice that:

$$\begin{aligned}
 \text{Cash flow} &= \text{Cash inflow} - \text{Cash outflow} \\
 &= (\$500 - \$30) - (\$310 - \$55) \\
 &= (\$500 - \$310) - (\$30 - \$55) \\
 &= \text{Operating cash flow} - \text{Change in NWC} \\
 &= \$190 - (-\$25) \\
 &= \$215
 \end{aligned}$$

More generally, this example illustrates that including net working capital changes in our calculations has the effect of adjusting for the discrepancy between accounting sales and costs and actual cash receipts and payments.

EXAMPLE 9.1

Cash Collections and Costs

For the year just completed, the Combat Wombat Telestat Co. (CWT) reports sales of \$998 and costs of \$734. You have collected the following beginning and ending balance sheet information:

	Beginning	Ending
Accounts receivable	\$100	\$110
Inventory	100	80
Accounts payable	100	70
Net working capital	\$100	\$120

Based on these figures, what are cash inflows? Cash outflows? What happened to each account? What is net cash flow?

Sales were \$998, but receivables rose by \$10. So, cash collections were \$10 less than sales, or \$988. Costs were \$734, but inventories fell by \$20. This means that we didn't replace \$20 worth of inventory, so costs are actually overstated by this amount. Also, payables fell by \$30. This means that, on a net basis, we actually paid our suppliers \$30 more than we received from them, resulting in a \$30 understatement of costs. Adjusting for these events, cash costs are $\$734 - \$20 + \$30 = \744 . Net cash flow is $\$988 - \$744 = \$244$.

Finally, notice that net working capital increased by \$20 overall. We can check our answer by noting that the original accounting sales less costs of $\$998 - \734 is \$264. In addition, CWT spent \$20 on net working capital, so the net result is a cash flow of $\$264 - \$20 = \$244$, as we calculated.

Accelerated Cost Recovery System (ACRS)

Depreciation method under U.S. tax law allowing for the accelerated write-off of property under various classifications.

Depreciation

As we note elsewhere, accounting depreciation is a noncash deduction. As a result, depreciation has cash flow consequences only because it influences the tax bill. The way that depreciation is computed for tax purposes is thus the relevant method for capital investment decisions. Not surprisingly, the procedures are governed by tax law. We now discuss some specifics of the depreciation system enacted by the Tax Reform Act of 1986. This system is a modification of the **Accelerated Cost Recovery System (ACRS)** instituted in 1981.

Class	Examples
3-year	Equipment used in research
5-year	Autos, computers
7-year	Most industrial equipment

TABLE 9.6

Modified ACRS
property classes

Year	Property Class		
	3-Year	5-Year	7-Year

2	44.45	32.00	24.49
3	14.81	19.20	17.49
4	7.41	11.52	12.49
5		11.52	8.93
6		5.76	8.92
7			8.93
8			4.46

TABLE 9.7

Modified ACRS
depreciation
allowances

Modified ACRS (MACRS) Depreciation Calculating depreciation is normally very mechanical. While there are a number of *ifs*, *ands*, and *buts* involved, the basic idea is that every asset is assigned to a particular class. An asset's class establishes its life for tax purposes. Once an asset's tax life is determined, we compute the depreciation for each year by multiplying the cost of the asset by a fixed percentage. The expected salvage value (what we think the asset will be worth when we dispose of it) and the actual expected economic life (how long we expect the asset to be in service) are not explicitly considered in the calculation of depreciation.

Some typical depreciation classes are described in Table 9.6, and associated percentages (rounded to two decimal places) are shown in Table 9.7. Remember that land cannot be depreciated.

To illustrate how depreciation is calculated, we consider an automobile costing \$12,000. Autos are normally classified as five-year property. Looking at Table 9.7, we see that the relevant figure for the first year of a five-year asset is 20 percent. The depreciation in the first year is thus $\$12,000 \times .20 = \$2,400$. The relevant percentage in the second year is 32 percent, so the depreciation in the second year is $\$12,000 \times .32 = \$3,840$, and so on. We can summarize these calculations as follows:

Year	MACRS Percentage	Depreciation
1	20.00%	$.2000 \times \$12,000 = \$2,400.00$
2	32.00	$.3200 \times 12,000 = 3,840.00$
3	19.20	$.1920 \times 12,000 = 2,304.00$
4	11.52	$.1152 \times 12,000 = 1,382.40$
5	11.52	$.1152 \times 12,000 = 1,382.40$
6	5.76	$.0576 \times 12,000 = 691.20$
	<u>100.00%</u>	<u>\$12,000.00</u>

TABLE 9.8

MACRS book values

Year	Beginning Book Value	Depreciation	Ending Book Value
1	\$12,000.00	\$2,400.00	\$9,600.00
2	9,600.00	3,840.00	5,760.00
3	5,760.00	2,304.00	3,456.00
4	3,456.00	1,382.40	2,073.60
5	2,073.60	1,382.40	691.20
6	691.20	691.20	0.00

Notice that the MACRS percentages sum up to 100 percent. As a result, we write off 100 percent of the cost of the asset, or \$12,000 in this case.

Book Value versus Market Value In calculating depreciation under current tax law, the economic life and future market value of the asset are not an issue. As a result, the book value of an asset can differ substantially from its actual market value. For example, with our \$12,000 car, book value after the first year is \$12,000 less the first year's depreciation of \$2,400, or \$9,600. The remaining book values are summarized in Table 9.8. After six years, the book value of the car is zero.

Suppose we wanted to sell the car after five years. Based on historical averages, it will be worth, say, 25 percent of the purchase price, or $.25 \times \$12,000 = \$3,000$. If we actually sold it for this, then we would have to pay taxes at the ordinary income tax rate on the difference between the sale price of \$3,000 and the book value of \$691.20. For a corporation in the 34 percent bracket, the tax liability is $.34 \times \$2,308.80 = \784.99 .

The reason that taxes must be paid in this case is that the difference in market value and book value is "excess" depreciation, and it must be "recaptured" when the asset is sold. What this means is that, as it turns out, we overdepreciated the asset by $\$3,000 - 691.20 = \$2,308.80$. Since we deducted \$2,308.80 too much in depreciation, we paid \$784.99 too little in taxes, and we simply have to make up the difference.

Notice that this is *not* a tax on a capital gain. As a general (albeit rough) rule, a capital gain only occurs if the market price exceeds the original cost. However, what is and what is not a capital gain is ultimately up to taxing authorities, and the specific rules can be very complex. We will ignore capital gains taxes for the most part.

Finally, if the book value exceeds the market value, then the difference is treated as a loss for tax purposes. For example, if we sell the car after two years for \$4,000, then the book value exceeds the market value by \$1,760. In this case, a tax saving of $.34 \times \$1,760 = \598.40 occurs.

EXAMPLE 9.2

MACRS Depreciation

The Staple Supply Co. has just purchased a new computerized information system with an installed cost of \$160,000. The computer is treated as five-year property. What are the yearly depreciation allowances? Based on historical experience, we think that the system will be worth only \$10,000 when we get rid of it in four years. What are the tax consequences of the sale? What is the total aftertax cash flow from the sale?

The yearly depreciation allowances are calculated by just multiplying \$160,000 by the five-year percentages in Table 9.7:

(continued)

Year	MACRS Percentage	Depreciation	Ending Book Value
1	20.00%	$.2000 \times \$160,000 = \$32,000$	\$128,000
2	32.00	$.3200 \times 160,000 = 51,200$	76,800
3	19.20	$.1920 \times 160,000 = 30,720$	46,080
4	11.52	$.1152 \times 160,000 = 18,432$	27,648
5	11.52	$.1152 \times 160,000 = 18,432$	9,216
6	5.76	$.0576 \times 160,000 = 9,216$	0
	<u>100.00%</u>	<u>\$160,000</u>	

Notice that we have also computed the book value of the system as of the end of each year. The book value at the end of Year 4 is \$27,648. If we sell the system for \$10,000 at that time, we will have a loss of \$17,648 (the difference) for tax purposes. This loss, of course, is like depreciation because it isn't a cash expense.

What really happens? Two things. First: We get \$10,000 from the buyer. Second: We save $.34 \times \$17,648 = \$6,000$ in taxes. So, the total aftertax cash flow from the sale is a \$16,000 cash inflow.

An Example: The Majestic Mulch and Compost Company (MMCC)

At this point, we want to go through a somewhat more involved capital budgeting analysis. Keep in mind as you read that the basic approach here is exactly the same as that in the shark attractant example above. We have only added some more “real-world” detail (and a lot more numbers).

MMCC is investigating the feasibility of a new line of power mulching tools aimed at the growing number of home composters. Based on exploratory conversations with buyers for large garden shops, it projects unit sales as follows:

Year	Unit Sales
1	3,000
2	5,000
3	6,000
4	6,500
5	6,000
6	5,000
7	4,000
8	3,000

The new power mulcher will be priced to sell at \$120 per unit to start. When the competition catches up after three years, however, MMCC anticipates that the price will drop to \$110.

The power mulcher project will require \$20,000 in net working capital at the start. Subsequently, total net working capital at the end of each year will be about 15 percent of sales for that year. The variable cost per unit is \$60, and total fixed costs are \$25,000 per year.

It will cost about \$800,000 to buy the equipment necessary to begin production. This investment is primarily in industrial equipment and thus qualifies as seven-year MACRS property. The equipment will actually be worth about 20 percent of its cost in eight years, or $.20 \times \$800,000 = \$160,000$. The relevant tax rate is 34 percent, and the required return is 15 percent. Based on this information, should MMCC proceed?

TABLE 9.9

Projected revenues,
power mulcher
project

Year	Unit Price	Unit Sales	Revenues
1	\$120	3,000	\$360,000
2	120	5,000	600,000
3	120	6,000	720,000
4	110	6,500	715,000
5	110	6,000	660,000
6	110	5,000	550,000
7	110	4,000	440,000
8	110	3,000	330,000

TABLE 9.10

Annual depreciation,
power mulcher
project

Year	MACRS Percentage	Depreciation	Ending Book Value
1	14.29%	$.1429 \times \$800,000 = \$114,320$	\$685,680
2	24.49	$.2449 \times 800,000 = 195,920$	489,760
3	17.49	$.1749 \times 800,000 = 139,920$	349,840
4	12.49	$.1249 \times 800,000 = 99,920$	249,920
5	8.93	$.0893 \times 800,000 = 71,440$	178,480
6	8.92	$.0892 \times 800,000 = 71,360$	107,120
7	8.93	$.0893 \times 800,000 = 71,440$	35,680
8	4.46	$.0446 \times 800,000 = 35,680$	0
	<u>100.00%</u>	<u>\$800,000</u>

Fixed costs	25,000	25,000	25,000	25,000	25,000	25,000	25,000	25,000
Depreciation	114,320	195,920	139,920	99,920	71,440	71,360	71,440	35,680
EBIT	\$ 40,680	\$ 79,080	\$195,080	\$200,080	\$203,560	\$153,640	\$103,560	\$ 89,320
Taxes (34%)	13,831	26,887	66,327	68,027	69,210	52,238	35,210	30,369
Net income	<u>\$ 26,849</u>	<u>\$ 52,193</u>	<u>\$128,753</u>	<u>\$132,053</u>	<u>\$134,350</u>	<u>\$101,402</u>	<u>\$ 68,350</u>	<u>\$ 58,951</u>

Operating Cash Flows There is a lot of information here that we need to organize. The first thing we can do is calculate projected sales. Sales in the first year are projected at 3,000 units at \$120 apiece, or \$360,000 total. The remaining figures are shown in Table 9.9.

Next, we compute the depreciation on the \$800,000 investment in Table 9.10. With this information, we can prepare the pro forma income statements, as shown in Table 9.11. From here, computing the operating cash flows is straightforward. The results are illustrated in the first part of Table 9.13 (on page 282).

Year	Revenues	Net Working Capital	Cash Flow
0		\$ 20,000	–\$20,000
1	\$360,000	54,000	–34,000
2	600,000	90,000	–36,000
3	720,000	108,000	–18,000
4	715,000	107,250	750
5	660,000	99,000	8,250
6	550,000	82,500	16,500
7	440,000	66,000	16,500
8	330,000	49,500	16,500

TABLE 9.12

Changes in net working capital, power mulcher project

Changes in NWC Now that we have the operating cash flows, we need to determine the changes in NWC. By assumption, net working capital requirements change as sales change. In each year, we will generally either add to or recover some of our project net working capital. Recalling that NWC starts out at \$20,000 and then rises to 15 percent of sales, we can calculate the amount of NWC for each year as illustrated in Table 9.12.

As illustrated, during the first year, net working capital grows from \$20,000 to $.15 \times \$360,000 = \$54,000$. The increase in net working capital for the year is thus $\$54,000 - 20,000 = \$34,000$. The remaining figures are calculated the same way.

Remember that an increase in net working capital is a cash outflow, so we use a negative sign in this table to indicate an additional investment that the firm makes in net working capital. A positive sign represents net working capital returning to the firm. Thus, for example, \$16,500 in NWC flows back to the firm in Year 6. Over the project's life, net working capital builds to a peak of \$108,000 and declines from there as sales begin to drop off.

We show the result for changes in net working capital in the second part of Table 9.13. Notice that at the end of the project's life there is \$49,500 in net working capital still to be recovered. Therefore, in the last year, the project returns \$16,500 of NWC during the year and then returns the remaining \$49,500 at the end of the year for a total of \$66,000.

Capital Spending Finally, we have to account for the long-term capital invested in the project. In this case, we invest \$800,000 at Year 0. By assumption, this equipment will be worth \$160,000 at the end of the project. It will have a book value of zero at that time. As we discussed above, this \$160,000 excess of market value over book value is taxable, so the aftertax proceeds will be $\$160,000 \times (1 - .34) = \$105,600$. These figures are shown in the third part of Table 9.13.

Total Cash Flow and Value We now have all the cash flow pieces, and we put them together in Table 9.14. In addition to the total project cash flows, we have calculated the cumulative cash flows. At this point, it's essentially plug-and-chug to calculate the net present value, internal rate of return, and payback.

If we sum the discounted cash flows and the initial investment, the net present value (at 15 percent) works out to be \$65,485. This is positive; so, based on these preliminary projections, the power mulcher project is acceptable. The internal, or DCF, rate of return is greater than 15 percent since the NPV is positive. It works out to be 17.24 percent, again, indicating that the project is acceptable.

Looking at the cumulative cash flows, we see that the project has almost paid back after four years since the cumulative cash flow is almost zero at that time. As indicated, the fractional year works out to be $\$17,322/\$214,040 = .08$, so the payback is 4.08 years. We can't say whether or not this is good since we don't have a benchmark for MMCC. This is the usual problem with payback periods.

TABLE 9.13 Projected cash flows, power mulcher project

	Year								
	0	1	2	3	4	5	6	7	8
I. Operating Cash Flow									
EBIT		\$ 40,680	\$ 79,080	\$195,080	\$200,080	\$203,560	\$153,640	\$103,560	\$ 89,320
Depreciation		114,320	195,920	139,920	99,920	71,440	71,360	71,440	35,680
Taxes		– 13,831	– 26,887	– 66,327	– 68,027	– 69,210	– 52,238	– 35,210	– 30,369
Operating cash flow		\$141,169	\$248,113	\$268,673	\$231,973	\$205,790	\$172,762	\$139,790	\$ 94,631
II. Net Working Capital									
Initial NWC	–\$ 20,000								
Increases in NWC		–\$ 34,000	–\$ 36,000	–\$ 18,000	\$ 750	\$ 8,250	\$ 16,500	\$ 16,500	\$ 16,500
NWC recovery									49,500
Changes in NWC	–\$ 20,000	–\$ 34,000	–\$ 36,000	–\$ 18,000	\$ 750	\$ 8,250	\$ 16,500	\$ 16,500	\$ 66,000
III. Capital Spending									
Initial outlay	–\$800,000								
Aftertax salvage									\$105,600
Capital spending	–\$800,000								\$105,600

TABLE 9.14 Projected total cash flows, power mulcher project

	Year								
	0	1	2	3	4	5	6	7	8
Operating cash flow		\$141,169	\$248,113	\$268,673	\$231,973	\$205,790	\$172,762	\$139,790	\$ 94,631
Changes in NWC	–\$ 20,000	– 34,000	– 36,000	– 18,000	750	8,250	16,500	16,500	66,000
Capital spending	– 800,000								105,600
Total project cash flow	<u>–\$820,000</u>	<u>\$107,169</u>	<u>\$212,113</u>	<u>\$250,673</u>	<u>\$232,723</u>	<u>\$214,040</u>	<u>\$189,262</u>	<u>\$156,290</u>	<u>\$266,231</u>
Cumulative cash flow	–\$820,000	–\$712,831	–\$500,718	–\$250,046	–\$ 17,323	\$196,717	\$385,979	\$542,269	\$808,500

Net present value (15%) = \$65,485

Internal rate of return = 17.24%

Payback = 4.08 years

Conclusion

This completes our preliminary DCF analysis. Where do we go from here? If we have a great deal of confidence in our projections, then there is no further analysis to be done. We should begin production and marketing immediately. It is unlikely that this will be the case. It is important to remember that the result of our analysis is an estimate of NPV, and we will usually have less than complete confidence in our projections. This means we have more work to do. In particular, we will almost surely want to spend some time evaluating the quality of our estimates. We will take up this subject in the next several sections.

CONCEPT QUESTIONS

- 9.4a** Why is it important to consider changes in net working capital in developing cash flows? What is the effect of doing so?
- 9.4b** How is depreciation calculated for fixed assets under current tax law? What effect do expected salvage value and estimated economic life have on the calculated depreciation deduction?

EVALUATING NPV ESTIMATES

9.5

As we discussed in Chapter 8, an investment has a positive net present value if its market value exceeds its cost. Such an investment is desirable because it creates value for its owner. The primary problem in identifying such opportunities is that most of the time we can't actually observe the relevant market value. Instead, we estimate it. Having done so, it is only natural to wonder whether or not our estimates are at least close to the true values. We consider this question next.

The Basic Problem

Suppose we are working on a preliminary DCF analysis along the lines we described in previous sections. We carefully identify the relevant cash flows, avoiding such things as sunk costs, and we remember to consider working capital requirements. We add back any depreciation; we account for possible erosion; and we pay attention to opportunity costs. Finally, we double-check our calculations, and, when all is said and done, the bottom line is that the estimated NPV is positive.

Now what? Do we stop here and move on to the next proposal? Probably not. The fact that the estimated NPV is positive is definitely a good sign, but, more than anything, this tells us that we need to take a closer look.

If you think about it, there are two circumstances under which a discounted cash flow analysis could lead us to conclude that a project has a positive NPV. The first possibility is that the project really does have a positive NPV. That's the good news. The bad news is the second possibility: A project may appear to have a positive NPV because our estimate is inaccurate.

Notice that we could also err in the opposite way. If we conclude that a project has a negative NPV when the true NPV is positive, then we lose a valuable opportunity.

When Things Go Wrong . . .

If you think about it, the decision by a company to acquire another company is a capital budgeting decision. One important difference, however, is that an acquisition may be more expensive than a typical project, and possibly much more expensive. Of course, as with any other project, acquisitions can fail. When they do, the losses can be huge.

In 2008, Bank of America (BOA) appeared to have made two such financial mistakes. In July, BOA acquired Countrywide Financial for \$4 billion. Countrywide became the symbol for loose lending and risky mortgages when the housing market began to falter in 2007. These practices affected the ability of Countrywide to continue as a stand-alone business. At that point, BOA stepped in with the purchase, evidently believing there was still value in the company. But was there? BOA was expected to ultimately absorb about \$30 billion in losses related to the purchase. And given the damage done to Countrywide's reputation, it wasn't surprising that BOA changed the Countrywide name to Bank of America Home Loans in April 2009.

The other BOA acquisition that appears to have been problematic is the \$50 billion purchase of struggling brokerage giant Merrill Lynch. When BOA shareholders voted in December 2008 to do the deal, Merrill Lynch had lost about \$13 billion in October and November of that year. By the time the merger took place in January 2009, the final total for the fourth quarter amounted to

about \$16 billion. BOA had to request an additional \$20 billion in government assistance to deal with the unanticipated losses (on top of the \$25 billion the company had received in 2008). Even with this money, S&P lowered BOA's credit rating to A, with indications that the rating could be lowered even further. Further controversy erupted in 2009 over whether BOA's management had adequately informed shareholders of the potential risks associated with the acquisition.

One of the largest acquisitions in U.S. history was America Online's (AOL) purchase of Time Warner in 2001. AOL purchased Time Warner under the assumption that AOL was part of the "new economy" and primed for fast growth. Time Warner was the "old" communications company, owning cable stations and a music label, among other things. But things didn't work as well as planned. Infighting among employees from the two companies hurt production and morale. In 2002, accounting irregularities were uncovered at AOL, and, as a result of the acquisition costs, the company was saddled with massive debt. To make matters worse, AOL began to lose customers and money. Although AOL was the acquirer, and once dominant partner, things got so bad at AOL that the company changed its name back to Time Warner. To cap things off, in 2002, Time Warner wrote off a stunning \$54 billion in assets associated with the acquisition, which was at the time the largest such write-off in history.

Forecasting Risk

The key inputs into a DCF analysis are projected future cash flows. If these projections are seriously in error, then we have a classic GIGO, or garbage-in, garbage-out, system. In this case, no matter how carefully we arrange the numbers and manipulate them, the resulting answer can still be grossly misleading. This is the danger in using a relatively sophisticated technique like DCF. It is sometimes easy to get caught up in number crunching and forget the underlying nuts-and-bolts economic reality.

The possibility that we will make a bad decision because of errors in the projected cash flows is called **forecasting risk** (or *estimation risk*). Because of forecasting risk, there is the danger that we will think a project has a positive NPV when it really does not. How is this possible? It occurs if we are overly optimistic about the future, and, as a result, our projected cash flows don't realistically reflect the possible future cash flows. Our nearby *Reality Bytes* box shows what can happen in such cases.

So far, we have not explicitly considered what to do about the possibility of errors in our forecasts, so our goal is to develop some tools that will be useful in identifying areas where potential errors exist and where they might be especially damaging. In one form or another, we will be trying to assess the economic "reasonableness" of our estimates. We will also be wondering how much damage will be done by errors in those estimates.

Sources of Value

The first line of defense against forecasting risk is simply to ask: What is it about this investment that leads to a positive NPV? We should be able to point to something specific as the source of value. For example, if the proposal under consideration involved a new

forecasting risk

The possibility that errors in projected cash flows will lead to incorrect decisions. Also estimation risk.

product, then we might ask questions such as the following: Are we certain that our new product is significantly better than that of the competition? Can we truly manufacture at lower cost, or distribute more effectively, or identify undeveloped market niches, or gain control of a market?

These are just a few of the potential sources of value. There are many others. A key factor to keep in mind is the degree of competition in the market. It is a basic principle of economics that positive NPV investments will be rare in a highly competitive environment. Therefore, proposals that appear to show significant value in the face of stiff competition are particularly troublesome, and the likely reaction of the competition to any innovations must be closely examined.

The point to remember is that positive NPV investments are probably not all that common, and the number of positive NPV projects is almost certainly limited for any given firm. If we can't articulate some sound economic basis for thinking ahead of time that we have found something special, then the conclusion that our project has a positive NPV should be viewed with some suspicion.

CONCEPT QUESTIONS

9.5a What is forecasting risk? Why is it a concern for the financial manager?

9.5b What are some potential sources of value in a new project?

SCENARIO AND OTHER WHAT-IF ANALYSES

9.6

Our basic approach to evaluating cash flow and NPV estimates involves asking what-if questions. Accordingly, we discuss some organized ways of going about a what-if analysis. Our goal in doing so is to assess the degree of forecasting risk and to identify those components most critical to the success or failure of an investment.

Getting Started

We are investigating a new project. Naturally, the first thing we do is estimate NPV based on our projected cash flows. We will call this the *base case*. Now, however, we recognize the possibility of error in those cash flow projections. After completing the base case, we thus wish to investigate the impact of different assumptions about the future on our estimates.

One way to organize this investigation is to put an upper and lower bound on the various components of the project. For example, suppose we forecast sales at 100 units per year. We know this estimate may be high or low, but we are relatively certain it is not off by more than 10 units in either direction. We would thus pick a lower bound of 90 and an upper bound of 110. We go on to assign such bounds to any other cash flow components we are unsure about.

When we pick these upper and lower bounds, we are not ruling out the possibility that the actual values could be outside this range. What we are saying, loosely speaking, is that it is unlikely that the true average (as opposed to our estimated average) of the possible values is outside this range.

An example is useful to illustrate the idea here. The project under consideration costs \$200,000, has a five-year life, and has no salvage value. Depreciation is straight-line to zero. The required return is 12 percent, and the tax rate is 34 percent. In addition, we have compiled the following information:

	Base Case	Lower Bound	Upper Bound
Unit sales	6,000	5,500	6,500
Price per unit	\$80	\$75	\$85
Variable cost per unit	\$60	\$58	\$62
Fixed costs per year	\$50,000	\$45,000	\$55,000

With this information, we can calculate the base-case NPV by first calculating net income:

Sales	\$480,000
Variable costs	360,000
Fixed costs	50,000
Depreciation	40,000
EBIT	\$ 30,000
Taxes (34%)	10,200
Net income	<u>\$ 19,800</u>

Operating cash flow is thus $\$30,000 + 40,000 - 10,200 = \$59,800$ per year. At 12 percent, the five-year annuity factor is 3.6048, so the base-case NPV is:

$$\begin{aligned}\text{Base-case NPV} &= -\$200,000 + 59,800 \times 3.6048 \\ &= \$15,567\end{aligned}$$

Thus, the project looks good so far.

Scenario Analysis

scenario analysis

The determination of what happens to NPV estimates when we ask what-if questions.

The basic form of what-if analysis is called **scenario analysis**. What we do is investigate the changes in our NPV estimates that result from asking questions like: “What if unit sales realistically should be projected at 5,500 units instead of 6,000?”

Once we start looking at alternative scenarios, we might find that most of the plausible ones result in positive NPVs. In this case, we have some confidence in proceeding with the project. If a substantial percentage of the scenarios look bad, then the degree of forecasting risk is high and further investigation is in order.

There are a number of possible scenarios we could consider. A good place to start is with the worst-case scenario. This will tell us the minimum NPV of the project. If this is positive, we will be in good shape. While we are at it, we will go ahead and determine the other extreme, the best case. This puts an upper bound on our NPV.

To get the worst case, we assign the least favorable value to each item. This means *low* values for items such as units sold and price per unit and *high* values for costs. We do the reverse for the best case. For our project, these values would be:

	Worst Case	Best Case
Unit sales	5,500	6,500
Price per unit	\$75	\$85
Variable cost per unit	\$62	\$58
Fixed costs	\$55,000	\$45,000

With this information, we can calculate the net income and cash flows under each scenario (check these for yourself):

Scenario	Net Income	Cash Flow	Net Present Value	IRR
Base case	\$19,800	\$59,800	\$15,567	15.1%
Worst case*	−15,510	24,490	−111,719	−14.4
Best case	59,730	99,730	159,504	40.9

* We assume a tax credit is created in our worst-case scenario.

What we learn is that under the worst scenario, the cash flow is still positive at \$24,490. That's good news. The bad news is that the return is −14.4 percent in this case, and the NPV is −\$111,719. Since the project costs \$200,000, we stand to lose a little more than half of the original investment under the worst possible scenario. The best case offers an attractive 41 percent return.

The terms *best case* and *worst case* are very commonly used, and we will stick with them, but we should note that they are somewhat misleading. The absolutely best thing that could happen would be something absurdly unlikely, such as launching a new diet soda and subsequently learning that our (patented) formulation also just happens to cure the common cold. Similarly, the true worst case would involve some incredibly remote possibility of total disaster. We're not claiming that these things don't happen; once in a while they do. Some products, such as personal computers, succeed beyond the wildest of expectations, and some, such as asbestos, turn out to be absolute catastrophes. Instead, our point is that in assessing the reasonableness of an NPV estimate, we need to stick to cases that are reasonably likely to occur.

Instead of *best* and *worst*, then, it is probably more accurate to say *optimistic* and *pessimistic*. In broad terms, if we were thinking about a reasonable range for, say, unit sales, then what we call the best case would correspond to something near the upper end of that range. The worst case would simply correspond to the lower end. Of course, when things go really well, even the best-case estimates may not be good enough. For example, when Amazon.com delayed the release of its electronic book reader, Kindle, it appeared to be bad news for the company. However, after the product was mentioned on the television show *Oprah*, sales skyrocketed, and the company was unable to meet the demand. In late November 2008, the company announced that it would take 11 to 13 weeks to ship a Kindle, which meant new orders would not arrive in time for Christmas, thereby costing Amazon significant revenues.

As we have mentioned, there are an unlimited number of different scenarios that we could examine. At a minimum, we might want to investigate two intermediate cases by going halfway between the base amounts and the extreme amounts. This would give us five scenarios in all, including the base case.

Beyond this point, it is hard to know when to stop. As we generate more and more possibilities, we run the risk of “paralysis of analysis.” The difficulty is that no matter how many scenarios we run, all we can learn are possibilities, some good and some bad. Beyond that, we don't get any guidance as to what to do. Scenario analysis is thus useful in telling us what can happen and in helping us gauge the potential for disaster, but it does not tell us whether or not to take the project.

Sensitivity Analysis

Sensitivity analysis is a variation on scenario analysis that is useful in pinpointing the areas where forecasting risk is especially severe. The basic idea with a sensitivity analysis is to freeze all of the variables except one and then see how sensitive our estimate of NPV

sensitivity analysis

Investigation of what happens to NPV when only one variable is changed.

is to changes in that one variable. If our NPV estimate turns out to be very sensitive to relatively small changes in the projected value of some component of project cash flow, then the forecasting risk associated with that variable is high.

To illustrate how sensitivity analysis works, we go back to our base case for every item except unit sales. We can then calculate cash flow and NPV using the largest and smallest unit sales figures.

Scenario	Unit Sales	Cash Flow	Net Present Value	IRR
Base case	6,000	\$59,800	\$15,567	15.1%
Worst case	5,500	53,200	-8,226	10.3
Best case	6,500	66,400	39,357	19.7

The results of our sensitivity analysis for unit sales can be illustrated graphically as in Figure 9.1. Here we place NPV on the vertical axis and unit sales on the horizontal axis. When we plot the combinations of unit sales versus NPV, we see that all possible combinations fall on a straight line. The steeper the resulting line is, the greater is the sensitivity of the estimated NPV to the projected value of the variable being investigated.

By way of comparison, we now freeze everything except fixed costs and repeat the analysis:

Scenario	Fixed Costs	Cash Flow	Net Present Value	IRR
Base case	\$50,000	\$59,800	\$15,567	15.1%
Worst case	55,000	56,500	3,670	12.7
Best case	45,000	63,100	27,461	17.4

What we see here is that, given our ranges, the estimated NPV of this project is more sensitive to projected unit sales than it is to projected fixed costs. In fact, under the worst case for fixed costs, the NPV is still positive.

FIGURE 9.1

Sensitivity analysis
for unit sales

As we have illustrated, sensitivity analysis is useful in pinpointing those variables that deserve the most attention. If we find that our estimated NPV is especially sensitive to a variable that is difficult to forecast (such as unit sales), then the degree of forecasting risk is high. We might decide that further market research would be a good idea in this case.

Because sensitivity analysis is a form of scenario analysis, it suffers from the same drawbacks. Sensitivity analysis is useful for pointing out where forecasting errors will do the most damage, but it does not tell us what to do about possible errors.

CONCEPT QUESTIONS

9.6a What are scenario and sensitivity analyses?

9.6b What are the drawbacks to what-if analyses?

ADDITIONAL CONSIDERATIONS IN CAPITAL BUDGETING

9.7

Our final task for this chapter is a brief discussion of two additional considerations in capital budgeting: managerial options and capital rationing. Both of these can be very important in practice, but, as we will see, explicitly dealing with either of them is difficult.

Managerial Options and Capital Budgeting

In our capital budgeting analysis thus far, we have more or less ignored the possibility of future managerial actions. Implicitly, we have assumed that once a project is launched, its basic features cannot be changed. For this reason, we say that our analysis is *static* (as opposed to dynamic).

In reality, depending on what actually happens in the future, there will always be ways to modify a project. We will call these opportunities **managerial options**. Because they involve real (as opposed to financial) assets, such options are often called “real” options. There are a great number of these options. The way a product is priced, manufactured, advertised, and produced can all be changed, and these are just a few of the possibilities. We discuss some of the most important managerial options in the next few sections.

managerial options

Opportunities that managers can exploit if certain things happen in the future. Also known as “real” options.

Contingency Planning The various what-if procedures in this chapter have another use. We can also view them as primitive ways of exploring the dynamics of a project and investigating managerial options. What we think about in this case are some of the possible futures that could come about and what actions we might take if they do.

For example, we might find that a project fails to break even when sales drop below 10,000 units. This is a fact that is interesting to know, but the more important thing is to then go on and ask “What actions are we going to take if this actually occurs?” This is called **contingency planning**, and it amounts to an investigation of some of the managerial options implicit in a project.

contingency planning

Taking into account the managerial options implicit in a project.

There is no limit to the number of possible futures, or contingencies, that we could investigate. However, there are some broad classes, and we consider these next.

The option to expand One particularly important option we have not explicitly addressed is the option to expand. If we truly find a positive NPV project, then there is an obvious consideration: Can we expand the project or repeat it to get an even larger NPV? Our static analysis implicitly assumes that the scale of the project is fixed.

For example, if the sales demand for a particular product were to greatly exceed expectations, we might investigate increasing production. If this were not feasible for some reason, then we could always increase cash flow by raising the price. Either way, the potential cash flow is higher than we have indicated because we have implicitly assumed that no expansion or price increase is possible. Overall, because we ignore the option to expand in our analysis, we *underestimate* NPV (all other things being equal).

The option to abandon At the other extreme, the option to scale back or even abandon a project is also quite valuable. For example, if a project does not even cover its own expenses, we might be better off if we just abandoned it. Our DCF analysis implicitly assumes that we would keep operating even in this case.

In reality, if sales demand were significantly below expectations, we might be able to sell off some capacity or put it to another use. Maybe the product or service could be redesigned or otherwise improved. Regardless of the specifics, we once again *underestimate* NPV if we assume that the project must last for some fixed number of years, no matter what happens in the future.

The option to wait Implicitly, we have treated proposed investments as if they were “go or no-go” decisions. Actually, there is a third possibility. The project can be postponed, perhaps in hope of more favorable conditions. We call this the option to wait.

For example, suppose an investment costs \$120 and has a perpetual cash flow of \$10 per year. If the discount rate is 10 percent, then the NPV is $\$10/.10 - 120 = -\20 , so the project should not be undertaken now. However, this does not mean that we should forget about the project forever, because in the next period, the appropriate discount rate could be different. If it fell to, say, 5 percent, then the NPV would be $\$10/.05 - 120 = \80 , and we would take the project.

More generally, as long as there is some possible future scenario under which a project has a positive NPV, then the option to wait is valuable.

To illustrate some of these ideas, consider the case of Euro Disney. The deal to open Euro Disney occurred in 1987, and the park opened its doors outside of Paris in 1992. Disney’s management thought Europeans would go goofy over the new park, but trouble soon began. The number of visitors never met expectations, in part because the company priced tickets too high. Disney also decided not to serve alcohol in a country that was accustomed to wine with meals. French labor inspectors fought Disney’s strict dress codes, and so on.

After several years of operations, the park began serving wine in its restaurants, lowered ticket prices, and made other adjustments. In other words, management exercised its option to reformulate the product. The park began to make a small profit. Then, the company exercised the option to expand by adding a “second gate,” which was another theme park next to Euro Disney named Walt Disney Studios. The second gate was intended to encourage visitors to extend their stays. But the new park flopped. The reasons ranged from high ticket prices, attractions geared toward Hollywood rather than European filmmaking, labor strikes in Paris, and a summer heat wave.

By the summer of 2003, Euro Disney was close to bankruptcy again. Executives discussed a variety of options. These options ranged from letting the company go broke (the option to abandon) to pulling the Disney name from the park. In 2005, the company finally agreed to a restructuring with the help of the French government.

After all the changes made at Euro Disney, the park appears to be gaining momentum. During 2008, the park had a record 15.3 million visitors, and its revenue jumped 9 percent. The park lost \$3.7 million for the year, an improvement from the \$46.6 million loss the previous year.

Disney hopes to leverage the lessons learned to its other theme parks around the world. Hong Kong Disneyland fell 400,000 visitors short of its 5.6 million target for 2008. And Disney was still planning expansion. In January 2009, it announced an agreement with the Shanghai municipal government to submit a proposal to the Chinese government for a \$3.59 billion theme park to be near Shanghai.

The whole idea of managerial options was summed up aptly by Jay Rasulo, the overseer of Disney's theme parks, when he said: "One thing we know for sure is that you never get it 100 percent right the first time. We open every one of our parks with the notion that we're going to add content."

Strategic Options Companies sometimes undertake new projects just to explore possibilities and evaluate potential future business strategies. This is a little like testing the water by sticking a toe in before diving. Such projects are difficult to analyze using conventional DCF methods because most of the benefits come in the form of **strategic options**, that is, options for future, related business moves. Projects that create such options may be very valuable, but that value is difficult to measure. Research and development, for example, is an important and valuable activity for many firms precisely because it creates options for new products and procedures.

strategic options

Options for future, related business products or strategies.

To give another example, a large manufacturer might decide to open a retail outlet as a pilot study. The primary goal is to gain some market insight. Because of the high start-up costs, this one operation won't break even. However, based on the sales experience from the pilot, we can then evaluate whether or not to open more outlets, to change the product mix, to enter new markets, and so on. The information gained and the resulting options for actions are all valuable, but coming up with a reliable dollar figure is probably not feasible.

Conclusion We have seen that incorporating options into capital budgeting analysis is not easy. What can we do about them in practice? The answer is that we can only keep them in the back of our minds as we work with the projected cash flows. We will tend to underestimate NPV by ignoring options. The damage might be small for a highly structured, very specific proposal, but it might be great for an exploratory one.

Capital Rationing

Capital rationing is said to exist when we have profitable (positive NPV) investments available but we can't get the needed funds to undertake them. For example, as division managers for a large corporation, we might identify \$5 million in excellent projects, but find that, for whatever reason, we can spend only \$2 million. Now what? Unfortunately, for reasons we will discuss, there may be no truly satisfactory answer.

capital rationing

The situation that exists if a firm has positive NPV projects but cannot obtain the necessary financing.

Soft Rationing The situation we have just described is **soft rationing**. This occurs when, for example, different units in a business are allocated some fixed amount of money each year for capital spending. Such an allocation is primarily a means of controlling and keeping track of overall spending. The important thing about soft rationing is that the corporation as a whole isn't short of capital; more can be raised on ordinary terms if management so desires.

soft rationing

The situation that occurs when units in a business are allocated a certain amount of financing for capital budgeting.

If we face soft rationing, the first thing to do is try and get a larger allocation. Failing that, one common suggestion is to generate as large a net present value as possible within the existing budget. This amounts to choosing those projects with the largest benefit-cost ratio (profitability index).

Strictly speaking, this is the correct thing to do only if the soft rationing is a one-time event; that is, it won't exist next year. If the soft rationing is a chronic problem, then something is amiss. The reason goes all the way back to Chapter 1. Ongoing soft rationing

means we are constantly bypassing positive NPV investments. This contradicts our goal of the firm. If we are not trying to maximize value, then the question of which projects to take becomes ambiguous because we no longer have an objective goal in the first place.

hard rationing

The situation that occurs when a business cannot raise financing for a project under any circumstances.

Hard Rationing With **hard rationing**, a business cannot raise capital for a project under any circumstances. For large, healthy corporations, this situation probably does not occur very often. This is fortunate because with hard rationing, our DCF analysis breaks down, and the best course of action is ambiguous.

The reason DCF analysis breaks down has to do with the required return. Suppose we say that our required return is 20 percent. Implicitly, we are saying that we will take a project with a return that exceeds this. However, if we face hard rationing, then we are not going to take a new project no matter what the return on that project is, so the whole concept of a required return is ambiguous. About the only interpretation we can give this situation is that the required return is so large that no project has a positive NPV in the first place.

Hard rationing can occur when a company experiences financial distress, meaning that bankruptcy is a possibility. Also, a firm may not be able to raise capital without violating a preexisting contractual agreement. We discuss these situations in greater detail in a later chapter.

CONCEPT QUESTIONS	
9.7a	Why do we say that our standard discounted cash flow analysis is static?
9.7b	What are managerial options in capital budgeting? Give some examples.
9.7c	What is capital rationing? What types are there? What problems does capital rationing create for discounted cash flow analysis?

SUMMARY AND CONCLUSIONS

This chapter has described how to go about putting together a discounted cash flow analysis and evaluating the results. In it, we covered:

- 1. The identification of relevant project cash flows. We discussed project cash flows and described how to handle some issues that often come up, including sunk costs, opportunity costs, financing costs, net working capital, and erosion.
- 2. Preparing and using pro forma, or projected, financial statements. We showed how pro forma financial statement information is useful in coming up with projected cash flows.
- 3. The use of scenario and sensitivity analysis. These tools are widely used to evaluate the impact of assumptions made about future cash flows and NPV estimates.
- 4. Additional issues in capital budgeting. We examined the managerial options implicit in many capital budgeting situations. We also discussed the capital rationing problem.

The discounted cash flow analysis we’ve covered here is a standard tool in the business world. It is a very powerful tool, so care should be taken in its use. The most important thing is to get the cash flows identified in a way that makes economic sense. This chapter gives you a good start on learning to do this.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

9.1 Calculating Operating Cash Flow. Mater Pasta, Inc., has projected a sales volume of \$1,432 for the second year of a proposed expansion project. Costs normally run 70 percent of sales, or about \$1,002 in this case. The depreciation expense will be \$80, and the tax rate is 34 percent. What is the operating cash flow?

9.2 Scenario Analysis. A project under consideration costs \$500,000, has a five-year life, and has no salvage value. Depreciation is straight-line to zero. The required return is 15 percent, and the tax rate is 34 percent. Sales are projected at 400 units per year. Price per unit is \$3,000, variable cost per unit is \$1,900, and fixed costs are \$250,000 per year. No net working capital is required.

Suppose you think the unit sales, price, variable cost, and fixed cost projections are accurate to within 5 percent. What are the upper and lower bounds for these projections? What is the base-case NPV? What are the best- and worst-case scenario NPVs?

■ Answers to Chapter Review and Self-Test Problems

9.1 First, we can calculate the project's EBIT, its tax bill, and its net income.

$$\text{EBIT} = \$1,432 - 1,002 - 80 = \$350$$

$$\text{Taxes} = \$350 \times .34 = \$119$$

$$\text{Net income} = \$350 - 119 = \$231$$

With these numbers, operating cash flow is:

$$\begin{aligned}\text{OCF} &= \text{EBIT} + \text{Depreciation} - \text{Taxes} \\ &= \$350 + 80 - 119 \\ &= \$311\end{aligned}$$

9.2 We can summarize the relevant information as follows:

	Base Case	Lower Bound	Upper Bound
Unit sales	400	380	420
Price per unit	\$3,000	\$2,850	\$3,150
Variable cost per unit	\$1,900	\$1,805	\$1,995
Fixed costs	\$250,000	\$237,500	\$262,500

The depreciation is \$100,000 per year, and the tax rate is 34 percent, so we can calculate the cash flows under each scenario. Remember that we assign high costs and low prices and volume under the worst case and just the opposite for the best case.

Scenario	Unit Sales	Price	Variable Costs	Fixed Costs	Cash Flow
Base case	400	\$3,000	\$1,900	\$250,000	\$159,400
Best case	420	3,150	1,805	237,500	250,084
Worst case	380	2,850	1,995	262,500	75,184

At 15 percent, the five-year annuity factor is 3.35216, so the NPVs are:

$$\begin{aligned}\text{Base-case NPV} &= -\$500,000 + 159,400 \times 3.35216 \\ &= \$34,334\end{aligned}$$

$$\begin{aligned}\text{Best-case NPV} &= -\$500,000 + 250,084 \times 3.35216 \\ &= \$338,320\end{aligned}$$

$$\begin{aligned}\text{Worst-case NPV} &= -\$500,000 + 75,184 \times 3.35216 \\ &= -\$247,972\end{aligned}$$

CRITICAL THINKING AND CONCEPTS REVIEW

- L0 1** **9.1 Opportunity Cost.** In the context of capital budgeting, what is an opportunity cost?
- L0 1** **9.2 Depreciation.** Given the choice, would a firm prefer to use MACRS depreciation or straight-line depreciation? Why?
- L0 1** **9.3 Net Working Capital.** In our capital budgeting examples, we assumed that a firm would recover all of the working capital it invested in a project. Is this a reasonable assumption? When might it not be valid?
- L0 1** **9.4 Stand-Alone Principle.** Suppose a financial manager is quoted as saying, “Our firm uses the stand-alone principle. Because we treat projects like minifirms in our evaluation process, we include financing costs because they are relevant at the firm level.” Critically evaluate this statement.
- L0 1** **9.5 Cash Flow and Depreciation.** “When evaluating projects, we’re only concerned with the relevant incremental aftertax cash flows. Therefore, because depreciation is a noncash expense, we should ignore its effects when evaluating projects.” Critically evaluate this statement.
- L0 1** **9.6 Capital Budgeting Considerations.** A major college textbook publisher has an existing finance textbook. The publisher is debating whether or not to produce an “essentialized” version, meaning a shorter (and lower-priced) book. What are some of the considerations that should come into play?

To answer the next three questions, refer to the following example. In 2003, Porsche unveiled its new sports-utility vehicle (SUV), the Cayenne. With a price tag of over \$40,000, the Cayenne goes from zero to 62 mph in 9.7 seconds. Porsche’s decision to enter the SUV market was in response to the runaway success of other high-priced SUVs such as the Mercedes-Benz M-class. Vehicles in this class had generated years of very high profits. The Cayenne certainly spiced up the market, and Porsche subsequently introduced the Cayenne Turbo S, which goes from zero to 60 mph in 4.8 seconds and has a top speed of 168 mph. The price tag for the Cayenne Turbo S? Over \$120,000 in 2009.

Some analysts questioned Porsche’s entry into the luxury SUV market. The analysts were concerned not only that Porsche was a late entry into the market, but also that the introduction of the Cayenne would damage Porsche’s reputation as a maker of high-performance automobiles.

- L0 1** **9.7 Erosion.** In evaluating the Cayenne, would you consider the possible damage to Porsche’s reputation?

- L01** 9.8 **Capital Budgeting.** Porsche was one of the last manufacturers to enter the sports-utility vehicle market. Why would one company decide to proceed with a product when other companies, at least initially, decide not to enter the market?
- L01** 9.9 **Capital Budgeting.** In evaluating the Cayenne, what do you think Porsche needs to assume regarding the substantial profit margins that exist in this market? Is it likely they will be maintained as the market becomes more competitive, or will Porsche be able to maintain the profit margin because of its image and the performance of the Cayenne?
- L02** 9.10 **Sensitivity Analysis and Scenario Analysis.** What is the essential difference between sensitivity analysis and scenario analysis?
- L01** 9.11 **Marginal Cash Flows.** A co-worker claims that looking at all this marginal this and incremental that is just a bunch of nonsense and states: “Listen, if our average revenue doesn’t exceed our average cost, then we will have a negative cash flow, and we will go broke!” How do you respond?
- L01** 9.12 **Capital Rationing.** Going all the way back to Chapter 1, recall that we saw that partnerships and proprietorships can face difficulties when it comes to raising capital. In the context of this chapter, the implication is that small businesses will generally face what problem?
- L02** 9.13 **Forecasting Risk.** What is forecasting risk? In general, would the degree of forecasting risk be greater for a new product or a cost-cutting proposal? Why?
- L02** 9.14 **Options and NPV.** What is the option to abandon? The option to expand? Explain why we tend to underestimate NPV when we ignore these options.

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

- L01** 1. **Relevant Cash Flows.** Kenny, Inc., is looking at setting up a new manufacturing plant in South Park. The company bought some land six years ago for \$7 million in anticipation of using it as a warehouse and distribution site, but the company has since decided to rent facilities elsewhere. The land would net \$9.8 million if it were sold today. The company now wants to build its new manufacturing plant on this land; the plant will cost \$21 million to build, and the site requires \$850,000 worth of grading before it is suitable for construction. What is the proper cash flow amount to use as the initial investment in fixed assets when evaluating this project? Why?
- L01** 2. **Relevant Cash Flows.** Winnebagel Corp. currently sells 28,000 motor homes per year at \$73,000 each and 7,000 luxury motor coaches per year at \$115,000 each. The company wants to introduce a new portable camper to fill out its product line; it hopes to sell 23,000 of these campers per year at \$19,000 each. An independent consultant has determined that if Winnebagel introduces the new campers, it should boost the sales of its existing motor homes by 2,600 units per year and reduce the sales of its motor coaches by 850 units per year. What is the amount to use as the annual sales figure when evaluating this project? Why?
- L02** 3. **Calculating Projected Net Income.** A proposed new investment has projected sales of \$825,000. Variable costs are 55 percent of sales, and fixed costs are \$187,150; depreciation is \$91,000. Prepare a pro forma income statement assuming a tax rate of 35 percent. What is the projected net income?

Basic

(Questions 1–20)

LO 2

4. **Calculating OCF.** Consider the following income statement:

Sales	\$643,800
Costs	345,300
Depreciation	96,000
EBIT	?
Taxes (35%)	?
Net income	?

Fill in the missing numbers and then calculate the OCF. What is the depreciation tax shield?

LO 2

5. **Calculating Depreciation.** A piece of newly purchased industrial equipment costs \$960,000 and is classified as seven-year property under MACRS. Calculate the annual depreciation allowances and end-of-the-year book values for this equipment.

LO 2

6. **Calculating Salvage Value.** Consider an asset that costs \$780,000 and is depreciated straight-line to zero over its eight-year tax life. The asset is to be used in a five-year project; at the end of the project, the asset can be sold for \$135,000. If the relevant tax rate is 35 percent, what is the aftertax cash flow from the sale of this asset?

LO 2

7. **Calculating Salvage Value.** An asset used in a four-year project falls in the five-year MACRS class for tax purposes. The asset has an acquisition cost of \$7,100,000 and will be sold for \$1,750,000 at the end of the project. If the tax rate is 34 percent, what is the aftertax salvage value of the asset?

LO 2

8. **Calculating Project OCF.** Herrera Music Company is considering the sale of a new sound board used in recording studios. The new board would sell for \$25,500, and the company expects to sell 1,400 per year. The company currently sells 1,900 units of its existing model per year. If the new model is introduced, sales of the existing model will fall to 1,720 units per year. The old board retails for \$21,400. Variable costs are 55 percent of sales, depreciation on the equipment to produce the new board will be \$1,350,000 per year, and fixed costs are \$1,250,000 per year. If the tax rate is 38 percent, what is the annual OCF for the project?

LO 2

9. **Calculating Project OCF.** Cochrane, Inc., is considering a new three-year expansion project that requires an initial fixed asset investment of \$2.1 million. The fixed asset will be depreciated straight-line to zero over its three-year tax life, after which time it will be worthless. The project is estimated to generate \$2,150,000 in annual sales, with costs of \$1,140,000. If the tax rate is 35 percent, what is the OCF for this project?

LO 2

10. **Calculating Project NPV.** In the previous problem, suppose the required return on the project is 14 percent. What is the project's NPV?

LO 2

11. **Calculating Project Cash Flow from Assets.** In the previous problem, suppose the project requires an initial investment in net working capital of \$150,000, and the fixed asset will have a market value of \$175,000 at the end of the project. What is the project's Year 0 net cash flow? Year 1? Year 2? Year 3? What is the new NPV?

- L0 2** 12. **NPV and Modified ACRS.** In the previous problem, suppose the fixed asset actually falls into the three-year MACRS class. All the other facts are the same. What is the project's Year 1 net cash flow now? Year 2? Year 3? What is the new NPV?
- L0 2** 13. **Project Evaluation.** Kolby's Korndogs is looking at a new sausage system with an installed cost of \$625,000. This cost will be depreciated straight-line to zero over the project's five-year life, at the end of which the sausage system can be scrapped for \$95,000. The sausage system will save the firm \$183,000 per year in pretax operating costs, and the system requires an initial investment in net working capital of \$41,000. If the tax rate is 34 percent and the discount rate is 8 percent, what is the NPV of this project?
- L0 2** 14. **Project Evaluation.** Your firm is contemplating the purchase of a new \$520,000 computer-based order entry system. The system will be depreciated straight-line to zero over its five-year life. It will be worth \$40,000 at the end of that time. You will save \$160,000 before taxes per year in order processing costs, and you will be able to reduce working capital by \$35,000 at the beginning of the project. Working capital will revert back to normal at the end of the project. If the tax rate is 35 percent, what is the IRR for this project?
- L0 2** 15. **Project Evaluation.** In the previous problem, suppose your required return on the project is 10 percent and your pretax cost savings are \$190,000 per year. Will you accept the project? What if the pretax cost savings are only \$130,000 per year?
- L0 3** 16. **Scenario Analysis.** Automatic Transmissions, Inc., has the following estimates for its new gear assembly project: price = \$1,070 per unit; variable cost = \$290 per unit; fixed costs = \$4.8 million; quantity = 70,000 units. Suppose the company believes all of its estimates are accurate only to within ± 15 percent. What values should the company use for the four variables given here when it performs its best-case scenario analysis? What about the worst-case scenario?
- L0 3** 17. **Sensitivity Analysis.** For the company in the previous problem, suppose management is most concerned about the impact of its price estimate on the project's profitability. How could you address this concern for Automatic Transmissions? Describe how you would calculate your answer. What values would you use for the other forecast variables?
- L0 3** 18. **Sensitivity Analysis and Breakeven.** We are evaluating a project that costs \$1,350,000, has a six-year life, and has no salvage value. Assume that depreciation is straight-line to zero over the life of the project. Sales are projected at 87,000 units per year. Price per unit is \$34.25, variable cost per unit is \$20.50, and fixed costs are \$750,000 per year. The tax rate is 35 percent, and we require an 11 percent return on this project.
- a. Calculate the base-case cash flow and NPV. What is the sensitivity of NPV to changes in the sales figure? Explain what your answer tells you about a 500-unit decrease in projected sales.
- b. What is the sensitivity of OCF to changes in the variable cost figure? Explain what your answer tells you about a \$1 decrease in estimated variable costs.
- L0 3** 19. **Scenario Analysis.** In the previous problem, suppose the projections given for price, quantity, variable costs, and fixed costs are all accurate to within ± 10 percent. Calculate the best-case and worst-case NPV figures.
- L0 2** 20. **Calculating Project Cash Flows and NPV.** Pappy's Potato has come up with a new product, the Potato Pet (they are freeze-dried to last longer). Pappy's

paid \$120,000 for a marketing survey to determine the viability of the product. It is felt that Potato Pet will generate sales of \$575,000 per year. The fixed costs associated with this will be \$179,000 per year, and variable costs will amount to 20 percent of sales. The equipment necessary for production of the Potato Pet will cost \$620,000 and will be depreciated in a straight-line manner for the four years of the product life (as with all fads, it is felt the sales will end quickly). This is the only initial cost for the production. Pappy's is in a 40 percent tax bracket and has a required return of 13 percent. Calculate the payback period, NPV, and IRR.

L0 2

21. Cost-Cutting Proposals. CSM Machine Shop is considering a four-year project to improve its production efficiency. Buying a new machine press for \$485,000 is estimated to result in \$184,000 in annual pretax cost savings. The press falls in the MACRS five-year class, and it will have a salvage value at the end of the project of \$55,000. The press also requires an initial investment in spare parts inventory of \$21,000, along with an additional \$3,000 in inventory for each succeeding year of the project. If the shop's tax rate is 34 percent and its discount rate is 11 percent, should the company buy and install the machine press?

L0 3

22. Sensitivity Analysis. Consider a three-year project with the following information: initial fixed asset investment = \$840,000; straight-line depreciation to zero over the five-year life; zero salvage value; price = \$32.85; variable costs = \$21.95; fixed costs = \$204,000; quantity sold = 90,000 units; tax rate = 34 percent. How sensitive is OCF to changes in quantity sold?

L0 2

23. Project Analysis. You are considering a new product launch. The project will cost \$950,000, have a four-year life, and have no salvage value; depreciation is straight-line to zero. Sales are projected at 220 units per year; price per unit will be \$18,400, variable cost per unit will be \$14,900, and fixed costs will be \$320,000 per year. The required return on the project is 12 percent, and the relevant tax rate is 35 percent.

a. Based on your experience, you think the unit sales, variable cost, and fixed cost projections given here are probably accurate to within ± 10 percent. What are the best and worst cases for these projections? What is the base-case NPV? What are the best-case and worst-case scenarios?

b. Evaluate the sensitivity of your base-case NPV to changes in fixed costs.

L0 2

24. Project Analysis. McGilla Golf has decided to sell a new line of golf clubs. The clubs will sell for \$730 per set and have a variable cost of \$360 per set. The company has spent \$150,000 for a marketing study that determined the company will sell 75,000 sets per year for seven years. The marketing study also determined that the company will lose sales of 8,500 sets per year of its high-priced clubs. The high-priced clubs sell at \$1,200 and have variable costs of \$540. The company will also increase sales of its cheap clubs by 11,000 sets per year. The cheap clubs sell for \$340 and have variable costs of \$125 per set. The fixed costs each year will be \$11,200,000. The company has also spent \$1,000,000 on research and development for the new clubs. The plant and equipment required will cost \$24,500,000 and will be depreciated on a straight-line basis. The new clubs will also require an increase in net working capital of \$1,500,000 that will be returned at the end of the project. The tax rate is 40 percent, and the cost of capital is 14 percent. Calculate the payback period, the NPV, and the IRR.

Intermediate

(Questions 21–24)

L0 2

25. **Project Evaluation.** Aguilera Acoustics, Inc. (AAI), projects unit sales for a new seven-octave voice emulation implant as follows:

Year	Unit Sales
1	108,000
2	127,000
3	115,000
4	98,000
5	84,000

Challenge
(Questions 25–26)

Production of the implants will require \$1,500,000 in net working capital to start and additional net working capital investments each year equal to 15 percent of the projected sales increase for the following year. Total fixed costs are \$1,350,000 per year, variable production costs are \$225 per unit, and the units are priced at \$345 each. The equipment needed to begin production has an installed cost of \$23,000,000. Because the implants are intended for professional singers, this equipment is considered industrial machinery and thus qualifies as seven-year MACRS property. In five years, this equipment can be sold for about 20 percent of its acquisition cost. AAI is in the 35 percent marginal tax bracket and has a required return on all its projects of 18 percent. Based on these preliminary project estimates, what is the NPV of the project? What is the IRR?

L0 2

26. **Calculating Required Savings.** A proposed cost-saving device has an installed cost of \$647,000. The device will be used in a five-year project but is classified as three-year MACRS property for tax purposes. The required initial net working capital investment is \$45,000, the marginal tax rate is 35 percent, and the project discount rate is 12 percent. The device has an estimated year 5 salvage value of \$70,000. What level of pretax cost savings do we require for this project to be profitable?

CHAPTER CASE

CONCH REPUBLIC ELECTRONICS

Conch Republic Electronics is a midsized electronics manufacturer located in Key West, Florida. The company president is Shelly Coutts, who inherited the company. The company originally repaired radios and other household appliances when it was founded over 70 years ago. Over the years, the company has expanded, and it is now a reputable manufacturer of various specialty electronic items. Jay McCanless, a recent MBA graduate, has been hired by the company in its finance department.

One of the major revenue-producing items manufactured by Conch Republic is a Personal Digital Assistant (PDA). Conch Republic currently has one PDA model on the market and sales have been excellent. The PDA is a unique item in that it comes in a variety of tropical colors and is preprogrammed to play Jimmy Buffett music. However, as with any electronic item, technology changes rapidly, and the current PDA has limited features in comparison with newer models. Conch Republic spent \$750,000 to develop a prototype for a new PDA that has all the features of the existing one, but adds new features such as cell phone

capability. The company has spent a further \$200,000 for a marketing study to determine the expected sales figures for the new PDA.

Conch Republic can manufacture the new PDA for \$215 each in variable costs. Fixed costs for the operation are estimated to run \$4.3 million per year. The estimated sales volume is 65,000, 82,000, 108,000, 94,000, and 57,000 per year for the next five years, respectively. The unit price of the new PDA will be \$500. The necessary equipment can be purchased for \$32.5 million and will be depreciated on a seven-year MACRS schedule. It is believed the value of the equipment in five years will be \$3.5 million.

Net working capital for the PDAs will be 20 percent of sales and will occur with the timing of the cash flows for the year (i.e., there is no initial outlay for NWC). Changes in NWC will thus first occur in Year 1 with the first year's sales. Conch Republic has a 35 percent corporate tax rate and a 12 percent required return.

Shelly has asked Jay to prepare a report that answers the following questions: ■

QUESTIONS

1. What is the payback period of the project?
2. What is the profitability index of the project?
3. What is the IRR of the project?
4. What is the NPV of the project?
5. How sensitive is the NPV to changes in the price of the new PDA?
6. How sensitive is the NPV to changes in the quantity sold?
7. Should Conch Republic produce the new PDA?
8. Suppose Conch Republic loses sales on other models because of the introduction of the new model. How would this affect your analysis?

Some Lessons from Capital Market History

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- L0 1** Calculate the return on an investment.
- L0 2** Discuss the historical returns on various important types of investments.
- L0 3** Explain the historical risks on various important types of investments.
- L0 4** Assess the implications of market efficiency.

With the S&P 500 index down about 39 percent and the NASDAQ index down about 41 percent in 2008, stock market performance overall was pretty bad. In fact, the loss on the S&P 500 was the worst since 1937, and the loss for the NASDAQ was the worst in its relatively short history. Overall, the declines in U.S. stock markets wiped out about \$6.9 *trillion* in equity during 2008. Of course, some stocks did worse than others. For example, stock in insurance giant American International Group (AIG) fell over 97 percent during the year, and stock in both mortgage giants

Fannie Mae and Freddie Mac dropped about 98 percent. Even so, it was a great year for investors in biopharmaceutical company Emergent BioSolutions, which gained a whopping 461 percent. And investors in gas and oil company Mexco Energy Corp. had to be energized by the 211 percent gain of that stock. These examples show that there were tremendous potential profits to be made during 2008, but there was also the risk of losing money—and lots of it. So what should you, as a stock market investor, expect when you invest your own money? In this chapter, we study more than eight decades of market history to find out.

This chapter and the next take us into new territory: the relation between risk and return. As you will see, this chapter has a lot of very practical information for anyone thinking of investing in financial assets such as stocks and bonds. For example, suppose you were to start investing in stocks today. Do you think your money would grow at an average rate of 5 percent per year? Or 10 percent? Or 20 percent? This chapter gives you an idea of what to expect (the answer may surprise you). The chapter also shows how risky certain investments can be, and it gives you the tools to think about risk in an objective way.

Visit us at www.mhhe.com/rwj

Thus far, we haven't had much to say about what determines the required return on an investment. In one sense, the answer is very simple: The required return depends on the risk of the investment. The greater the risk, the greater is the required return.

Having said this, we are left with a somewhat more difficult problem. How can we measure the amount of risk present in an investment? Put another way, what does it mean to say that one investment is riskier than another? Obviously, we need to define what we mean by risk if we are going to answer these questions. This is our task in the next two chapters.

From the last several chapters, we know that one of the responsibilities of the financial manager is to assess the value of proposed investments. In doing this, it is important that we first look at what financial investments have to offer. At a minimum, the return we require from a proposed nonfinancial investment must be at least as large as what we can get from buying financial assets of similar risk.

Our goal in this chapter is to provide a perspective on what capital market history can tell us about risk and return. The most important thing to get out of this chapter is a feel for the numbers. What is a high return? What is a low one? More generally, what returns should we expect from financial assets and what are the risks from such investments? This perspective is essential for understanding how to analyze and value risky investment projects.

We start our discussion of risk and return by describing the historical experience of investors in the U.S. financial markets. In 1931, for example, the stock market lost 43 percent of its value. Just two years later, the stock market gained 54 percent. In more recent memory, the market lost about 25 percent of its value on October 19, 1987, alone, and as we saw in the chapter opener, stocks lost almost 40 percent in 2008. What lessons, if any, can financial managers learn from such shifts in the stock market? We will explore the last half century (and then some) of market history to find out.

Not everyone agrees on the value of studying history. On the one hand, there is philosopher George Santayana's famous comment "Those who cannot remember the past are condemned to repeat it." On the other hand, there is industrialist Henry Ford's equally famous comment "History is more or less bunk." Nonetheless, perhaps everyone would agree with the following observation from Mark Twain: "October. This is one of the peculiarly dangerous months to speculate in stocks in. The others are July, January, September, April, November, May, March, June, December, August, and February."

There are two central lessons that emerge from our study of market history. First: There is a reward for bearing risk. Second: The greater the potential reward is, the greater is the risk. To understand these facts about market returns, we devote much of this chapter to reporting the statistics and numbers that make up the modern capital market history of the United States. In the next chapter, these facts provide the foundation for our study of how financial markets put a price on risk.

The number of Web sites devoted to financial markets and instruments is astounding, and increasing daily. Be sure to check out the RWJ Web page for links to finance-related sites!

10.1

RETURNS

We wish to discuss historical returns on different types of financial assets. The first thing we need to do, then, is to briefly discuss how to calculate the return from investing.

Dollar Returns

If you buy an asset of any sort, your gain (or loss) from that investment is called your *return on investment*. This return will usually have two components. First: You may receive some

cash directly while you own the investment. This is called the income component of your return. Second: The value of the asset you purchase will often change. In this case, you have a capital gain or capital loss on your investment.¹

To illustrate, suppose the Video Concept Company has several thousand shares of stock outstanding. You purchased some of these shares of stock in the company at the beginning of the year. It is now year-end, and you want to determine how well you have done on your investment.

First, over the year, a company may pay cash dividends to its shareholders. As a stockholder in Video Concept Company, you are a part owner of the company. If the company is profitable, it may choose to distribute some of its profits to shareholders (we discuss the details of dividend policy in a later chapter). So, as the owner of some stock, you will receive some cash. This cash is the income component from owning the stock.

In addition to the dividend, the other part of your return is the capital gain or capital loss on the stock. This part arises from changes in the value of your investment. For example, consider the cash flows illustrated in Figure 10.1. At the beginning of the year, the stock is selling for \$37 per share. If you buy 100 shares, you have a total outlay of \$3,700. Suppose, over the year, the stock pays a dividend of \$1.85 per share. By the end of the year, then, you will have received income of:

$$\text{Dividend} = \$1.85 \times 100 = \$185$$

Also, the value of the stock rises to \$40.33 per share by the end of the year. Your 100 shares are worth \$4,033, so you have a capital gain of:

$$\text{Capital gain} = (\$40.33 - \$37) \times 100 = \$333$$

On the other hand, if the price had dropped to, say, \$34.78, you would have had a capital loss of:

$$\text{Capital loss} = (\$34.78 - \$37) \times 100 = -\$222$$

Notice that a capital loss is the same thing as a negative capital gain.

¹ As we mentioned in an earlier chapter, strictly speaking, what is and what is not a capital gain (or loss) is determined by the IRS. We thus use the terms loosely.

The total dollar return on your investment is the sum of the dividend and the capital gain:

$$\text{Total dollar return} = \text{Dividend income} + \text{Capital gain (or loss)} \quad [10.1]$$

In our first example, the total dollar return is thus given by:

$$\text{Total dollar return} = \$185 + 333 = \$518$$

Notice that, if you sold the stock at the end of the year, the total amount of cash you would have would be your initial investment plus the total return. In the preceding example, then:

$$\begin{aligned} \text{Total cash if stock is sold} &= \text{Initial investment} + \text{Total return} \\ &= \$3,700 + 518 \\ &= \$4,218 \end{aligned} \quad [10.2]$$

As a check, notice that this is the same as the proceeds from the sale of the stock plus the dividends:

$$\begin{aligned} \text{Proceeds from stock sale} + \text{Dividends} &= \$40.33 \times 100 + 185 \\ &= \$4,033 + 185 \\ &= \$4,218 \end{aligned}$$

Suppose you hold on to your Video Concept stock and don't sell it at the end of the year. Should you still consider the capital gain as part of your return? Isn't this only a "paper" gain and not really a return if you don't sell the stock?

The answer to the first question is a strong yes, and the answer to the second is an equally strong no. The capital gain is every bit as much a part of your return as the dividend, and you should certainly count it as part of your return. That you actually decided to keep the stock and not sell (you don't "realize" the gain) is irrelevant because you could have converted it to cash if you had wanted to. Whether you choose to do so or not is up to you.

After all, if you insisted on converting your gain to cash, you could always sell the stock at year-end and immediately reinvest by buying the stock back. There is no net difference between doing this and just not selling (assuming, of course, that there are no tax consequences from selling the stock). Again, the point is that whether you actually cash out and buy sodas (or whatever) or reinvest by not selling doesn't affect the return you earn.

Percentage Returns

It is usually more convenient to summarize information about returns in percentage terms, rather than dollar terms, because that way your return doesn't depend on how much you actually invest. The question we want to answer is this: How much do we get for each dollar we invest?

To answer this question, let P_t be the price of the stock at the beginning of the year and let D_{t+1} be the dividend paid on the stock during the year. Consider the cash flows in Figure 10.2. These are the same as those in Figure 10.1, except that we have now expressed everything on a per-share basis.

In our example, the price at the beginning of the year was \$37 per share and the dividend paid during the year on each share was \$1.85. As we discussed in Chapter 7, expressing the dividend as a percentage of the beginning stock price results in the dividend yield:

$$\begin{aligned} \text{Dividend yield} &= D_{t+1}/P_t \\ &= \$1.85/37 = .05 = 5\% \end{aligned}$$

This says that, for each dollar we invest, we get five cents in dividends.

Go to
www.smartmoney.com/marketmap
 for a cool Java applet
 that shows today's
 returns by market
 sector.

The second component of our percentage return is the capital gains yield. Recall (from Chapter 7) that this is calculated as the change in the price during the year (the capital gain) divided by the beginning price:

$$\begin{aligned}
 \text{Capital gains yield} &= (P_{t+1} - P_t)/P_t \\
 &= (\$40.33 - 37)/37 \\
 &= \$3.33/37 \\
 &= 9\%
 \end{aligned}$$

So, per dollar invested, we get nine cents in capital gains.

Putting it together, per dollar invested, we get 5 cents in dividends and 9 cents in capital gains; so, we get a total of 14 cents. Our percentage return is 14 cents on the dollar, or 14 percent.

To check this, notice that we invested $\$3,700$ and ended up with $\$4,218$. By what percentage did our $\$3,700$ increase? As we saw, we picked up $\$4,218 - \$3,700 = \$518$. This is a $\$518/\$3,700 = 14\%$ increase.

To give a more concrete example, stock in McDonald's, the famous hamburger chain, began 2008 at $\$58.91$ per share. McDonald's paid dividends of $\$1.63$ during 2008, and the stock price at the end of the year was $\$62.19$. What was the return on McDonald's for the year? For practice, see if you agree that the answer is 8.33 percent. Of course, negative returns occur as well. For example, again in 2008, IBM's stock price at the beginning of the year was $\$107.26$ per share, and dividends of $\$1.90$ were paid. The stock ended the year at $\$84.16$ per share. Verify that the loss was 19.77 percent for the year.

Calculating Returns

EXAMPLE 10.1

Suppose you buy some stock for $\$25$ per share. At the end of the year, the price is $\$35$ per share. During the year, you get a $\$2$ dividend per share. This is the situation illustrated in Figure 10.3. What is the dividend yield? The capital gains yield? The percentage return? If your total investment was $\$1,000$, how much do you have at the end of the year?

Your $\$2$ dividend per share works out to a dividend yield of:

$$\begin{aligned}
 \text{Dividend yield} &= D_{t+1}/P_t \\
 &= \$2/25 = .08 = 8\%
 \end{aligned}$$

(continued)

The per-share capital gain is \$10, so the capital gains yield is:

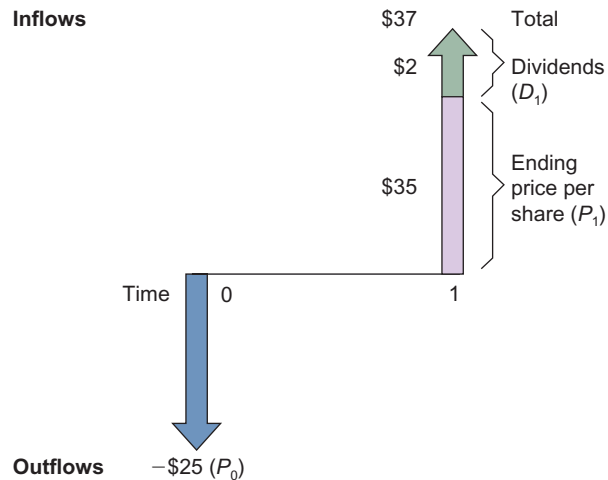

$$\begin{aligned}\text{Capital gains yield} &= (P_{t+1} - P_t)/P_t \\ &= (\$35 - 25)/25 \\ &= \$10/25 \\ &= 40\%\end{aligned}$$

The total percentage return is thus 48 percent.

If you had invested \$1,000, you would have had \$1,480 at the end of the year, representing a 48 percent increase. To check this, note that your \$1,000 would have bought you $\$1,000/25 = 40$ shares. Your 40 shares would then have paid you a total of $40 \times \$2 = \80 in cash dividends. Your \$10 per share gain would have given you a total capital gain of $\$10 \times 40 = \400 . Add these together, and you get the \$480 increase.

FIGURE 10.3

Cash flow—an investment example

CONCEPT QUESTIONS

- 10.1a** What are the two parts of total return?
- 10.1b** Why are unrealized capital gains or losses included in the calculation of returns?
- 10.1c** What is the difference between a dollar return and a percentage return? Why are percentage returns more convenient?

10.2

THE HISTORICAL RECORD

Roger Ibbotson and Rex Sinquefeld conducted a famous set of studies dealing with rates of return in U.S. financial markets.² They presented year-to-year historical rates of return on five important types of financial investments. The returns can be interpreted as what you would have earned if you had held portfolios of the following:

1. Large-company stocks. The large-company stock portfolio is based on the Standard & Poor's 500 index, which contains 500 of the largest companies (in terms of total market value of outstanding stock) in the United States.

² R. G. Ibbotson and R. A. Sinquefeld, *Stocks, Bonds, Bills, and Inflation [SBBI]* (Charlottesville, VA: Financial Analysis Research Foundation, 1982).

For more on market history, visit www.globalfindata.com where you can download free sample data.

2. Small-company stocks. This is a portfolio composed of stock of smaller companies, where “small” corresponds to the smallest 20 percent of the companies listed on the New York Stock Exchange, again as measured by market value of outstanding stock.
3. Long-term corporate bonds. This is a portfolio of high-quality bonds with 20 years to maturity.
4. Long-term U.S. government bonds. This is a portfolio of U.S. government bonds with 20 years to maturity.
5. U.S. Treasury bills. This is based on Treasury bills (T-bills for short) with a one-month maturity.

These returns are not adjusted for inflation or taxes; thus, they are nominal, pretax returns.

In addition to the year-to-year returns on these financial instruments, the year-to-year percentage change in the consumer price index (CPI) is also computed. This is a commonly used measure of inflation, so we can calculate real returns using this as the inflation rate.

A First Look

Before looking closely at the different portfolio returns, we take a look at the big picture. Figure 10.4 shows what happened to \$1 invested in these different portfolios at the beginning of 1926. The growth in value for each of the different portfolios over the 83-year period ending in 2008 is given separately (the long-term corporate bonds are omitted). Notice that to get everything on a single graph, some modification in scaling is used. As is commonly done with financial series, the vertical axis is scaled such that equal distances measure equal percentage (as opposed to dollar) changes in values.

Looking at Figure 10.4, we see that the small-company, or “small-cap” (short for small-capitalization), investment did the best overall. Every dollar invested grew to a remarkable \$9,548.94 over the 83 years. The larger common stock portfolio did less well; a dollar invested in it grew to \$2,049.45.

At the other end, the T-bill portfolio grew to only \$20.51. This is even less impressive when we consider the inflation over this period. As illustrated, the increase in the price level was such that \$11.73 is needed just to replace the original \$1.

Given the historical record, why would anybody buy anything other than small-cap stocks? If you look closely at Figure 10.4, you will probably see the answer. The T-bill portfolio and the long-term government bond portfolio grew more slowly than did the stock portfolios, but they also grew much more steadily. The small stocks ended up on top, but, as you can see, they grew quite erratically at times. For example, the small stocks were the worst performers for about the first 10 years and had a smaller return than long-term government bonds for almost 15 years.

A Closer Look

To illustrate the variability of the different investments, Figures 10.5 through 10.8 plot the year-to-year percentage returns in the form of vertical bars drawn from the horizontal axis. The height of the bar tells us the return for the particular year. For example, looking at the long-term government bonds (Figure 10.7), we see that the largest historical return (40.35 percent) occurred in 1982. This was a good year for bonds. In comparing these charts, notice the differences in the vertical axis scales. With these differences in mind,

you can see how predictably the Treasury bills (Figure 10.7) behaved compared to the small stocks (Figure 10.6).

The returns shown in these bar graphs are sometimes very large. Looking at the graphs, we see, for example, that the largest single-year return was a remarkable 143 percent for

the small-cap stocks in 1933. In the same year, the large-company stocks “only” returned 53 percent. In contrast, the largest Treasury bill return was 15 percent in 1981. For future reference, the actual year-to-year returns for the S&P 500, long-term government bonds, Treasury bills, and the CPI are shown in Table 10.1.

TABLE 10.1 Year-to-year total returns: 1926-2008

CONCEPT QUESTIONS

- 10.2a** With 20-20 hindsight, what was the best investment for the period 1926–35?
- 10.2b** Why doesn't everyone just buy small stocks as investments?
- 10.2c** What was the smallest return observed over the 83 years for each of these investments? Approximately when did it occur?
- 10.2d** About how many times did large stocks (common stocks) return more than 30 percent? How many times did they return less than -20 percent?
- 10.2e** What was the longest "winning streak" (years without a negative return) for large stocks? For long-term government bonds?
- 10.2f** How often did the T-bill portfolio have a negative return?

FIGURE 10.8

Year-to-year

10.3

AVERAGE RETURNS: THE FIRST LESSON

As you've probably begun to notice, the history of capital market returns is too complicated to be of much use in its undigested form. We need to begin summarizing all these numbers. Accordingly, we discuss how to go about condensing the detailed data. We start out by calculating average returns.

Calculating Average Returns

The obvious way to calculate the average returns on the different investments in Table 10.1 is simply to add up the yearly returns and divide by 83. The result is the historical average of the individual values.

For example, if you add up the returns for the common stocks for the 83 years, you will get about 9.71. The average annual return is thus $9.71/83 = .117 = 11.7\%$. You interpret this 11.7 percent just like any other average. If you picked a year at random from the 83-year history and you had to guess what the return in that year was, the best guess would be 11.7 percent.

Average Returns: The Historical Record

Table 10.2 shows the average returns for the investments we have discussed. As shown, in a typical year, the small stocks increased in value by **16.4 percent**. Notice also how much larger the stock returns are than the bond returns.

These averages are, of course, nominal since we haven't worried about inflation. Notice that the average inflation rate was **3.1 percent** per year over this 83-year span. The nominal return on U.S. Treasury bills was **3.8 percent** per year. The average real return on Treasury bills was thus approximately **.7 percent** per year; so, the real return on T-bills has been quite low historically.

At the other extreme, small stocks had an average real return of about $16.4\% - 3.1\% = 13.3\%$, which is relatively large. If you remember the Rule of 72 (Chapter 4), then you recall that a quick back-of-the-envelope calculation tells us that 13.3 percent real growth doubles your buying power about every five years. Notice also that the real value of the large stock portfolio increased by **8.6 percent** in a typical year.

Investment	Average Return
Large stocks	11.7%
Small stocks	16.4
Long-term corporate bonds	6.2
Long-term government bonds	6.1
U.S. Treasury bills	3.8
Inflation	3.1

Average annual returns and risk premiums: 1926–2008

Risk Premiums

Now that we have computed some average returns, it seems logical to see how they compare with each other. Based on our discussion above, one such comparison involves government-issued securities. These are free of much of the variability we see in, for example, the stock market.

The government borrows money by issuing bonds. These bonds come in different forms. The ones we will focus on are Treasury bills. These have the shortest time to maturity of the different government bonds. Because the government can always raise taxes to pay its bills, this debt is virtually free of any default risk over its short life. Thus, we will call the rate of return on such debt the *risk-free return*, and we will use it as a kind of benchmark.

A particularly interesting comparison involves the virtually risk-free return on T-bills and the very risky return on common stocks. The difference between these two returns can be interpreted as a measure of the *excess return* on the average risky asset (assuming the stock of a large U.S. corporation has about average risk compared to all risky assets).

We call this the “excess” return since it is the additional return we earn by moving from a relatively risk-free investment to a risky one. Because it can be interpreted as a reward for bearing risk, we will call it a **risk premium**.

From Table 10.2, we can calculate the risk premiums for the different investments. We report only the nominal risk premium in Table 10.3 because there is only a slight difference between the historical nominal and real risk premiums.

The risk premium on T-bills is shown as zero in the table because we have assumed that they are riskless.

risk premium

The excess return required from an investment in a risky asset over that required from a risk-free investment.

The First Lesson

Looking at Table 10.3, we see that the average risk premium earned by a typical large common stock is $11.7\% - 3.8\% = 7.9\%$. This is a significant reward. The fact that it exists historically is an important observation, and it is the basis for our first lesson: Risky assets, on average, earn a risk premium. Put another way: There is a reward for bearing risk.

Why is this so? Why, for example, is the risk premium for small stocks so much larger than the risk premium for large stocks? More generally, what determines the relative sizes of the risk premiums for the different assets? The answers to these questions are at the heart of modern finance, and the next chapter is devoted to them. For now, part of the answer can be found by looking at the historical variability of the returns of these different investments. So, to get started, we now turn our attention to measuring variability in returns.

CONCEPT QUESTIONS

10.3a What do we mean by excess return and risk premium?

10.3b What was the real (as opposed to nominal) risk premium on the common stock portfolio?

10.3c What was the nominal risk premium on corporate bonds? The real risk premium?

10.3d What is the first lesson from capital market history?

10.4

THE VARIABILITY OF RETURNS: THE SECOND LESSON

We have already seen that the year-to-year returns on common stocks tend to be more volatile than the returns on, say, long-term government bonds. We now discuss measuring this variability so we can begin examining the subject of risk.

Frequency Distributions and Variability

To get started, we can draw a *frequency distribution* for the common stock returns like the one in Figure 10.9. What we have done here is to count up the number of times the annual return on the large stock portfolio falls within each 10 percent range. For example, in Figure 10.9, the height of 13 in the range 20 percent to 30 percent means that 13 of the 83 annual returns were in that range. Notice also that the returns are very concentrated between -10 and 40 percent.

FIGURE 10.9

Frequency distribution of returns on common stocks: 1926–2008

Source: *Stocks, Bonds, Bills, and Inflation Yearbook*TM, Morningstar, Inc., Chicago (annually updates work by Roger G. Ibbotson and Rex A. Sinquefeld). All rights reserved.

What we need to do now is to actually measure the spread in returns. We know, for example, that the return on small stocks in a typical year was 16.4 percent. We now want to know how far the actual return deviates from this average in a typical year. In other words, we need a measure of how volatile the return is. The **variance** and its square root, the **standard deviation**, are the most commonly used measures of volatility. We describe how to calculate them next.

The Historical Variance and Standard Deviation

The variance essentially measures the average squared difference between the actual returns and the average return. The bigger this number is, the more the actual returns tend to differ from the average return. Also, the larger the variance or standard deviation is, the more spread out the returns will be.

The way we will calculate the variance and standard deviation depends on the specific situation. In this chapter, we are looking at historical returns; so, the procedure we describe here is the correct one for calculating the *historical* variance and standard deviation. If we were examining projected future returns, then the procedure would be different. We describe this procedure in the next chapter.

To illustrate how we calculate the historical variance, suppose a particular investment had returns of 10 percent, 12 percent, 3 percent, and −9 percent over the last four years. The average return is $(.10 + .12 + .03 - .09)/4 = 4\%$. Notice that the return is never actually equal to 4 percent. Instead, the first return deviates from the average by $.10 - .04 = .06$, the second return deviates from the average by $.12 - .04 = .08$, and so on. To compute the variance, we square each of these deviations, add up the squares, and divide the result by the number of returns less 1, or 3 in this case. This information is summarized in the following table:

Year	(1) Actual Return	(2) Average Return	(3) Deviation (1) − (2)	(4) Squared Deviation
1	.10	.04	.06	.0036
2	.12	.04	.08	.0064
3	.03	.04	−.01	.0001
4	−.09	.04	−.13	.0169
Totals	<u>.16</u>		<u>.00</u>	<u>.0270</u>

In the first column, we write down the four actual returns. In the third column, we calculate the difference between the actual returns and the average by subtracting out 4 percent. Finally, in the fourth column, we square the numbers in Column 3 to get the squared deviations from the average.

The variance can now be calculated by dividing **.0270**, the sum of the squared deviations, by the number of returns less 1. Let $\text{Var}(R)$, or σ^2 (read this as “sigma squared”), stand for the variance of the return:

$$\text{Var}(R) = \sigma^2 = .027/(4 - 1) = .009$$

The standard deviation is the square root of the variance. So, if $\text{SD}(R)$, or σ , stands for the standard deviation of the return:

$$\text{SD}(R) = \sigma = \sqrt{.009} = .09487$$

The square root of the variance is used because the variance is measured in “squared” percentages and thus is hard to interpret. The standard deviation is an ordinary percentage, so the answer here could be written as **9.487 percent**.

variance

The average squared difference between the actual return and the average return.

standard deviation

The positive square root of the variance.

For an easy-to-read review of basic stats, check out www.robertniles.com/stats.

In the table above, notice that the sum of the deviations is equal to zero. This will always be the case, and it provides a good way to check your work. In general, if we have T historical returns, where T is some number, we can write the historical variance as:

$$\text{Var}(R) = \frac{1}{T-1} [(R_1 - \bar{R})^2 + \cdots + (R_T - \bar{R})^2] \quad [10.3]$$

This formula tells us to do just what we did above: Take each of the T individual returns (R_1, R_2, \dots) and subtract the average return, \bar{R} ; square the results, and add up all these squares; and finally, divide this total by the number of returns less 1 ($T - 1$). The standard deviation is always the square root of $\text{Var}(R)$. Standard deviations are a widely used measure of volatility. Our nearby *Work the Web* box gives a real-world example.

WORK THE WEB

Standard deviations are widely reported for mutual funds. For example, the Fidelity Magellan Fund is one of the largest mutual funds in the United States. How volatile is it? To find out, we went to www.morningstar.com, entered the ticker symbol FMAGX, and hit the “Ratings and Risk” link. Here is what we found:

Fidelity Magellan FMAGX		
See Fund Family Data ▶▶		
Volatility Measurements		
Trailing 3-Yr through 02-28-09 *Trailing 5-Yr through 02-28-09		
Standard Deviation	21.95	Sharpe Ratio -1.00
Mean	-18.24	Bear Market Decile Rank* 8
Modern Portfolio Theory Statistics		
Trailing 3-Yr through 02-28-09		
	Standard Index	Best Fit Index
	S&P 500 TR	Russell Midcap Growth
R-Squared	86	96
Beta	1.22	1.04
Alpha	0.68	-1.72
S&P 500 index data: S&P 500 Copyright © 2009		

The standard deviation for the Fidelity Magellan Fund is 21.95 percent. When you consider the average stock has a standard deviation of about 50 percent, this seems like a low number. The reason for the low standard deviation has to do with the power of diversification, a topic we discuss in the next chapter. The mean is the average return, so over the last three years, investors in the Magellan Fund lost 18.24 percent per year. Also under the Volatility Measurements section, you will see the Sharpe ratio. The Sharpe ratio is calculated as the risk premium of the asset divided by the standard deviation. As such, it is a measure of return to the level of risk taken (as measured by standard deviation). The “beta” for the Fidelity Magellan Fund is 1.22. We will have more to say about this number—lots more—in the next chapter.

Questions

1. Go to the Morningstar Web site at www.morningstar.com. What does the Bear Market Decile Rank measure?
2. Get a quote for the Fidelity Magellan fund at Morningstar. What are the five sectors that have the highest percentage investment for this fund? What are the five stocks with the highest percentage investment?

Calculating the Variance and Standard Deviation

EXAMPLE 10.2

Suppose the Supertech Company and the Hyperdrive Company have experienced the following returns in the last four years:

Year	Supertech Returns	Hyperdrive Returns
2005	-.20	.05
2006	.50	.09
2007	.30	-.12
2008	.10	.20

What are the average returns? The variances? The standard deviations? Which investment was more volatile?

To calculate the average returns, we add up the returns and divide by 4. The results are:

$$\text{Supertech average return} = \bar{R} = .70/4 = .175$$

$$\text{Hyperdrive average return} = \bar{R} = .22/4 = .055$$

To calculate the variance for Supertech, we can summarize the relevant calculations as follows:

Year	(1) Actual Return	(2) Average Return	(3) Deviation (1) - (2)	(4) Squared Deviation
2005	-.20	.175	-.375	.140625
2006	.50	.175	.325	.105625
2007	.30	.175	.125	.015625
2008	.10	.175	-.075	.005625
Totals	.70		.000	.267500

Since there are four years of returns, we calculate the variance by dividing .2675 by $(4 - 1) = 3$:

	Supertech	Hyperdrive
Variance (σ^2)	.2675/3 = .0892	.0529/3 = .0176
Standard deviation (σ)	$\sqrt{.0892} = .2987$	$\sqrt{.0176} = .1327$

For practice, verify that you get the same answer as we do for Hyperdrive. Notice that the standard deviation for Supertech, 29.87 percent, is a little more than twice Hyperdrive's 13.27 percent; Supertech was thus the more volatile investment.

The Historical Record

Figure 10.10 summarizes much of our discussion of capital market history so far. It displays average returns, standard deviations, and frequency distributions of annual returns on a common scale. In Figure 10.10, notice, for example, that the standard deviation for the small-stock portfolio (33.0 percent per year) is more than 10 times larger than the T-bill portfolio's standard deviation (3.1 percent per year). We will return to these figures momentarily.

FIGURE 10.10

Historical average returns, standard deviations, and frequency distributions: 1926–2008

*The 1933 small-company stocks total return was 142.9 percent.

Normal Distribution

normal distribution
A symmetric, bell-shaped frequency distribution that is completely defined by its average and standard deviation.

For many different random events in nature, a particular frequency distribution, the **normal distribution** (or *bell curve*), is useful for describing the probability of ending up in a given range. For example, the idea behind “grading on a curve” comes from the fact that exam scores often resemble a bell curve.

Figure 10.11 illustrates a normal distribution and its distinctive bell shape. As you can see, this distribution has a much cleaner appearance than the actual return distributions illustrated in Figure 10.10. Even so, like the normal distribution, the actual distributions do appear to be at least roughly mound-shaped and symmetric. When this is true, the normal distribution is often a very good approximation.

Also, keep in mind that the distributions in Figure 10.10 are based on only 83 yearly observations, while Figure 10.11 is, in principle, based on an infinite number. So, if we

had been able to observe returns for, say, 1,000 years, we might have filled in a lot of the irregularities and ended up with a much smoother picture. For our purposes, it is enough to observe that the returns are at least roughly normally distributed.

The usefulness of the normal distribution stems from the fact that it is completely described by the average and the standard deviation. If you have these two numbers, then there is nothing else to know. For example, with a normal distribution, the probability that we end up within one standard deviation of the average is about $2/3$. The probability that we end up within two standard deviations is about 95 percent. Finally, the probability of being more than three standard deviations away from the average is less than 1 percent. These ranges and the probabilities are illustrated in Figure 10.11.

To see why this is useful, recall from Figure 10.10 that the standard deviation of returns on the large common stocks is 20.6 percent. The average return is 11.7 percent. So, assuming that the frequency distribution is at least approximately normal, the probability that the return in a given year is in the range of -8.9 percent to 32.3 percent (11.7 percent plus or minus one standard deviation, 20.6 percent) is about $2/3$. This range is illustrated in Figure 10.11. In other words, there is about one chance in three that the return will be *outside* this range. This literally tells you that, if you buy stocks in large companies, you should expect to be outside this range in one year out of every three. This reinforces our earlier observations about stock market volatility. However, there is only a 5 percent chance (approximately) that we would end up outside the range of -29.5 percent to 52.9 percent (11.7 percent plus or minus $2 \times 20.6\%$). These points are also illustrated in Figure 10.11.

The Second Lesson

Our observations concerning the year-to-year variability in returns are the basis for our second lesson from capital market history. On average, bearing risk is handsomely rewarded, but, in a given year, there is a significant chance of a dramatic change in value. Thus, our second lesson is this: The greater the potential reward, the greater is the risk.

Thus far in this chapter, we have emphasized the year-to-year variability in returns. We should note that even day-to-day movements can exhibit considerable volatility. For example, on September 17, 2001, the Dow Jones Industrial Average (DJIA) plummeted 684.81 points, or 7.13 percent. By historical standards, it was one of the worst days ever

for the 30 stocks that comprise the DJIA (as well as for a majority of stocks in the market). Still, while the drop was the largest decrease in the DJIA ever in terms of points, it actually wasn't quite in the top 12 largest one-day percentage decreases in history, as illustrated in the following table:

Top 12 One-Day Percentage Changes in the Dow Jones Industrial Average			
October 19, 1987	−22.6%	September 29, 2008	−8.8%
October 28, 1929	−12.8	December 18, 1899	−8.7
October 29, 1929	−11.7	August 12, 1932	−8.4
November 6, 1929	−9.9	March 14, 1907	−8.3
October 13, 2008	−9.0	October 26, 1987	−8.0
December 1, 2008	−8.9	July 21, 1933	−7.8

Source: Dow Jones

This discussion also highlights the importance of looking at returns in terms of percentages rather than dollar amounts or index points. For example, as we noted before, the biggest one-day loss in terms of points was on September 17, 2001, when the DJIA declined by 685 points. The second worst was the 554-point drop of October 27, 1997. In contrast, the 5.57-point drop in the DJIA on December 18, 1899, marked the eighth worst day in the history of the index, but a 5.6-point loss in the DJIA in today's market would hardly be noticed. This is precisely why we relied on percentage returns when we examined market history in this chapter.³

Using Capital Market History

Based on the discussion in this section, you should begin to have an idea of the risks and rewards from investing. For example, in early 2009, Treasury bills were paying about 0.2 percent. Suppose we had an investment that we thought had about the same risk as a portfolio of large-firm common stocks. At a minimum, what return would this investment have to offer for us to be interested?

From Table 10.3, the risk premium on larger common stocks has been 7.9 percent historically, so a reasonable estimate of our required return would be this premium plus the T-bill rate, $7.9\% + .2\% = 8.1\%$. If we were thinking of starting a new business, then the risks of doing so might resemble those of investing in small-company stocks. In this case, the risk premium is 12.6 percent, so we might require more like 12.8 percent from such an investment at a minimum.

We will discuss the relationship between risk and required return in more detail in the next chapter. For now, you should notice that a projected internal rate of return, or IRR, on a risky investment in the 10 percent to 20 percent range isn't particularly outstanding. It depends on how much risk there is. This, too, is an important lesson from capital market history.

The discussion in this section shows that there is much to be learned from capital market history. As the accompanying *Reality Bytes* box describes, capital market history also provides some odd coincidences.

³ By the way, as you may have noticed, what's kind of weird is that 5 of the 12 worst days in the history of the DJIA occurred in October, including the top 3. We have no clue as to why. Furthermore, looking back at the Mark Twain quote near the beginning of the chapter, how do you suppose he knew? Sounds like a case for *CSI: Wall Street*.

The Super Guide to Investing

Every year, in late January or early February, about 90 million people in the United States watch television for a prediction of how well the stock market is going to do in the upcoming year. So you missed it this year? Maybe not. The stock market predictor we're talking about is the Super Bowl!

The Super Bowl indicator has become one of the more famous (or infamous) indicators of stock market performance. Here's how it works. In the 1960s, the original National Football League (NFL) and the upstart American Football League (AFL) were fighting for dominance. The Super Bowl indicator says that if a team from the original AFL wins the Super Bowl, the market posts a negative return for the year, and, if a team from the original NFL wins, the market will post a gain for the year. So, how has the Super Bowl predictor performed?

For the first 31 Super Bowls, the indicator was correct 28 out of 31 times! The Miami Dolphins are perhaps the best market predictor. When Miami won the Super Bowl in 1973, the market proceeded to drop by 14.7 percent. The next year, the Dolphins beat the Minnesota Vikings, and the S&P 500 lost 26.5 percent, one of the worst one-year performances in its history. When the Dolphins lost the Super Bowl in 1972, 1983, and 1985, the S&P 500 posted double-digit gains each time.

So are you ready to bet the ranch on the Super Bowl indicator? Maybe that's not a good idea. Between 1998 and 2008, the Super Bowl indicator has only been right three times, in 2002, 2006, and 2007. The New England Patriots, an AFL team, won in 2002, and the S&P 500 dropped over 20 percent. In 2006 and 2007, the Pittsburgh Steelers and Indianapolis Colts, both original NFL teams, won and the market was up both years.

In 2004 and 2005, the New England Patriots, an original AFL team, won, but the market was up both years. Of course,

one of the worst predictions occurred in 2008 when the New York Giants, another original NFL team, won and the market dropped by about 39 percent. In good news for the stock market, the Pittsburgh Steelers won in 2009, so the market should be up for the year. Was it?

If you want a more recent indicator of stock market performance from the world of sports, consider the Daytona 500 indicator. While winning this race is an accomplishment for the driver, it doesn't seem to carry over to the stock of the winning driver's sponsor. For example, in 2005, Jeff Gordon won the Daytona 500 and stock in his sponsor company, Du Pont, was down 13 percent for the year. Things were even worse for Du Pont stock when Gordon won in 1997; the stock lost 36 percent on the year. Overall, in the last 17 years, stock in the sponsor of the winning driver has trailed the market by about 19 percent per year.

So you want more predictors? How about the hemline indicator, also known as the "bull markets and bare knees" indicator? Through much of the nineteenth century, long skirts dominated women's fashion, and the stock market experienced many bear markets. In the 1920s, flappers revealed their knees and the stock market boomed. Even the stock market crash of October 1987 was predicted by hemlines. During the 1980s, miniskirts flourished, but by October 1987 a fashion shift had women wearing longer skirts.

These are only three examples of what are known as "technical" trading rules. There are lots of others. How seriously should you take them? That's up to you, but our advice is to keep in mind that life is full of odd coincidences. Just because a bizarre stock market predictor seems to have worked well in the past doesn't mean that it's going to work in the future.

Investing in Growth Stocks

EXAMPLE 10.3

The term *growth stock* is frequently a euphemism for small-company stock. Are such investments suitable for "widows and orphans"? Before answering, you should consider the historical volatility. For example, from the historical record, what is the approximate probability that you will actually lose 16 percent or more of your money in a single year if you buy a portfolio of such companies?

Looking back at Figure 10.10, we see that the average return on small stocks is 16.4 percent, and the standard deviation is 33.0 percent. Assuming that the returns are approximately normal, there is about a $\frac{1}{3}$ probability that you will experience a return outside the range of -16.6 percent to 49.4 percent ($16.4\% \pm 33.0\%$).

Because the normal distribution is symmetric, the odds of being above or below this range are equal. There is thus a $\frac{1}{6}$ chance (half of $\frac{1}{3}$) that you will lose more than 16.6 percent. So, you should expect this to happen once in every six years, on average. Such investments can thus be very volatile, and they are not well suited for those who cannot afford the risk.

More on the Stock Market Risk Premium

As we have discussed, the historical stock market risk premium has been substantial. In fact, based on standard economic models, it has been argued that the historical risk premium is *too* big and is thus an overestimate of what is likely to happen in the future.

Of course, any time we use the past to predict the future, there is the danger that the past period we observe isn't representative of what the future will hold. For example, in this chapter, we studied the period 1926–2008. Perhaps investors got lucky over this period and earned particularly high returns. Data from earlier years is available, though it is not of the same quality. With that caveat in mind, researchers have traced returns back to 1802, and the risk premiums seen in the pre-1926 era are perhaps a little smaller, but not dramatically so.

Another possibility is that the U.S. stock market experience was unusually good. Investors in at least some other major countries did not do as well because their financial markets were nearly or completely wiped out because of revolution, war, and/or hyperinflation. A recent study addresses this issue by examining data from 1900–2005 for 17 countries.

Figure 10.12 shows the historical average stock market risk premium for all 17 countries over the 106-year period. Looking at the numbers, the U.S. risk premium is the 10th highest at 7.4 percent (which differs from our earlier estimate because of the differing time periods examined). The overall average risk premium is 7.1 percent. These numbers make it clear that U.S. investors did well, but not exceptionally so relative to investors in many other countries.

FIGURE 10.12**Stock market risk premiums for 17 countries: 1900–2005**

Source: Based on information in Elroy Dimson, Paul Marsh, and Michael Staunton, "The Worldwide Equity Premium: A Smaller Puzzle," in *Handbook of the Equity Risk Premium*, Rajnish Mehra, ed. (Elsevier: 2007).

So, is the U.S. stock market risk premium estimated from 1926–2008 too high? The evidence seems to suggest that the answer is “maybe a little.” One thing we haven’t stressed so far is that even with 106 years of data, the average risk premium is still not measured with great precision. From a statistical standpoint, the standard error associated with the U.S. estimated risk premium of 7.4 percent is about 2 percent. So, even one standard error range covers 5.4 to 9.4 percent.

CONCEPT QUESTIONS

- 10.4a** In words, how do we calculate a variance? A standard deviation?
- 10.4b** With a normal distribution, what is the probability of ending up more than one standard deviation below the average?
- 10.4c** Assuming that long-term corporate bonds have an approximately normal distribution, what is the approximate probability of earning 14.6 percent or more in a given year? With T-bills, approximately what is this probability?
- 10.4d** What is the second lesson from capital market history?

MORE ON AVERAGE RETURNS

10.5

Thus far in this chapter, we have looked closely at simple average returns. But there is another way of computing an average return. The fact that average returns are calculated two different ways leads to some confusion, so our goal in this section is to explain the two approaches and also the circumstances under which each is appropriate.

Arithmetic versus Geometric Averages

Let’s start with a simple example. Suppose you buy a particular stock for \$100. Unfortunately, the first year you own it, it falls to \$50. The second year you own it, it rises back to \$100, leaving you where you started (no dividends were paid).

What was your average return on this investment? Common sense seems to say that your average return must be exactly zero since you started with \$100 and ended with \$100. But if we calculate the returns year-by-year, we see that you lost 50 percent the first year (you lost half of your money). The second year, you made 100 percent (you doubled your money). Your average return over the two years was thus $(-50\% + 100\%)/2 = 25\%$!

So which is correct, 0 percent or 25 percent? The answer is that both are correct: They just answer different questions. The 0 percent is called the **geometric average return**. The 25 percent is called the **arithmetic average return**. The geometric average return answers the question “*What was your average compound return per year over a particular period?*” The arithmetic average return answers the question “*What was your return in an average year over a particular period?*”

Notice that, in previous sections, the average returns we calculated were all arithmetic averages, so we already know how to calculate them. What we need to do now is (1) learn how to calculate geometric averages and (2) learn the circumstances under which one average is more meaningful than the other.

Calculating Geometric Average Returns

First, to illustrate how we calculate a geometric average return, suppose a particular investment had annual returns of 10 percent, 12 percent, 3 percent, and –9 percent over the last four years. The geometric average return over this four-year period is calculated as

geometric average return

The average compound return earned per year over a multiyear period.

arithmetic average return

The return earned in an average year over a multiyear period.

$(1.10 \times 1.12 \times 1.03 \times .91)^{1/4} - 1 = 3.66\%$. In contrast, the average arithmetic return we have been calculating is $(.10 + .12 + .03 - .09)/4 = 4.0\%$.

In general, if we have T years of returns, the geometric average return over these T years is calculated using this formula:

$$\text{Geometric average return} = [(1 + R_1) \times (1 + R_2) \times \cdots \times (1 + R_T)]^{1/T} - 1 \quad [10.4]$$

This formula tells us that four steps are required:

1. Take each of the T annual returns R_1, R_2, \dots, R_T and add a one to each (after converting them to decimals!).
2. Multiply all the numbers from step 1 together.
3. Take the result from step 2 and raise it to the power of $1/T$.
4. Finally, subtract one from the result of step 3. The result is the geometric average return.

EXAMPLE 10.4

Calculating the Geometric Average Return

Calculate the geometric average return for the S&P 500 using the returns given below. To do so, convert percentages to decimal returns, add one, and then calculate their product:

S&P 500 Returns	Product
11.14%	1.1114
37.13	$\times 1.3713$
43.31	$\times 1.4331$
-8.91	$\times .9109$
-25.26	$\times .7474$
	1.4870

Notice that the number 1.4870 is what our investment is worth after five years if we started with a one dollar investment. The geometric average return is then calculated as:

$$\text{Geometric average return} = 1.4870^{1/5} - 1 = 0.0826, \text{ or } 8.26\%$$

Thus the geometric average return is about 8.26 percent in this example. Here is a tip: If you are using a financial calculator, you can put \$1 in as the present value, \$1.4870 as the future value, and 5 as the number of periods. Then, solve for the unknown rate. You should get the same answer we did.

One thing you may have noticed in our examples thus far is that the geometric average returns seem to be smaller. It turns out that this will always be true (as long as the returns are not all identical, in which case the two “averages” would be the same). To illustrate, Table 10.4 shows the arithmetic averages and standard deviations from Figure 10.10, along with the geometric average returns.

As shown in Table 10.4, the geometric averages are all smaller, but the magnitude of the difference varies quite a bit. The reason is that the difference is greater for more volatile investments. In fact, there is a useful approximation. Assuming all the numbers are expressed in decimals (as opposed to percentages), the geometric average return is approximately equal to the arithmetic average return minus half the variance. For example, looking at the large-company stocks, the arithmetic average is .117 and the standard deviation is .206, implying that the variance is .0424. The approximate geometric average is thus $.117 - \frac{.0424}{2} = .096$, which is the same as the actual value.

Series	Average Return		Standard Deviation
	Geometric	Arithmetic	
Large-company stocks	9.6%	11.7%	20.6%
Small-company stocks	11.7	16.4	33.0
Long-term corporate bonds	5.9	6.2	8.4
Long-term government bonds	5.7	6.1	9.4
Intermediate-term government bonds	5.4	5.6	5.7
U.S. Treasury bills	3.7	3.8	3.1
Inflation	3.0	3.1	4.2

TABLE 10.4

Geometric versus arithmetic average returns: 1926–2008

More Geometric Averages

EXAMPLE 10.5

Take a look back at Figure 10.4. There, we showed the value of a \$1 investment after 83 years. Use the value for the large-company stock investment to check the geometric average in Table 10.4.

In Figure 10.4, the large-company investment grew to \$2,049.45 over 83 years. The geometric average return is thus:

$$\text{Geometric average return} = 2,049.45^{1/83} - 1 = .096, \text{ or } 9.6\%$$

This 9.6% is the value shown in Table 10.4. For practice, check some of the other numbers in Table 10.4 the same way.

Arithmetic Average Return or Geometric Average Return?

When we look at historical returns, the difference between the geometric and arithmetic average returns isn't too hard to understand. To put it slightly differently, the geometric average tells you what you actually earned per year on average, compounded annually. The arithmetic average tells you what you earned in a typical year. You should use whichever one answers the question you want answered.

A somewhat trickier question concerns which average return to use when forecasting future wealth levels, and there's a lot of confusion on this point among analysts and financial planners. First, let's get one thing straight: If you *know* the true arithmetic average return, then this is what you should use in your forecast. So, for example, if you know the arithmetic return is 10 percent, then your best guess of the value of a \$1,000 investment in 10 years is the future value of \$1,000 at 10 percent for 10 years, or \$2,593.74.

The problem we face, however, is that we usually only have *estimates* of the arithmetic and geometric returns, and estimates have errors. In this case, the arithmetic average return is probably too high for longer periods and the geometric average is probably too low for shorter periods. So, you should regard long-run projected wealth levels calculated using arithmetic averages as optimistic. Short-run projected wealth levels calculated using geometric averages are probably pessimistic.

As a practical matter, if you are using averages calculated over a long period of time (such as the 83 years we use) to forecast up to a decade or so into the future, then you should use the arithmetic average. If you are forecasting a few decades into the future (such as you might do for retirement planning), then you should just split the difference between the arithmetic and geometric average returns. Finally, if for some reason you are doing very long forecasts covering many decades, use the geometric average.

This concludes our discussion of geometric versus arithmetic averages. One last note: In the future, when we say "average return," we mean arithmetic unless we explicitly say otherwise.

CONCEPT QUESTIONS

- 10.5a** If you wanted to forecast what the stock market is going to do over the next year, should you use an arithmetic or geometric average?
- 10.5b** If you wanted to forecast what the stock market is going to do over the next century, should you use an arithmetic or geometric average?

10.6

CAPITAL MARKET EFFICIENCY

efficient capital market

Market in which security prices reflect available information.

Capital market history suggests that the market values of stocks and bonds can fluctuate widely from year to year. Why does this occur? At least part of the answer is that prices change because new information arrives, and investors reassess asset values based on that information.

The behavior of market prices has been extensively studied. A question that has received particular attention is whether prices adjust quickly and correctly when new information arrives. A market is said to be *efficient* if this is the case. To be more precise, in an **efficient capital market**, current market prices fully reflect available information. By this we simply mean that, based on available information, there is no reason to believe that the current price is too low or too high.

The concept of market efficiency is a rich one, and much has been written about it. A full discussion of the subject goes beyond the scope of our study of business finance. However, because the concept figures so prominently in studies of market history, we briefly describe the key points here.

Price Behavior in an Efficient Market

To illustrate how prices behave in an efficient market, suppose the F-Stop Camera Corporation (FCC) has, through years of secret research and development, developed a camera whose autofocus system will double the speed of those now available. FCC's capital budgeting analysis suggests that launching the new camera is a highly profitable move; in other words, the NPV appears to be positive and substantial. The key assumption thus far is that FCC has not released any information about the new system, so the fact of its existence is "inside" information only.

Now, consider a share of stock in FCC. In an efficient market, its price reflects what is known about FCC's current operations and profitability, and it reflects market opinion about FCC's potential for future growth and profits. The value of the new autofocus system is not reflected, however, because the market is unaware of its existence.

If the market agrees with FCC's assessment of the value of the new project, FCC's stock price will rise when the decision to launch is made public. For example, assume the announcement is made in a press release on Wednesday morning. In an efficient market, the price of shares in FCC will adjust quickly to this new information. Investors should not be able to buy the stock on Wednesday afternoon and make a profit on Thursday. This would imply that it took the stock market a full day to realize the implication of the FCC press release. If the market is efficient, the price of shares of FCC stock on Wednesday afternoon will already reflect the information contained in the Wednesday morning press release.

Figure 10.13 presents three possible stock price adjustments for FCC. In the figure, Day 0 represents the announcement day. As illustrated, before the announcement, FCC's stock sells for \$140 per share. The NPV per share of the new system is, say, \$40, so the new price will be \$180 once the value of the new project is fully reflected.

FIGURE 10.13 Reaction of stock price to new information in efficient and inefficient markets

Efficient market reaction: The price instantaneously adjusts to and fully reflects new information; there is no tendency for subsequent increases and decreases.

Delayed reaction: The price partially adjusts to the new information; eight days elapse before the price completely reflects the new information.

Overreaction and correction: The price overadjusts to the new information; it overshoots the new price and subsequently corrects.

The solid line in Figure 10.13 represents the path taken by the stock price in an efficient market. In this case, the price adjusts immediately to the new information and no further changes in the price of the stock take place. The broken line in Figure 10.13 depicts a delayed reaction. Here, it takes the market eight days or so to fully absorb the information. Finally, the dotted line illustrates an overreaction and subsequent adjustment to the correct price.

The broken line and the dotted line in Figure 10.13 illustrate paths that the stock price might take in an inefficient market. If, for example, stock prices don't adjust immediately to new information (the broken line), then buying stock immediately following the release of new information and then selling it several days later would be a positive NPV activity because the price is too low for several days after the announcement.

The Efficient Markets Hypothesis

The **efficient markets hypothesis (EMH)** asserts that well-organized capital markets, such as the NYSE, are efficient markets, at least as a practical matter. In other words, an advocate of the EMH might argue that while inefficiencies may exist, they are relatively small and not common.

If a market is efficient, then there is a very important implication for market participants: All investments in an efficient market are *zero* NPV investments. The reason is not complicated. If prices are neither too low nor too high, then the difference between the market value of an investment and its cost is zero; hence, the NPV is zero. As a result, in an efficient market, investors get exactly what they pay for when they buy securities, and firms receive exactly what their stocks and bonds are worth when they sell them.

What makes a market efficient is competition among investors. Many individuals spend their entire lives trying to find mispriced stocks. For any given stock, they study what has happened in the past to the stock's price and its dividends. They learn, to the extent possible, what a company's earnings have been, how much it owes to creditors, what taxes it pays, what businesses it is in, what new investments are planned, how sensitive it is to changes in the economy, and so on.

Not only is there a great deal to know about any particular company, there is a powerful incentive for knowing it, namely, the profit motive. If you know more about some company

efficient markets hypothesis (EMH)

The hypothesis that actual capital markets, such as the NYSE, are efficient.

Can the Pros Beat the Market?

2008 was a good year for investors in the Forester Value fund, which posted a gain of 0.4 percent for the year. While a return this small does not usually grab attention, with the market down 39 percent for the year, it was the only mutual fund out of about 8,200 U.S. stock funds that posted a positive return for the year! Unfortunately, the success did not carry over into 2009 as the fund lost 13 percent in the first two months of the year. So, the question remains: Can professional investors consistently beat the market?

Heading into 2008, 14 U.S. mutual funds had outperformed the S&P 500 for nine straight years. However, only one of these funds, the Manning & Napier Pro-Blend Maximum Term Series, outperformed the market during the year, with a loss of “only” 35.4 percent. Several of the other funds were not as fortunate. For example, the Ivy Global Natural Resources fund lost about 61 percent, and the Fidelity Advisors Energy fund lost about 54 percent.

One thing we know for sure is that past performance is no predictor of future returns. For example, in July 1994, the American Century Giftrust fund had been the best performing mutual fund for the previous 10 years, with an average annual return above 20 percent. But the next 10 years weren’t as kind to the investors in this fund. The average annual return for 1994 to 2004 was 2.87 percent, which was lower than U.S. Treasury bills during the same period. Following the old saying “What

goes up, must come down,” other funds have had similar stories. The Van Wagoner Emerging Growth Fund returned 291.2 percent in 1999, only to lose 59.7 percent and 64.6 percent the next two years. Similarly, the Oppenheimer Enterprise Fund gained 105.75 percent in 1999, but lost 40.6 percent in 2000, followed by two more years of double-digit losses.

Sometimes we see proposed evidence showing that mutual fund managers collectively can beat the market. Consider 2005, when the S&P 500 gained about 3 percent. Diversified U.S. stock funds averaged 7 percent for the year, so it appears at first glance that mutual fund managers outperform the market. However, in 2008, only 42 percent of all managers outperformed the market, with an average return about 1 percent lower than the market return. Over the years, the track record of the pros is relatively clear: More often than not, they underperform. In fact, based on historical averages, about 70 percent of all managers will underperform in a typical year.

The inability of the pros to consistently beat the market doesn’t prove that markets are efficient. The evidence does, however, lend some credence to the semistrong form version of market efficiency. Plus, it adds to a growing body of evidence that tends to support a basic premise: While it may be possible to outperform the market for relatively short periods of time, it is very difficult to do so consistently over the long haul.

than other investors in the marketplace, you can profit from that knowledge by investing in the company’s stock if you have good news and by selling it if you have bad news.

The logical consequence of all this information being gathered and analyzed is that mispriced stocks will become fewer and fewer. In other words, because of competition among investors, the market will become increasingly efficient. A kind of equilibrium comes into being where there is just enough mispricing around for those who are best at identifying it to make a living at it. For most other investors, the activity of information gathering and analysis will not pay.⁴ Having said this, the accompanying *Reality Bytes* box indicates just how hard it is for *anybody* to “beat the market.”

Some Common Misconceptions about the EMH

No idea in finance has attracted as much attention as that of efficient markets, and not all of the attention has been flattering. Rather than rehash the arguments here, we will be content to observe that some markets are more efficient than others. For example, financial markets on the whole are probably much more efficient than real asset markets.

⁴ The idea behind the EMH can be illustrated by the following short story: A student was walking down the hall with her finance professor when they both saw a \$20 bill on the ground. As the student bent down to pick it up, the professor shook her head slowly and, with a look of disappointment on her face, said patiently to the student, “Don’t bother. If it were really there, someone else would have picked it up already.” The moral of the story reflects the logic of the efficient markets hypothesis: If you think you have found a pattern in stock prices or a simple device for picking winners, you probably have not.

Look under the “contents” link at www.investorhome.com for more info on the EMH.

Having said this, it is the case that much of the criticism of the EMH is misguided because it is based on a misunderstanding of what the hypothesis says and what it doesn't say. For example, when the notion of market efficiency was first publicized and debated in the popular financial press, it was often characterized by words to the effect that "throwing darts at the financial page will produce a portfolio that can be expected to do as well as any managed by professional security analysts."

Confusion over statements of this sort has often led to a failure to understand the implications of market efficiency. For example, sometimes it is wrongly argued that market efficiency means that it doesn't matter how you invest your money because the efficiency of the market will protect you from making a mistake. However, a random dart-thrower might wind up with all of the darts sticking into one or two high-risk stocks that deal in genetic engineering. Would you really want all of your money in two such stocks?

What efficiency does imply is that the price a firm will obtain when it sells a share of its stock is a "fair" price in the sense that it reflects the value of that stock given the information available about the firm. Shareholders do not have to worry that they are paying too much for a stock with a low dividend or some other sort of characteristic because the market has already incorporated that characteristic into the price. We sometimes say the information has been "priced out."

The concept of efficient markets can be explained further by replying to a frequent objection. It is sometimes argued that the market cannot be efficient because stock prices fluctuate from day to day. If the prices are right, the argument goes, then why do they change so much and so often? From our discussion above, we can see that these price movements are in no way inconsistent with efficiency. Investors are bombarded with information every day. The fact that prices fluctuate is, at least in part, a reflection of that information flow. In fact, the absence of price movements in a world that changes as rapidly as ours would suggest inefficiency.

The Forms of Market Efficiency

It is common to distinguish between three forms of market efficiency. Depending on the degree of efficiency, we say that markets are either *weak form efficient*, *semistrong form efficient*, or *strong form efficient*. The difference between these forms relates to what information is reflected in prices.

We start with the extreme case. If the market is strong form efficient, then *all* information of *every* kind is reflected in stock prices. In such a market, there is no such thing as inside information. Therefore, in our FCC example above, we apparently were assuming that the market was not strong form efficient.

Casual observation, particularly in recent years, suggests that inside information does exist and it can be valuable to possess. Whether it is lawful or ethical to use that information is another issue. In any event, we conclude that private information about a particular stock may exist that is not currently reflected in the price of the stock. For example, prior knowledge of a takeover attempt could be very valuable.

The second form of efficiency, semistrong efficiency, is the most controversial. If a market is semistrong form efficient, then all *public* information is reflected in the stock price. The reason this form is controversial is that it implies that security analysts who try to identify mispriced stocks using, for example, financial statement information are wasting their time because that information is already reflected in the current price.

The third form of efficiency, weak form efficiency, suggests that, at a minimum, the current price of a stock reflects its own past prices. In other words, studying past prices

in an attempt to identify mispriced securities is futile if the market is weak form efficient. While this form of efficiency might seem rather mild, it implies that searching for patterns in historical prices that are useful in identifying mispriced stocks will not work (this practice, known as “technical” analysis, is quite common).

What does capital market history say about market efficiency? Here again, there is great controversy. At the risk of going out on a limb, the evidence does seem to tell us three things. First: Prices do appear to respond very rapidly to new information, and the response is at least not grossly different from what we would expect in an efficient market. Second: The future of market prices, particularly in the short run, is very difficult to predict based on publicly available information. Third: If mispriced stocks do exist, then there is no obvious means of identifying them. Put another way: Simpleminded schemes based on public information will probably not be successful.

CONCEPT QUESTIONS

- 10.6a** What is an efficient market?
10.6b What are the forms of market efficiency?

SUMMARY AND CONCLUSIONS

This chapter has explored the subject of capital market history. Such history is useful because it tells us what to expect in the way of returns from risky assets. We summed up our study of market history with two key lessons:

1. Risky assets, on average, earn a risk premium. There is a reward for bearing risk.
2. The greater the potential reward from a risky investment, the greater is the risk.

These lessons have significant implications for the financial manager. We will be considering these implications in the chapters ahead.

We also discussed the concept of market efficiency. In an efficient market, prices adjust quickly and correctly to new information. Consequently, asset prices in efficient markets are rarely too high or too low. How efficient capital markets (such as the NYSE) are is a matter of debate, but, at a minimum, they are probably much more efficient than most real asset markets.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

- 10.1 Recent Return History.** Use Table 10.1 to calculate the average return over the years 1997–2001 for large-company stocks, long-term government bonds, and Treasury bills.
- 10.2 More Recent Return History.** Calculate the standard deviations using information from Problem 10.1. Which of the investments was the most volatile over this period?

■ Answers to Chapter Review and Self-Test Problems

10.1 We calculate the averages as follows:

Year	Actual Returns and Averages		
	Large-Company Stocks	Long-Term Government Bonds	Treasury Bills
1997	0.3336	0.1770	0.0519
1998	0.2858	0.1922	0.0486
1999	0.2104	-0.1276	0.0480
2000	-0.0910	0.2216	0.0598
2001	-0.1189	0.0530	0.0333
Average:	0.1240	0.1032	0.0483

10.2 We first need to calculate the deviations from the average returns. Using the averages from Problem 10.1, we get:

Year	Deviations from Average Returns		
	Large-Company Stocks	Long-Term Government Bonds	Treasury Bills
1997	0.2096	0.0738	0.0036
1998	0.1618	0.0890	0.0003
1999	0.0864	-0.2308	-0.0003
2000	-0.2150	0.1184	0.0115
2001	-0.2429	-0.0502	-0.0150
Total:	<u>0.0000</u>	<u>0.0000</u>	<u>0.0000</u>

We square these deviations and calculate the variances and standard deviations:

Year	Squared Deviations from Average Returns		
	Large-Company Stocks	Long-Term Government Bonds	Treasury Bills
1997	0.043941	0.0054	0.000013
1998	0.026186	0.0079	0.000000
1999	0.007468	0.0533	0.000000
2000	0.046216	0.0140	0.000132
2001	0.058991	0.0025	0.000226
Variance:	0.0457	0.0208	0.0001
Standard deviation:	0.2138	0.1442	0.0096

To calculate the variances, we added up the squared deviations and divided by 4, the number of returns less 1. Notice that the stocks had substantially greater volatility with a larger average return. Once again, such investments are risky, particularly over short periods of time.

CRITICAL THINKING AND CONCEPTS REVIEW

- L0 3** **10.1 Investment Selection.** Given that Emergent BioSolutions was up by 461 percent for 2008, why didn't all investors hold Emergent BioSolutions?
- L0 3** **10.2 Investment Selection.** Given that Fannie Mae was down by 98 percent for 2008, why did some investors hold the stock? Why didn't they sell out before the price declined so sharply?
- L0 3** **10.3 Risk and Return.** We have seen that over long periods of time, stock investments have tended to substantially outperform bond investments. However, it is not at all uncommon to observe investors with long horizons holding entirely bonds. Are such investors irrational?
- L0 4** **10.4 Market Efficiency Implications.** Explain why a characteristic of an efficient market is that investments in that market have zero NPVs.
- L0 4** **10.5 Efficient Markets Hypothesis.** A stock market analyst is able to identify mispriced stocks by comparing the average price for the last 10 days to the average price for the last 60 days. If this is true, what do you know about the market?
- L0 4** **10.6 Semistrong Efficiency.** If a market is semistrong form efficient, is it also weak form efficient? Explain.
- L0 4** **10.7 Efficient Markets Hypothesis.** What are the implications of the efficient markets hypothesis for investors who buy and sell stocks in an attempt to "beat the market"?
- L0 4** **10.8 Stocks versus Gambling.** Critically evaluate the following statement: Playing the stock market is like gambling. Such speculative investing has no social value, other than the pleasure people get from this form of gambling.
- L0 4** **10.9 Efficient Markets Hypothesis.** There are several celebrated investors and stock pickers frequently mentioned in the financial press who have recorded huge returns on their investments over the past two decades. Is the success of these particular investors an invalidation of the EMH? Explain.
- L0 4** **10.10 Efficient Markets Hypothesis.** For each of the following scenarios, discuss whether profit opportunities exist from trading in the stock of the firm under the conditions that (1) the market is not weak form efficient, (2) the market is weak form but not semistrong form efficient, (3) the market is semistrong form but not strong form efficient, and (4) the market is strong form efficient.
- The stock price has risen steadily each day for the past 30 days.
 - The financial statements for a company were released three days ago, and you believe you've uncovered some anomalies in the company's inventory and cost control reporting techniques that are causing the firm's true liquidity strength to be understated.
 - You observe that the senior management of a company has been buying a lot of the company's stock on the open market over the past week.

QUESTIONS AND PROBLEMS

connect

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

- L0 1** **1. Calculating Returns.** Suppose a stock had an initial price of \$83 per share, paid a dividend of \$1.40 per share during the year, and had an ending share price of \$96. Compute the percentage total return. What was the dividend yield? The capital gains yield?

Basic

(Questions 1–18)

- L0 1** 2. **Calculating Returns.** Rework Problem 1 assuming the ending share price is \$71.
- L0 1** 3. **Calculating Dollar Returns.** You purchased 250 shares of a particular stock at the beginning of the year at a price of \$75.13. The stock paid a dividend of \$0.85 per share, and the stock price at the end of the year was \$81.64. What was your dollar return on this investment?
- L0 1** 4. **Calculating Returns.** Suppose you bought a 7 percent coupon bond one year ago for \$893. The bond sells for \$918 today.
- Assuming a \$1,000 face value, what was your total dollar return on this investment over the past year?
 - What was your total nominal rate of return on this investment over the past year?
 - If the inflation rate last year was 4 percent, what was your total real rate of return on this investment?
- L0 2** 5. **Nominal versus Real Returns.** What was the arithmetic average annual return on large-company stocks from 1926 through 2008:
- In nominal terms?
 - In real terms?
- L0 2** 6. **Bond Returns.** What is the historical real return on long-term government bonds? On long-term corporate bonds?
- L0 1** 7. **Calculating Returns and Variability.** Using the following returns, calculate the average returns, the variances, and the standard deviations for X and Y.

Year	Returns	
	X	Y
1	21%	24%
2	-16	-3
3	9	26
4	18	-13
5	4	30

- L0 2** 8. **Risk Premiums.** Refer to Table 10.1 in the text and look at the period from 1973 through 1978.
- Calculate the arithmetic average returns for large-company stocks and T-bills over this time period.
 - Calculate the standard deviation of the returns for large-company stocks and T-bills over this time period.
 - Calculate the observed risk premium in each year for the large-company stocks versus the T-bills. What was the arithmetic average risk premium over this period? What was the standard deviation of the risk premium over this period?
 - Is it possible for the risk premium to be negative before an investment is undertaken? Can the risk premium be negative after the fact? Explain.

- L0 1** 9. **Calculating Returns and Variability.** You've observed the following returns on Staverosky Corporation's stock over the past five years: -24 percent, 13 percent, 29 percent, 2 percent, and 21 percent.
- What was the arithmetic average return on the stock over this five-year period?
 - What was the variance of the returns over this period? The standard deviation?
- L0 1** 10. **Calculating Real Returns and Risk Premiums.** For Problem 9, suppose the average inflation rate over this period was 3.2 percent and the average T-bill rate over the period was 4.3 percent.
- What was the average real return on the stock?
 - What was the average nominal risk premium on the stock?
- L0 1** 11. **Calculating Real Rates.** Given the information in Problem 10, what was the average real risk-free rate over this time period? What was the average real risk premium?
- L0 2** **L0 3** 12. **Effects of Inflation.** Look at Table 10.1 and Figure 10.7 in the text. When were T-bill rates at their highest over the period from 1926 through 2008? Why do you think they were so high during this period? What relationship underlies your answer?
- L0 1** 13. **Calculating Returns.** You purchased a zero-coupon bond one year ago for \$275.83. The market interest rate is now 9 percent. If the bond had 15 years to maturity when you originally purchased it, what was your total return for the past year?
- L0 1** 14. **Calculating Returns.** You bought a share of 5.5 percent preferred stock for \$92.18 last year. The market price for your stock is now \$94.17. What is your total return for last year?
- L0 1** 15. **Calculating Returns.** You bought a stock three months ago for \$73.82 per share. The stock paid no dividends. The current share price is \$76.09. What is the APR of your investment? The EAR?
- L0 1** 16. **Calculating Real Returns.** Refer to Table 10.1. What was the average real return for Treasury bills from 1926 through 1932?
- L0 3** 17. **Return Distributions.** Refer back to Figure 10.10. What range of returns would you expect to see 68 percent of the time for long-term corporate bonds? What about 95 percent of the time?
- L0 3** 18. **Return Distributions.** Refer back to Figure 10.10. What range of returns would you expect to see 68 percent of the time for large-company stocks? What about 95 percent of the time?
- L0 1** 19. **Calculating Returns and Variability.** You find a certain stock that had returns of 12 percent, -21 percent, 27 percent, and 18 percent for four of the last five years. If the average return of the stock over this period was 10 percent, what was the stock's return for the missing year? What is the standard deviation of the stock's returns?
- L0 1** 20. **Arithmetic and Geometric Returns.** A stock has had returns of -18 percent, 28 percent, 12 percent, -9 percent, 34 percent, and 26 percent over the last six years. What are the arithmetic and geometric returns for the stock?
- L0 1** 21. **Arithmetic and Geometric Returns.** A stock has had the following year-end prices and dividends:

Intermediate
(Questions 19–26)

Year	Price	Dividend
1	\$64.18	—
2	71.05	\$0.57
3	76.85	0.62
4	63.12	0.68
5	72.81	0.77
6	78.25	0.84

What are the arithmetic and geometric returns for the stock?

- L0 2** 22. **Calculating Returns.** Refer to Table 10.1 in the text and look at the period from 1973 through 1980.
- L0 3**
- Calculate the average return for Treasury bills and the average annual inflation rate (consumer price index) for this period.
 - Calculate the standard deviation of Treasury bill returns and inflation over this time period.
 - Calculate the real return for each year. What is the average real return for Treasury bills?
 - Many people consider Treasury bills to be risk-free. What does this tell you about the potential risks of Treasury bills?
- L0 1** 23. **Calculating Investment Returns.** You bought one of Rocky Mountain Manufacturing Co.'s 8 percent coupon bonds one year ago for \$1,045.30. These bonds make annual payments and mature nine years from now. Suppose you decide to sell your bonds today, when the required return on the bonds is 7.5 percent. If the inflation rate was 3.5 percent over the past year, what would be your total real return on investment?
- L0 3** 24. **Using Return Distributions.** Suppose the returns on long-term government bonds are normally distributed. Based on the historical record, what is the approximate probability that your return on these bonds will be less than -3.3 percent in a given year? What range of returns would you expect to see 95 percent of the time? What range would you expect to see 99 percent of the time?
- L0 3** 25. **Using Return Distributions.** Assuming that the returns from holding small-company stocks are normally distributed, what is the approximate probability that your money will double in value in a single year? What about triple in value?
- L0 3** 26. **Distributions.** In the previous problem, what is the probability that the return is less than -100 percent (think)? What are the implications for the distribution of returns?
- L0 3** 27. **Using Probability Distributions.** Suppose the returns on large-company stocks are normally distributed. Based on the historical record, use the NORMDIST function in Excel® to determine the probability that in any given year you will lose money by investing in common stock.
- L0 3** 28. **Using Probability Distributions.** Suppose the returns on long-term corporate bonds and T-bills are normally distributed. Based on the historical record, use the NORMDIST function in Excel® to answer the following questions:
- What is the probability that in any given year, the return on long-term corporate bonds will be greater than 10 percent? Less than 0 percent?

Challenge
(Questions 27–28)

- b. What is the probability that in any given year, the return on T-bills will be greater than 10 percent? Less than 0 percent?
- c. In 1979, the return on long-term corporate bonds was -4.18 percent. How likely is it that such a low return will recur at some point in the future? T-bills had a return of 10.56 percent in this same year. How likely is it that such a high return on T-bills will recur at some point in the future?

WHAT'S ON THE WEB?

10.1 Historical Interest Rates. Go to the St. Louis Federal Reserve Web site at www.stlouisfed.org and find the “FRED®” link and the “Interest Rates” link. You will find a list of links for different historical interest rates. Follow the “10-Year Treasury Constant Maturity Rate” link and you will find the monthly 10-year Treasury note interest rates. Calculate the average annual 10-year Treasury interest rate for 2007 and 2008. Compare this number to the long-term government bond returns and the U.S. Treasury bill returns found in Table 10.1. How does the 10-year Treasury interest rate compare to these numbers? Do you expect this relationship to always hold? Why or why not?

CHAPTER CASE

A JOB AT S&S AIR

You recently graduated from college, and your job search led you to S&S Air. Since you felt the company's business was headed skyward, you accepted the job offer. As you are finishing your employment paperwork, Chris Guthrie, who works in the finance department, stops by to inform you about the company's new 401(k) plan.

A 401(k) is a type of retirement plan offered by many companies. A 401(k) is tax deferred, which means that any deposits you make into the plan are deducted from your current income, so no current taxes are paid on the money. For example, assume your salary will be \$30,000 per year. If you contribute \$1,500 to the 401(k) plan, you will pay taxes only on \$28,500 in income. No taxes will be due on any capital gains or plan income while you are invested in the plan, but you will pay taxes when you withdraw the money at retirement. You can contribute up to 15 percent of your salary to the plan. As is common, S&S Air also has a five percent match program. This means that the company will match your contribution dollar-for-dollar up to five percent of your salary, but you must contribute to get the match.

The 401(k) plan has several options for investments, most of which are mutual funds. As you know, a mutual fund is a portfolio of assets. When you purchase shares in a mutual fund, you are actually purchasing partial ownership of the fund's assets, similar to purchasing shares of stock in a company. The return of the fund is the weighted average of the return of the assets owned by the fund, minus any expenses. The largest expense is typically the management fee paid to the fund manager, who makes all of the investment decisions for the fund. S&S Air uses Arias Financial Services as its 401(k) plan administrator.

Chris Guthrie then explains that the retirement investment options offered for employees are as follows:

1. *Company Stock*. One option is stock in S&S Air. The company is currently privately held. The price you would pay for the stock is based on an annual appraisal, less a 20 percent discount. When you interviewed with the owners, Mark Sexton and Todd Story, they informed you that the company stock was expected to be publicly sold in three to five years. If you needed to sell the stock before it became publicly traded, the company would buy it back at the then-current appraised value.
2. *Arias S&P 500 Index Fund*. This mutual fund tracks the S&P 500. Stocks in the fund are weighted exactly the same as they are in the S&P 500. This means that the fund's return is approximately the return of the S&P 500, minus expenses. With an index fund, the manager is not required to research stocks and make investment decisions, so fund expenses are usually low. The Arias S&P 500 Index Fund charges expenses of 0.20 percent of assets per year.
3. *Arias Small-Cap Fund*. This fund primarily invests in small capitalization stocks. As such, the returns of the fund are more volatile. The fund can also invest 10 percent of its assets in companies based outside the United States. This fund charges 1.70 percent of assets in expenses per year.
4. *Arias Large-Company Stock Fund*. This fund invests primarily in large capitalization stocks of companies based in the United States. The fund is managed by Melissa Arias and has outperformed the market in six of the last eight years. The fund charges 1.50 percent in expenses.
5. *Arias Bond Fund*. This fund invests in long-term corporate bonds issued by U.S. domiciled companies. The fund is restricted to investments in bonds with an investment grade credit rating. This fund charges 1.40 percent in expenses.
6. *Arias Money Market Fund*. This fund invests in short-term, high credit quality debt instruments, which include Treasury bills. As such, the return on money market funds is only slightly higher than the return on Treasury bills. Because of the credit quality and short-term nature of the investments, there is only a very slight risk of negative return. The fund charges 0.60 percent in expenses. ■

QUESTIONS

1. What advantages/disadvantages do the mutual funds offer compared to company stock for your retirement investing?
2. Notice that, for every dollar you invest, S&S Air also invests a dollar. What return on your investment does this represent? What does your answer suggest about matching programs?
3. Assume you decide you should invest at least part of your money in large capitalization stocks of companies based in the United States. What are the advantages and disadvantages of choosing the Arias Large-Company Stock Fund compared to the Arias S&P 500 Index Fund?
4. The returns of the Arias Small-Cap Fund are the most volatile of all the mutual funds offered in the 401 (k) plan. Why would you ever want to invest in this fund? When you examine the expenses of the mutual funds, you will notice that this fund also has the highest expenses. Will this affect your decision to invest in this fund?
5. A measure of risk-adjusted performance that is often used in practice is the Sharpe ratio. The Sharpe ratio is calculated as the risk premium of an asset divided by its standard deviation.
The standard deviations and returns for the funds over the past 10 years are listed below. Assuming a risk-free rate of 4 percent, calculate the Sharpe ratio for each of these. In broad terms, what do you suppose the Sharpe ratio is intended to measure?

	10-year Annual Return	Standard Deviation
Arias S&P 500 Index Fund	9.75%	17.32%
Arias Small-Cap Fund	13.05	21.05
Arias Large-Company Stock Fund	10.08	19.86
Arias Bond Fund	8.45	9.01

Risk and Return

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Calculate expected returns.
- LO 2** Explain the impact of diversification.
- LO 3** Define the systematic risk principle.
- LO 4** Discuss the security market line and the risk-return trade-off.

In March 2009, American Eagle Outfitters, Jackson Hewitt, and D. R. Horton joined a host of other companies in announcing operating results. As you might expect, news such as this tends to move stock prices. American Eagle reported that revenue had dropped by 9 percent from the previous year, and net income was about 15 percent below analysts' expectations. Surprisingly, the stock price jumped up 1.25 percent on that day. Jackson Hewitt, the tax preparation company, announced earnings that exceeded estimates and were, in fact, 18 percent higher than the previous year's, but the stock price dropped about 45 percent. D. R. Horton's CEO exclaimed, "It was a wonderful quarter!" after the company's orders fell by 35 percent. The stock jumped 21 percent on the announcement.

Two of these announcements seem negative, yet the stock price rose. The other announcement seems to be positive, yet the stock price fell sharply. So when is good news really good news? The answer is fundamental to understanding risk and return, and—the good news is—this chapter explores it in detail.

This chapter continues the discussion we began in the previous chapter. We've seen pretty clearly that some investments have greater risks than others. We now begin to drill down a bit to investigate one of the most fundamental problems in finance: Just what is risk? What we will learn is that risk is not always what it seems, and the reward for bearing risk is more subtle than we have indicated so far. Understanding how risks are rewarded is important for everyone in business for the simple reason that business is risky, and only businesses that manage risk wisely will survive over the long haul.

Visit us at www.mhhe.com/rwj

In our last chapter, we learned some important lessons from capital market history. Most importantly, there is a reward, on average, for bearing risk. We called this reward a *risk premium*. The second lesson is that this risk premium is larger for riskier investments. This chapter explores the economic and managerial implications of this basic idea.

Thus far, we have concentrated mainly on the return behavior of a few large portfolios. We need to expand our consideration to include individual assets. Specifically, we have two tasks to accomplish. First, we have to define risk and then discuss how to measure it. We then must quantify the relationship between an asset's risk and its required return.

When we examine the risks associated with individual assets, we find there are two types of risk: systematic and unsystematic. This distinction is crucial because, as we will see, systematic risk affects almost all assets in the economy, at least to some degree, while unsystematic risk affects at most a small number of assets. We then develop the principle of diversification, which shows that highly diversified portfolios will tend to have almost no unsystematic risk.

The principle of diversification has an important implication: To a diversified investor, only systematic risk matters. It follows that in deciding whether or not to buy a particular individual asset, a diversified investor will only be concerned with that asset's systematic risk. This is a key observation, and it allows us to say a great deal about the risks and returns on individual assets. In particular, it is the basis for a famous relationship between risk and return called the *security market line*, or SML. To develop the SML, we introduce the equally famous "beta" coefficient, one of the centerpieces of modern finance. Beta and the SML are key concepts because they supply us with at least part of the answer to the question of how to go about determining the required return on an investment.

11.1

EXPECTED RETURNS AND VARIANCES

In our previous chapter, we discussed how to calculate average returns and variances using historical data. We now begin to discuss how to analyze returns and variances when the information we have concerns future possible returns and their probabilities.

Expected Return

We start with a straightforward case. Consider a single period of time, say, a year. We have two stocks, L and U, which have the following characteristics: Stock L is expected to have a return of 25 percent in the coming year. Stock U is expected to have a return of 20 percent for the same period.

In a situation like this, if all investors agreed on the expected returns, why would anyone want to hold Stock U? After all, why invest in one stock when the expectation is that another will do better? Clearly, the answer must depend on the risk of the two investments. The return on Stock L, although it is *expected* to be 25 percent, could actually turn out to be higher or lower.

For example, suppose the economy booms. In this case, we think Stock L will have a **70 percent** return. If the economy enters a recession, we think the return will be **−20 percent**. In this case, we say that there are two *states of the economy*, which means that these are the only two possible situations. This setup is oversimplified, of course, but it allows us to illustrate some key ideas without a lot of computation.

Suppose we think a boom and a recession are equally likely to happen, for a 50–50 chance of each. Table 11.1 illustrates the basic information we have described and some additional information about Stock U. Notice that Stock U earns **30 percent** if there is a recession and **10 percent** if there is a boom.

State of Economy	Probability of State of Economy	Security Returns if State Occurs	
		Stock L	Stock U
Recession	.5	-20%	30%
Boom	.5	70	10
	1.0		

TABLE 11.1

States of the economy and stock returns

(1) State of Economy	(2) Probability of State of Economy	Stock L		Stock U	
		(3) Rate of Return if State Occurs	(4) Product (2) × (3)	(5) Rate of Return if State Occurs	(6) Product (2) × (5)
Recession	.5	-.20	-.10	.30	.15
Boom	.5	.70	.35	.10	.05
	1.0		$E(R_L) = .25$		$E(R_U) = .20$

TABLE 11.2

Calculation of expected return

Obviously, if you buy one of these stocks, say Stock U, what you earn in any particular year depends on what the economy does during that year. However, suppose the probabilities stay the same through time. If you hold U for a number of years, you'll earn 30 percent about half the time and 10 percent the other half. In this case, we say that your **expected return** on Stock U, $E(R_U)$, is 20 percent:

$$E(R_U) = .50 \times 30\% + .50 \times 10\% = 20\%$$

In other words, you should expect to earn 20 percent from this stock, on average.

For Stock L, the probabilities are the same, but the possible returns are different. Here we lose 20 percent half the time, and we gain 70 percent the other half. The expected return on L, $E(R_L)$, is thus 25 percent:

$$E(R_L) = .50 \times -20\% + .50 \times 70\% = 25\%$$

Table 11.2 illustrates these calculations.

In our previous chapter, we defined the risk premium as the difference between the return on a risky investment and that on a risk-free investment, and we calculated the historical risk premiums on some different investments. Using our projected returns, we can calculate the *projected*, or *expected*, risk premium as the difference between the expected return on a risky investment and the certain return on a risk-free investment.

For example, suppose risk-free investments are currently offering 8 percent. We will say that the risk-free rate, which we label as R_f , is 8 percent. Given this, what is the projected risk premium on Stock U? On Stock L? Since the expected return on Stock U, $E(R_U)$, is 20 percent, the projected risk premium is:

$$\begin{aligned}
 \text{Risk premium} &= \text{Expected return} - \text{Risk-free rate} \\
 &= E(R_U) - R_f \\
 &= 20\% - 8\% \\
 &= 12\%
 \end{aligned}
 \tag{11.1}$$

Similarly, the risk premium on Stock L is $25\% - 8\% = 17\%$.

expected return

Return on a risky asset expected in the future

In general, the expected return on a security or other asset is simply equal to the sum of the possible returns multiplied by their probabilities. So, if we had 100 possible returns, we would multiply each one by its probability and then add the results up. The result would be the expected return. The risk premium would then be the difference between this expected return and the risk-free rate.

EXAMPLE 11.1

Unequal Probabilities

Look again at Tables 11.1 and 11.2. Suppose you thought a boom would occur only 20 percent of the time instead of 50 percent. What are the expected returns on Stocks U and L in this case? If the risk-free rate is 10 percent, what are the risk premiums?

The first thing to notice is that a recession must occur 80 percent of the time ($1 - .20 = .80$) since there are only two possibilities. With this in mind, we see that Stock U has a 30 percent return in 80 percent of the years and a 10 percent return in 20 percent of the years. To calculate the expected return, we again just multiply the possibilities by the probabilities and add up the results:

$E(R_U) = .80 \times 30\% + .20 \times 10\% = 26\%$

Table 11.3 summarizes the calculations for both stocks. Notice that the expected return on L is -2 percent.

The risk premium for Stock U is $26\% - 10\% = 16\%$ in this case. The risk premium for Stock L is negative: $-2\% - 10\% = -12\%$. This is a little odd, but, for reasons we discuss later, it is not impossible.

Calculating the Variance

To calculate the variances of the returns on our two stocks, we first determine the squared deviations from the expected returns. We then multiply each possible squared deviation by its probability. We add these up, and the result is the variance. The standard deviation, as always, is the square root of the variance.

To illustrate, Stock U above has an expected return of $E(R_U) = 20\%$. In a given year, it will actually return either 30 percent or 10 percent. The possible deviations are thus $30\% - 20\% = 10\%$ and $10\% - 20\% = -10\%$. In this case, the variance is:

$Variance = \sigma_U^2 = .50 \times (10\%)^2 + .50 \times (-10\%)^2 = .01$

TABLE 11.3		Stock L		Stock U	
Calculation of expected return	(1) State of Economy	(2) Probability of State of Economy	(3) Rate of Return if State Occurs	(5) Rate of Return if State Occurs	(6) Product (2) × (5)
			(4) Product (2) × (3)		(2) × (5)
	Recession	.8	-.20	.30	.24
	Boom	.2	.70	.10	.02
		1.0			
			$E(R_L) = -.02$		$E(R_U) = .26$

					TABLE 11.4
(1) State of Economy	(2) Probability of State of Economy	(3) Return Deviation from Expected Return	(4) Squared Return Deviation from Expected Return	(5) Product (2) × (4)	Calculation of variance
Stock L					
Recession	.5	$-.20 - .25 = -.45$	$-.45^2 = .2025$.10125	
Boom	.5	$.70 - .25 = .45$	$.45^2 = .2025$.10125	
	1.0			$\sigma_L^2 = .2025$	
Stock U					
Recession	.5	$.30 - .20 = .10$	$.10^2 = .01$.00500	
Boom	.5	$.10 - .20 = -.10$	$-.10^2 = .01$.00500	
	1.0			$\sigma_U^2 = .0100$	

The standard deviation is the square root of this:

$$\text{Standard deviation} = \sigma_U = \sqrt{.01} = .10 = 10\%$$

Table 11.4 summarizes these calculations for both stocks. Notice that Stock L has a much larger variance.

When we put the expected return and variability information for our two stocks together, we have:

	Stock L	Stock U
Expected return, $E(R)$	25%	20%
Variance, σ^2	.2025	.0100
Standard deviation, σ	45%	10%

Stock L has a higher expected return, but U has less risk. You could get a 70 percent return on your investment in L, but you could also lose 20 percent. Notice that an investment in U will always pay at least 10 percent.

Which of these two stocks should you buy? We can't really say; it depends on your personal preferences. We can be reasonably sure, however, that some investors would prefer L to U and some would prefer U to L.

You've probably noticed that the way we calculated expected returns and variances here is somewhat different from the way we did it in the last chapter. The reason is that, in Chapter 10, we were examining actual historical returns, so we estimated the average return and the variance based on some actual events. Here, we have projected *future* returns and their associated probabilities, so this is the information with which we must work.

More Unequal Probabilities

EXAMPLE 11.2

Going back to Example 11.1, what are the variances on the two stocks once we have unequal probabilities? The standard deviations?

(continued)

We can summarize the needed calculations as follows:

(1) State of Economy	(2) Probability of State of Economy	(3) Return Deviation from Expected Return	(4) Squared Return Deviation from Expected Return	(5) Product (2) × (4)
Stock L				
Recession	.80	$-.20 - (-.02) = -.18$.0324	.02592
Boom	.20	$.70 - (-.02) = .72$.5184	.10368
				$\sigma_L^2 = .12960$
Stock U				
Recession	.80	$.30 - .26 = .04$.0016	.00128
Boom	.20	$.10 - .26 = -.16$.0256	.00512
				$\sigma_U^2 = .00640$

Based on these calculations, the standard deviation for L is $\sigma_L = \sqrt{.1296} = .36$, or 36%. The standard deviation for U is much smaller; $\sigma_U = \sqrt{.0064} = .08$, or 8%.

CONCEPT QUESTIONS

11.1a How do we calculate the expected return on a security?

11.1b In words, how do we calculate the variance of the expected return?

11.2

PORTFOLIOS

portfolio

Group of assets such as stocks and bonds held by an investor.

Thus far in this chapter, we have concentrated on individual assets considered separately. However, most investors actually hold a **portfolio** of assets. All we mean by this is that investors tend to own more than just a single stock, bond, or other asset. Given that this is so, portfolio return and portfolio risk are of obvious relevance. Accordingly, we now discuss portfolio expected returns and variances.

Portfolio Weights

There are many equivalent ways of describing a portfolio. The most convenient approach is to list the percentages of the total portfolio's value that are invested in each portfolio asset. We call these percentages the **portfolio weights**.

portfolio weight

Percentage of a portfolio's total value in a particular asset.

For example, if we have \$50 in one asset and \$150 in another, then our total portfolio is worth \$200. The percentage of our portfolio in the first asset is $\$50/\$200 = .25$. The percentage of our portfolio in the second asset is $\$150/\200 , or .75. Our portfolio weights are thus .25 and .75. Notice that the weights have to add up to 1.00 since all of our money is invested somewhere.¹

Portfolio Expected Returns

Let's go back to Stocks L and U. You put half your money in each. The portfolio weights are obviously .50 and .50. What is the pattern of returns on this portfolio? The expected return?

¹ Some of it could be in cash, of course, but we would then just consider the cash to be one of the portfolio assets.

(1) State of Economy	(2) Probability of State of Economy	(3) Portfolio Return if State Occurs	(4) Product (2) × (3)
Recession	.50	$.50 \times -20\% + .50 \times 30\% = 5\%$.025
Boom	.50	$.50 \times 70\% + .50 \times 10\% = 40\%$.200
	1.00		$E(R_p) = .225$

TABLE 11.5

Expected return on an equally weighted portfolio of Stock L and Stock U

To answer these questions, suppose the economy actually enters a recession. In this case, half your money (the half in L) loses 20 percent. The other half (the half in U) gains 30 percent. Your portfolio return, R_p , in a recession will thus be:

$$R_p = .50 \times -20\% + .50 \times 30\% = 5\%$$

Table 11.5 summarizes the remaining calculations. Notice that when a boom occurs, your portfolio will return 40 percent:

$$R_p = .50 \times 70\% + .50 \times 10\% = 40\%$$

As indicated in Table 11.5, the expected return on your portfolio, $E(R_p)$, is 22.5 percent.

We can save ourselves some work by calculating the expected return more directly. Given these portfolio weights, we could have reasoned that we expect half of our money to earn 25 percent (the half in L) and half of our money to earn 20 percent (the half in U). Our portfolio expected return is thus:

$$\begin{aligned} E(R_p) &= .50 \times E(R_L) + .50 \times E(R_U) \\ &= .50 \times 25\% + .50 \times 20\% \\ &= 22.5\% \end{aligned}$$

This is the same portfolio expected return we had before.

This method of calculating the expected return on a portfolio works no matter how many assets there are in the portfolio. Suppose we had n assets in our portfolio, where n is any number. If we let x_i stand for the percentage of our money in Asset i , then the expected return is:

$$E(R_p) = x_1 \times E(R_1) + x_2 \times E(R_2) + \cdots + x_n \times E(R_n) \quad [11.2]$$

This says that the expected return on a portfolio is a straightforward combination of the expected returns on the assets in that portfolio. This seems somewhat obvious, but, as we will examine next, the obvious approach is not always the right one.

Portfolio Expected Return

EXAMPLE 11.3

Suppose we have the following projections on three stocks:

State of Economy	Probability of State	Returns		
		Stock A	Stock B	Stock C
Boom	.40	10%	15%	20%
Bust	.60	8	4	0

(continued)

We want to calculate portfolio expected returns in two cases. First: What would be the expected return on a portfolio with equal amounts invested in each of the three stocks? Second: What would be the expected return if half of the portfolio were in A, with the remainder equally divided between B and C?

From our earlier discussions, the expected returns on the individual stocks are (check these for practice):

$E(R_A) = 8.8\%$
 $E(R_B) = 8.4\%$
 $E(R_C) = 8.0\%$

If a portfolio has equal investments in each asset, the portfolio weights are all the same. Such a portfolio is said to be *equally weighted*. Since there are three stocks in this case, the weights are all equal to $1/3$. The portfolio expected return is thus:

$E(R_P) = 1/3 \times 8.8\% + 1/3 \times 8.4\% + 1/3 \times 8.0\% = 8.4\%$

In the second case, verify that the portfolio expected return is 8.5 percent.

Portfolio Variance

From our discussion above, the expected return on a portfolio that contains equal investments in Stocks U and L is 22.5 percent. What is the standard deviation of return on this portfolio? Simple intuition might suggest that half of the money has a standard deviation of 45 percent and the other half has a standard deviation of 10 percent, so the portfolio’s standard deviation might be calculated as:

$\sigma_P = .50 \times 45\% + .50 \times 10\% = 27.5\%$

Unfortunately, this approach is completely incorrect!

Let’s see what the standard deviation really is. Table 11.6 summarizes the relevant calculations. As we see, the portfolio’s variance is about .031, and its standard deviation is less than we thought—it’s only 17.5 percent. What is illustrated here is that the variance on a portfolio is not generally a simple combination of the variances of the assets in the portfolio.

We can illustrate this point a little more dramatically by considering a slightly different set of portfolio weights. Suppose we put $2/11$ (about 18 percent) in L and the other $9/11$ (about 82 percent) in U. If a recession occurs, this portfolio will have a return of:

$R_P = 2/11 \times -20\% + 9/11 \times 30\% = 20.91\%$

If a boom occurs, this portfolio will have a return of:

$R_P = 2/11 \times 70\% + 9/11 \times 10\% = 20.91\%$

TABLE 11.6	(1)	(2)	(3)	(4)	(5)
	State of Economy	Probability of State of Economy	Portfolio Return if State Occurs	Squared Deviation from Expected Return	Product (2) × (4)
Variance on an equally weighted portfolio of Stock L and Stock U	Recession	.50	5%	$(.05 - .225)^2 = .030625$.0153125
	Boom	.50	40	$(.40 - .225)^2 = .030625$.0153125
		1.00			$\sigma_P^2 = .030625$
					$\sigma_P = \sqrt{.030625} = 17.5\%$

Notice that the return is the same no matter what happens. No further calculations are needed: This portfolio has a zero variance. Apparently, combining assets into portfolios can substantially alter the risks faced by the investor. This is a crucial observation, and we will begin to explore its implications in the next section.

Portfolio Variance and Standard Deviation

EXAMPLE 11.4

In Example 11.3, what are the standard deviations on the two portfolios? To answer, we first have to calculate the portfolio returns in the two states. We will work with the second portfolio, which has 50 percent in Stock A and 25 percent in each of Stocks B and C. The relevant calculations can be summarized as follows:

State of Economy	Probability of State	Returns			
		Stock A	Stock B	Stock C	Portfolio
Boom	.40	10%	15%	20%	13.75%
Bust	.60	8	4	0	5.00

The portfolio return when the economy booms is calculated as:

$$.50 \times 10\% + .25 \times 15\% + .25 \times 20\% = 13.75\%$$

The return when the economy goes bust is calculated the same way. The expected return on the portfolio is .085. The variance is thus:

$$\begin{aligned}\sigma^2 &= .40 \times (.1375 - .085)^2 + .60 \times (.05 - .085)^2 \\ &= .0018375\end{aligned}$$

The standard deviation is thus about 4.3 percent. For our equally weighted portfolio, verify that the standard deviation is about 5.4 percent.

CONCEPT QUESTIONS

11.2a What is a portfolio weight?

11.2b How do we calculate the expected return on a portfolio?

11.2c Is there a simple relationship between the standard deviation on a portfolio and the standard deviations of the assets in the portfolio?

ANNOUNCEMENTS, SURPRISES, AND EXPECTED RETURNS

11.3

Now that we know how to construct portfolios and evaluate their returns, we begin to describe more carefully the risks and returns associated with individual securities. Thus far, we have measured volatility by looking at the difference between the actual return on an asset or portfolio, R , and the expected return, $E(R)$. We now look at why such deviations exist.

Expected and Unexpected Returns

To begin, for concreteness, we consider the return on the stock of a company called Flyers. What will determine this stock's return in, say, the coming year?

The return on any stock traded in a financial market is composed of two parts. First, the normal, or expected, return from the stock is the part of the return that shareholders in the market predict or expect. This return depends on the information shareholders have that bears on the stock, and it is based on the market's understanding today of the important factors that will influence the stock in the coming year.

The second part of the return on the stock is the uncertain, or risky, part. This is the portion that comes from unexpected information revealed within the year. A list of all possible sources of such information would be endless, but here are a few examples:

- News about research on Flyers
- Government figures released on gross domestic product (GDP).
- The results from the latest arms control talks.
- The news that Flyers's sales figures are higher than expected.
- A sudden, unexpected drop in interest rates.

Based on this discussion, one way to express the return on Flyers stock in the coming year would be:

$$\begin{aligned}\text{Total return} &= \text{Expected return} + \text{Unexpected return} \\ R &= E(R) + U\end{aligned}\quad [11.3]$$

where R stands for the actual total return in the year, $E(R)$ stands for the expected part of the return, and U stands for the unexpected part of the return. What this says is that the actual return, R , differs from the expected return, $E(R)$, because of surprises that occur during the year. In any given year, the unexpected return will be positive or negative, but, through time, the average value of U will be zero. This simply means that, on average, the actual return equals the expected return.

Announcements and News

We need to be careful when we talk about the effect of news items on the return. For example, suppose Flyers's business is such that the company prospers when GDP grows at a relatively high rate and suffers when GDP is relatively stagnant. In this case, in deciding what return to expect this year from owning stock in Flyers, shareholders either implicitly or explicitly must think about what GDP is likely to be for the year.

When the government actually announces GDP figures for the year, what will happen to the value of Flyers stock? Obviously, the answer depends on what figure is released. More to the point, however, the impact depends on how much of that figure is *new* information.

At the beginning of the year, market participants will have some idea or forecast of what the yearly GDP will be. To the extent that shareholders have predicted GDP, that prediction will already be factored into the expected part of the return on the stock, $E(R)$. On the other hand, if the announced GDP is a surprise, then the effect will be part of U , the unanticipated portion of the return.

As an example, suppose shareholders in the market had forecast that the GDP increase this year would be .5 percent. If the actual announcement this year is exactly .5 percent, the same as the forecast, then the shareholders don't really learn anything, and the announcement isn't news. There will be no impact on the stock price as a result. This is like receiving confirmation of something that you suspected all along; it doesn't reveal anything new.

A common way of saying that an announcement isn't news is to say that the market has already "discounted" the announcement. The use of the word *discount* here is different from the use of the term in computing present values, but the spirit is the same. When we

discount a dollar in the future, we say it is worth less to us because of the time value of money. When we say that we discount an announcement, or a news item, we mean that it has less of an impact on the market because the market already knew much of it.

For example, going back to Flyers, suppose the government announces that the actual GDP increase during the year has been 1.5 percent. Now shareholders have learned something, namely, that the increase is one percentage point higher than they had forecast. This difference between the actual result and the forecast, one percentage point in this example, is sometimes called the *innovation* or the *surprise*.

An announcement, then, can be broken into two parts, the anticipated, or expected, part and the surprise, or innovation:

$$\text{Announcement} = \text{Expected part} + \text{Surprise} \quad [11.4]$$

The expected part of any announcement is the part of the information that the market uses to form the expectation, $E(R)$, of the return on the stock. The surprise is the news that influences the unanticipated return on the stock, U .

To take another example, if shareholders knew in January that the president of the firm was going to resign, the official announcement in February would be fully expected and would be discounted by the market. Because the announcement was expected before February, its influence on the stock would have taken place before February. The announcement itself will contain no surprise, and the stock's price shouldn't change at all when it is actually made.

The fact that only the unexpected, or surprise, part of an announcement matters explains why two companies can make similar announcements but experience different stock price reactions. For example, to open the chapter, we compared American Eagle, Jackson Hewitt, and D. R. Horton. In American Eagle's case, although the revenue and earnings fell in the previous quarter, the company announced that it expected sales for the following year to be in line with previous projections. In D. R. Horton's case, the 35 percent decline in orders was actually one of the "better declines" in the industry. Competitors had previously announced results that reported order declines of up to 80 percent. The relatively low expected sales drop indicated that D. R. Horton was likely to survive the housing downturn. In Jackson Hewitt's case, the company indicated that the results in the next quarter would likely be lower than previously expected. Additionally, Jackson Hewitt announced its results on a day when investors turned sour on the future of stocks, thereby dragging stocks down in general (keep this case in mind as you read the next section).

Our discussion of market efficiency in the previous chapter bears on this discussion. We are assuming that relevant information known today is already reflected in the expected return. This is identical to saying that the current price reflects relevant publicly available information. We are thus implicitly assuming that markets are at least reasonably efficient in the semistrong form sense.

Henceforth, when we speak of news, we will mean the surprise part of an announcement and not the portion that the market has expected and therefore already discounted.

CONCEPT QUESTIONS

11.3a What are the two basic parts of a return?

11.3b Under what conditions will an announcement have no effect on common stock prices?

11.4

RISK: SYSTEMATIC AND UNSYSTEMATIC

The unanticipated part of the return, that portion resulting from surprises, is the true risk of any investment. After all, if we always receive exactly what we expect, then the investment is perfectly predictable and, by definition, risk-free. In other words, the risk of owning an asset comes from surprises—unanticipated events.

There are important differences, though, among various sources of risk. Look back at our previous list of news stories. Some of these stories are directed specifically at Flyers, and some are more general. Which of the news items are of specific importance to Flyers?

Announcements about interest rates or GDP are clearly important for nearly all companies, whereas the news about Flyers's president, its research, or its sales is of specific interest to Flyers. We will distinguish between these two types of events, because, as we shall see, they have very different implications.

Systematic and Unsystematic Risk

The first type of surprise, the one that affects a large number of assets, we will label **systematic risk**. Because systematic risks have marketwide effects, they are sometimes called *market risks*.

The second type of surprise we will call **unsystematic risk**. An unsystematic risk is one that affects a single asset or a small group of assets. Because these risks are unique to individual companies or assets, they are sometimes called *unique* or *asset-specific risks*. We will use these terms interchangeably.

As we have seen, uncertainties about general economic conditions, such as GDP, interest rates, or inflation, are examples of systematic risks. These conditions affect nearly all companies to some degree. An unanticipated increase, or surprise, in inflation, for example, affects wages and the costs of the supplies that companies buy; it affects the value of the assets that companies own; and it affects the prices at which companies sell their products. Forces such as these, to which all companies are susceptible, are the essence of systematic risk.

In contrast, the announcement of an oil strike by a company will primarily affect that company and, perhaps, a few others (such as primary competitors and suppliers). It is unlikely to have much of an effect on the world oil market, however, or on the affairs of companies not in the oil business, so this is an unsystematic event.

Systematic and Unsystematic Components of Return

The distinction between a systematic risk and an unsystematic risk is never really as exact as we make it out to be. Even the most narrow and peculiar bit of news about a company ripples through the economy. This is true because every enterprise, no matter how tiny, is a part of the economy. It's like the tale of a kingdom that was lost because one horse lost a shoe. This is mostly hairsplitting, however. Some risks are clearly much more general than others. We'll see some evidence on this point in just a moment.

The distinction between the types of risk allows us to break down the surprise portion, U , of the return on Flyers's stock into two parts. From before, we had the actual return broken down into its expected and surprise components:

$$R = E(R) + U$$

We now recognize that the total surprise for Flyers, U , has a systematic and an unsystematic component, so:

$$R = E(R) + \text{Systematic portion} + \text{Unsystematic portion} \quad [11.5]$$

systematic risk

A risk that influences a large number of assets. Also *market risk*.

unsystematic risk

A risk that affects at most a small number of assets. Also *unique* or *asset-specific risk*.

Because it is traditional, we will use the Greek letter epsilon, ϵ , to stand for the unsystematic portion. Since systematic risks are often called market risks, we will use the letter m to stand for the systematic part of the surprise. With these symbols, we can rewrite the total return:

$$\begin{aligned} R &= E(R) + U \\ &= E(R) + m + \epsilon \end{aligned}$$

The important thing about the way we have broken down the total surprise, U , is that the unsystematic portion, ϵ , is more or less unique to Flyers. For this reason, it is unrelated to the unsystematic portion of return on most other assets. To see why this is important, we need to return to the subject of portfolio risk.

CONCEPT QUESTIONS

11.4a What are the two basic types of risk?

11.4b What is the distinction between the two types of risk?

DIVERSIFICATION AND PORTFOLIO RISK

11.5

We've seen earlier that portfolio risks can, in principle, be quite different from the risks of the assets that make up the portfolio. We now look more closely at the riskiness of an individual asset versus the risk of a portfolio of many different assets. We will once again examine some market history to get an idea of what happens with actual investments in U.S. capital markets.

The Effect of Diversification: Another Lesson from Market History

In our previous chapter, we saw that the standard deviation of the annual return on a portfolio of 500 large common stocks has historically been about 20 percent per year (see Figure 10.10, for example). Does this mean that the standard deviation of the annual return on a typical stock in that group of 500 is about 20 percent? As you might suspect by now, the answer is *no*. This is an extremely important observation.

To examine the relationship between portfolio size and portfolio risk, Table 11.7 illustrates typical average annual standard deviations for portfolios that contain different numbers of randomly selected NYSE securities.

In Column 2 of Table 11.7, we see that the standard deviation for a “portfolio” of one security is about 49 percent. What this means is that, if you randomly selected a single NYSE stock and put all your money into it, your standard deviation of return would typically be a substantial 49 percent per year. If you were to randomly select two stocks and invest half your money in each, your standard deviation would be about 37 percent on average, and so on.

The important thing to notice in Table 11.7 is that the standard deviation declines as the number of securities is increased. By the time we have 100 randomly chosen stocks, the portfolio's standard deviation has declined by about 60 percent, from 49 percent to about 20 percent. With 500 securities, the standard deviation is 19.27 percent, similar to the 20 percent we saw in our previous chapter for the large common stock portfolio. The small difference exists because the portfolio securities and time periods examined are not identical.

For more on risk and diversification, visit www.investopedia.com/university.

Standard deviations of annual portfolio returns	TABLE 11.7		
	(1) Number of Stocks in Portfolio	(2) Average Standard Deviation of Annual Portfolio Returns	(3) Ratio of Portfolio Standard Deviation to Standard Deviation of a Single Stock
	1	49.24%	1.00
	2	37.36	.76
	4	29.69	.60
	6	26.64	.54
	8	24.98	.51

	20	21.68	.44
	30	20.87	.42
	40	20.46	.42
	50	20.20	.41
	100	19.69	.40
	200	19.42	.39
	300	19.34	.39
	400	19.29	.39
	500	19.27	.39
	1,000	19.21	.39

Sources: These figures are from Table 1 in Meir Statman, “How Many Stocks Make a Diversified Portfolio?” *Journal of Financial and Quantitative Analysis* 22 (September 1987), pp. 353–64. They were derived from E. J. Elton and M. J. Gruber, “Risk Reduction and Portfolio Size: An Analytical Solution,” *Journal of Business* 50 (October 1977), pp. 415–37.

The Principle of Diversification

Figure 11.1 illustrates the point we’ve been discussing. What we have plotted is the standard deviation of return versus the number of stocks in the portfolio. Notice in Figure 11.1 that the benefit in terms of risk reduction from adding securities drops off as we add more and more. By the time we have 10 securities, most of the effect is already realized, and by the time we get to 30 or so, there is very little remaining benefit.

Figure 11.1 illustrates two key points. First: Some of the riskiness associated with individual assets can be eliminated by forming portfolios. The process of spreading an investment across assets (and thereby forming a portfolio) is called *diversification*. The principle of diversification tells us that spreading an investment across many assets will eliminate some of the risk. The green shaded area in Figure 11.1, labeled “diversifiable risk,” is the part that can be eliminated by diversification.

The second point is equally important: There is a minimum level of risk that cannot be eliminated simply by diversifying. This minimum level is labeled “nondiversifiable risk” in Figure 11.1. Taken together, these two points are another important lesson from capital market history: Diversification reduces risk, but only up to a point. Put another way: Some risk is diversifiable and some is not.

Diversification and Unsystematic Risk

From our discussion of portfolio risk, we know that some of the risk associated with individual assets can be diversified away and some cannot. We are left with an obvious question: Why is this so? It turns out that the answer hinges on the distinction we made earlier between systematic and unsystematic risk.

By definition, an unsystematic risk is one that is particular to a single asset or, at most, a small group. For example, if the asset under consideration is stock in a single company,

principle of diversification
Spreading an investment across a number of assets will eliminate some, but not all, of the risk.

**FIGURE 11.1****Portfolio
diversification**

the discovery of positive NPV projects such as successful new products and innovative cost savings will tend to increase the value of the stock. Unanticipated lawsuits, industrial accidents, strikes, and similar events will tend to decrease future cash flows and thereby reduce share values.

Here is the important observation: If we only held a single stock, then the value of our investment would fluctuate because of company-specific events. If we hold a large portfolio, on the other hand, some of the stocks in the portfolio will go up in value because of positive company-specific events and some will go down in value because of negative events. The net effect on the overall value of the portfolio will be relatively small, however, as these effects will tend to cancel each other out.

Now we see why some of the variability associated with individual assets is eliminated by diversification. When we combine assets into portfolios, the unique, or unsystematic, events—both positive and negative—tend to “wash out” once we have more than just a few assets.

This is an important point that bears restating:

Unsystematic risk is essentially eliminated by diversification, so a relatively large portfolio has almost no unsystematic risk.

In fact, the terms *diversifiable risk* and *unsystematic risk* are often used interchangeably.

Diversification and Systematic Risk

We’ve seen that unsystematic risk can be eliminated by diversifying. What about systematic risk? Can it also be eliminated by diversification? The answer is no because, by definition, a systematic risk affects almost all assets to some degree. As a result, no matter how

many assets we put into a portfolio, the systematic risk doesn’t go away. Thus, for obvious reasons, the terms *systematic risk* and *nondiversifiable risk* are used interchangeably.

Because we have introduced so many different terms, it is useful to summarize our discussion before moving on. What we have seen is that the total risk of an investment, as measured by the standard deviation of its return, can be written as:

Total risk = Systematic risk + Unsystematic risk

[11.6]

Systematic risk is also called *nondiversifiable risk* or *market risk*. Unsystematic risk is also called *diversifiable risk*, *unique risk*, or *asset-specific risk*. For a well-diversified portfolio, the unsystematic risk is negligible. For such a portfolio, essentially all of the risk is systematic.

CONCEPT QUESTIONS

11.5a

What happens to the standard deviation of return for a portfolio if we increase the number of securities in the portfolio?

11.5b

What is the principle of diversification?

11.5c

Why is some risk diversifiable?

11.5d

Why can’t systematic risk be diversified away?

11.6

SYSTEMATIC RISK AND BETA

The question that we now begin to address is this: What determines the size of the risk premium on a risky asset? Put another way: Why do some assets have a larger risk premium than other assets? The answer to these questions, as we discuss next, is also based on the distinction between systematic and unsystematic risk.

The Systematic Risk Principle

Thus far, we’ve seen that the total risk associated with an asset can be decomposed into two components: systematic and unsystematic risk. We have also seen that unsystematic risk can be essentially eliminated by diversification. The systematic risk present in an asset, on the other hand, cannot be eliminated by diversification.

Based on our study of capital market history, we know that there is a reward, on average, for bearing risk. However, we now need to be more precise about what we mean by risk. The **systematic risk principle** states that the reward for bearing risk depends only on the systematic risk of an investment. The underlying rationale for this principle is straightforward: Since unsystematic risk can be eliminated at virtually no cost (by diversifying), there is no reward for bearing it. Put another way: The market does not reward risks that are borne unnecessarily.

The systematic risk principle has a remarkable and very important implication:

The expected return on an asset depends only on that asset’s systematic risk.

There is an obvious corollary to this principle: No matter how much total risk an asset has, only the systematic portion is relevant in determining the expected return (and the risk premium) on that asset.

For more on beta, see money.cnn.com.

systematic risk principle

The expected return on a risky asset depends only on that asset’s systematic risk.

Company	Beta Coefficient (β_i)
Home Depot	0.46
Kellogg Co.	0.57
Southwest Airlines	0.85
American Eagle Outfitters	0.96
Google	1.28
Abercrombie & Fitch	1.33
General Electric	1.39
eBay	1.43
Citigroup	2.42

Source: finance.yahoo.com, 2009.

TABLE 11.8

Beta coefficients for selected companies

Measuring Systematic Risk

Since systematic risk is the crucial determinant of an asset's expected return, we need some way of measuring the level of systematic risk for different investments. The specific measure we will use is called the **beta coefficient**, for which we will use the Greek symbol β . A beta coefficient, or beta for short, tells us how much systematic risk a particular asset has relative to an average asset. By definition, an average asset has a beta of 1.0 relative to itself. An asset with a beta of .50, therefore, has half as much systematic risk as an average asset; an asset with a beta of 2.0 has twice as much.

Table 11.8 contains the estimated beta coefficients for the stocks of some well-known companies. The range of betas in Table 11.8 is typical for stocks of large U.S. corporations. Betas outside this range occur, but they are less common. See our nearby *Work the Web* box to learn how to find betas online.

The important thing to remember is that the expected return, and thus the risk premium, on an asset depends only on its systematic risk. Since assets with larger betas have greater systematic risks, they will have greater expected returns. Thus, from Table 11.8, an investor who buys stock in Kellogg, with a beta of .57, should expect to earn less, on average, than an investor who buys stock in Abercrombie & Fitch, with a beta of about 1.33. To learn more about “real-world” betas, see the *Reality Bytes* box on page 357.

beta coefficient

Amount of systematic risk present in a particular risky asset relative to that in an average risky asset.

Total Risk versus Beta

Consider the following information on two securities. Which has greater total risk? Which has greater systematic risk? Greater unsystematic risk? Which asset will have a higher risk premium?

	Standard Deviation	Beta
Security A	40%	.50
Security B	20	1.50

From our discussion in this section, Security A has greater total risk, but it has substantially less systematic risk. Since total risk is the sum of systematic and unsystematic risk, Security A must have greater unsystematic risk. Finally, from the systematic risk principle, Security B will have a higher risk premium and a greater expected return, despite the fact that it has less total risk.

EXAMPLE 11.5

WORK THE WEB

Suppose you want to find the beta for a company like amusement parks operator Six Flags. One way is to go to the Web. We went to finance.yahoo.com, found and entered the ticker symbol for Six Flags, and followed the “Key Statistics” link. Here is part of what we found:

Stock Price History	
Beta:	2.39
52-Week Change ³ :	-88.04%
S&P500 52-Week Change ³ :	-45.51%
52-Week High (07-May-08) ³ :	2.50
52-Week Low (19-Nov-08) ³ :	0.16
50-Day Moving Average ³ :	0.29
200-Day Moving Average ³ :	0.45

The reported beta for Six Flags is 2.39, which means that Six Flags has about 2.4 times the systematic risk of a typical stock. You would expect that the company's stock is a risky bet, and, looking at the other numbers, we agree. During 2008, Six Flags reported a net loss of about \$135 million and a negative book value of equity of about -\$444 million. So, the ROE for the company is 30.41 percent, a relatively good number. However, a closer look shows that the more Six Flags loses, the higher its ROE becomes. Not a good situation! The reason is that Six Flags has reported a loss every year from 1999 to 2008. In all, Six Flags appears to be a good candidate for a high beta.

Questions

1. Has Six Flags's ROE “improved” since this was written? Check out the current numbers on the Web site to see.
2. What growth rate are analysts projecting for Six Flags? How does this growth rate compare to the industry?

Portfolio Betas

Earlier, we saw that the riskiness of a portfolio has no simple relationship to the risks of the assets in the portfolio. A portfolio beta, however, can be calculated just like a portfolio expected return. For example, looking again at Table 11.8, suppose you put half of your money in Southwest Airlines and half in eBay. What would the beta of this combination be? Since Southwest Airlines has a beta of .85 and eBay has a beta of 1.43, the portfolio's beta, β_P , would be:

$$\begin{aligned}
 \beta_P &= .50 \times \beta_{\text{Southwest Airlines}} + .50 \times \beta_{\text{eBay}} \\
 &= .50 \times .85 + .50 \times 1.43 \\
 &= 1.14
 \end{aligned}$$

In general, if we had a large number of assets in a portfolio, we would multiply each asset's beta by its portfolio weight and then add the results up to get the portfolio's beta.

Betas are easy to find on the Web. Try finance.yahoo.com and money.cnn.com.

Beta, Beta, Who’s Got the Beta?

Based on what we’ve studied so far, you can see that beta is a pretty important topic. You might wonder then, are all published betas created equal? Read on for a partial answer to this question.

We did some checking on betas and found some interesting results. The Value Line *Investment Survey* is one of the best-known sources for information on publicly traded companies. However, with the explosion of online investing, there has been a corresponding increase in the amount of investment information available online. We decided to compare the betas presented by Value Line to those reported by Yahoo! Finance (finance.yahoo.com) and CNN Money (money.cnn.com). What we found leads to an important note of caution.

Consider Amazon.com, the big online retailer. Its beta reported on the Internet was 1.46, which is larger than Value Line’s beta of 1.10. Amazon.com wasn’t the only stock that showed a divergence in betas from different sources. In fact, for most of the technology companies we looked at, Value Line reported betas that were significantly lower than their online cousins. For example, the online beta for Dell was 1.30, but Value Line reported 0.90. The online beta for Adobe (maker of the ubiquitous Acrobat software) was 1.69 versus a Value Line beta of 1.15. Value Line’s betas are not always lower. For example, the online beta for Yahoo! was 0.87, compared to Value Line’s 1.00.

We also found some unusual, and even hard to believe, estimates for beta. Brink’s Home Security had a very low online

beta of 0.00, while Value Line reported Brink’s beta as not meaningful. The online estimate for Walmart was a “Low, Low” 0.26, compared to Value Line’s 0.65. Perhaps the most outrageous reported betas were the online betas for the International Fight League and Energy Composites, with betas of 81.08 and –94.93 (notice the minus sign!), respectively. Value Line did not report a beta for these companies. How do you suppose we should interpret a beta of –94.93?

There are a few lessons to be learned from all of this. First, not all betas are created equal. Some are computed using weekly returns and some using daily returns. Some are computed using 60 months of stock returns; some consider more or less. Some betas are computed by comparing the stock to the S&P 500 index, while others use alternative indices. Finally, some reporting firms (including Value Line) make adjustments to raw betas to reflect information other than just the fluctuation in stock prices.

The second lesson is perhaps more subtle. We are interested in knowing what the betas of the stocks will be in the future, but betas have to be estimated using historical data. Anytime we use the past to predict the future, there is the danger of a poor estimate. As we will see later in the chapter (and the next one), it is very unlikely that International Fight League has a beta anything like 81.08 or that Energy Composites has a beta of –94.93. Instead, the estimates are almost certainly poor ones. The moral of the story is that, as with any financial tool, beta is not a black box that should be taken without question.

Suppose we had the following investments:

Security	Amount Invested	Expected Return	Beta
Stock A	\$1,000	8%	.80
Stock B	2,000	12	.95
Stock C	3,000	15	1.10
Stock D	4,000	18	1.40

What is the expected return on this portfolio? What is the beta of this portfolio? Does this portfolio have more or less systematic risk than an average asset?

To answer, we first have to calculate the portfolio weights. Notice that the total amount invested is \$10,000. Of this, $\$1,000/\$10,000 = 10\%$ is invested in Stock A. Similarly, 20 percent is invested

Portfolio Betas

EXAMPLE11.6

(continued)

in Stock B, 30 percent is invested in Stock C, and 40 percent is invested in Stock D. The expected return, $E(R_P)$, is thus:

$$\begin{aligned} E(R_P) &= .10 \times E(R_A) + .20 \times E(R_B) + .30 \times E(R_C) + .40 \times E(R_D) \\ &= .10 \times 8\% + .20 \times 12\% + .30 \times 15\% + .40 \times 18\% \\ &= 14.9\% \end{aligned}$$

Similarly, the portfolio beta, β_P , is:

$$\begin{aligned} \beta_P &= .10 \times \beta_A + .20 \times \beta_B + .30 \times \beta_C + .40 \times \beta_D \\ &= .10 \times .80 + .20 \times .95 + .30 \times 1.10 + .40 \times 1.40 \\ &= 1.16 \end{aligned}$$

This portfolio thus has an expected return of 14.9 percent and a beta of 1.16. Since the beta is larger than 1.0, this portfolio has greater systematic risk than an average asset.

CONCEPT QUESTIONS

- 11.6a** What is the systematic risk principle?
- 11.6b** What does a beta coefficient measure?
- 11.6c** How do you calculate a portfolio beta?
- 11.6d** True or false: The expected return on a risky asset depends on that asset's total risk. Explain.

11.7

THE SECURITY MARKET LINE

We're now in a position to see how risk is rewarded in the marketplace. To begin, suppose that Asset A has an expected return of $E(R_A) = 20\%$ and a beta of $\beta_A = 1.6$. Furthermore, the risk-free rate is $R_f = 8\%$. Notice that a risk-free asset, by definition, has no systematic risk (or unsystematic risk), so a risk-free asset has a beta of 0.

Beta and the Risk Premium

Consider a portfolio made up of Asset A and a risk-free asset. We can calculate some different possible portfolio expected returns and betas by varying the percentages invested in these two assets. For example, if 25 percent of the portfolio is invested in Asset A, then the expected return is:

$$\begin{aligned} E(R_P) &= .25 \times E(R_A) + (1 - .25) \times R_f \\ &= .25 \times 20\% + .75 \times 8\% \\ &= 11.0\% \end{aligned}$$

Similarly, the beta on the portfolio, β_P , would be:

$$\begin{aligned} \beta_P &= .25 \times \beta_A + (1 - .25) \times 0 \\ &= .25 \times 1.6 \\ &= .40 \end{aligned}$$

Notice that, since the weights have to add up to 1, the percentage invested in the risk-free asset is equal to 1 minus the percentage invested in Asset A.

One thing that you might wonder about is whether it is possible for the percentage invested in Asset A to exceed 100 percent. The answer is yes. The way this can happen is for the investor to borrow at the risk-free rate. For example, suppose an investor has \$100 and borrows an additional \$50 at 8 percent, the risk-free rate. The total investment in Asset A would be \$150, or 150 percent of the investor's wealth. The expected return in this case would be:

$$\begin{aligned} E(R_P) &= 1.50 \times E(R_A) + (1 - 1.50) \times R_f \\ &= 1.50 \times 20\% - .50 \times 8\% \\ &= 26.0\% \end{aligned}$$

The beta on the portfolio would be:

$$\begin{aligned} \beta_P &= 1.50 \times \beta_A + (1 - 1.50) \times 0 \\ &= 1.50 \times 1.6 \\ &= 2.4 \end{aligned}$$

We can calculate some other possibilities as follows:

Percentage of Portfolio in Asset A	Portfolio Expected Return	Portfolio Beta
0%	8%	.0
25	11	.4
50	14	.8
75	17	1.2
100	20	1.6
125	23	2.0
150	26	2.4

In Figure 11.2A, these portfolio expected returns are plotted against the portfolio betas. Notice that all the combinations fall on a straight line.

The Reward-to-Risk Ratio What is the slope of the straight line in Figure 11.2A? As always, the slope of a straight line is equal to “the rise over the run.” In this case, as we move out of the risk-free asset into Asset A, the beta increases from 0 to 1.6 (a “run” of 1.6). At the same time, the expected return goes from 8 percent to 20 percent, a “rise” of 12 percent. The slope of the line is thus $12\%/1.6 = 7.50\%$.

Notice that the slope of our line is just the risk premium on Asset A, $E(R_A) - R_f$, divided by Asset A's beta, β_A :

$$\begin{aligned} \text{Slope} &= \frac{E(R_A) - R_f}{\beta_A} \\ &= \frac{20\% - 8\%}{1.6} \\ &= 7.50\% \end{aligned}$$

What this tells us is that Asset A offers a *reward-to-risk ratio* of 7.50 percent.² In other words, Asset A has a risk premium of 7.50 percent per “unit” of systematic risk.

² This ratio is sometimes called the *Treynor index*, after one of its originators.

FIGURE 11.2A

Portfolio expected returns and betas for Asset A

The Basic Argument Now suppose we consider a second asset, Asset B. This asset has a beta of 1.2 and an expected return of 16 percent. Which investment is better, Asset A or Asset B? You might think that, once again, we really cannot say. Some investors might prefer A; some investors might prefer B. Actually, however, we can say: A is better because, as we shall demonstrate, B offers inadequate compensation for its level of systematic risk, at least relative to A.

To begin, we calculate different combinations of expected returns and betas for portfolios of Asset B and a risk-free asset just as we did for Asset A. For example, if we put 25 percent in Asset B and the remaining 75 percent in the risk-free asset, the portfolio's expected return would be:

$$\begin{aligned} E(R_p) &= .25 \times E(R_B) + (1 - .25) \times R_f \\ &= .25 \times 16\% + .75 \times 8\% \\ &= 10.0\% \end{aligned}$$

Similarly, the beta on the portfolio, β_p , would be:

$$\begin{aligned} \beta_p &= .25 \times \beta_B + (1 - .25) \times 0 \\ &= .25 \times 1.2 \\ &= .30 \end{aligned}$$

Some other possibilities are as follows:

Percentage of Portfolio in Asset B	Portfolio Expected Return	Portfolio Beta
0%	8%	.0
25	10	.3
50	12	.6
75	14	.9
100	16	1.2
125	18	1.5
150	20	1.8

When we plot these combinations of portfolio expected returns and portfolio betas in Figure 11.2B, we get a straight line just as we did for Asset A.

**FIGURE 11.2B**

Portfolio expected returns and betas for Asset B

**FIGURE 11.2C**

Portfolio expected returns and betas for both assets

The key thing to notice is that when we compare the results for Assets A and B, as in Figure 11.2C, the line describing the combinations of expected returns and betas for Asset A is higher than the one for Asset B. What this tells us is that for any given level of systematic risk (as measured by β), some combination of Asset A and the risk-free asset always offers a larger return. This is why we were able to state that Asset A is a better investment than Asset B.

Another way of seeing that A offers a superior return for its level of risk is to note that the slope of our line for Asset B is:

$$\begin{aligned} \text{Slope} &= \frac{E(R_B) - R_f}{\beta_B} \\ &= \frac{16\% - 8\%}{1.2} = 6.67\% \end{aligned}$$

Thus, Asset B has a reward-to-risk ratio of 6.67 percent, which is less than the 7.5 percent offered by Asset A.

The Fundamental Result The situation we have described for Assets A and B cannot persist in a well-organized, active market, because investors would be attracted to Asset A and away from Asset B. As a result, Asset A's price would rise and Asset B's price would fall. Since prices and returns move in opposite directions, the result would be that A's expected return would decline and B's would rise.

This buying and selling would continue until the two assets plotted on exactly the same line, which means they would offer the same reward for bearing risk. In other words, in an active, competitive market, we must have that:

$$\frac{E(R_A) - R_f}{\beta_A} = \frac{E(R_B) - R_f}{\beta_B}$$

This is the fundamental relationship between risk and return.

Our basic argument can be extended to more than just two assets. In fact, no matter how many assets we had, we would always reach the same conclusion:

The reward-to-risk ratio must be the same for all the assets in the market.

This result is really not so surprising. What it says, for example, is that, if one asset has twice as much systematic risk as another asset, its risk premium will simply be twice as large.

Since all of the assets in the market must have the same reward-to-risk ratio, they all must plot on the same line. This argument is illustrated in Figure 11.3. As shown, Assets A and B plot directly on the line and thus have the same reward-to-risk ratio. If an asset plotted above the line, such as C in Figure 11.3, its price would rise, and its expected return would fall until it plotted exactly on the line. Similarly, if an asset plotted below the line, such as D in Figure 11.3, its expected return would rise until it too plotted directly on the line.

The arguments we have presented apply to active, competitive, well-functioning markets. The financial markets, such as the NYSE, best meet these criteria. Other markets,

FIGURE 11.3

Expected returns and systematic risk

The fundamental relationship between beta and expected return is that all assets must have the same reward-to-risk ratio, $[E(R_i) - R_f]/\beta_i$. This means that they would all plot on the same straight line. Assets A and B are examples of this behavior. Asset C's expected return is too high; Asset D's is too low.

such as real asset markets, may or may not. For this reason, these concepts are most useful in examining financial markets. We will thus focus on such markets here. However, as we discuss in a later section, the information about risk and return gleaned from financial markets is crucial in evaluating the investments that a corporation makes in real assets.

Buy Low, Sell High

An asset is said to be *overvalued* if its price is too high given its expected return and risk. Suppose you observe the following situation:

Security	Expected Return	Beta
Fama Co.	14%	1.3
French Co.	10	.8

The risk-free rate is currently 6 percent. Is one of the two securities above overvalued relative to the other?

To answer, we compute the reward-to-risk ratio for both. For Fama, this ratio is $(14\% - 6\%) / 1.3 = 6.15\%$. For French, this ratio is 5 percent. What we conclude is that French offers an insufficient expected return for its level of risk, at least relative to Fama. Since its expected return is too low, its price is too high. In other words, French is overvalued relative to Fama, and we would expect to see its price fall relative to Fama's. Notice that we could also say Fama is *undervalued* relative to French.

EXAMPLE 11.7

The Security Market Line

The line that results when we plot expected returns and beta coefficients is obviously of some importance, so it's time we gave it a name. This line, which we use to describe the relationship between systematic risk and expected return in financial markets, is usually called the **security market line**, or **SML**. After NPV, the SML is arguably the most important concept in modern finance.

Market Portfolios It will be very useful to know the equation of the SML. There are many different ways we could write it, but one way is particularly common. Suppose we consider a portfolio made up of all of the assets in the market. Such a portfolio is called a market portfolio, and we will express the expected return on this market portfolio as $E(R_M)$.

Since all the assets in the market must plot on the SML, so must a market portfolio made up of those assets. To determine where it plots on the SML, we need to know the beta of the market portfolio, β_M . Since this portfolio is representative of all of the assets in the market, it must have average systematic risk. In other words, it has a beta of 1.0. We could therefore write the slope of the SML as:

$$\text{SML slope} = \frac{E(R_M) - R_f}{\beta_M} = \frac{E(R_M) - R_f}{1} = E(R_M) - R_f$$

The term $E(R_M) - R_f$ is often called the **market risk premium** since it is the risk premium on a market portfolio.

The Capital Asset Pricing Model To finish up, if we let $E(R_i)$ and β_i stand for the expected return and beta, respectively, on any asset in the market, then we know that asset

security market line (SML)

Positively sloped straight line displaying the relationship between expected return and beta.

market risk premium

Slope of the SML, the difference between the expected return on a market portfolio and the risk-free rate.

must plot on the SML. As a result, we know that its reward-to-risk ratio is the same as the overall market's:

$$\frac{E(R_i) - R_f}{\beta_i} = E(R_M) - R_f$$

If we rearrange this, then we can write the equation for the SML as:

$$E(R_i) = R_f + [E(R_M) - R_f] \times \beta_i \quad [11.7]$$

capital asset pricing model (CAPM)

Equation of the SML showing the relationship between expected return and beta.

This result is identical to the famous **capital asset pricing model (CAPM)**.

What the CAPM shows is that the expected return for a particular asset depends on three things:

1. *The pure time value of money.* As measured by the risk-free rate, R_f , this is the reward for merely waiting for your money, without taking any risk.
2. *The reward for bearing systematic risk.* As measured by the market risk premium, $[E(R_M) - R_f]$, this component is the reward the market offers for bearing an average amount of systematic risk in addition to waiting.
3. *The amount of systematic risk.* As measured by β_i , this is the amount of systematic risk present in a particular asset, relative to an average asset.

By the way, the CAPM works for portfolios of assets just as it does for individual assets. In an earlier section, we saw how to calculate a portfolio's β . To find the expected return on a portfolio, we simply use this β in the CAPM equation.

Figure 11.4 summarizes our discussion of the SML and the CAPM. As before, we plot expected return against beta. Now we recognize that, based on the CAPM, the slope of the SML is equal to the market risk premium, $[E(R_M) - R_f]$.

This concludes our presentation of concepts related to the risk-return trade-off. For future reference, Table 11.9 summarizes the various concepts in the order in which we discussed them.

FIGURE 11.4

The security market line, or SML

The slope of the security market line is equal to the market risk premium, i.e., the reward for bearing an average amount of systematic risk. The equation describing the SML can be written:

$$E(R_i) = R_f + [E(R_M) - R_f] \times \beta_i$$

which is the capital asset pricing model, or CAPM.

TABLE 11.9**Summary of risk and return concepts****I. Total return**

The *total return* on an investment has two components: the expected return and the unexpected return. The unexpected return comes about because of unanticipated events. The risk from investing stems from the possibility of an unanticipated event.

II. Total risk

The *total risk* of an investment is measured by the variance or, more commonly, the standard deviation of its return.

III. Systematic and unsystematic risks

Systematic risks (also called *market risks*) are unanticipated events that affect almost all assets to some degree because the effects are economywide. *Unsystematic risks* are unanticipated events that affect single assets or small groups of assets. Unsystematic risks are also called *unique* or *asset-specific risks*.

IV. The effect of diversification

Some, but not all, of the risk associated with a risky investment can be eliminated by diversification. The reason is that unsystematic risks, which are unique to individual assets, tend to wash out in a large portfolio, but systematic risks, which affect all of the assets in a portfolio to some extent, do not.

V. The systematic risk principle and beta

Because unsystematic risk can be freely eliminated by diversification, the *systematic risk principle*

states that the reward for bearing risk depends only on the level of systematic risk. The level of systematic risk in a particular asset, relative to the average, is given by the beta of that asset.

VI. The reward-to-risk ratio and the security market line

The *reward-to-risk ratio* for Asset *i* is the ratio of its risk premium, $E(R_i) - R_f$, to its beta, β_i :

$$\frac{E(R_i) - R_f}{\beta_i}$$

In a well-functioning market, this ratio is the same for every asset. As a result, when asset expected returns are plotted against asset betas, all assets plot on the same straight line, called the *security market line* (SML).

VII. The capital asset pricing model

From the SML, the expected return on Asset *i* can be written:

$$E(R_i) = R_f + [E(R_M) - R_f] \times \beta_i$$

This is the *capital asset pricing model* (CAPM). The expected return on a risky asset thus has three components. The first is the pure time value of money, R_f ; the second is the market risk premium, $[E(R_M) - R_f]$; and the third is the beta for that asset, β_i .

Risk and Return**EXAMPLE 11.8**

Suppose the risk-free rate is 4 percent, the market risk premium is 7 percent, and a particular stock has a beta of 1.3. Based on the CAPM, what is the expected return on this stock? What would the expected return be if the beta were to double?

With a beta of 1.3, the risk premium for the stock would be $1.3 \times 7\%$, or 9.1 percent. The risk-free rate is 4 percent, so the expected return is 13.1 percent. If the beta doubled to 2.6, the risk premium would double to 18.2 percent, so the expected return would be 22.2 percent.

CONCEPT QUESTIONS

- 11.7a** What is the fundamental relationship between risk and return in well-functioning markets?
- 11.7b** What is the security market line? Why must all assets plot directly on it in a well-functioning market?
- 11.7c** What is the capital asset pricing model, or CAPM? What does it tell us about the required return on a risky investment?

11.8

THE SML AND THE COST OF CAPITAL: A PREVIEW

Our goal in studying risk and return is twofold. First, risk is an extremely important consideration in almost all business decisions, so we want to discuss just what risk is and how it is rewarded in the market. Our second purpose is to learn what determines the appropriate discount rate for future cash flows. We briefly discuss this second subject now; we discuss it in more detail in Chapter 12.

The Basic Idea

The security market line tells us the reward for bearing risk in financial markets. At an absolute minimum, any new investment our firm undertakes must offer an expected return that is no worse than what the financial markets offer for the same risk. The reason for this is simply that our shareholders can always invest for themselves in the financial markets.

The only way we benefit our shareholders is by finding investments with expected returns that are superior to what the financial markets offer for the same risk. Such an investment will have a positive NPV. So, if we ask: “What is the appropriate discount rate?” the answer is that we should use the expected return offered in financial markets on investments with the same systematic risk.

In other words, to determine whether or not an investment has a positive NPV, we essentially compare the expected return on that new investment to what the financial market offers on an investment with the same beta. This is why the SML is so important; it tells us the “going rate” for bearing risk in the economy.

The Cost of Capital

The appropriate discount rate on a new project is the minimum expected rate of return an investment must offer to be attractive. This minimum required return is often called the **cost of capital** associated with the investment. It is called this because the required return is what the firm must earn on its capital investment in a project just to break even. It can thus be interpreted as the opportunity cost associated with the firm’s capital investment.

Notice that when we say an investment is attractive if its expected return exceeds what is offered in financial markets for investments of the same risk, we are effectively using the internal rate of return, or IRR, criterion that we developed and discussed in Chapter 8. The only difference is that now we have a much better idea of what determines the required return on an investment. This understanding will be critical when we discuss cost of capital and capital structure in Part Seven of our book.

cost of capital

The minimum required return on a new investment.

CONCEPT QUESTIONS

11.8a If an investment has a positive NPV, would it plot above or below the SML? Why?

11.8b What is meant by the term *cost of capital*?

SUMMARY AND CONCLUSIONS

This chapter has covered the essentials of risk. Along the way, we have introduced a number of definitions and concepts. The most important of these is the security market line, or SML. The SML is important because it tells us the reward offered in financial markets for bearing risk. Once we know this, we have a benchmark against which we compare the returns expected from real asset investments to determine if they are desirable.

Because we have covered quite a bit of ground, it's useful to summarize the basic economic logic underlying the SML as follows:

1. Based on capital market history, there is a reward for bearing risk. This reward is the risk premium on an asset.
2. The total risk associated with an asset has two parts: systematic risk and unsystematic risk. Unsystematic risk can be freely eliminated by diversification (this is the principle of diversification), so only systematic risk is rewarded. As a result, the risk premium on an asset is determined by its systematic risk. This is the systematic risk principle.
3. An asset's systematic risk, relative to the average, can be measured by its beta coefficient, β_i . The risk premium on an asset is then given by its beta coefficient multiplied by the market risk premium, $[E(R_M) - R_f] \times \beta_i$.
4. The expected return on an asset, $E(R_i)$, is equal to the risk-free rate, R_f , plus the risk premium:

$$E(R_i) = R_f + [E(R_M) - R_f] \times \beta_i$$

This is the equation of the SML, and it is often called the *capital asset pricing model*, or CAPM.

This chapter completes our discussion of risk and return and concludes Part Six of our book. Now that we have a better understanding of what determines a firm's cost of capital for an investment, the next several chapters examine more closely how firms raise the long-term capital needed for investment.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

- 11.1 Expected Return and Standard Deviation.** This problem will give you some practice calculating measures of prospective portfolio performance. There are two assets and three states of the economy:

(1) State of Economy	(2) Probability of State of Economy	(3) Stock A Rate of Return if State Occurs	(4) Stock B Rate of Return if State Occurs
Recession	.10	-.20	.30
Normal	.60	.10	.20
Boom	.30	.70	.50

What are the expected returns and standard deviations for these two stocks?

- 11.2 Portfolio Risk and Return.** In the previous problem, suppose you have \$20,000 total. If you put \$6,000 in Stock A and the remainder in Stock B, what will be the expected return and standard deviation on your portfolio?
- 11.3 Risk and Return.** Suppose you observe the following situation:

Security	Beta	Expected Return
Cooley, Inc.	1.6	19%
Moyer Co.	1.2	16

If the risk-free rate is 8 percent, are these securities correctly priced? What would the risk-free rate have to be if they are correctly priced?

- 11.4 CAPM.** Suppose the risk-free rate is 8 percent. The expected return on the market is 14 percent. If a particular stock has a beta of .60, what is its expected return based on the CAPM? If another stock has an expected return of 20 percent, what must its beta be?

■ Answers to Chapter Review and Self-Test Problems

- 11.1** The expected returns are just the possible returns multiplied by the associated probabilities:

$$E(R_A) = .10 \times -.20 + .60 \times .10 + .30 \times .70 = 25\%$$

$$E(R_B) = .10 \times .30 + .60 \times .20 + .30 \times .50 = 30\%$$

The variances are given by the sums of the squared deviations from the expected returns multiplied by their probabilities:

$$\begin{aligned}\sigma_A^2 &= .10 \times (-.20 - .25)^2 + .60 \times (.10 - .25)^2 + .30 \times (.70 - .25)^2 \\ &= .10 \times -.45^2 + .60 \times -.15^2 + .30 \times .45^2 \\ &= .10 \times .2025 + .60 \times .0225 + .30 \times .2025 \\ &= .0945\end{aligned}$$

$$\begin{aligned}\sigma_B^2 &= .10 \times (.30 - .30)^2 + .60 \times (.20 - .30)^2 + .30 \times (.50 - .30)^2 \\ &= .10 \times .00^2 + .60 \times -.10^2 + .30 \times .20^2 \\ &= .10 \times .00 + .60 \times .01 + .30 \times .04 \\ &= .0180\end{aligned}$$

The standard deviations are thus:

$$\sigma_A = \sqrt{.0945} = 30.74\%$$

$$\sigma_B = \sqrt{.0180} = 13.42\%$$

- 11.2** The portfolio weights are $\$6,000/20,000 = .30$ and $\$14,000/20,000 = .70$. The expected return is thus:

$$\begin{aligned}E(R_P) &= .30 \times E(R_A) + .70 \times E(R_B) \\ &= .30 \times 25\% + .70 \times 30\% \\ &= 28.50\%\end{aligned}$$

Alternatively, we could calculate the portfolio's return in each of the states:

(1) State of Economy	(2) Probability of State of Economy	(3) Portfolio Return if State Occurs
Recession	.10	$.30 \times -.20 + .70 \times .30 = .15$
Normal	.60	$.30 \times .10 + .70 \times .20 = .17$
Boom	.30	$.30 \times .70 + .70 \times .50 = .56$

The portfolio's expected return is:

$$E(R_p) = .10 \times .15 + .60 \times .17 + .30 \times .56 = 28.50\%$$

This is the same as we had before.

The portfolio's variance is:

$$\begin{aligned}\sigma_p^2 &= .10 \times (.15 - .285)^2 + .60 \times (.17 - .285)^2 + .30 \times (.56 - .285)^2 \\ &= .03245\end{aligned}$$

So the standard deviation is $\sqrt{.03245} = 18.01\%$.

- 11.3** If we compute the reward-to-risk ratios, we get $(19\% - 8\%)/1.6 = 6.875\%$ for Cooley versus 6.67% for Moyer. Relative to that of Cooley, Moyer's expected return is too low, so its price is too high.

If they are correctly priced, then they must offer the same reward-to-risk ratio. The risk-free rate would have to be such that:

$$(19\% - R_f)/1.6 = (16\% - R_f)/1.2$$

With a little algebra, we find that the risk-free rate must be 7 percent:

$$\begin{aligned}(19\% - R_f) &= (16\% - R_f) (1.6/1.2) \\ 19\% - 16\% \times \frac{4}{3} &= R_f - R_f \times \frac{4}{3} \\ R_f &= 7\%\end{aligned}$$

- 11.4** Since the expected return on the market is 14 percent, the market risk premium is $14\% - 8\% = 6\%$ (the risk-free rate is 8 percent). The first stock has a beta of .60, so its expected return is $8\% + .60 \times 6\% = 11.6\%$.

For the second stock, notice that the risk premium is $20\% - 8\% = 12\%$. Since this is twice as large as the market risk premium, the beta must be exactly equal to 2. We can verify this using the CAPM:

$$\begin{aligned}E(R_i) &= R_f + [E(R_M) - R_f] \times \beta_i \\ 20\% &= 8\% + (14\% - 8\%) \times \beta_i \\ \beta_i &= 12\%/6\% = 2.0\end{aligned}$$

CRITICAL THINKING AND CONCEPTS REVIEW

L02

- 11.1 Diversifiable and Nondiversifiable Risks.** In broad terms, why is some risk diversifiable? Why are some risks nondiversifiable? Does it follow that an investor can control the level of unsystematic risk in a portfolio, but not the level of systematic risk?

L03

- 11.2 Information and Market Returns.** Suppose the government announces that, based on a just-completed survey, the growth rate in the economy is likely

to be 2 percent in the coming year, as compared to 5 percent for the year just completed. Will security prices increase, decrease, or stay the same following this announcement? Does it make any difference whether or not the 2 percent figure was anticipated by the market? Explain.

- L0 3** **11.3 Systematic versus Unsystematic Risk.** Classify the following events as mostly systematic or mostly unsystematic. Is the distinction clear in every case?
- Short-term interest rates increase unexpectedly.
 - The interest rate a company pays on its short-term debt borrowing is increased by its bank.
 - Oil prices unexpectedly decline.
 - An oil tanker ruptures, creating a large oil spill.
 - A manufacturer loses a multimillion-dollar product liability suit.
 - A Supreme Court decision substantially broadens producer liability for injuries suffered by product users.
- L0 3** **11.4 Systematic versus Unsystematic Risk.** Indicate whether the following events might cause stocks in general to change price, and whether they might cause Big Widget Corp.'s stock to change price.
- The government announces that inflation unexpectedly jumped by 2 percent last month.
 - Big Widget's quarterly earnings report, just issued, generally fell in line with analysts' expectations.
 - The government reports that economic growth last year was at 3 percent, which generally agreed with most economists' forecasts.
 - The directors of Big Widget die in a plane crash.
 - Congress approves changes to the tax code that will increase the top marginal corporate tax rate. The legislation had been debated for the previous six months.
- L0 1** **11.5 Expected Portfolio Returns.** If a portfolio has a positive investment in every asset, can the expected return on the portfolio be greater than that on every asset in the portfolio? Can it be less than that on every asset in the portfolio? If you answer yes to one or both of these questions, give an example to support your answer.
- L0 2** **11.6 Diversification.** True or false: The most important characteristic in determining the expected return of a well-diversified portfolio is the variances of the individual assets in the portfolio. Explain.
- L0 3** **11.7 Portfolio Risk.** If a portfolio has a positive investment in every asset, can the standard deviation on the portfolio be less than that on every asset in the portfolio? What about the portfolio beta?
- L0 4** **11.8 Beta and CAPM.** Is it possible that a risky asset could have a beta of zero? Explain. Based on the CAPM, what is the expected return on such an asset? Is it possible that a risky asset could have a negative beta? What does the CAPM predict about the expected return on such an asset? Can you give an explanation for your answer?
- L0 2** **11.9 Corporate Downsizing.** In recent years, it has been common for companies to experience significant stock price changes in reaction to announcements of massive layoffs. Critics charge that such events encourage companies to fire longtime employees and that Wall Street is cheering them on. Do you agree or disagree?

- L01 11.10 Earnings and Stock Returns.** As indicated by a number of examples in this chapter, earnings announcements by companies are closely followed by, and frequently result in, share price revisions. Two issues should come to mind. First: Earnings announcements concern past periods. If the market values stocks based on expectations of the future, why are numbers summarizing past performance relevant? Second: These announcements concern accounting earnings. Going back to Chapter 2, such earnings may have little to do with cash flow, so again, why are they relevant?

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

- L01 1. Determining Portfolio Weights.** What are the portfolio weights for a portfolio that has 110 shares of Stock A that sell for \$79 per share and 85 shares of Stock B that sell for \$62 per share? **Basic** (Questions 1–24)
- L01 2. Portfolio Expected Return.** You own a portfolio that has \$1,500 invested in Stock A and \$2,600 invested in Stock B. If the expected returns on these stocks are 10 percent and 16 percent, respectively, what is the expected return on the portfolio?
- L01 3. Portfolio Expected Return.** You own a portfolio that is 25 percent invested in Stock X, 40 percent in Stock Y, and 35 percent in Stock Z. The expected returns on these three stocks are 10 percent, 13 percent, and 15 percent, respectively. What is the expected return on the portfolio?
- L01 4. Portfolio Expected Return.** You have \$10,000 to invest in a stock portfolio. Your choices are Stock X with an expected return of 13 percent and Stock Y with an expected return of 10 percent. If your goal is to create a portfolio with an expected return of 12.25 percent, how much money will you invest in Stock X? In Stock Y? 
- L01 5. Calculating Expected Return.** Based on the following information, calculate the expected return.

State of Economy	Probability of State of Economy	Rate of Return if State Occurs
Recession	.35	−.09
Boom	.65	.21

- L01 6. Calculating Expected Return.** Based on the following information, calculate the expected return.

State of Economy	Probability of State of Economy	Rate of Return if State Occurs
Recession	.25	−.09
Normal	.45	.11
Boom	.30	.30

L0 1

- 7. Calculating Returns and Standard Deviations.** Based on the following information, calculate the expected return and standard deviation for the two stocks.

State of Economy	Probability of State of Economy	Rate of Return if State Occurs	
		Stock A	Stock B
Recession	.20	.01	-.25
Normal	.55	.09	.15
Boom	.25	.14	.38

L0 1

- 8. Calculating Expected Returns.** A portfolio is invested 20 percent in Stock G, 35 percent in Stock J, and 45 percent in Stock K. The expected returns on these stocks are 8.5 percent, 11 percent, and 16.4 percent, respectively. What is the portfolio's expected return? How do you interpret your answer?

L0 1

L0 2

- 9. Returns and Standard Deviations.** Consider the following information:

State of Economy	Probability of State of Economy	Rate of Return if State Occurs		
		Stock A	Stock B	Stock C
Boom	.65	.08	.02	.23
Bust	.35	.12	.18	-.03

- What is the expected return on an equally weighted portfolio of these three stocks?
- What is the variance of a portfolio invested 20 percent each in A and B and 60 percent in C?

L0 1

L0 2

- 10. Returns and Standard Deviations.** Consider the following information:

State of Economy	Probability of State of Economy	Rate of Return if State Occurs		
		Stock A	Stock B	Stock C
Boom	.15	.35	.45	.33
Good	.45	.12	.10	.17
Poor	.35	.01	.02	-.05
Bust	.05	-.11	-.25	-.09

- Your portfolio is invested 30 percent each in A and C and 40 percent in B. What is the expected return of the portfolio?
- What is the variance of this portfolio? The standard deviation?

L0 3

- 11. Calculating Portfolio Betas.** You own a stock portfolio invested 25 percent in Stock Q, 20 percent in Stock R, 45 percent in Stock S, and 10 percent in Stock T. The betas for these four stocks are .85, .91, 1.31, and 1.76, respectively. What is the portfolio beta?

L0 3

- 12. Calculating Portfolio Betas.** You own a portfolio equally invested in a risk-free asset and two stocks. If one of the stocks has a beta of 1.31 and the total portfolio is equally as risky as the market, what must the beta be for the other stock in your portfolio?

- L0 4** 13. **Using CAPM.** A stock has a beta of 1.25, the expected return on the market is 11.7 percent, and the risk-free rate is 4.5 percent. What must the expected return on this stock be?
- L0 4** 14. **Using CAPM.** A stock has an expected return of 14.2 percent, the risk-free rate is 5.5 percent, and the market risk premium is 6.9 percent. What must the beta of this stock be?
- L0 4** 15. **Using CAPM.** A stock has an expected return of 11 percent, its beta is .85, and the risk-free rate is 5.5 percent. What must the expected return on the market be?
- L0 4** 16. **Using CAPM.** A stock has an expected return of 11.90 percent and a beta of 1.15, and the expected return on the market is 10.90 percent. What must the risk-free rate be?
- L0 4** 17. **Using CAPM.** A stock has a beta of 1.2 and an expected return of 11.8 percent. A risk-free asset currently earns 3.8 percent.
- What is the expected return on a portfolio that is equally invested in the two assets?
 - If a portfolio of the two assets has a beta of .8, what are the portfolio weights?
 - If a portfolio of the two assets has an expected return of 11 percent, what is its beta?
 - If a portfolio of the two assets has a beta of 2.4, what are the portfolio weights? How do you interpret the weights for the two assets in this case? Explain.
- L0 4** 18. **Using the SML.** Asset W has an expected return of 13 percent and a beta of 1.25. If the risk-free rate is 4.5 percent, complete the following table for portfolios of Asset W and a risk-free asset. Illustrate the relationship between portfolio expected return and portfolio beta by plotting the expected returns against the betas. What is the slope of the line that results?

Percentage of Portfolio in Asset W	Portfolio Expected Return	Portfolio Beta
0%		
25		
50		
75		
100		
125		
150		

- L0 4** 19. **Reward-to-Risk Ratios.** Stock Y has a beta of 1.30 and an expected return of 13 percent. Stock Z has a beta of .75 and an expected return of 10.5 percent. If the risk-free rate is 4.5 percent and the market risk premium is 7 percent, are these stocks correctly priced?
- L0 4** 20. **Reward-to-Risk Ratios.** In the previous problem, what would the risk-free rate have to be for the two stocks to be correctly priced relative to each other?
- L0 1** 21. **Portfolio Returns.** Using information from Table 10.2 on capital market history, determine the return on a portfolio that was equally invested in large-company stocks and long-term corporate bonds. What was the return on a portfolio that was equally invested in small stocks and Treasury bills?

- L0 1** 22. **Portfolio Expected Return.** You have \$250,000 to invest in a stock portfolio. Your choices are Stock H, with an expected return of 14 percent, and Stock L, with an expected return of 10.1 percent. If your goal is to create a portfolio with an expected return of 12 percent, how much money will you invest in Stock H? In Stock L?
- L0 1** 23. **Calculating Portfolio Weights.** Stock J has a beta of 1.20 and an expected return of 13.16 percent, while Stock K has a beta of .75 and an expected return of 10.10 percent. You want a portfolio with the same risk as the market. How much will you invest in each stock? What is the expected return of your portfolio?
- L0 1** 24. **Calculating Portfolio Weights and Expected Return.** You have a portfolio with the following:

Stock	Number of Shares	Price	Expected Return
W	700	\$45	12%
X	600	22	16
Y	350	58	14
Z	575	43	15

What is the expected return of your portfolio?

L0 1**L0 2**

- 25. Portfolio Returns and Deviations.** Consider the following information on a portfolio of three stocks:

Intermediate

(Questions 25–27)

State of Economy	Probability of State of Economy	Stock A Rate of Return	Stock B Rate of Return	Stock C Rate of Return
Boom	.15	.02	.32	.60
Normal	.55	.10	.12	.20
Bust	.30	.16	-.11	-.35

L0 4

- 26. CAPM.** Using the CAPM, show that the ratio of the risk premiums on two assets is equal to the ratio of their betas.

L0 2

- 27. Analyzing a Portfolio.** You want to create a portfolio equally as risky as the market, and you have \$500,000 to invest. Given this information, fill in the rest of the following table:

Asset	Investment	Beta
Stock A	\$130,000	.75
Stock B	150,000	1.20
Stock C		1.35
Risk-free asset		

L01

- 28. Analyzing a Portfolio.** You have \$100,000 to invest in either Stock D, Stock F, or a risk-free asset. You must invest all of your money. Your goal is to create a portfolio that has an expected return of 10.5 percent. If D has an expected return of 14 percent, F has an expected return of 9.9 percent, and the risk-free rate is 5.5 percent, and if you invest \$50,000 in Stock D, how much will you invest in Stock F?

L04

- 29. SML.** Suppose you observe the following situation:

State of Economy	Probability of State	Return if State Occurs	
		Stock A	Stock B
Bust	.15	−.08	−.05
Normal	.70	.13	.14
Boom	.15	.48	.29

- Calculate the expected return on each stock.
- Assuming the capital asset pricing model holds and stock A's beta is greater than stock B's beta by .25, what is the expected market risk premium?

L03

- 30. Systematic versus Unsystematic Risk.** Consider the following information on Stocks I and II:

State of Economy	Probability of State of Economy	Rate of Return if State Occurs	
		Stock I	Stock II
Recession	.25	.02	−.20
Normal	.60	.32	.12
Irrational exuberance	.15	.18	.40

The market risk premium is 11 percent, and the risk-free rate is 4 percent. Which stock has the most systematic risk? Which one has the most unsystematic risk? Which stock is “riskier”? Explain.

- 11.1 Expected Return.** You want to find the expected return for Honeywell using the CAPM. First, you need the market risk premium. Use the average large-company stock return in Table 10.3 to estimate the market risk premium. Next, go to money.cnn.com and find the current interest rate for three-month Treasury bills. Finally, go to finance.yahoo.com, enter the ticker symbol HON for Honeywell, and find the beta for Honeywell. What is the expected return for Honeywell using CAPM? What assumptions have you made to arrive at this number?

- 11.2 Portfolio Beta.** You have decided to invest in an equally weighted portfolio consisting of American Express, Procter & Gamble, Home Depot, and Du Pont and need to find the beta of your portfolio. Go to finance.yahoo.com and find the ticker symbols for each of these companies. Next, find the beta for each company. What is the beta for your portfolio?

- 11.3 Beta.** Which stock has the highest and lowest betas? Go to finance.yahoo.com and locate the Stock Screener. Enter 0 as the maximum value. How many stocks have a beta less than zero? Which stock has the lowest beta? Go back to the screener and enter 3 as the minimum value. How many stocks have a beta greater than 3? What about greater than 4? Which stock has the highest beta?

Challenge

(Questions 28–30)

WHAT'S ON THE WEB?

CHAPTER CASE

THE BETA FOR FLIR SYSTEMS

Joey Moss, a recent finance graduate, has just begun his job with the investment firm of Covili and Wyatt. Paul Covili, one of the firm's founders, has been talking to Joey about the firm's investment portfolio.

As with any investment, Paul is concerned about the risk of the investment as well as the potential return. More specifically, because the company holds a diversified portfolio, Paul is concerned about the systematic risk of current and potential investments. One position the company currently holds is stock in FLIR Systems, Inc. (FLIR). FLIR Systems designs, manufactures, and markets thermal imaging and infrared camera systems. Although better known for its military applications, the company has divisions that design products for other applications such as

automotive night vision, commercial products that require minute temperature difference measurements, recreational marine usage, and firefighting.

Covili and Wyatt currently uses a commercial data vendor for information about its positions. Because of this, Paul is unsure exactly how the numbers provided are calculated. The data provider considers its methods proprietary, and it will not disclose how stock betas and other information are calculated. Paul is uncomfortable with not knowing exactly how these numbers are being computed and also believes that it could be less expensive to calculate the necessary statistics in-house. To explore this question, Paul has asked Joey to do the following assignments:

QUESTIONS

1. Go to finance.yahoo.com and download the ending monthly stock prices for FLIR Systems (FLIR) for the last 60 months. Be sure to use the adjusted closing price to account for any stock splits and dividend payments. Next, download the ending value of the S&P 500 index over the same period. For the historical risk-free rate, go to the St. Louis Federal Reserve Web site (www.stlouisfed.org) and find the three-month Treasury bill secondary market rate. Download this file. What are the monthly returns, average monthly returns, and standard deviations for FLIR Systems stock, the three-month Treasury bill, and the S&P 500 for this period?
2. Beta is often estimated by linear regression. A model often used is called the *market model*, which is:

$$R_t - R_{ft} = \alpha_i + \beta_i [R_{Mt} - R_{ft}] + \epsilon_t$$

In this regression, R_t is the return on the stock and R_{ft} is the risk-free rate for the same period.

R_{Mt} is the return on a stock market index such as the S&P 500 index. α_i is the regression intercept, and β_i is the slope (and the stock's estimated beta). ϵ_t represents the residuals for the regression. What do you think is the motivation for this particular regression? The intercept, α_i , is often called *Jensen's alpha*. What does it measure? If an asset has a positive Jensen's alpha, where would it plot with respect to the SML? What is the financial interpretation of the residuals in the regression?

3. Use the market model to estimate the beta for FLIR Systems using the last 60 months of returns (the regression procedure in Excel is one easy way to do this). Plot the monthly returns on FLIR Systems against the index and also show the fitted line.
4. Compare your beta for FLIR Systems to the beta you find on finance.yahoo.com. How similar are they? Why might they be different?

Cost of Capital

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Determine a firm's cost of equity capital.
- LO 2** Determine a firm's cost of debt.
- LO 3** Determine a firm's overall cost of capital.
- LO 4** Identify some of the pitfalls associated with a firm's overall cost of capital and what to do about them.

With over 95,000 employees on five continents, Germany-based BASF is a major international company. BASF operates in a variety of industries, including agriculture, oil and gas, chemicals, and plastics. In an attempt to increase value, BASF launched BASF 2015, a comprehensive plan that included all functions within the company and challenged and encouraged all employees to act in an entrepreneurial manner. The major financial component of the strategy was that the company expected to earn its weighted average cost of capital, or WACC, plus a premium. So, what exactly is the WACC?

The WACC is the minimum return a company needs to earn to satisfy all of its investors, including stockholders, bondholders, and preferred stockholders. In 2008, for example, BASF pegged its WACC at 10 percent, and it decreased this figure to 9 percent in 2009. In this chapter, we learn how to compute a firm's cost of capital and find out what it means to the firm and its investors. We will also learn when to use the firm's cost of capital and, perhaps more important, when not to use it.

From our chapters on capital budgeting, we know that the discount rate, or required return, on an investment is a critical input. Thus far, however, we haven't discussed how to come up with that particular number, so it's time now to do so. This chapter brings together many of our earlier discussions dealing with stocks and bonds, capital budgeting, and risk and return. Our goal is to illustrate how firms go about determining the required return on a proposed investment. Understanding required returns is important to everyone because all proposed projects, whether they relate to marketing, management, accounting, or any other area, must offer returns in excess of their required returns to be acceptable.

Visit us at www.mhhe.com/rwj

Suppose you have just become the president of a large company and the first decision you face is whether to go ahead with a plan to renovate the company's warehouse distribution system. The plan will cost the company \$50 million, and it is expected to save \$12 million per year after taxes over the next six years.

This is a familiar problem in capital budgeting. To address it, you would determine the relevant cash flows, discount them, and, if the net present value is positive, take on the project; if the NPV is negative, you would scrap it. So far, so good; but what should you use as the discount rate?

From our discussion of risk and return, you know that the correct discount rate depends on the riskiness of the warehouse distribution system. In particular, the new project will have a positive NPV only if its return exceeds what the financial markets offer on investments of similar risk. We called this minimum required return the *cost of capital* associated with the project.¹

Thus, to make the right decision as president, you must examine what the capital markets have to offer and use this information to arrive at an estimate of the project's cost of capital. Our primary purpose in this chapter is to describe how to go about doing this. There are a variety of approaches to this task, and a number of conceptual and practical issues arise.

One of the most important concepts we develop is that of the *weighted average cost of capital* (WACC). This is the cost of capital for the firm as a whole, and it can be interpreted as the required return on the overall firm. In discussing the WACC, we will recognize the fact that a firm will normally raise capital in a variety of forms and that these different forms of capital may have different costs associated with them.

We also recognize in this chapter that taxes are an important consideration in determining the required return on an investment, because we are always interested in valuing the aftertax cash flows from a project. We will therefore discuss how to incorporate taxes explicitly into our estimates of the cost of capital.

12.1

THE COST OF CAPITAL: SOME PRELIMINARIES

In Chapter 11, we developed the security market line, or SML, and used it to explore the relationship between the expected return on a security and its systematic risk. We concentrated on how the risky returns from buying securities looked from the viewpoint of, for example, a shareholder in the firm. This helped us understand more about the alternatives available to an investor in the capital markets.

In this chapter, we turn things around a bit and look more closely at the other side of the problem, which is how these returns and securities look from the viewpoint of the companies that issue the securities. The important fact to note is that the return an investor in a security receives is the cost of that security to the company that issued it.

Required Return versus Cost of Capital

When we say that the required return on an investment is, say, 10 percent, we usually mean that the investment will have a positive NPV only if its return exceeds 10 percent. Another way of interpreting the required return is to observe that the firm must earn 10 percent on

¹ The term *cost of money* is also used.

the investment just to compensate its investors for the use of the capital needed to finance the project. This is why we could also say that 10 percent is the cost of capital associated with the investment.

To illustrate the point further, imagine we are evaluating a risk-free project. In this case, how to determine the required return is obvious: We look at the capital markets and observe the current rate offered by risk-free investments, and we use this rate to discount the project's cash flows. Thus, the cost of capital for a risk-free investment is the risk-free rate.

If this project is risky, then, assuming that all the other information is unchanged, the required return is obviously higher. In other words, the cost of capital for this project, if it is risky, is greater than the risk-free rate, and the appropriate discount rate would exceed the risk-free rate.

We will henceforth use the terms *required return*, *appropriate discount rate*, and *cost of capital* more or less interchangeably because, as the discussion in this section suggests, they all mean essentially the same thing. The key fact to grasp is that the cost of capital associated with an investment depends on the risk of that investment. In other words, it's the use of the money, not the source, that matters. This is one of the most important lessons in corporate finance, so it bears repeating:

The cost of capital depends primarily on the use of the funds, not the source.

It is a common error to forget this crucial point and fall into the trap of thinking that the cost of capital for an investment depends primarily on how and where the capital is raised.

Financial Policy and Cost of Capital

We know that the particular mixture of debt and equity a firm chooses to employ—its capital structure—is a managerial variable. In this chapter, we will take the firm's financial policy as given. In particular, we will assume that the firm has a fixed debt-equity ratio that it maintains. This ratio reflects the firm's *target* capital structure. How a firm might choose that ratio is the subject of a later chapter.

From our discussion above, we know that a firm's overall cost of capital will reflect the required return on the firm's assets as a whole. Given that a firm uses both debt and equity capital, this overall cost of capital will be a mixture of the returns needed to compensate its creditors and its stockholders. In other words, a firm's cost of capital will reflect both its cost of debt capital and its cost of equity capital. We discuss these costs separately in the sections that follow.

CONCEPT QUESTIONS

- 12.1a** What is the primary determinant of the cost of capital for an investment?
- 12.1b** What is the relationship between the required return on an investment and the cost of capital associated with that investment?

12.2

cost of equity

The return that equity investors require on their investment in the firm.

THE COST OF EQUITY

We begin with the most difficult question on the subject of cost of capital: What is the firm's overall **cost of equity**? The reason this is a difficult question is that there is no way of directly observing the return that the firm's equity investors require on their investment. Instead, we must somehow estimate it. This section discusses two approaches to determining the cost of equity: the dividend growth model approach and the security market line, or SML, approach.

The Dividend Growth Model Approach

The easiest way to estimate the cost of equity capital is to use the dividend growth model we developed in Chapter 7. Recall that, under the assumption that the firm's dividend will grow at a constant rate, g , the price per share of the stock, P_0 , can be written as:

$$P_0 = \frac{D_0 \times (1 + g)}{R_E - g} = \frac{D_1}{R_E - g}$$

where D_0 is the dividend just paid and D_1 is the next period's projected dividend. Notice that we have used the symbol R_E (the E stands for *equity*) for the required return on the stock.

As we discussed in Chapter 7, we can rearrange this to solve for R_E as follows:

$$R_E = D_1/P_0 + g \quad [12.1]$$

Since R_E is the return that the shareholders require on the stock, it can be interpreted as the firm's cost of equity capital.

Implementing the Approach To estimate R_E using the dividend growth model approach, we obviously need three pieces of information: P_0 , D_0 , and g . Of these, for a publicly traded, dividend-paying company, the first two can be observed directly, so they are easily obtained.² Only the third component, the expected growth rate in dividends, must be estimated.

To illustrate how we estimate R_E , suppose Greater States Public Service, a large public utility, paid a dividend of \$4 per share last year. The stock currently sells for \$60 per share. You estimate that the dividend will grow steadily at 6 percent per year into the indefinite future. What is the cost of equity capital for Greater States?

Using the dividend growth model, we calculate that the expected dividend for the coming year, D_1 , is:

$$\begin{aligned} D_1 &= D_0 \times (1 + g) \\ &= \$4 \times 1.06 \\ &= \$4.24 \end{aligned}$$

Given this, the cost of equity, R_E , is:

$$\begin{aligned} R_E &= D_1/P_0 + g \\ &= \$4.24/60 + .06 \\ &= 13.07\% \end{aligned}$$

The cost of equity is thus 13.07%.

² Notice that if we have D_0 and g , we can simply calculate D_1 by multiplying D_0 by $(1 + g)$.

Estimating g To use the dividend growth model, we must come up with an estimate for g , the growth rate. There are essentially two ways of doing this: (1) use historical growth rates or (2) use analysts' forecasts of future growth rates. Analysts' forecasts are available from a variety of sources. Naturally, different sources will have different estimates, so one approach might be to obtain multiple estimates and then average them.

Alternatively, we might observe dividends for the previous, say, five years, calculate the year-to-year growth rates, and average them. For example, suppose we observe the following for some company:

Year	Dividend
2006	\$1.10
2007	1.20
2008	1.35
2009	1.40
2010	1.55

We can calculate the percentage change in the dividend for each year as follows:

Year	Dividend	Dollar Change	Percentage Change
2006	\$1.10	—	—
2007	1.20	\$.10	9.09%
2008	1.35	.15	12.50
2009	1.40	.05	3.70
2010	1.55	.15	10.71

Aggregate growth estimates can be found at www.zacks.com/research/earnings.

Notice that we calculated the change in the dividend on a year-to-year basis and then expressed the change as a percentage. Thus, in 2007, for example, the dividend rose from \$1.10 to \$1.20, for an increase of \$.10. This represents a $\$.10/\$1.10 = 9.09\%$ increase.

If we average the four growth rates, the result is $(9.09 + 12.50 + 3.70 + 10.71)/4 = 9\%$, so we could use this as an estimate for the expected growth rate, g . Notice that this 9 percent growth rate we have calculated is a simple, or arithmetic average. Going back to Chapter 10, we also could calculate a geometric growth rate. Here, the dividend grows from \$1.10 to \$1.55 over a four-year period. What's the compound, or geometric growth rate? See if you don't agree that it's 8.95 percent; you can view this as a simple time value of money problem where \$1.10 is the present value and \$1.55 is the future value.

As usual, the geometric average (8.95 percent) is lower than the arithmetic average (9.00 percent), but the difference here is not likely to be of any practical significance. In general, if the dividend has grown at a relatively steady rate, as we assume when we use this approach, then it can't make much difference which way we calculate the average dividend growth rate.

Advantages and Disadvantages of the Approach The primary advantage of the dividend growth model approach is its simplicity. It is both easy to understand and easy to use. However, there are a number of associated practical problems and disadvantages.

First and foremost, the dividend growth model is obviously only applicable to companies that pay dividends. This means that the approach is useless in many cases. Furthermore, even for companies that do pay dividends, the key underlying assumption is that the dividend grows at a constant rate. As our example above illustrates, this will never be *exactly* the case. More generally, the model is really only applicable to cases in which reasonably steady growth is likely to occur.

A second problem is that the estimated cost of equity is very sensitive to the estimated growth rate. For a given stock price, an upward revision of g by just one percentage point, for example, increases the estimated cost of equity by at least a full percentage point. Since D_1 will probably be revised upward as well, the increase will actually be somewhat larger than that.

Finally, this approach really does not explicitly consider risk. Unlike the SML approach (which we consider next), this one has no direct adjustment for the riskiness of the investment. For example, there is no allowance for the degree of certainty or uncertainty surrounding the estimated growth rate in dividends. As a result, it is difficult to say whether or not the estimated return is commensurate with the level of risk.³

The SML Approach

In Chapter 11, we discussed the security market line, or SML. Our primary conclusion was that the required or expected return on a risky investment depends on three things:

1. The risk-free rate, R_f
2. The market risk premium, $E(R_M) - R_f$
3. The systematic risk of the asset relative to average, which we called its beta coefficient, β

Using the SML, we can write the expected return on the company's equity, $E(R_E)$, as:

$$E(R_E) = R_f + \beta_E \times [E(R_M) - R_f]$$

where β_E is the estimated beta for the equity. To make the SML approach consistent with the dividend growth model, we will drop the E s denoting expectations and henceforth write the required return from the SML, R_E , as:

$$R_E = R_f + \beta_E \times (R_M - R_f) \quad [12.2]$$

Implementing the Approach To use the SML approach, we need a risk-free rate, R_f , an estimate of the market risk premium, $R_M - R_f$, and an estimate of the relevant beta, β_E . In Chapter 10, we saw that one estimate of the market risk premium is about 7 percent. U.S. Treasury bills are paying about 1 percent as this is being written, so we will use this as our risk-free rate. Beta coefficients for publicly traded companies are widely available.⁴

To illustrate, in Chapter 11, we saw that eBay had an estimated beta of 1.43 (Table 11.8). We could thus estimate eBay's cost of equity as:

$$\begin{aligned} R_{\text{eBay}} &= R_f + \beta_{\text{eBay}} \times (R_M - R_f) \\ &= 1\% + 1.43 \times 7\% \\ &= 11.01\% \end{aligned}$$

Thus, using the SML approach, eBay's cost of equity is about 11 percent.

³ There is an implicit adjustment for risk because the current stock price is used. All other things being equal, the higher the risk, the lower is the stock price. Further, the lower the stock price, the greater is the cost of equity, again assuming that all the other information is the same.

⁴ Beta coefficients can be estimated directly by using historical data. For a discussion of how to do this, see Chapters 10, 11, and 12 in S. A. Ross, R. W. Westerfield, and J. J. Jaffe, *Corporate Finance*, 9th ed. (Burr Ridge, Ill.: The McGraw-Hill Companies, 2010).

Advantages and Disadvantages of the Approach The SML approach has two primary advantages. First: It explicitly adjusts for risk. Second: It is applicable to companies other than just those with steady dividend growth. Thus, it may be useful in a wider variety of circumstances.

There are drawbacks, of course. The SML approach requires that two things be estimated, the market risk premium and the beta coefficient. To the extent that our estimates are poor, the resulting cost of equity will be inaccurate. For example, our estimate of the market risk premium, 7 percent, is based on about 100 years of returns on a particular portfolio of stocks. Using different time periods or different stocks could result in very different estimates.

Finally, as with the dividend growth model, we essentially rely on the past to predict the future when we use the SML approach. Economic conditions can change very quickly, so, as always, the past may not be a good guide to the future. In the best of all worlds, both approaches (dividend growth model and SML) are applicable and result in similar answers. If this happens, we might have some confidence in our estimates. We might also wish to compare the results to those for other, similar companies as a reality check.

The Cost of Equity

EXAMPLE 12.1

Suppose stock in Alpha Air Freight has a beta of 1.2. The market risk premium is 8 percent, and the risk-free rate is 6 percent. Alpha's last dividend was \$2 per share, and the dividend is expected to grow at 8 percent indefinitely. The stock currently sells for \$30. What is Alpha's cost of equity capital?

We can start off by using the SML. Doing this, we find that the expected return on the common stock of Alpha Air Freight is:

$$\begin{aligned} R_E &= R_f + \beta_E \times (R_M - R_f) \\ &= 6\% + 1.2 \times 8\% \\ &= 15.6\% \end{aligned}$$

This suggests that 15.6 percent is Alpha's cost of equity. We next use the dividend growth model. The projected dividend is $D_0 \times (1 + g) = \$2 \times 1.08 = \2.16 , so the expected return using this approach is:

$$\begin{aligned} R_E &= D_1/P_0 + g \\ &= \$2.16/30 + .08 \\ &= 15.2\% \end{aligned}$$

Our two estimates are reasonably close, so we might just average them to find that Alpha's cost of equity is approximately 15.4 percent.

CONCEPT QUESTIONS

12.2a What do we mean when we say that a corporation's cost of equity capital is 16 percent?

12.2b What are two approaches to estimating the cost of equity capital?

THE COSTS OF DEBT AND PREFERRED STOCK

12.3

In addition to ordinary equity, firms use debt and, to a lesser extent, preferred stock to finance their investments. As we discuss next, determining the costs of capital associated with these sources of financing is much easier than determining the cost of equity.

The Cost of Debt

cost of debt

The return that lenders require on the firm's debt.

The **cost of debt** is the return that the firm's creditors demand on new borrowing. In principle, we could determine the beta for the firm's debt and then use the SML to estimate the required return on debt just as we estimate the required return on equity. This isn't really necessary, however.

Unlike a firm's cost of equity, its cost of debt can normally be observed either directly or indirectly, because the cost of debt is simply the interest rate the firm must pay on new borrowing, and we can observe interest rates in the financial markets. For example, if the firm already has bonds outstanding, then the yield to maturity on those bonds is the market-required rate on the firm's debt.

Alternatively, if we knew that the firm's bonds were rated, say, AA, then we could simply find out what the interest rate on newly issued AA-rated bonds was. Either way, there is no need to actually estimate a beta for the debt since we can directly observe the rate we want to know.

There is one thing to be careful about, though. The coupon rate on the firm's outstanding debt is irrelevant here. That just tells us roughly what the firm's cost of debt was back when the bonds were issued, not what the cost of debt is today.⁵ This is why we have to look at the yield on the debt in today's marketplace. For consistency with our other notation, we will use the symbol R_D for the cost of debt.

EXAMPLE 12.2

The Cost of Debt

Suppose the General Tool Company issued a 30-year, 7 percent bond eight years ago. The bond is currently selling for 96 percent of its face value, or \$960. What is General Tool's cost of debt?

Going back to Chapter 6, we need to calculate the yield to maturity on this bond. Since the bond is selling at a discount, the yield is apparently greater than 7 percent, but not much greater, because the discount is fairly small. You can verify that the yield to maturity is about 7.37 percent, assuming annual coupons. General Tool's cost of debt, R_D , is thus 7.37 percent.

The Cost of Preferred Stock

Determining the *cost of preferred stock* is quite straightforward. As we discussed in Chapters 6 and 7, preferred stock has a fixed dividend paid every period forever, so a share of preferred stock is essentially a perpetuity. The cost of preferred stock, R_P , is thus:

$$R_P = D/P_0 \quad [12.3]$$

where D is the fixed dividend and P_0 is the current price per share of the preferred stock. Notice that the cost of preferred stock is simply equal to the dividend yield on the preferred stock. Alternatively, preferred stocks are rated in much the same way as bonds, so the cost of preferred stock can be estimated by observing the required returns on other, similarly rated shares of preferred stock.

EXAMPLE 12.3

Citigroup's Cost of Preferred Stock

In 2009, Citigroup had several issues of preferred stock that traded on the NYSE. One issue paid \$150 annually per share and sold for \$8.65 per share. Another paid \$3.25 per share annually and sold for \$23.50 per share. What was Citigroup's cost of preferred stock?

(continued)

⁵ The firm's cost of debt based on its historic borrowing is sometimes called the *embedded debt cost*.

Using the first issue, the cost of preferred stock was:

$$\begin{aligned} R_P &= D/P_0 \\ &= \$150/8.65 \\ &= 17.34\% \end{aligned}$$

Using the second issue, the cost was:

$$\begin{aligned} R_P &= D/P_0 \\ &= \$3.25/23.50 \\ &= 13.83\% \end{aligned}$$

So, Citigroup's cost of preferred stock appears to have been in the 14 to 18 percent range, which is much higher than is typical. Why do you think Citigroup's cost of preferred was so high in 2009?

CONCEPT QUESTIONS

- 12.3a** How can the cost of debt be calculated?
- 12.3b** How can the cost of preferred stock be calculated?
- 12.3c** Why is the coupon rate a bad estimate of a firm's cost of debt?

THE WEIGHTED AVERAGE COST OF CAPITAL

12.4

Now that we have the costs associated with the main sources of capital the firm employs, we need to worry about the specific mix. As we mentioned above, we will take this mix, which is the firm's capital structure, as given for now. Also, we will focus mostly on debt and ordinary equity in this discussion.

The Capital Structure Weights

We will use the symbol E (for *equity*) to stand for the *market* value of the firm's equity. We calculate this by taking the number of shares outstanding and multiplying it by the price per share. Similarly, we will use the symbol D (for *debt*) to stand for the *market* value of the firm's debt. For long-term debt, we calculate this by multiplying the market price of a single bond by the number of bonds outstanding.

If there are multiple bond issues (as there normally would be), we repeat this calculation for each and then add up the results. If there is debt that is not publicly traded (because it is held by a life insurance company, for example), we must observe the yield on similar, publicly traded debt and then estimate the market value of the privately held debt using this yield as the discount rate. For short-term debt, the book (accounting) values and market values should be somewhat similar, so we might use the book values as estimates of the market values.

Finally, we will use the symbol V (for *value*) to stand for the combined market value of the debt and equity:

$$V = E + D \quad [12.4]$$

If we divide both sides by V , we can calculate the percentages of the total capital represented by the debt and equity:

$$100\% = E/V + D/V \quad [12.5]$$

These percentages can be interpreted just like portfolio weights, and they are often called the *capital structure weights*.

For example, if the total market value of a company's stock were calculated as \$200 million and the total market value of the company's debt were calculated as \$50 million, then the combined value would be \$250 million. Of this total, $E/V = \$200/\$250 = 80\%$, so 80 percent of the firm's financing would be equity and the remaining 20 percent would be debt.

We emphasize here that the correct way to proceed is to use the *market* values of the debt and equity. Under certain circumstances, such as when considering a privately owned company, it may not be possible to get reliable estimates of these quantities. In this case, we might go ahead and use the accounting values for debt and equity. While this would probably be better than nothing, we would have to take the answer with a grain of salt.

Taxes and the Weighted Average Cost of Capital

There is one final issue we need to discuss. Recall that we are always concerned with aftertax cash flows. If we are determining the discount rate appropriate to those cash flows, then the discount rate also needs to be expressed on an aftertax basis.

As we discussed previously in various places in this book (and as we will discuss later), the interest paid by a corporation is deductible for tax purposes. Payments to stockholders, such as dividends, are not. What this means, effectively, is that the government pays some of the interest. Thus, in determining an aftertax discount rate, we need to distinguish between the pretax and the aftertax cost of debt.

To illustrate, suppose a firm borrows \$1 million at 9 percent interest. The corporate tax rate is 34 percent. What is the aftertax interest rate on this loan? The total interest bill will be \$90,000 per year. This amount is tax deductible, however, so the \$90,000 interest reduces our tax bill by $.34 \times \$90,000 = \$30,600$. The aftertax interest bill is thus $\$90,000 - \$30,600 = \$59,400$. The aftertax interest rate is thus $\$59,400/\$1 \text{ million} = 5.94\%$.

Notice that, in general, the aftertax interest rate is simply equal to the pretax rate multiplied by 1 minus the tax rate. Thus, if we use the symbol T_c to stand for the corporate tax rate, then the aftertax rate that we use for the cost of debt can be written as $R_D \times (1 - T_c)$. For example, using the numbers above, we find that the aftertax interest rate is $9\% \times (1 - .34) = 5.94\%$.

Collecting together the various topics we have discussed in this chapter, we now have the capital structure weights along with the cost of equity and the aftertax cost of debt. To calculate the firm's overall cost of capital, we multiply the capital structure weights by the associated costs and add up the pieces. The result of this is the **weighted average cost of capital**, or **WACC**.

$$\text{WACC} = (E/V) \times R_E + (D/V) \times R_D \times (1 - T_c) \quad [12.6]$$

This WACC has a very straightforward interpretation. It is the overall return the firm must earn on its existing assets to maintain the value of its stock. This is an important point, so it bears repeating:

The WACC is the overall return the firm must earn on its existing assets to maintain the value of its stock.

weighted average cost of capital (WACC)

The weighted average of the cost of equity and the aftertax cost of debt.

EVA: An Old Idea Moves into the Modern Age

You might not think of Briggs and Stratton, Coca-Cola, and Toys 'R' Us as having much in common. However, all three have linked their fortunes to a way of managing and measuring corporate performance that depends critically on the cost of capital. It goes by many names, but consulting firm Stern Stewart & Co., a well-known advocate, calls its particular flavor "economic value added," or EVA. Stockholder value added (SVA) is a common variant. Whatever the name, EVA and its cousins have become an important tool for corporate management since the mid-1990s.

Briefly stated, EVA is a method of measuring financial performance. To compute EVA, you must calculate your overall cost of capital. Then, you identify how much capital is tied up in your business. Next, you multiply the amount of capital by the cost of capital. The result is the amount, in dollars, you should be providing to your investors. Subtract out your actual operating cash flow, and the difference is a measure of EVA. A positive value means that you earned more than your cost of capital, thereby creating value, and vice versa (this is just a quick overview; for more detail visit www.eva.com).

Each year, Stern Stewart & Co. prepares the Stern Stewart 1000, a ranking of the 1,000 largest U.S. companies based on their respective EVAs. Over the history of the Stern Stewart 1000, several companies have shown consistently strong performances. For example, Microsoft, Intel, and ExxonMobil often appear near the top of the list. The list also has perennial poor performers, and some of the names may surprise you, for example, General Motors, Time Warner, Goodyear Tire & Rubber, and JDS Uniphase. Evidently, a well-known brand name does not always result in shareholder wealth.

One thing the Stern Stewart 1000 has done is to show the changing face of the economy. For instance, Intel, Dell

Computer, Cisco Systems, and eBay have all ranked rather well on the list. Consider that Intel is the oldest of these companies, having been publicly traded since 1971, while eBay has been publicly traded only since 1998. This highlights the dramatic impact of technology companies on the economy. Of course, not all technology-related companies have performed as well. For example, WebMD has appeared near the bottom of the list every year.

According to Bennett Stewart, one of the cofounders of Stern Stewart, EVA shows an important distinction between accounting income and economic profit. Accounting rules dictate that the interest expense a company incurs must be deducted from its reported profit, but those same rules forbid deducting a charge for the shareholders' funds used by a firm. In economic terms, equity capital is in fact a very costly financing source because shareholders bear the risk of being paid last, after all other stakeholders and investors are paid. But according to accountants, shareholder equity is essentially free. This oversight has dire practical consequences. For instance, it means that the profit figure accountants certify to be correct can conflict with the net present value decision rule. This conflict occurs when accounting rules lead to a focus on the accountant's bottom line rather than the more important question of whether a project's projected return exceeds its required return.

While EVA and its variants are sound in principle, they still have shortcomings. For one thing, they are typically computed using asset book values instead of market values. For another, they sometimes are based on accounting measures of income when cash flow would be a better choice. Nonetheless, potential problems aside, the concept of EVA focuses management attention on creating wealth for investors. That, in itself, makes EVA a worthwhile tool.

The WACC is also the required return on any investments by the firm that have essentially the same risks as existing operations. So, if we were evaluating the cash flows from a proposed expansion of our existing operations, this is the discount rate we would use.

If a firm uses preferred stock in its capital structure, then our expression for the WACC needs a simple extension. If we define P/V as the percentage of the firm's financing that comes from preferred stock, then the WACC is simply:

$$\text{WACC} = (E/V) \times R_E + (P/V) \times R_P + (D/V) \times R_D \times (1 - T_c) \quad [12.7]$$

where R_P is the cost of preferred stock.

The WACC is increasingly being used by corporations to evaluate financial performance. The accompanying *Reality Bytes* box provides some details on how this is being done.

EXAMPLE 12.4**Calculating the WACC**

The B. B. Lean Co. has 1.4 million shares of stock outstanding. The stock currently sells for \$20 per share. The firm's debt is publicly traded and was recently quoted at 93 percent of face value. It has a total face value of \$5 million, and it is currently priced to yield 11 percent. The risk-free rate is 8 percent, and the market risk premium is 7 percent. You've estimated that Lean has a beta of .74. If the corporate tax rate is 34 percent, what is the WACC of Lean Co.?

We can first determine the cost of equity and the cost of debt. From the SML, the cost of equity is $8\% + .74 \times 7\% = 13.18\%$. The total value of the equity is $1.4 \text{ million} \times \$20 = \$28 \text{ million}$. The pretax cost of debt is the current yield to maturity on the outstanding debt, 11 percent. The debt sells for 93 percent of its face value, so its current market value is $.93 \times \$5 \text{ million} = \4.65 million . The total market value of the equity and debt together is $\$28 + 4.65 = \32.65 million .

From here, we can calculate the WACC easily enough. The percentage of equity used by Lean to finance its operations is $\$28/\$32.65 = 85.76\%$. Since the weights have to add up to 1.0, the percentage of debt is $1.0 - .8576 = 14.24\%$. The WACC is thus:

$$\begin{aligned} \text{WACC} &= (E/V) \times R_E + (D/V) \times R_D \times (1 - T_c) \\ &= .8576 \times 13.18\% + .1424 \times 11\% \times (1 - .34) \\ &= 12.34\% \end{aligned}$$

B. B. Lean thus has an overall weighted average cost of capital of 12.34 percent.

Solving the Warehouse Problem and Similar Capital Budgeting Problems

Now we can use the WACC to solve the warehouse problem we posed at the beginning of the chapter. However, before we rush to discount the cash flows at the WACC to estimate NPV, we need to first make sure we are doing the right thing.

Going back to first principles, we need to find an alternative in the financial markets that is comparable to the warehouse renovation. To be comparable, an alternative must be of the same risk as the warehouse project. Projects that have the same risk are said to be in the same risk class.

The WACC for a firm reflects the risk and the target capital structure of the firm's existing assets as a whole. As a result, strictly speaking, the firm's WACC is the appropriate discount rate only if the proposed investment is a replica of the firm's existing operating activities.

In broader terms, whether or not we can use the firm's WACC to value the warehouse project depends on whether the warehouse project is in the same risk class as the firm. We will assume that this project is an integral part of the overall business of the firm. In such cases, it is natural to think that the cost savings will be as risky as the general cash flows of the firm, and the project will thus be in the same risk class as the overall firm. More generally, projects like the warehouse renovation that are intimately related to the firm's existing operations are often viewed as being in the same risk class as the overall firm.

We can now see what the president should do. Suppose the firm has a target debt-equity ratio of 1/3. From Chapter 3, we know that a debt-equity ratio of $D/E = 1/3$ implies that E/V is .75 and D/V is .25. Further suppose the cost of debt is 10 percent, and the cost of equity is 20 percent. Assuming a 34 percent tax rate, the WACC will then be:

$$\begin{aligned} \text{WACC} &= (E/V) \times R_E + (D/V) \times R_D \times (1 - T_c) \\ &= .75 \times 20\% + .25 \times 10\% \times (1 - .34) \\ &= 16.65\% \end{aligned}$$

Recall that the warehouse project had a cost of \$50 million and expected aftertax cash flows (the cost savings) of \$12 million per year for six years. The NPV is thus:

$$\text{NPV} = -\$50 + \frac{12}{(1 + \text{WACC})^1} + \dots + \frac{12}{(1 + \text{WACC})^6}$$

Since the cash flows are in the form of an ordinary annuity, we can calculate this NPV using 16.65 percent (the WACC) as the discount rate as follows:

$$\begin{aligned}\text{NPV} &= -\$50 + 12 \times \frac{1 - [1/(1 + .1665)^6]}{.1665} \\ &= -\$50 + 12 \times 3.6222 \\ &= -\$6.53 \text{ million}\end{aligned}$$

Should the firm take on the warehouse renovation? The project has a negative NPV using the firm's WACC. This means that the financial markets offer superior projects in the same risk class (namely, the firm itself). The answer is clear: The project should be rejected. For future reference, our discussion of the WACC is summarized in Table 12.1. Our nearby *Reality Bytes* box discusses a different use of the WACC.

Calculating the WACC for Eastman Chemical

In this section, we illustrate how to calculate the WACC for Eastman Chemical, a well-known chemical, plastics, and fiber producer. Our goal is to take you through, on a step-by-step basis, the process of finding and using the information needed using online sources. As you will see, there is a fair amount of detail involved, but the necessary information is, for the most part, readily available.

I. The cost of equity, R_E

- A. Dividend growth model approach (from Chapter 7):

$$R_E = D_1/P_0 + g$$

where D_1 is the expected dividend in one period, g is the dividend growth rate, and P_0 is the current stock price.

- B. SML approach (from Chapter 11):

$$R_E = R_f + \beta_E \times (R_M - R_f)$$

where R_f is the risk-free rate, R_M is the expected return on the overall market, and β_E is the systematic risk of the equity.

II. The cost of debt, R_D

- A. For a firm with publicly held debt, the cost of debt can be measured as the yield to maturity on the outstanding debt. The coupon rate is irrelevant. Yield to maturity is covered in Chapter 6.
- B. If the firm has no publicly traded debt, then the cost of debt can be measured as the yield to maturity on similarly rated bonds (bond ratings are discussed in Chapter 6).

III. The weighted average cost of capital, WACC

- A. The firm's WACC is the overall required return on the firm as a whole. It is the appropriate discount rate to use for cash flows similar in risk to the overall firm.
- B. The WACC is calculated as:

$$\text{WACC} = (E/V) \times R_E + (D/V) \times R_D \times (1 - T_C)$$

where T_C is the corporate tax rate, E is the *market* value of the firm's equity, D is the *market* value of the firm's debt, and $V = E + D$. Note that E/V is the percentage of the firm's financing (in market value terms) that is equity, and D/V is the percentage that is debt.

TABLE 12.1

Summary of capital cost calculations

The Cost of Capital, Texas Style

We have seen how the WACC is used in the corporate world. It is also used by state governments to value property for tax purposes. Property valuation can be tricky. The value of a home depends on what it could be sold for, which is not too hard to estimate, but how do you value an oil or gas field? For the Texas Comptroller of Public Accounts, the answer

and Occidental has the highest at 17.31 percent, but most other companies are in the 15 to 16 percent range. The average WACC for a company in this industry is 15.42 percent, with a standard deviation of 1.19 percent. When Texas uses this calculation, a two percent adjustment factor is added, plus any property-specific risk adjustment. The range

2008 Property Value Study: Discount Rate for Oil and Gas Properties

is to estimate the present value of the future cash flows of the property. As you know by now, the cost of capital depends on the use of funds, not the source of funds. So, Texas calculates the WACC for companies in the oil industry and adjusts the industry average WACC for company-specific factors. The table above shows the state's calculations for integrated oil companies.

As you can see, the WACC numbers for the companies are similar. Anadarko has the lowest WACC at 12.95 percent

used by the state for 2008 was 17.25 percent to 22.68 percent, before any property-specific factors.

Notice that the Texas Comptroller of Public Accounts calculated these numbers on a pretax, rather than aftertax, basis. In other words, the state did not account for the tax deductibility of interest payments in this calculation. The reason is that the state adjusts the cost of capital for taxes on a company-by-company basis.

Eastman's Cost of Equity Our first stop is the stock price for Eastman, available at finance.yahoo.com (ticker: "EMN"). As of early 2009, here's what the screen looked like:

According to this screen, Eastman has 72.46 million shares of stock outstanding. The book value per share is \$21.431, but the stock sells for \$23.82. Total equity is therefore about \$1.553 billion on a book value basis, but it is closer to \$1.726 billion on a market value basis.

To estimate Eastman's cost of equity, we will assume a market risk premium of 7 percent, similar to what we calculated in Chapter 10. Eastman's beta on Yahoo! is 1.42, which is higher than the beta of the average stock. This seems a little high for this type of company, so we went to www.reuters.com for another opinion. The beta we found there was 1.46. Since the estimates are similar, we'll average the numbers. According to the bond section of finance.yahoo.com, T-bills were paying about 0.21 percent. Using the CAPM to estimate the cost of equity, we find:

$$R_E = 0.0021 + 1.44(0.07) = .1029 \text{ or } 10.29\%$$

Eastman has only paid dividends for a few years, so calculating the future growth rate for the dividend discount model is problematic. However, under the analysts' estimates

link at finance.yahoo.com, we found the following:

Growth Est	EMN	Industry	Sector	S&P 500
Current Qtr.	-91.2%	-66.5%	-76.8%	-35.6%
Next Qtr.	-56.2%	-42.9%	-59.5%	30.9%
This Year	-48.7%	-29.7%	-46.1%	-6.2%
Next Year	32.5%	29.0%	49.8%	27.0%
Past 5 Years (per annum)	6.739%	N/A	N/A	N/A
Next 5 Years (per annum)	7%	9.39%	9.69%	N/A
Price/Earnings (avg. for comparison categories)	10.11	11.82	13.16	12.36
PEG Ratio (avg. for comparison categories)	1.44	1.26	1.36	N/A

Analysts estimate the growth in earnings per share for the company will be 7.0 percent for the next five years. For now, we will use this growth rate in the dividend discount model to estimate the cost of equity; the link between earnings growth and dividends is discussed in a later chapter. The estimated cost of equity using the dividend discount model is thus:

$$R_E = \left(\frac{\$1.76(1 + .07)}{\$23.82} \right) + .07 = .1491 \text{ or } 14.91\%$$

Notice that the estimates for the cost of equity are quite different, probably due, at least in part, to the relatively high growth rate and dividend yield we used. In broader terms, remember that each method of estimating the cost of equity relies on different assumptions, so different estimates should not surprise us. If the estimates are different, there are two simple solutions. First, we could ignore one of the estimates. We would look at each estimate to see if one of them seemed too high or too low to be reasonable. Second, we could average the two estimates. Averaging the two estimates for Eastman's cost of equity gives us a cost of equity of 12.60 percent. Since this seems like a reasonable number, we will use it in calculating the cost of capital.

Eastman's Cost of Debt Eastman has five long-term bond issues that account for essentially all of its long-term debt. To calculate the cost of debt, we will have to combine these five issues. What we will do is compute a weighted average. We went to www.nasdbondinfo.com to find quotes on the bonds. We should note here that finding the yield to maturity for all of a company's outstanding bond issues on a single day is unusual. If you remember our previous discussion on bonds, the bond market is not as liquid as the stock market, and, on many days, individual bond issues may not trade. To find the book value of the bonds, we went to www.sec.gov and found the 10K report dated December 31, 2008, and filed with the SEC on February 25, 2009. The basic information is as follows:

Coupon Rate	Maturity	Book Value (face value, in millions)	Price (% of par)	Yield to Maturity
7.00%	2012	\$154	106.124	4.846%
6.30	2018	207	87.307	8.222
7.25	2024	497	82.066	9.530
7.625	2024	200	85.771	9.397
7.60	2027	298	82.085	9.732

To calculate the weighted average cost of debt, we take the percentage of the total debt represented by each issue and multiply by the yield on the issue. We then add to get the overall weighted average debt cost. We use both book values and market values here for comparison. The results of the calculations are as follows:

Coupon Rate	Book Value (face value, in millions)	Percentage of Total	Market Value (in millions)	Percentage of Total	Yield to Maturity	Book Values	Market Values
7.00%	\$154	0.11	\$ 163.43	0.14	4.85%	0.55%	0.68%
6.30	207	0.15	180.73	0.15	8.22	1.26	1.27
7.25	497	0.37	407.87	0.35	9.53	3.49	3.33
7.625	200	0.15	171.54	0.15	9.40	1.39	1.38
7.60	298	0.22	244.61	0.21	9.73	2.14	2.04
	<u>\$1,356</u>	<u>1.00</u>	<u>\$1,168.18</u>	<u>1.00</u>		<u>8.82%</u>	<u>8.70%</u>

As these calculations show, Eastman's cost of debt is 8.82 percent on a book value basis and 8.70 percent on a market value basis. Thus, for Eastman, whether market values or book values are used makes little difference. The reason is simply that the market values and book values are similar. This will often be the case and explains why companies frequently use book values for debt in WACC calculations. Also, Eastman has no preferred stock, so we don't need to consider a cost of preferred.

Eastman's WACC We now have the various pieces necessary to calculate Eastman's WACC. First, we need to calculate the capital structure weights. On a book value basis, Eastman's equity and debt are worth \$1.553 billion and \$1.356 billion, respectively. The total value is \$2.909 billion, so the equity and debt percentages are \$1.553 billion/\$2.909 billion = .53 and \$1.356 billion/\$2.909 billion = .47. Assuming a tax rate of 35 percent, Eastman's WACC is:

$$\begin{aligned}\text{WACC} &= .53 \times 12.60\% + .47 \times 8.82\% \times (1 - .35) \\ &= 9.40\%\end{aligned}$$

Thus, using book value capital structure weights, we get about 9.40 percent for Eastman's WACC.

If we use market value weights, however, the WACC will be slightly higher. To see why, notice that on a market value basis, Eastman's equity and debt are worth \$1.726 billion and \$1.168 billion, respectively. The capital structure weights are therefore \$1.726 billion/\$2.894 billion = .60 and \$1.168 billion/\$2.894 billion = .40, so the equity percentage is higher. With these weights, Eastman's WACC is:

$$\begin{aligned}\text{WACC} &= .60 \times 12.60\% + .40 \times 8.70\% \times (1 - .35) \\ &= 9.79\%\end{aligned}$$

Thus, using market value weights, we get 9.79 percent for Eastman's WACC, which is only slightly higher than the 9.40 percent WACC we got using book value weights.

In this example, the WACC using book values is similar. However, using book values can lead to trouble, particularly if equity book values are used. Going back to Chapter 3, recall that we discussed the market-to-book ratio (the ratio of market value per share to book value per share). This ratio is frequently substantially bigger than 1.0 (and sometimes smaller). For Eastman, verify that it's about 1.11; so book values are similar to market values in this case. In addition, if we were computing a WACC for a company that did not have publicly traded

stock, we would try to come up with a suitable market-to-book ratio by looking at publicly traded companies, and we would then use this ratio to adjust the book value of the company under consideration. As we have seen, failure to do so can lead to significant underestimation of the WACC. See our nearby *Work the Web* box for more on the WACC.

WORK THE WEB

So how does our estimate of the WACC for Eastman compare to others? One place to find estimates for WACC is www.valuepro.net. We went there and found the following information for Eastman.

Online Valuation for EMN - 3 / 16 / 2009

---	---	---	---

As you can see, ValuePro estimates the WACC for Eastman as 7.07 percent, which is more than 2 percent less than our estimate of 9.79 percent. The methods used by this site are not identical to ours, but they are similar in the most important regards. However, notice that several important estimates differ. For example, ValuePro uses a market risk premium of 3 percent, while our estimate was 7 percent. Using our estimate of the market risk premium in the ValuePro Web site results in a WACC estimate of 10.13 percent, which is higher than our estimate. Visit the site to learn more if you are so inclined.

CONCEPT QUESTIONS

12.4a How is the WACC calculated?

12.4b Why do we multiply the cost of debt by $(1 - T_C)$ when we compute the WACC?

12.4c Under what conditions is it correct to use the WACC to determine NPV?

DIVISIONAL AND PROJECT COSTS OF CAPITAL

12.5

As we have seen, using the WACC as the discount rate for future cash flows is only appropriate when the proposed investment is similar to the firm's existing activities. This is not as restrictive as it sounds. If we were in the pizza business, for example, and we were thinking of opening a new location, then the WACC would be the discount rate to use. The same would be true of a retailer thinking of a new store, a manufacturer thinking of expanding production, or a consumer products company thinking of expanding its markets.

Nonetheless, despite the usefulness of the WACC as a benchmark, there will clearly be situations where the cash flows under consideration have risks distinctly different from those of the overall firm. We consider how to cope with this problem next.

The SML and the WACC

When we are evaluating investments with risks that are substantially different from those of the overall firm, the use of the WACC will potentially lead to poor decisions. Figure 12.1 illustrates why.

FIGURE 12.1

The security market line, SML, and the weighted average cost of capital, WACC

If a firm uses its WACC to make accept-reject decisions for all types of projects, it will have a tendency toward incorrectly accepting risky projects and incorrectly rejecting less risky projects.

In Figure 12.1, we have plotted an SML corresponding to a risk-free rate of 7 percent and a market risk premium of 8 percent. To keep things simple, we consider an all-equity company with a beta of 1. As we have indicated, the WACC and the cost of equity are exactly equal to 15 percent for this company since there is no debt.

Suppose our firm uses its WACC to evaluate all investments. This means that any investment with a return of greater than 15 percent will be accepted and any investment with a return of less than 15 percent will be rejected. We know from our study of risk and return, however, that a desirable investment is one that plots above the SML. As Figure 12.1 illustrates, using the WACC for all types of projects can result in the firm's incorrectly accepting relatively risky projects and incorrectly rejecting relatively safe ones.

For example, consider Point A. This project has a beta of $\beta_A = .60$ compared to the firm's beta of 1.0. It has an expected return of 14 percent. Is this a desirable investment? The answer is yes, because its required return is only:

$$\begin{aligned}\text{Required return} &= R_f + \beta_A \times (R_M - R_f) \\ &= 7\% + .60 \times 8\% \\ &= 11.8\%\end{aligned}$$

However, if we use the WACC as a cutoff, then this project will be rejected because its return is less than 15 percent. This example illustrates that a firm that uses its WACC as a cutoff will tend to reject profitable projects with risks less than those of the overall firm.

At the other extreme, consider Point B. This project has a beta of $\beta_B = 1.2$. It offers a 16 percent return, which exceeds the firm's cost of capital. This is not a good investment, however, because, given its level of systematic risk, its return is inadequate. Nonetheless, if we use the WACC to evaluate it, it will appear to be attractive. So the second error that will arise if we use the WACC as a cutoff is that we will tend to make unprofitable investments with risks greater than those of the overall firm. As a consequence, through time, a firm that uses its WACC to evaluate all projects will have a tendency to both accept unprofitable investments and become increasingly risky.

Divisional Cost of Capital

The same type of problem with the WACC can arise in a corporation with more than one line of business. Imagine, for example, a corporation that has two divisions, a regulated telephone company and an electronics manufacturing operation. The first of these (the phone operation) has relatively low risk; the second has relatively high risk.

In this case, the firm's overall cost of capital is really a mixture of two different costs of capital, one for each division. If the two divisions were competing for resources, and the firm used a single WACC as a cutoff, which division would tend to be awarded greater funds for investment?

The answer is that the riskier division would tend to have greater returns (ignoring the greater risk), so it would tend to be the "winner." The less glamorous operation might have great profit potential that would end up being ignored. Large corporations in the United States are aware of this problem, and many work to develop separate divisional costs of capital.

The Pure Play Approach

We've seen that using the firm's WACC inappropriately can lead to problems. How can we come up with the appropriate discount rates in such circumstances? Because we cannot observe the returns on these investments, there generally is no direct way of coming up with a beta, for example. Instead, what we must do is examine other investments outside the firm that are in

the same risk class as the one we are considering and use the market-required returns on these investments as the discount rate. In other words, we will try to determine what the cost of capital is for such investments by trying to locate some similar investments in the marketplace.

For example, going back to our telephone division, suppose we want to come up with a discount rate to use for that division. What we can do is identify several other phone companies that have publicly traded securities. We might find that a typical phone company has a beta of .80, AA-rated debt, and a capital structure that is about 50 percent debt and 50 percent equity. Using this information, we could develop a WACC for a typical phone company and use this as our discount rate.

Alternatively, if we were thinking of entering a new line of business, we would try to develop the appropriate cost of capital by looking at the market-required returns on companies already in that business. In the language of Wall Street, a company that focuses only on a single line of business is called a *pure play*. For example, if you wanted to bet on the price of crude oil by purchasing common stocks, you would try to identify companies that dealt exclusively with this product since they would be the most affected by changes in the price of crude oil. Such companies would be called *pure plays* on the price of crude oil.

What we try to do here is to find companies that focus as exclusively as possible on the type of project in which we are interested. Our approach, therefore, is called the **pure play approach** to estimating the required return on an investment. To illustrate, suppose McDonald's decides to enter the personal computer and network server business with a line of machines called McPuters. The risks involved are quite different from those in the fast-food business. As a result, McDonald's would need to look at companies already in the personal computer business to compute a cost of capital for the new division. An obvious "pure play" candidate would be Dell, which is predominately in this line of business. IBM, on the other hand, would not be as good a choice because its primary focus is elsewhere, and it has many different product lines.

pure play approach

Use of a WACC that is unique to a particular project, based on companies in similar lines of business.

In Chapter 3, we discussed the subject of identifying similar companies for comparison purposes. The same problems we described there come up here. The most obvious one is that we may not be able to find any suitable companies. In this case, how to objectively determine a discount rate becomes a very difficult question. Even so, the important thing is to be aware of the issue so that we at least reduce the possibility of the kinds of mistakes that can arise when the WACC is used as a cutoff on all investments.

The Subjective Approach

Because of the difficulties that exist in objectively establishing discount rates for individual projects, firms often adopt an approach that involves making subjective adjustments to the overall WACC. To illustrate, suppose a firm has an overall WACC of 14 percent. It places all proposed projects into four categories as follows:

Category	Examples	Adjustment Factor	Discount Rate
High risk	New products	+6%	20%
Moderate risk	Cost savings, expansion of existing lines	+0	14
Low risk	Replacement of existing equipment	-4	10
Mandatory	Pollution control equipment	n/a	n/a

n/a = Not applicable.

FIGURE 12.2

The security market line, SML, and the subjective approach

With the subjective approach, the firm places projects into one of several risk classes. The discount rate used to value the project is then determined by adding (for high risk) or subtracting (for low risk) an adjustment factor to or from the firm's WACC. This results in fewer incorrect decisions than if the firm simply used the WACC to make the decisions.

The effect of this crude partitioning is to assume that all projects either fall into one of three risk classes or else are mandatory. In this last case, the cost of capital is irrelevant since the project must be taken. Of course, the firm's WACC may change through time as economic conditions change. As this happens, the discount rates for the different types of projects will also change.

Within each risk class, some projects will presumably have more risk than others, and the danger of incorrect decisions will still exist. Figure 12.2 illustrates this point. Comparing Figures 12.1 and 12.2, we see that similar problems exist, but the magnitude of the potential error is less with the subjective approach. For example, the project labeled "A" would be accepted if the WACC were used, but it is rejected once it is classified as a high-risk investment. What this illustrates is that some risk adjustment, even if it is subjective, is probably better than no risk adjustment.

It would be better, in principle, to objectively determine the required return for each project separately. However, as a practical matter, it may not be possible to go much beyond subjective adjustments because either the necessary information is unavailable or else the cost and effort required are simply not worthwhile.

CONCEPT QUESTIONS

- 12.5a** What are the likely consequences if a firm uses its WACC to evaluate all proposed investments?
- 12.5b** What is the pure play approach to determining the appropriate discount rate? When might it be used?

SUMMARY AND CONCLUSIONS

This chapter has discussed cost of capital. The most important concept is the weighted average cost of capital, or WACC, which we interpreted as the required rate of return on the overall firm. It is also the discount rate appropriate for cash flows that are similar in risk to the overall firm. We described how the WACC can be calculated, and we illustrated how it can be used in certain types of analysis.

We also pointed out situations in which it is inappropriate to use the WACC as the discount rate. To handle such cases, we described some alternative approaches to developing discount rates, such as the pure play approach.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

- 12.1 Calculating the Cost of Equity.** Suppose stock in Boone Corporation has a beta of .90. The market risk premium is 7 percent, and the risk-free rate is 8 percent. Boone's last dividend was \$1.80 per share, and the dividend is expected to grow at 7 percent indefinitely. The stock currently sells for \$25. What is Boone's cost of equity capital?
- 12.2 Calculating the WACC.** In addition to the information in the previous problem, suppose Boone has a target debt-equity ratio of 50 percent. Its cost of debt is 8 percent, before taxes. If the tax rate is 34 percent, what is the WACC?

■ Answers to Chapter Review and Self-Test Problems

- 12.1** We start off with the SML approach. Based on the information given, the expected return on Boone's common stock is:

$$\begin{aligned} R_E &= R_f + \beta_E \times (R_M - R_f) \\ &= 8\% + .9 \times 7\% \\ &= 14.3\% \end{aligned}$$

We now use the dividend growth model. The projected dividend is $D_0 \times (1 + g) = \$1.80 \times 1.07 = \1.926 , so the expected return using this approach is:

$$\begin{aligned} R_E &= D_1/P_0 + g \\ &= \$1.926/25 + .07 \\ &= 14.704\% \end{aligned}$$

Since these two estimates, 14.3 percent and 14.7 percent, are fairly close, we will average them. Boone's cost of equity is approximately 14.5 percent.

- 12.2** Since the target debt-equity ratio is .50, Boone uses \$.50 in debt for every \$1.00 in equity. In other words, Boone's target capital structure is $1/3$ debt and $2/3$ equity. The WACC is thus:

$$\begin{aligned} \text{WACC} &= (E/V) \times R_E + (D/V) \times R_D \times (1 - T_C) \\ &= 2/3 \times 14.5\% + 1/3 \times 8\% \times (1 - .34) \\ &= 11.427\% \end{aligned}$$

CRITICAL THINKING AND CONCEPTS REVIEW

- L0 3** **12.1 WACC.** On the most basic level, if a firm's WACC is 12 percent, what does this mean?
- L0 3** **12.2 Book Values versus Market Values.** In calculating the WACC, if you had to use book values for either debt or equity, which would you choose? Why?
- L0 4** **12.3 Project Risk.** If you can borrow all the money you need for a project at 6 percent, doesn't it follow that 6 percent is your cost of capital for the project?
- L0 4** **12.4 WACC and Taxes.** Why do we use an aftertax figure for cost of debt but not for cost of equity?
- L0 1** **12.5 DGM Cost of Equity Estimation.** What are the advantages of using the dividend growth model (DGM) for determining the cost of equity capital? What are the disadvantages? What specific piece of information do you need to find the cost of equity using this model? What are some of the ways in which you could get an estimate of this number?
- L0 1** **12.6 SML Cost of Equity Estimation.** What are the advantages of using the SML approach to finding the cost of equity capital? What are the disadvantages? What are the specific pieces of information needed to use this method? Are all of these variables observable, or do they need to be estimated? What are some of the ways in which you could get these estimates?
- L0 2** **12.7 Cost of Debt Estimation.** How do you determine the appropriate cost of debt for a company? Does it make a difference if the company's debt is privately placed as opposed to being publicly traded? How would you estimate the cost of debt for a firm whose only debt issues are privately held by institutional investors?
- L0 4** **12.8 Cost of Capital.** Suppose Tom O'Bedlam, president of Bedlam Products, Inc., has hired you to determine the firm's cost of debt and cost of equity capital.
- The stock currently sells for \$50 per share, and the dividend per share will probably be about \$5. Tom argues, "It will cost us \$5 per share to use the stockholders' money this year, so the cost of equity is equal to 10 percent ($= \$5/\50)." What's wrong with this conclusion?
 - Based on the most recent financial statements, Bedlam Products' total liabilities are \$8 million. Total interest expense for the coming year will be about \$1 million. Tom therefore reasons, "We owe \$8 million, and we will pay \$1 million interest. Therefore, our cost of debt is obviously \$1 million/8 million = 12.5%." What's wrong with this conclusion?
 - Based on his own analysis, Tom is recommending that the company increase its use of equity financing, because "Debt costs 12.5 percent, but equity only costs 10 percent; thus equity is cheaper." Ignoring all the other issues, what do you think about the conclusion that the cost of equity is less than the cost of debt?
- L0 4** **12.9 Company Risk versus Project Risk.** Both Dow Chemical Company, a large natural gas user, and Superior Oil, a major natural gas producer, are thinking of investing in natural gas wells near Houston. Both are all-equity-financed companies. Dow and Superior are looking at identical projects. They've analyzed their respective investments, which would involve a negative cash flow now and positive expected cash flows in the future. These cash flows would be the same for both firms. No debt would be used to finance the projects. Both companies estimate that their project would have a net present value of \$1 million at an 18 percent discount rate and a $-\$1.1$ million NPV at a 22 percent discount rate. Dow has a beta of 1.25, whereas Superior has a beta of .75. The expected risk

premium on the market is 8 percent, and risk-free bonds are yielding 12 percent. Should either company proceed? Should both? Explain.

L0 4

- 12.10 Divisional Cost of Capital.** Under what circumstances would it be appropriate for a firm to use different costs of capital for its different operating divisions? If the overall firm WACC were used as the hurdle rate for all divisions, would the riskier divisions or the more conservative divisions tend to get most of the investment projects? Why? If you were to try to estimate the appropriate cost of capital for different divisions, what problems might you encounter? What are two techniques you could use to develop a rough estimate for each division's cost of capital?

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

L0 1

- 1. Calculating Cost of Equity.** The Lo Tech Co. just issued a dividend of \$2.20 per share on its common stock. The company is expected to maintain a constant 6 percent growth rate in its dividends indefinitely. If the stock sells for \$43 a share, what is the company's cost of equity?

Basic
(Questions 1–20)

L0 1

- 2. Calculating Cost of Equity.** Bohannon Corporation's common stock has a beta of 1.10. If the risk-free rate is 4.5 percent and the expected return on the market is 12 percent, what is the company's cost of equity capital?

L0 1

- 3. Calculating Cost of Equity.** Stock in CDB Industries has a beta of 0.90. The market risk premium is 7 percent, and T-bills are currently yielding 4 percent. CDB's most recent dividend was \$1.90 per share, and dividends are expected to grow at a 5 percent annual rate indefinitely. If the stock sells for \$41 per share, what is your best estimate of CDB's cost of equity?

L0 1

- 4. Estimating the DCF Growth Rate.** Suppose Matta Ltd. just issued a dividend of \$2.46 per share on its common stock. The company paid dividends of \$1.96, \$2.03, \$2.20, and \$2.30 per share in the last four years. If the stock currently sells for \$65, what is your best estimate of the company's cost of equity capital using arithmetic and geometric growth rates?

L0 1

- 5. Calculating Cost of Preferred Stock.** Sixth Fourth Bank has an issue of preferred stock with a \$5.50 stated dividend that just sold for \$97 per share. What is the bank's cost of preferred stock?

L0 2

- 6. Calculating Cost of Debt.** ICU Window, Inc., is trying to determine its cost of debt. The firm has a debt issue outstanding with seven years to maturity that is quoted at 108 percent of face value. The issue makes semiannual payments and has an embedded cost of 7.4 percent annually. What is ICU's pretax cost of debt? If the tax rate is 38 percent, what is the aftertax cost of debt?

L0 2

- 7. Calculating Cost of Debt.** Peyton's Colt Farm issued a 30-year, 7 percent semiannual bond 7 years ago. The bond currently sells for 94 percent of its face value. The company's tax rate is 35 percent.

- What is the pretax cost of debt?
- What is the aftertax cost of debt?
- Which is more relevant, the pretax or the aftertax cost of debt? Why?

L0 2

- 8. Calculating Cost of Debt.** For the firm in Problem 7, suppose the book value of the debt issue is \$90 million. In addition, the company has a second debt issue, a zero coupon bond with 10 years left to maturity; the book value of this issue is \$60 million, and it sells for 52.5 percent of par. What is the total book value of debt? The total market value? What is the aftertax cost of debt now?

LO 3

9. **Calculating WACC.** Mullineaux Corporation has a target capital structure of 60 percent common stock, 5 percent preferred stock, and 35 percent debt. Its cost of equity is 12.5 percent, the cost of preferred stock is 5.5 percent, and the cost of debt is 7.2 percent. The relevant tax rate is 35 percent.

- What is Mullineaux's WACC?
- The company president has approached you about Mullineaux's capital structure. He wants to know why the company doesn't use more preferred stock financing, since it costs less than debt. What would you tell the president?

LO 3

10. **Taxes and WACC.** Rainbow in the Dark Manufacturing has a target debt-equity ratio of .65. Its cost of equity is 13 percent, and its cost of debt is 8 percent. If the tax rate is 35 percent, what is the company's WACC?

LO 3

11. **Finding the Target Capital Structure.** Fama's Llamas has a WACC of 11.20 percent. The company's cost of equity is 15 percent, and its cost of debt is 8 percent. The tax rate is 35 percent. What is Fama's target debt-equity ratio?

LO 4

12. **Book Value versus Market Value.** Regions, Inc., has 6 million shares of common stock outstanding. The current share price is \$61, and the book value per share is \$4. Regions also has two bond issues outstanding. The first bond issue has a face value of \$70 million, a 7 percent coupon, and sells for 98 percent of par. The second issue has a face value of \$35 million, a 6.5 percent coupon, and sells for 97 percent of par. The first issue matures in 20 years, the second in 12 years.

- What are the company's capital structure weights on a book value basis?
- What are the company's capital structure weights on a market value basis?
- Which are more relevant, the book or market value weights? Why?

LO 3

13. **Calculating the WACC.** In Problem 12, suppose the most recent dividend was \$2.85 and the dividend growth rate is 6 percent. Assume that the overall cost of debt is the weighted average of that implied by the two outstanding debt issues. Both bonds make semiannual payments. The tax rate is 35 percent. What is the company's WACC?

LO 3

14. **WACC.** Blue Bull, Inc., has a target debt-equity ratio of .70. Its WACC is 8.4 percent, and the tax rate is 35 percent.

- If the company's cost of equity is 11 percent, what is its pretax cost of debt?
- If the aftertax cost of debt is 5.2 percent, what is the cost of equity?

LO 3

15. **Finding the WACC.** Given the following information for Janicek Power Co., find the WACC. Assume the company's tax rate is 35 percent.

Debt: 8,500 7.8 percent coupon bonds outstanding, \$1,000 par value, 25 years to maturity, selling for 105 percent of par; the bonds make semiannual payments.

Common stock: 210,000 shares outstanding, selling for \$83 per share; beta is 1.15.

Preferred stock: 12,000 shares of 5.75 percent preferred stock outstanding, currently selling for \$98 per share.

Market: 7 percent market risk premium and 4.8 percent risk-free rate.

LO 3

16. **Finding the WACC.** Organic Produce Corporation has 7.5 million shares of common stock outstanding, 500,000 shares of 7 percent preferred stock outstanding, and 175,000 of 8.2 percent semiannual bonds outstanding, par value \$1,000 each. The common stock currently sells for \$64 per share and has a beta of 1.2, the preferred stock currently sells for \$108 per share, and the bonds have

15 years to maturity and sell for 96 percent of par. The market risk premium is 6.8 percent, T-bills are yielding 5.5 percent, and the firm's tax rate is 34 percent.

- a. What is the firm's market value capital structure?
- b. If the firm is evaluating a new investment project that has the same risk as the firm's typical project, what rate should the firm use to discount the project's cash flows?

L0 4

17. **SML and WACC.** An all-equity firm is considering the following projects:

Project	Beta	Expected Return
W	.70	10%
X	.85	10.5
Y	1.25	14
Z	1.75	17

The T-bill rate is 5 percent, and the expected return on the market is 12 percent.

- a. Which projects have a higher expected return than the firm's 12 percent cost of capital?
- b. Which projects should be accepted?
- c. Which projects will be incorrectly accepted or rejected if the firm's overall cost of capital were used as a hurdle rate?

L0 3

18. **Calculating the WACC.** You are given the following information concerning Parrothead Enterprises:

Debt: 9,000 6.2 percent coupon bonds outstanding, with 20 years to maturity and a quoted price of 104. These bonds pay interest semiannually.

Common stock: 225,000 shares of common stock selling for \$64.50 per share. The stock has a beta of 0.85 and will pay a dividend of \$2.70 next year. The dividend is expected to grow by 5 percent per year indefinitely.

Preferred stock: 8,000 shares of 4.5 percent preferred stock selling at \$94 per share.

Market: A 12 percent expected return, a 5 percent risk-free rate, and a 35 percent tax rate.

Calculate the WACC for Parrothead Enterprises.

L0 3

19. **Calculating Capital Structure Weights.** DeVille Industrial Machines issued 135,000 zero coupon bonds four years ago. The bonds originally had 30 years to maturity with a 6.5 percent yield to maturity. Interest rates have recently increased, and the bonds now have an 8.1 percent yield to maturity. If the company has a \$45 million market value of equity, what weight should it use for debt when calculating the cost of capital?

L0 3

20. **Calculating the WACC.** Gnomes R Us is considering a new project. The company has a debt-equity ratio of .80. The company's cost of equity is 14.5 percent, and the aftertax cost of debt is 7.8 percent. The firm feels that the project is riskier than the company as a whole and that it should use an adjustment factor of +3 percent. What is the WACC it should use for the project?

L0 4

21. **WACC and NPV.** Bono, Inc., is considering a project that will result in initial aftertax cash savings of \$5.1 million at the end of the first year, and these savings will grow at a rate of 3 percent per year indefinitely. The firm has a target

Intermediate
(Questions 21–23)

debt-equity ratio of .50, a cost of equity of 13 percent, and an aftertax cost of debt of 6.4 percent. The cost-saving proposal is somewhat riskier than the usual project the firm undertakes; management uses the subjective approach and applies an adjustment factor of +2 percent to the cost of capital for such risky projects. Under what circumstances should the company take on the project?

LO 2

22. **Calculating the Cost of Debt.** Ying Import has several bond issues outstanding, each making semiannual interest payments. The bonds are listed in the table below. If the corporate tax rate is 34 percent, what is the aftertax cost of the company's debt?

Bond	Coupon Rate	Price Quote	Maturity	Face Value
1	8.50%	105.0	5 years	\$20,000,000
2	6.80	95.4	8 years	40,000,000
3	8.20	103.8	15½ years	45,000,000
4	8.70	105.7	25 years	60,000,000

LO 1

23. **Calculating the Cost of Equity.** Laverne Industries stock has a beta of 1.25. The company just paid a dividend of \$0.75, and the dividends are expected to grow at 5 percent. The expected return of the market is 11.5 percent, and Treasury bills are yielding 5 percent. The most recent stock price is \$81.

- Calculate the cost of equity using the dividend growth model method.
- Calculate the cost of equity using the SML method.
- Why do you think your estimates in (a) and (b) are so different?

LO 3

24. **Flotation Costs and NPV.** Photochronograph Corporation (PC) manufactures time series photographic equipment. It is currently at its target debt-equity ratio of .6. It's considering building a new \$65 million manufacturing facility. This new plant is expected to generate aftertax cash flows of \$7.75 million in perpetuity. The company raises all equity from outside financing. There are three financing options:

- A new issue of common stock:* The required return on the company's new equity is 15 percent.
- A new issue of 20-year bonds:* If the company issues these new bonds at an annual coupon rate of 7 percent, they will sell at par.
- Increased use of accounts payable financing:* Because this financing is part of the company's ongoing daily business, the company assigns it a cost that is the same as the overall firm WACC. Management has a target ratio of accounts payable to long-term debt of .15. (Assume there is no difference between the pretax and aftertax accounts payable cost.)

What is the NPV of the new plant? Assume that the company has a 35 percent tax rate.

LO 3

25. **Project Evaluation.** This is a comprehensive project evaluation problem bringing together much of what you have learned in this and previous chapters. Suppose you have been hired as a financial consultant to Defense Electronics, Inc. (DEI), a large, publicly traded firm that is the market share leader in radar detection systems (RDSs). The company is looking at setting up a manufacturing plant overseas to produce a new line of RDSs. This will be a five-year project. The company bought some land three years ago for \$7 million in anticipation of using it as a toxic dump site for waste chemicals, but it built a piping system to safely discard the chemicals instead. If the land were sold today, the net proceeds would be \$7.6 million after taxes. In five years, the land will be worth \$7.9 million after taxes. The company wants to build its new manufacturing plant on

Challenge

(Questions 24–25)

this land; the plant will cost \$13 million to build. The following market data on DEI's securities are current:

<i>Debt:</i>	45,000 6.8 percent coupon bonds outstanding, 20 years to maturity, selling for 95 percent of par; the bonds have a \$1,000 par value each and make semiannual payments.
<i>Common stock:</i>	750,000 shares outstanding, selling for \$94 per share; the beta is 1.20.
<i>Preferred stock:</i>	35,000 shares of 6.2 percent preferred stock outstanding, selling for \$92 per share.
<i>Market:</i>	7 percent expected market risk premium; 5.20 percent risk-free rate.

DEI's tax rate is 34 percent. The project requires \$825,000 in initial net working capital investment to get operational.

- Calculate the project's Time 0 cash flow, taking into account all side effects.
- The new RDS project is somewhat riskier than a typical project for DEI, primarily because the plant is being located overseas. Management has told you to use an adjustment factor of +2 percent to account for this increased riskiness. Calculate the appropriate discount rate to use when evaluating DEI's project.
- The manufacturing plant has an eight-year tax life, and DEI uses straight-line depreciation. At the end of the project (i.e., the end of year 5), the plant can be scrapped for \$1.5 million. What is the aftertax salvage value of this manufacturing plant?
- The company will incur \$2,300,000 in annual fixed costs. The plan is to manufacture 13,000 RDSs per year and sell them at \$10,400 per machine; the variable production costs are \$9,600 per RDS. What is the annual operating cash flow, OCF, from this project?
- Finally, DEI's president wants you to throw all your calculations, all your assumptions, and everything else into a report for the chief financial officer; all he wants to know is what the RDS project's internal rate of return, IRR, and net present value, NPV, are. What will you report?

12.1 Cost of Equity. Go to finance.yahoo.com and look up the information for Allegheny Technologies (ATI), a metal manufacturing company in the S&P 500. You want to estimate the cost of equity for the company. First, find the current Treasury bill rate. Next, find the beta for Allegheny Technologies. Using the historical market risk premium, what is the estimated cost of equity for ATI using the CAPM? Now find the analysts' growth rate estimates for the next five years for the company. Using this growth rate in the dividend growth model, what is the estimated cost of equity? Now find the dividends paid by the company over the past five years and calculate the arithmetic and geometric growth rates in dividends. Using these growth rates, what is the estimated cost of equity? Looking at these four estimates, what cost of equity would you use for the company?

12.2 Cost of Debt. Go to www.nasdbondinfo.com and look up the outstanding bonds for Nike. Record the most recent price and YTM of each bond issue. Now go to www.sec.gov and find the most recent 10Q or 10K report filed by the company and find the book value of each bond issue. Assuming Nike's tax rate is 38 percent, what is the cost of debt using book value weights? What is the cost of debt using market value weights? Which of these numbers is more relevant?

**WHAT'S ON
THE WEB?**

CHAPTER CASE

COST OF CAPITAL FOR HUBBARD COMPUTER, INC.

You have recently been hired by Hubbard Computer, Inc. (HCI), in its relatively new treasury management department. HCI was founded eight years ago by Bob Hubbard and currently operates 74 stores in the Southeast. HCI is privately owned by Bob and his family, and had sales of \$97 million last year.

HCI primarily sells to in-store customers who come to the store and talk with a sales representative. The sales representative assists the customer in determining the type of computer and peripherals that are necessary for the individual customer's computing needs. After the order is taken, the customer pays for the order immediately, and the computer is made to fill the order. Delivery of the computer averages 15 days, and it is guaranteed in 30 days.

HCI's growth to date has been financed by its profits. When the company had sufficient capital, it would open a new store. Other than scouting locations, relatively little formal analysis has been used in its capital budgeting process. Bob has just read about capital budgeting techniques and has come to you for help. For starters, the company has never attempted to determine its cost of capital, and Bob would like you to perform the analysis. Since the company is privately owned, it is difficult to determine the cost of equity for the company. Bob wants you to use the pure play approach to estimating the cost of capital for HCI, and he has chosen Dell as a representative company. The following steps will allow you to calculate this estimate. ■

QUESTIONS

- Most publicly traded corporations are required to submit quarterly (10Q) and annual reports (10K) to the SEC detailing the financial operations of the company over the past quarter or year, respectively. These corporate filings are available on the SEC Web site at www.sec.gov. Go to the SEC Web site and search for SEC filings made by Dell. Find the most recent 10Q or 10K and download the form. Look on the balance sheet to find the book value of debt and the book value of equity. If you look further down the report, you should find a section titled "Long-term Debt and Interest Rate Risk Management" that will provide a breakdown of Dell's long-term debt.
- To estimate the cost of equity for Dell, go to finance.yahoo.com and enter the ticker symbol DELL. Follow the various links to answer the following questions: What is the most recent stock price listed for Dell? What is the market value of equity, or market capitalization? How many shares of stock does Dell have outstanding? What is the most recent annual dividend? Can you use the dividend discount model in this case? What is the beta for Dell? Now go back to finance.yahoo.com and find the "Bonds" link. What is the yield on 3-month Treasury bills? Using the historical market risk premium, what is the cost of equity for Dell using the CAPM?
- You now need to calculate the cost of debt for Dell. Go to www.nasdbondinfo.com, enter Dell as the company and find the yield to maturity for each of Dell's bonds. What is the weighted average cost of debt for Dell using the book value weights and the market value weights? Does it make a difference in this case if you use book value weights or market value weights?
- You now have all the necessary information to calculate the weighted average cost of capital for Dell. Calculate the weighted average cost of capital for Dell using book value weights and market value weights. Assume Dell has a 35 percent marginal tax rate. Which cost of capital number is more relevant?
- You used Dell as a pure play company to estimate the cost of capital for HCI. Are there any potential problems with this approach in this situation?

Leverage and Capital Structure

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

LO 1

Discuss the effect of financial leverage.

LO 2

Analyze the impact of taxes and bankruptcy on capital structure choice.

LO 3

Identify the essentials of the bankruptcy process.

What do Circuit City and Midway, the publisher of the *Mortal Kombat* video games, have in common? In early 2009, both companies were in bankruptcy. In Circuit City's case, the company owed more than \$635 million to its 30 largest creditors, including about \$119 million to Hewlett-Packard, \$116 million to Samsung, and \$60 million to Sony. Circuit City was a Chapter 7 bankruptcy, meaning that the company will cease to exist. Its assets will be sold, and creditors

will receive the proceeds as partial payment. Midway owed more than \$281 million, including \$150 million to Wells Fargo Bank. Unlike Circuit City, Midway filed a Chapter 11 bankruptcy, which is an attempt by a company to work with its creditors to reorganize its finances and continue in business.

A firm's choice of how much debt it should have relative to equity is known as a capital structure decision. Such a choice has many implications for a firm and is far from being a settled issue in either theory or practice. In this chapter, we discuss the basic ideas underlying capital structures and how firms choose them.

A firm's capital structure is really just a reflection of its borrowing policy. Should we borrow a lot of money, or just a little? At first glance, it probably seems that debt is something to be avoided. After all, the more debt a firm has, the greater is the risk of bankruptcy. What we learn is that debt is really a double-edged sword, and, properly used, debt can be enormously beneficial to the firm.

A good understanding of the effects of debt financing is important simply because the role of debt is so misunderstood, and many firms (and individuals) are far too conservative in their use of debt. Having said this, we can also say that firms sometimes err in the opposite direction, becoming much too heavily indebted, with bankruptcy as the unfortunate consequence. Striking the right balance is what the capital structure issue is all about.

Visit us at www.mhhe.com/rwj

Thus far, we have taken the firm's capital structure as given. Debt-equity ratios don't just drop on firms from the sky, of course, so now it's time to wonder where they do come from. Going back to Chapter 1, we call decisions about a firm's debt-equity ratio *capital structure decisions*.¹

For the most part, a firm can choose any capital structure that it wants. If management so desired, a firm could issue some bonds and use the proceeds to buy back some stock, thereby increasing the debt-equity ratio. Alternatively, it could issue stock and use the money to pay off some debt, thereby reducing the debt-equity ratio. Activities such as these that alter the firm's existing capital structure are called *capital restructurings*. In general, such restructurings take place whenever the firm substitutes one capital structure for another while leaving the firm's assets unchanged.

Since the assets of a firm are not directly affected by a capital restructuring, we can examine the firm's capital structure decision separately from its other activities. This means that a firm can consider capital restructuring decisions in isolation from its investment decisions. In this chapter, then, we will ignore investment decisions and focus on the long-term financing, or capital structure, question.

What we will see in this chapter is that capital structure decisions can have important implications for the value of the firm and its cost of capital. We will also find that important elements of the capital structure decision are easy to identify, but precise measures of these elements are generally not obtainable. As a result, we are only able to give an incomplete answer to the question of what the best capital structure might be for a particular firm at a particular time.

13.1

THE CAPITAL STRUCTURE QUESTION

How should a firm go about choosing its debt-equity ratio? Here, as always, we assume that the guiding principle is to choose the course of action that maximizes the value of a share of stock. However, when it comes to capital structure decisions, this is essentially the same thing as maximizing the value of the whole firm, and, for convenience, we will tend to frame our discussion in terms of firm value.

In Chapter 12, we discussed the concept of the firm's weighted average cost of capital, or WACC. You may recall that the WACC tells us that the firm's overall cost of capital is a weighted average of the costs of the various components of the firm's capital structure. When we described the WACC, we took the firm's capital structure as given. Thus, one important issue that we will want to explore in this chapter is what happens to the cost of capital when we vary the amount of debt financing, or the debt-equity ratio.

A primary reason for studying the WACC is that the value of the firm is maximized when the WACC is minimized. To see this, recall that the WACC is the discount rate appropriate for the firm's overall cash flows. Since values and discount rates move in opposite directions, minimizing the WACC will maximize the value of the firm's cash flows.

Thus, we will want to choose the firm's capital structure so that the WACC is minimized. For this reason, we will say that one capital structure is better than another if it results in a lower weighted average cost of capital. Further, we say that a particular

¹ It is conventional to refer to decisions regarding debt and equity as *capital structure decisions*. However, the term *financial structure* would be more accurate, and we use the terms interchangeably.

debt-equity ratio represents the *optimal capital structure* if it results in the lowest possible WACC. This optimal capital structure is sometimes called the firm's *target* capital structure as well.

CONCEPT QUESTIONS

13.1a What is the relationship between the WACC and the value of the firm?

13.1b What is an optimal capital structure?

THE EFFECT OF FINANCIAL LEVERAGE

13.2

In this section, we examine the impact of financial leverage on the payoffs to stockholders. As you may recall, financial leverage refers to the extent to which a firm relies on debt. The more debt financing a firm uses in its capital structure, the more financial leverage it employs.

As we describe, financial leverage can dramatically alter the payoffs to shareholders in the firm. Remarkably, however, financial leverage may not affect the overall cost of capital. If this is true, then a firm's capital structure is irrelevant because changes in capital structure won't affect the value of the firm. We will return to this issue a little later.

The Impact of Financial Leverage

We start by illustrating how financial leverage works. For now, we ignore the impact of taxes. Also, for ease of presentation, we describe the impact of leverage in terms of its effects on earnings per share, EPS, and return on equity, ROE. These are, of course, accounting numbers and, as such, are not our primary concern. Using cash flows instead of these accounting numbers would lead to precisely the same conclusions, but a little more work would be needed. We discuss the impact of leverage on market values in a subsequent section.

Financial Leverage, EPS, and ROE: An Example The Trans Am Corporation currently has no debt in its capital structure. The CFO, Ms. Morris, is considering a restructuring that would involve issuing debt and using the proceeds to buy back some of the outstanding equity. Table 13.1 presents both the current and proposed capital structures. As shown, the firm's assets have a market value of **\$8 million**, and there are **400,000** shares outstanding. Because Trans Am is an all-equity firm, the price per share is **\$20**.

The proposed debt issue would raise **\$4 million**; the interest rate would be **10 percent**. Since the stock sells for **\$20 per share**, the \$4 million in new debt would be used to purchase $\$4 \text{ million} / 20 = 200,000$ shares, leaving **200,000** outstanding. After the restructuring, Trans Am would have a capital structure that was 50 percent debt, so the debt-equity ratio would be 1. Notice that, for now, we assume that the stock price will remain at \$20.

To investigate the impact of the proposed restructuring, Ms. Morris has prepared Table 13.2, which compares the firm's current capital structure to the proposed capital

TABLE 13.1

Current and proposed capital structures for the Trans Am Corporation

	Current	Proposed
Assets	\$8,000,000	\$8,000,000
Debt	\$0	\$4,000,000
Equity	\$8,000,000	\$4,000,000
Debt-equity ratio	0	1
Share price	\$20	\$20
Shares outstanding	400,000	200,000
Interest rate	10%	10%

TABLE 13.2

Capital structure scenarios for the Trans Am Corporation

	Current Capital Structure: No Debt		
	Recession	Expected	Expansion
EBIT	\$500,000	\$1,000,000	\$1,500,000
Interest	0	0	0
Net income	\$500,000	\$1,000,000	\$1,500,000
ROE	6.25%	12.50%	18.75%
EPS	\$1.25	\$2.50	\$3.75

	Proposed Capital Structure: Debt = \$4 million		
	Recession	Expected	Expansion
EBIT	\$500,000	\$1,000,000	\$1,500,000
Interest	400,000	400,000	400,000
Net income	\$100,000	\$ 600,000	\$1,100,000
ROE	2.50%	15.00%	27.50%
EPS	\$.50	\$3.00	\$5.50

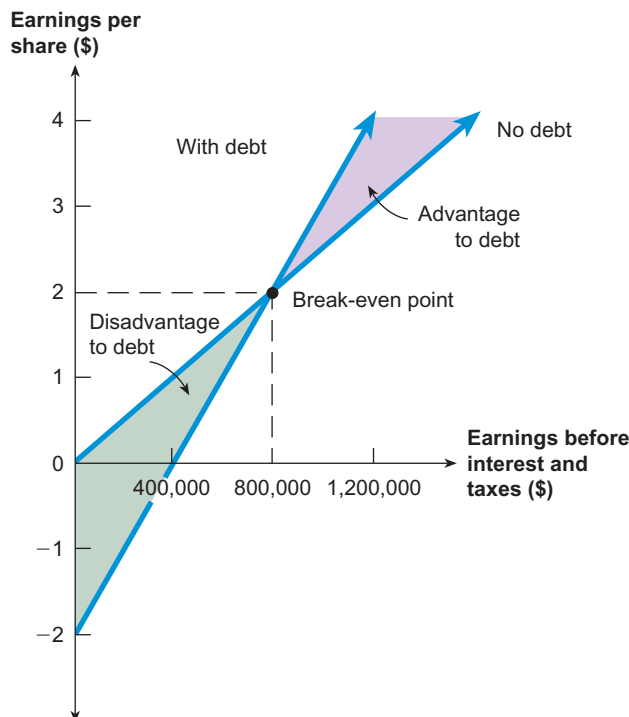

structure under three scenarios. The scenarios reflect different assumptions about the firm's EBIT. Under the expected scenario, EBIT is \$1 million. In the recession scenario, EBIT falls to \$500,000. In the expansion scenario, it rises to \$1.5 million.

To illustrate some of the calculations in Table 13.2, consider the expansion case. EBIT is \$1.5 million. With no debt (the current capital structure) and no taxes, net income is also \$1.5 million. In this case, there are 400,000 shares worth \$8 million total. EPS is therefore \$1.5 million/400,000 = \$3.75 per share. Also, since accounting return on equity, ROE, is net income divided by total equity, ROE is \$1.5 million/8 million = 18.75%.²

With \$4 million in debt (the proposed capital structure), things are somewhat different. Since the interest rate is 10 percent, the interest bill is \$400,000. With EBIT of \$1.5 million, interest of \$400,000, and no taxes, net income is \$1.1 million. Now there are only 200,000 shares worth \$4 million total. EPS is therefore \$1.1 million/200,000 = \$5.5 per share versus the \$3.75 per share that we calculated above. Furthermore, ROE is \$1.1 million/4 million = 27.5%. This is well above the 18.75 percent we calculated for the current capital structure.

EPS versus EBIT The impact of leverage is evident in Table 13.2 when the effect of the restructuring on EPS and ROE is examined. In particular, the variability in both EPS

² ROE is discussed in some detail in Chapter 3.

**FIGURE 13.1**

**Financial leverage:
EPS and EBIT for the
Trans Am Corporation**

and ROE is much larger under the proposed capital structure. This illustrates how financial leverage acts to magnify gains and losses to shareholders.

In Figure 13.1, we take a closer look at the effect of the proposed restructuring. This figure plots earnings per share, EPS, against earnings before interest and taxes, EBIT, for the current and proposed capital structures. The first line, labeled “No debt,” represents the case of no leverage. This line begins at the origin, indicating that EPS would be zero if EBIT were zero. From there, every \$400,000 increase in EBIT increases EPS by \$1 (because there are 400,000 shares outstanding).

The second line represents the proposed capital structure. Here, EPS is negative if EBIT is zero. This follows because \$400,000 of interest must be paid regardless of the firm’s profits. Since there are 200,000 shares in this case, EPS is $-\$2$ per share as shown. Similarly, if EBIT were \$400,000, EPS would be exactly zero.

The important thing to notice in Figure 13.1 is that the slope of the line in this second case is steeper. In fact, for every \$400,000 increase in EBIT, EPS rises by \$2, so the line is twice as steep. This tells us that EPS is twice as sensitive to changes in EBIT because of the financial leverage employed.

Another observation to make in Figure 13.1 is that the lines intersect. At that point, EPS is exactly the same for both capital structures. To find this point, note that EPS is equal to $\text{EBIT}/400,000$ in the no-debt case. In the with-debt case, EPS is $(\text{EBIT} - \$400,000)/200,000$. If we set these equal to each other, EBIT is:

$$\text{EBIT}/400,000 = (\text{EBIT} - \$400,000)/200,000$$

$$\text{EBIT} = 2 \times (\text{EBIT} - \$400,000)$$

$$\text{EBIT} = \$800,000$$

When EBIT is \$800,000, EPS is \$2 per share under either capital structure. This is labeled as the break-even point in Figure 13.1; we could also call it the indifference point. If EBIT is above this level, leverage is beneficial; if it is below this point, it is not.

There is another, more intuitive, way of seeing why the break-even point is \$800,000. Notice that, if the firm has no debt and its EBIT is \$800,000, its net income is also \$800,000. In this case, the ROE is $\$800,000/\$8,000,000 = 10\%$. This is precisely the same as the interest rate on the debt, so the firm earns a return that is just sufficient to pay the interest.

EXAMPLE 13.1

Break-Even EBIT

The MPD Corporation has decided in favor of a capital restructuring. Currently, MPD uses no-debt financing. Following the restructuring, however, debt will be \$1 million. The interest rate on the debt will be 9 percent. MPD currently has 200,000 shares outstanding, and the price per share is \$20. If the restructuring is expected to increase EPS, what is the minimum level for EBIT that MPD's management must be expecting? Ignore taxes in answering.

To answer, we calculate the break-even EBIT. At any EBIT above this, the increased financial leverage will increase EPS, so this will tell us the minimum level for EBIT. Under the old capital structure, EPS is simply $\text{EBIT}/200,000$. Under the new capital structure, the interest expense will be $\$1 \text{ million} \times .09 = \$90,000$. Furthermore, with the \$1 million proceeds, MPD will repurchase $\$1 \text{ million}/\$20 = 50,000$ shares of stock, leaving 150,000 outstanding. EPS is thus $(\text{EBIT} - \$90,000)/150,000$.

Now that we know how to calculate EPS under both scenarios, we set the two expressions for EPS equal to each other and solve for the break-even EBIT:

$$\text{EBIT}/200,000 = (\text{EBIT} - \$90,000)/150,000$$

$$\text{EBIT} = (4/3) \times (\text{EBIT} - \$90,000)$$

$$\text{EBIT} = \$360,000$$

Verify that, in either case, EPS is \$1.80 when EBIT is \$360,000. Management at MPD is apparently of the opinion that EPS will exceed \$1.80.

Corporate Borrowing and Homemade Leverage

Based on Tables 13.1 and 13.2 and Figure 13.1, Ms. Morris draws the following conclusions:

1. The effect of financial leverage depends on the company's EBIT. When EBIT is relatively high, leverage is beneficial.
2. Under the expected scenario, leverage increases the returns to shareholders, as measured by both ROE and EPS.
3. Shareholders are exposed to more risk under the proposed capital structure since the EPS and ROE are much more sensitive to changes in EBIT in this case.
4. Because of the impact that financial leverage has on both the expected return to stockholders and the riskiness of the stock, capital structure is an important consideration.

The first three of these conclusions are clearly correct. Does the last conclusion necessarily follow? Surprisingly, the answer is no. As we discuss next, the reason is that shareholders can adjust the amount of financial leverage by borrowing and lending on

Proposed Capital Structure			
	Recession	Expected	Expansion
EPS	\$.50	\$ 3.00	\$ 5.50
Earnings for 100 shares	50.00	300.00	550.00
Net cost = 100 shares at \$20 = \$2,000			

Original Capital Structure and Homemade Leverage			
	Recession	Expected	Expansion
EPS	\$ 1.25	\$ 2.50	\$ 3.75
Earnings for 200 shares	250.00	500.00	750.00
Less: Interest on \$2,000 at 10%	200.00	200.00	200.00
Net earnings	\$ 50.00	\$300.00	\$550.00
Net cost = 200 shares at \$20 – Amount borrowed = \$4,000 – 2,000 = \$2,000			

TABLE 13.3

Proposed capital structure versus original capital structure with homemade leverage

their own. This use of personal borrowing to alter the degree of financial leverage is called **homemade leverage**.

We will now illustrate that it actually makes no difference whether or not Trans Am adopts the proposed capital structure, because any stockholder who prefers the proposed capital structure can simply create it using homemade leverage. To begin, the first part of Table 13.3 shows what will happen to an investor who buys \$2,000 worth of Trans Am stock if the proposed capital structure is adopted. This investor purchases 100 shares of stock. From Table 13.2, EPS will either be \$.50, \$3, or \$5.50, so the total earnings for 100 shares will either be \$50, \$300, or \$550 under the proposed capital structure.

Now, suppose Trans Am does not adopt the proposed capital structure. In this case, EPS will be \$1.25, \$2.50, or \$3.75. The second part of Table 13.3 demonstrates how a stockholder who prefers the payoffs under the proposed structure can create them using personal borrowing. To do this, the stockholder borrows \$2,000 at 10 percent on his or her own. Our investor uses this amount, along with the original \$2,000, to buy 200 shares of stock. As shown, the net payoffs are exactly the same as those for the proposed capital structure.

How did we know to borrow \$2,000 to create the right payoffs? We are trying to replicate Trans Am's proposed capital structure at the personal level. The proposed capital structure results in a debt-equity ratio of 1. To replicate this capital structure at the personal level, the stockholder must borrow enough to create this same debt-equity ratio. Since the stockholder has \$2,000 in equity invested, borrowing another \$2,000 will create a personal debt-equity ratio of 1.

This example demonstrates that investors can always increase financial leverage themselves to create a different pattern of payoffs. It thus makes no difference whether or not Trans Am chooses the proposed capital structure.

homemade leverage

The use of personal borrowing to change the overall amount of financial leverage to which the individual is exposed.

Unlevering the Stock

EXAMPLE 13.2

In our Trans Am example, suppose management adopted the proposed capital structure. Further, suppose that an investor who owned 100 shares preferred the original capital structure. Show how this investor could “unlever” the stock to recreate the original payoffs.

(continued)

To create leverage, investors borrow on their own. To undo leverage, investors must loan out money. For Trans Am, the corporation borrowed an amount equal to half its value. The investor can unlever the stock by simply loaning out money in the same proportion. In this case, the investor sells 50 shares for \$1,000 total and then loans out the \$1,000 at 10 percent. The payoffs are calculated in the table below.

	Recession	Expected	Expansion
EPS (proposed structure)	\$.50	\$ 3.00	\$ 5.50
Earnings for 50 shares	25.00	150.00	275.00
Plus: Interest on \$1,000 @ 10%	100.00	100.00	100.00
Total payoff	\$125.00	\$250.00	\$375.00

These are precisely the payoffs the investor would have experienced under the original capital structure.

CONCEPT QUESTIONS

13.2a What is the impact of financial leverage on stockholders?

13.2b What is homemade leverage?

13.2c Why is Trans Am's capital structure irrelevant?

13.3

CAPITAL STRUCTURE AND THE COST OF EQUITY CAPITAL

We have seen that there is nothing special about corporate borrowing because investors can borrow or lend on their own. As a result, whichever capital structure Trans Am chooses, the stock price will be the same. Trans Am's capital structure is thus irrelevant, at least in the simple world we have examined.

Our Trans Am example is based on a famous argument advanced by two Nobel laureates, Franco Modigliani and Merton Miller, whom we will henceforth call M&M. What we illustrated for the Trans Am Corporation is a special case of **M&M Proposition I**. M&M Proposition I states that it is completely irrelevant how a firm chooses to arrange its finances.

M&M Proposition I

The value of the firm is independent of its capital structure.

M&M Proposition I: The Pie Model

One way to illustrate M&M Proposition I is to imagine two firms that are identical on the left-hand side of the balance sheet. Their assets and operations are exactly the same. The right-hand sides are different because the two firms finance their operations differently. In this case, we can view the capital structure question in terms of a "pie" model. Why we choose this name is apparent in Figure 13.2. Figure 13.2 gives two possible ways of cutting up this pie between the equity slice, E , and the debt slice, D : 40%–60% and 60%–40%. However, the size of the pie in Figure 13.2 is the same for both firms because the value of the assets is the same. This is precisely what M&M Proposition I states: The size of the pie doesn't depend on how it is sliced.

**FIGURE 13.2**

Two pie models of capital structure

**FIGURE 13.3**

The cost of equity and the WACC: M&M Propositions I and II with no taxes

$$R_E = R_A + (R_A - R_D) \times (D/E) \text{ by M\&M Proposition II}$$

$$R_A = \text{WACC} = (E/V) \times R_E + (D/V) \times R_D$$

$$\text{where } V = D + E$$

The Cost of Equity and Financial Leverage: M&M Proposition II

Although changing the capital structure of the firm may not change the firm's *total* value, it does cause important changes in the firm's debt and equity. We now examine what happens to a firm financed with debt and equity when the debt-equity ratio is changed. To simplify our analysis, we will continue to ignore taxes.

Based on our discussion in Chapter 12, if we ignore taxes, the weighted average cost of capital, WACC, is:

$$\text{WACC} = (E/V) \times R_E + (D/V) \times R_D$$

where $V = E + D$. We also saw that one way of interpreting the WACC is as the required return on the firm's overall assets. To remind us of this, we will use the symbol R_A to stand for the WACC and write:

$$R_A = (E/V) \times R_E + (D/V) \times R_D$$

If we rearrange this to solve for the cost of equity capital, we see that:

$$R_E = R_A + (R_A - R_D) \times (D/E) \quad [13.1]$$

This is the famous **M&M Proposition II**, which tells us that the cost of equity depends on three things: the required rate of return on the firm's assets, R_A ; the firm's cost of debt, R_D ; and the firm's debt-equity ratio, D/E .

Figure 13.3 summarizes our discussion thus far by plotting the cost of equity capital, R_E , against the debt-equity ratio. As shown, M&M Proposition II indicates that the cost of

M&M Proposition II

A firm's cost of equity capital is a positive linear function of its capital structure.

equity, R_E , is given by a straight line with a slope of $(R_A - R_D)$. The y -intercept corresponds to a firm with a debt-equity ratio of zero, so $R_A = R_E$ in that case. Figure 13.3 shows that, as the firm raises its debt-equity ratio, the increase in leverage raises the risk of the equity and therefore the required return, or cost of equity (R_E).

Notice in Figure 13.3 that the WACC doesn't depend on the debt-equity ratio; it's the same no matter what the debt-equity ratio is. This is another way of stating M&M Proposition I: The firm's overall cost of capital is unaffected by its capital structure. As illustrated, the fact that the cost of debt is lower than the cost of equity is exactly offset by the increase in the cost of equity from borrowing. In other words, the change in the capital structure weights (E/V and D/V) is exactly offset by the change in the cost of equity (R_E), so the WACC stays the same.

EXAMPLE 13.3

The Cost of Equity Capital

The Ricardo Corporation has a weighted average cost of capital (ignoring taxes) of 12 percent. It can borrow at 8 percent. Assuming that Ricardo has a target capital structure of 80 percent equity and 20 percent debt, what is its cost of equity? What is the cost of equity if the target capital structure is 50 percent equity? Calculate the WACC, using your answers to verify that it is the same in both cases.

According to M&M Proposition II, the cost of equity, R_E , is:

$$R_E = R_A + (R_A - R_D) \times (D/E)$$

In the first case, the debt-equity ratio is $.2/.8 = .25$, so the cost of the equity is:

$$\begin{aligned} R_E &= 12\% + (12\% - 8\%) \times .25 \\ &= 13\% \end{aligned}$$

In the second case, verify that the debt-equity ratio is 1.0, so the cost of equity is 16 percent.

We can now calculate the WACC assuming that the percentage of equity financing is 80 percent, the cost of equity is 13 percent, and the tax rate is zero:

$$\begin{aligned} \text{WACC} &= (E/V) \times R_E + (D/V) \times R_D \\ &= .80 \times 13\% + .20 \times 8\% \\ &= 12\% \end{aligned}$$

In the second case, the percentage of equity financing is 50 percent and the cost of equity is 16 percent. The WACC is:

$$\begin{aligned} \text{WACC} &= (E/V) \times R_E + (D/V) \times R_D \\ &= .50 \times 16\% + .50 \times 8\% \\ &= 12\% \end{aligned}$$

As we calculated, the WACC is 12 percent in both cases.

Business and Financial Risk

M&M Proposition II shows that the firm's cost of equity can be broken down into two components. The first component, R_A , is the required return on the firm's overall assets, and it depends on the nature of the firm's operating activities. The risk inherent in a firm's operations is called the **business risk** of the firm's equity. Referring back to Chapter 11, we see that this business risk depends on the systematic risk of the firm's assets. The greater a firm's business risk, the greater R_A will be, and, all other things being the same, the greater will be the firm's cost of equity.

business risk

The equity risk that comes from the nature of the firm's operating activities.

The second component in the cost of equity, $(R_A - R_D) \times (D/E)$, is determined by the firm's financial structure. For an all-equity firm, this component is zero. As the firm begins to rely on debt financing, the required return on equity rises. This occurs because the debt financing increases the risks borne by the stockholders. This extra risk that arises from the use of debt financing is called the **financial risk** of the firm's equity.

The total systematic risk of the firm's equity thus has two parts: business risk and financial risk. The first part (the business risk) depends on the firm's assets and operations and is not affected by capital structure. Given the firm's business risk (and its cost of debt), the second part (the financial risk) is completely determined by financial policy. As we have illustrated, the firm's cost of equity rises when it increases its use of financial leverage because the financial risk of the equity increases while the business risk remains the same.

financial risk

The equity risk that comes from the financial policy (i.e., capital structure) of the firm.

CONCEPT QUESTIONS

13.3a What does M&M Proposition I state?

13.3b What are the three determinants of a firm's cost of equity?

13.3c The total systematic risk of a firm's equity has two parts. What are they?

CORPORATE TAXES AND CAPITAL STRUCTURE

13.4

Debt has two distinguishing features that we have not taken into proper account. First, as we have mentioned in a number of places, interest paid on debt is tax deductible. This is good for the firm, and it may be an added benefit to debt financing. Second, failure to meet debt obligations can result in bankruptcy. This is not good for the firm, and it may be an added cost of debt financing. Since we haven't explicitly considered either of these two features of debt, we may get a different answer about capital structure once we do. Accordingly, we consider taxes in this section and bankruptcy in the next one.

We can start by considering what happens when we consider the effect of corporate taxes. To do this, we will examine two firms, Firm U (unlevered) and Firm L (levered). These two firms are identical on the left-hand side of the balance sheet, so their assets and operations are the same.

We assume that EBIT is expected to be \$1,000 every year forever for both firms. The difference between the two firms is that Firm L has issued \$1,000 worth of perpetual bonds on which it pays 8 percent interest each year. The interest bill is thus $.08 \times \$1,000 = \80 every year forever. Also, we assume that the corporate tax rate is 30 percent.

For our two firms, U and L, we can now calculate the following:

	Firm U	Firm L
EBIT	\$1,000	\$1,000
Interest	0	80
Taxable income	\$1,000	\$ 920
Taxes (30%)	300	276
Net income	\$ 700	\$ 644

The Interest Tax Shield

To simplify things, we will assume that depreciation is zero. We will also assume that capital spending is zero and that there are no additions to NWC. In this case, cash flow from assets is simply equal to EBIT – Taxes. For Firms U and L, we thus have:

Cash Flow from Assets	Firm U	Firm L
EBIT	\$1,000	\$1,000
– Taxes	300	276
Total	\$ 700	\$ 724

We immediately see that capital structure is now having some effect because the cash flows from U and L are not the same even though the two firms have identical assets.

To see what's going on, we can compute the cash flow to stockholders and bondholders.

Cash Flow	Firm U	Firm L
To stockholders	\$700	\$644
To bondholders	0	80
Total	\$700	\$724

What we are seeing is that the total cash flow to L is \$24 more. This occurs because L's tax bill (which is a cash outflow) is \$24 less. The fact that interest is deductible for tax purposes has generated a tax saving equal to the interest payment (\$80) multiplied by the corporate tax rate (30 percent): $\$80 \times .30 = \24 . We call this tax saving the **interest tax shield**.

interest tax shield

The tax saving attained by a firm from the tax deductibility of interest expense.

Taxes and M&M Proposition I

Since the debt is perpetual, the same \$24 shield will be generated every year forever. The aftertax cash flow to L will thus be the same \$700 that U earns plus the \$24 tax shield. Since L's cash flow is always \$24 greater, Firm L is worth more than Firm U by the value of this \$24 perpetuity.

Because the tax shield is generated by paying interest, it has the same risk as the debt, and 8 percent (the cost of debt) is therefore the appropriate discount rate. The value of the tax shield is thus:

$$PV = \frac{\$24}{.08} = \frac{.30 \times \$1,000 \times .08}{.08} = .30 \times \$1,000 = \$300$$

As our example illustrates, the present value of the interest tax shield can be written as:

$$\begin{aligned} \text{Present value of the interest tax shield} &= (T_c \times D \times R_D) / R_D \\ &= T_c \times D \end{aligned} \quad [13.2]$$

We have now come up with another famous result, M&M Proposition I with corporate taxes. We have seen that the value of Firm L, V_L , exceeds the value of Firm U, V_U , by the

FIGURE 13.4

M&M Proposition I
with taxes

The value of the firm increases as total debt increases because of the interest tax shield. This is the basis of M&M Proposition I with taxes.

present value of the interest tax shield, $T_C \times D$. M&M Proposition I with taxes therefore states that:

$$V_L = V_U + T_C \times D \quad [13.3]$$

The effect of borrowing in this case is illustrated in Figure 13.4. We have plotted the value of the levered firm, V_L , against the amount of debt, D . M&M Proposition I with corporate taxes implies that the relationship is given by a straight line with a slope of T_C .

In Figure 13.4, we have also drawn a horizontal line representing V_U . As is shown, the distance between the two lines is $T_C \times D$, the present value of the tax shield.

As Figure 13.4 indicates, the value of the firm goes up by \$.30 for every \$1 in debt. In other words, the NPV *per dollar* of debt is \$.30. It is difficult to imagine why any corporation would not borrow to the absolute maximum under these circumstances.

Conclusion

The result of our analysis in this section is that, once we include taxes, capital structure definitely matters. However, we immediately reach the illogical conclusion that the optimal capital structure is 100 percent debt. Of course, we have not yet considered the impact of bankruptcy, so our story may change. For future reference, Table 13.4 contains a summary of the various M&M calculations and conclusions.

CONCEPT QUESTIONS

- 13.4a** What is the relationship between the value of an unlevered firm and the value of a levered firm once we consider the effect of corporate taxes?
- 13.4b** If we only consider the effect of taxes, what is the optimum capital structure?

TABLE 13.4**Modigliani and Miller
summary****I. The no-tax case**

- A. Proposition I: The value of the leveraged firm (V_L) is equal to the value of the unleveraged firm (V_U):

$$V_L = V_U$$

- B. Implications of Proposition I:

1. A firm's capital structure is irrelevant.
2. A firm's weighted average cost of capital, WACC, is the same no matter what mixture of debt and equity is used to finance the firm.

- C. Proposition II: The cost of equity, R_E , is:

$$R_E = R_A + (R_A - R_D) \times D/E$$

where R_A is the WACC, R_D is the cost of debt, and D/E is the debt-equity ratio.

- D. Implications of Proposition II:

1. The cost of equity rises as the firm increases its use of debt financing.
2. The risk of the equity depends on two things: the riskiness of the firm's operations (*business risk*) and the degree of financial leverage (*financial risk*). Business risk determines R_A ; financial risk is determined by D/E .

II. The tax case

- A. Proposition I with taxes: The value of the leveraged firm (V_L) is equal to the value of the unleveraged firm (V_U) plus the present value of the interest tax shield:

$$V_L = V_U + T_C \times D$$

where T_C is the corporate tax rate and D is the amount of debt.

- B. Implications of Proposition I with taxes:

1. Debt financing is highly advantageous, and, in the extreme, a firm's optimal capital structure is 100 percent debt.
2. A firm's weighted average cost of capital, WACC, decreases as the firm relies more heavily on debt financing.

13.5**BANKRUPTCY COSTS**

One limit to the amount of debt a firm might use comes in the form of *bankruptcy costs*. As the debt-equity ratio rises, so too does the probability that the firm will be unable to pay its bondholders what was promised to them. When this happens, ownership of the firm's assets is ultimately transferred from the stockholders to the bondholders.

In principle, a firm becomes bankrupt when the value of its assets equals the value of its debt. When this occurs, the value of equity is zero, and the stockholders turn over control of the firm to the bondholders. At this point, the bondholders hold assets whose value is exactly equal to what is owed on the debt. In a perfect world, there are no costs associated with this transfer of ownership, and the bondholders don't lose anything.

This idealized view of bankruptcy is not, of course, what happens in the real world. Ironically, it is expensive to go bankrupt. As we discuss, the costs associated with bankruptcy may eventually offset the tax-related gains from leverage.

Direct Bankruptcy Costs

When the value of a firm's assets equals the value of its debt, then the firm is economically bankrupt in the sense that the equity has no value. However, the formal turning over of the assets to the bondholders is a *legal* process, not an economic one. There are legal and administrative costs to bankruptcy, and it has been remarked that bankruptcies are to lawyers what blood is to sharks.

Because of the expenses associated with bankruptcy, bondholders won't get all that they are owed. Some fraction of the firm's assets will "disappear" in the legal process of

going bankrupt. These are the legal and administrative expenses associated with the bankruptcy proceeding. We call these costs **direct bankruptcy costs**.

Indirect Bankruptcy Costs

Because it is expensive to go bankrupt, a firm will spend resources to avoid doing so. When a firm is having significant problems in meeting its debt obligations, we say that it is experiencing financial distress. Some financially distressed firms ultimately file for bankruptcy, but most do not because they are able to recover or otherwise survive.

The costs of avoiding a bankruptcy filing incurred by a financially distressed firm are called **indirect bankruptcy costs**. We use the term **financial distress costs** to refer generically to the direct and indirect costs associated with going bankrupt and/or avoiding a bankruptcy filing.

The problems that come up in financial distress are particularly severe, and the financial distress costs are thus larger, when the stockholders and the bondholders are different groups. Until the firm is legally bankrupt, the stockholders control it. They, of course, will take actions in their own economic interests. Since the stockholders can be wiped out in a legal bankruptcy, they have a very strong incentive to avoid a bankruptcy filing.

The bondholders, on the other hand, are primarily concerned with protecting the value of the firm's assets and will try to take control away from the stockholders. They have a strong incentive to seek bankruptcy to protect their interests and keep stockholders from further dissipating the assets of the firm. The net effect of all this fighting is that a long, drawn-out, and potentially quite expensive legal battle gets started.

Meanwhile, as the wheels of justice turn in their ponderous way, the assets of the firm lose value because management is busy trying to avoid bankruptcy instead of running the business. Normal operations are disrupted, and sales are lost. Valuable employees leave, potentially fruitful programs are dropped to preserve cash, and otherwise profitable investments are not taken.

These are all indirect bankruptcy costs, or costs of financial distress. Whether or not the firm ultimately goes bankrupt, the net effect is a loss of value because the firm chose to use debt in its capital structure. It is this possibility of loss that limits the amount of debt that a firm will choose to use.

direct bankruptcy costs

The costs that are directly associated with bankruptcy, such as legal and administrative expenses.

indirect bankruptcy costs

The costs of avoiding a bankruptcy filing incurred by a financially distressed firm.

financial distress costs

The direct and indirect costs associated with going bankrupt or experiencing financial distress.

CONCEPT QUESTIONS

13.5a What are direct bankruptcy costs?

13.5b What are indirect bankruptcy costs?

OPTIMAL CAPITAL STRUCTURE

13.6

Our previous two sections have established the basis for an optimal capital structure. A firm will borrow because the interest tax shield is valuable. At relatively low debt levels, the probability of bankruptcy and financial distress is low, and the benefit from debt outweighs the cost. At very high debt levels, the possibility of financial distress is a chronic, ongoing problem for the firm, so the benefit from debt financing may be more than offset by the financial distress costs. Based on our discussion, it would appear that an optimal capital structure exists somewhere in between these extremes.

FIGURE 13.5

The static theory of capital structure:
The optimal capital structure and the value of the firm

According to the static theory, the gain from the tax shield on debt is offset by financial distress costs. An optimal capital structure exists that just balances the additional gain from leverage against the added financial distress costs.

The Static Theory of Capital Structure

static theory of capital structure

Theory that a firm borrows up to the point where the tax benefit from an extra dollar in debt is exactly equal to the cost that comes from the increased probability of financial distress.

The theory of capital structure that we have outlined is called the **static theory of capital structure**. It says that firms borrow up to the point where the tax benefit from an extra dollar in debt is exactly equal to the cost that comes from the increased probability of financial distress. We call this the static theory because it assumes that the firm is fixed in terms of its assets and operations, and it only considers possible changes in the debt-equity ratio.

The static theory is illustrated in Figure 13.5, which plots the value of the firm, V_L , against the amount of debt, D . In Figure 13.5, we have drawn lines corresponding to three different stories. The first is M&M Proposition I with no taxes. This is the horizontal line extending from V_U , and it indicates that the value of the firm is unaffected by its capital structure. The second case, M&M Proposition I with corporate taxes, is given by the upward-sloping straight line. These two cases are exactly the same as the ones we previously illustrated in Figure 13.4.

The third case in Figure 13.5 illustrates our current discussion: The value of the firm rises to a maximum and then declines beyond that point. This is the picture that we get from our static theory. The maximum value of the firm, V_L^* , is reached at a debt level of D^* , so this is the optimal amount of borrowing. Put another way, the firm's optimal capital structure is composed of D^*/V_L^* in debt and $(1 - D^*/V_L^*)$ in equity.

The final thing to notice in Figure 13.5 is that the difference between the value of the firm in our static theory and the M&M value of the firm with taxes is the loss in value from the possibility of financial distress. Also, the difference between the static theory value of the firm and the M&M value with no taxes is the gain from leverage, net of distress costs.

Optimal Capital Structure and the Cost of Capital

As we discussed earlier, the capital structure that maximizes the value of the firm is also the one that minimizes the cost of capital. With the help of Figure 13.6, we can illustrate this point and tie together our discussion of capital structure and cost of capital. As we have seen, there are essentially three cases. We will use the simplest of the three cases as a starting point and then build up to the static theory of capital structure. Along the way, we will pay particular attention to the connection between capital structure, firm value, and cost of capital.

Figure 13.6 illustrates the original Modigliani and Miller, M&M, no-tax, no-bankruptcy argument in **Case I**. This is the most basic case. In the top part, we have plotted the value of the firm, V_L , against total debt, D . When there are no taxes, bankruptcy costs, or other real-world imperfections, we know that the total value of the firm is not affected by its debt policy, so V_L is simply constant. The bottom part of Figure 13.6 tells the same story in terms of the cost of capital. Here, the weighted average cost of capital, WACC, is plotted against the debt-to-equity ratio, D/E . As with total firm value, the overall cost of capital is not affected by debt policy in this basic case, so the WACC is constant.

Next, we consider what happens to the original M&M arguments once taxes are introduced. As **Case II** illustrates, the firm's value now critically depends on its debt policy. The more the firm borrows, the more it is worth. From our earlier discussion, we know that this happens because interest payments are tax deductible, and the gain in firm value is just equal to the present value of the interest tax shield.

In the bottom part of Figure 13.6, notice how the WACC declines as the firm uses more and more debt financing. As the firm increases its financial leverage, the cost of equity does increase, but this increase is more than offset by the tax break associated with debt financing. As a result, the firm's overall cost of capital declines.

To finish our story, we include the impact of bankruptcy, or financial distress, costs to get **Case III**. As is shown in the top part of Figure 13.6, the value of the firm will not be as large as we previously indicated. The reason is that the firm's value is reduced by the present value of the potential future bankruptcy costs. These costs grow as the firm borrows more and more, and they eventually overwhelm the tax advantage of debt financing. The optimal capital structure occurs at D^* , the point at which the tax saving from an additional dollar in debt financing is exactly balanced by the increased bankruptcy costs associated with the additional borrowing. This is the essence of the static theory of capital structure.

The bottom part of Figure 13.6 presents the optimal capital structure in terms of the cost of capital. Corresponding to D^* , the optimal debt level, is the optimal debt-to-equity ratio, D^*/E^* . At this level of debt financing, the lowest possible weighted average cost of capital, $WACC^*$, occurs.

Capital Structure: Some Managerial Recommendations

The static model that we have described is not capable of identifying a precise optimal capital structure, but it does point out two of the more relevant factors: taxes and financial distress. We can draw some limited conclusions concerning these.

Taxes First of all, the tax benefit from leverage is obviously only important to firms that are in a tax-paying position. Firms with substantial accumulated losses will get little value from the interest tax shield. Furthermore, firms that have substantial tax shields from other sources, such as depreciation, will get less benefit from leverage.

Also, not all firms have the same tax rate. The higher the tax rate, the greater the incentive to borrow.

FIGURE 13.6

The capital structure question

Case I

With no taxes or bankruptcy costs, the value of the firm and its weighted average cost of capital are not affected by capital structures.

Case II

With corporate taxes and no bankruptcy costs, the value of the firm increases and the weighted average cost of capital decreases as the amount of debt goes up.

Case III

With corporate taxes and bankruptcy costs, the value of the firm, V_L , reaches a maximum at D^* , the optimal amount of borrowing. At the same time, the weighted average cost of capital, $WACC$, is minimized at D^*/E^* .

Financial Distress Firms with a greater risk of experiencing financial distress will borrow less than firms with a lower risk of financial distress. For example, all other things being equal, the greater the volatility in EBIT, the less a firm should borrow.

In addition, financial distress is more costly for some firms than for others. The costs of financial distress depend primarily on the firm's assets. In particular, financial distress costs will be determined by how easily ownership of those assets can be transferred.

For example, a firm with mostly tangible assets that can be sold without great loss in value will have an incentive to borrow more. For firms that rely heavily on intangibles, such as employee talent or growth opportunities, debt will be less attractive since these assets effectively cannot be sold.

CONCEPT QUESTIONS

13.6a Can you describe the trade-off that defines the static theory of capital structure?

13.6b What are the important factors in making capital structure decisions?

OBSERVED CAPITAL STRUCTURES

13.7

No two firms have identical capital structures. Nonetheless, there are some regular elements that we see when we start looking at actual capital structures. We discuss a few of these next.

The most striking thing we observe about capital structures, particularly in the United States, is that most corporations seem to have relatively low debt-equity ratios. In fact, most corporations use much less debt financing than equity financing. To illustrate, Table 13.5 presents median debt ratios and debt-equity ratios for various U.S. industries classified by SIC code (we discussed such codes in Chapter 3).

In Table 13.5, what is most striking is the wide variation across industries, ranging from essentially no debt for drug and computer companies to relatively heavy debt usage in the airline and cable television industries. Notice that these last two industries are the

TABLE 13.5 Capital structures for U.S. industries

Industry	Ratio of Debt to Total Capital(%)*	Ratio of Debt to Equity(%)	Number of Companies	SIC Code	Representative Companies
Dairy products	25.88	34.92	5	202	Dean Foods, Lifeway Foods
Fabric apparel	15.56	18.43	25	23	VF Corp, Liz Claiborne
Paper	25.06	33.44	20	26	Kimberly-Clark, Avery Dennison
Drugs	6.76	7.25	229	283	Pfizer, Merck
Petroleum refining	16.47	19.78	14	29	ExxonMobil, Chevron
Steel	28.57	40.00	11	331	Nucor, US Steel
Computers	5.31	5.61	71	357	Apple, Hewlett-Packard (HP)
Motor vehicles	19.48	24.19	31	371	Ford, General Motors (GM)
Airlines	56.30	129.40	14	4512	Continental, Southwest
Cable television	61.84	162.03	9	484	Comcast, Charter Communications
Electric utilities	49.40	97.65	46	491	Exelon, Southern Co.
Department stores	38.90	63.66	7	531	Macy's, J.C. Penney
Eating places	17.14	20.68	48	5812	McDonald's, Starbucks

*Debt is the book value of preferred stock and long-term debt, including amounts due in one year. Equity is the market value of outstanding shares. Total capital is the sum of debt and equity. Median values are shown.

Source: *Cost of Capital*, 2008 Yearbook (Chicago: Morningstar, 2008).

only ones for which more debt is used than equity, and most of the other industries rely far more heavily on equity than debt. This is true even though many of the companies in these industries pay substantial taxes. Table 13.5 makes it clear that corporations have not, in general, issued debt up to the point that tax shelters have been completely used up, and we conclude that there must be limits to the amount of debt corporations can use. Take a look at our nearby *Work the Web* box for more on actual capital structures.

Different industries have different operating characteristics in terms of, for example, EBIT volatility and asset types, and there does appear to be some connection between these characteristics and capital structure. Our story involving tax savings and financial distress costs undoubtedly supplies part of the reason, but, to date, there is no fully satisfactory theory that explains these regularities in capital structures.

WORK THE WEB

When it comes to capital structure, all companies (and industries) are not created equal. To illustrate, we looked up some capital structure information on American Electric Power (AEP) and Johnson & Johnson (JNJ) using the “Ratio” area of www.reuters.com. American Electric Power’s capital structure looks like this (note that leverage ratios are expressed as percentages on this site):

FINANCIAL STRENGTH

	Company	Industry	Sector	S&P 500
Quick Ratio (MRQ)	0.41	0.52	0.58	1.18
Current Ratio (MRQ)	0.60	0.65	0.72	1.43
LT Debt to Equity (MRQ)	144.47	200.66	177.90	80.37
Total Debt to Equity (MRQ)	167.00	241.05	214.60	111.20
Interest Coverage (TTM)	--	0.00	0.00	30.83

For every dollar of equity, American Electric Power has long-term debt of \$1.4447 and total debt of \$1.6700. Compare this result to Johnson & Johnson:

FINANCIAL STRENGTH

	Company	Industry	Sector	S&P 500
Quick Ratio (MRQ)	1.41	2.75	2.47	1.18
Current Ratio (MRQ)	1.65	3.18	2.94	1.43
LT Debt to Equity (MRQ)	19.10	12.20	18.37	80.37
Total Debt to Equity (MRQ)	27.88	17.40	28.60	111.20
Interest Coverage (TTM)	--	2.29	9.06	30.83

For every dollar of equity, Johnson & Johnson has only \$0.1910 of long-term debt and total debt of \$.2788. When we examine the industry and sector averages, the differences are again apparent. The electric utility industry on average has \$2.0066 of long-term and \$2.4105 of total debt for every dollar of equity. By comparison, the pharmaceutical industry on average has only \$0.1220 of long-term debt and \$0.1740 of total debt for every dollar of equity. Thus, we see that choice of capital structure is a management decision, but it is also clearly influenced by industry characteristics.

Questions

1. The ratios shown for these companies are based on March 2009 figures. Go to www.reuters.com and find the current long-term debt-to-equity and total debt-to-equity ratios for both American Electric Power (AEP) and Johnson & Johnson (JNJ). How have these ratios changed over this time?
2. Go to www.reuters.com and find the long-term debt-to-equity and total debt-to-equity ratios for Bank of America (BAC), Dell (DELL), and Chevron (CVX). Why do you think these three companies use such differing amounts of debt?

CONCEPT QUESTIONS

- 13.7a** Do U.S. corporations rely heavily on debt financing?
- 13.7b** What regularities do we observe in capital structures?

A QUICK LOOK AT THE BANKRUPTCY PROCESS

13.8

As we have discussed, one of the consequences of using debt is the possibility of financial distress, which can be defined in several ways:

1. *Business failure.* This term is usually used to refer to a situation in which a business has terminated with a loss to creditors, but even an all-equity firm can fail.
2. *Legal bankruptcy.* Firms or creditors bring petitions to a federal court for bankruptcy. **Bankruptcy** is a legal proceeding for liquidating or reorganizing a business.
3. *Technical insolvency.* Technical insolvency occurs when a firm is unable to meet its financial obligations.
4. *Accounting insolvency.* Firms with negative net worth are insolvent on the books. This happens when the total book liabilities exceed the book value of the total assets.

We now very briefly discuss some of the terms and more relevant issues associated with bankruptcy and financial distress.

Liquidation and Reorganization

Firms that cannot or choose not to make contractually required payments to creditors have two basic options: liquidation or reorganization. **Liquidation** means termination of the firm as a going concern, and it involves selling off the assets of the firm. The proceeds, net of selling costs, are distributed to creditors in order of established priority. **Reorganization** is the option of keeping the firm a going concern; it often involves issuing new securities to replace old securities. Liquidation or reorganization is the result of a bankruptcy proceeding. Which occurs depends on whether the firm is worth more “dead or alive.”

Bankruptcy Liquidation Chapter 7 of the Federal Bankruptcy Reform Act of 1978 deals with “straight” liquidation. The following sequence of events is typical:

1. A petition is filed in a federal court. A corporation may file a voluntary petition, or involuntary petitions may be filed against the corporation by several of its creditors.
2. A trustee-in-bankruptcy is elected by the creditors to take over the assets of the debtor corporation. The trustee will attempt to liquidate the assets.
3. When the assets are liquidated, after payment of the bankruptcy administration costs, the proceeds are distributed among the creditors.
4. If any proceeds remain, after expenses and payments to creditors, they are distributed to the shareholders.

The distribution of the proceeds of the liquidation occurs according to the following priority list:

1. Administrative expenses associated with the bankruptcy.
2. Other expenses arising after the filing of an involuntary bankruptcy petition but before the appointment of a trustee.

bankruptcy

A legal proceeding for liquidating or reorganizing a business.

The SEC has a good overview of the bankruptcy process in its “online publications” section of www.sec.gov.

liquidation

Termination of the firm as a going concern.

reorganization

Financial restructuring of a failing firm to attempt to continue operations as a going concern.

3. Wages, salaries, and commissions.
4. Contributions to employee benefit plans.
5. Consumer claims.
6. Government tax claims.
7. Payment to unsecured creditors.
8. Payment to preferred stockholders.
9. Payment to common stockholders.

absolute priority rule (APR)

The rule establishing priority of claims in liquidation.

This priority list for liquidation is a reflection of the **absolute priority rule (APR)**. The higher a claim is on this list, the more likely it is to be paid. In many of these categories, there are various limitations and qualifications that we omit for the sake of brevity.

Two qualifications to this list are in order. The first concerns secured creditors. Such creditors are entitled to the proceeds from the sale of the security and are outside this ordering. However, if the secured property is liquidated and provides cash insufficient to cover the amount owed, the secured creditors join with unsecured creditors in dividing the remaining liquidated value. In contrast, if the secured property is liquidated for proceeds greater than the secured claim, the net proceeds are used to pay unsecured creditors and others. The second qualification to the APR is that, in reality, what happens, and who gets what in the event of bankruptcy, is subject to much negotiation, and, as a result, the APR is frequently not followed.

The American Bankruptcy Institute provides extensive information. See www.abiworld.org.

Bankruptcy Reorganization Corporate reorganization takes place under Chapter 11 of the Federal Bankruptcy Reform Act of 1978. The general objective of a proceeding under Chapter 11 is to plan to restructure the corporation with some provision for repayment of creditors. A typical sequence of events follows:

1. A voluntary petition can be filed by the corporation, or an involuntary petition can be filed by creditors.
2. A federal judge either approves or denies the petition. If the petition is approved, a time for filing proofs of claims is set.
3. In most cases, the corporation (the “debtor in possession”) continues to run the business.
4. The corporation (and, in certain cases, the creditors) submits a reorganization plan.
5. Creditors and shareholders are divided into classes. A class of creditors accepts the plan if a majority of the class agrees to the plan.
6. After its acceptance by creditors, the plan is confirmed by the court.
7. Payments in cash, property, and securities are made to creditors and shareholders. The plan may provide for the issuance of new securities.
8. For some fixed length of time, the firm operates according to the provisions of the reorganization plan.

The corporation may wish to allow the old stockholders to retain some participation in the firm. Needless to say, this may involve some protest by the holders of unsecured debt.

To give you some idea of the costs associated with a bankruptcy, consider the case of the energy giant Enron, which filed for bankruptcy in December 2001. The company wanted to reorganize through the bankruptcy process, but complications soon arose. In fact, the company filed at least six reorganization plans. In the end, it was estimated that lawyers, consultants, accountants, and other professionals had earned nearly \$1 *billion* in

fees. The next largest fees appear to have been paid to those involved in the WorldCom bankruptcy. The fees in that case reached a mere \$600 million.

So-called prepackaged bankruptcies are a relatively new phenomenon. What happens is that the corporation secures the necessary approval of a bankruptcy plan from a majority of its creditors first, and then it files for bankruptcy. As a result, the company enters bankruptcy and reemerges almost immediately.

For example, in November 2004, Trump Hotels and Casinos filed for Chapter 11 bankruptcy. This was the second bankruptcy proceeding for the company. Fortunately for “The Donald,” creditors didn’t say “You’re fired!” Under the terms of the deal, Trump’s stake in the company was cut, but he stayed on as chairman of the board and CEO. He also received, among other things, a 25 percent stake in the Miss USA Pageant and four acres of land in Atlantic City. The then-current bondholders agreed to exchange their bonds for a combination of new bonds with a lower coupon rate, along with cash and stock. Unfortunately for The Donald, this was not his last experience with the bankruptcy process. In early 2009, Trump Hotels filed Chapter 11 bankruptcy for the third time, making it a “Chapter 33” bankruptcy.

In some cases, the bankruptcy procedure is needed to invoke the “cram-down” power of the bankruptcy court. Under certain circumstances, a class of creditors can be forced to accept a bankruptcy plan even if they vote not to approve it, hence the remarkably apt description “cram down.”

In 2005, Congress passed the most significant overhaul of U.S. bankruptcy laws in the last 25 years, the Bankruptcy Abuse Prevention and Consumer Protection Act of 2005 (BAPCPA). Most of the changes were aimed at individual debtors, but corporations were also affected. Before BAPCPA, a bankrupt company had the exclusive right to submit reorganization plans to the bankruptcy court. It has been argued that this exclusivity is one reason some companies have remained in bankruptcy for so long. Under the new law, after 18 months, creditors can submit their own plan for the court’s consideration. This change is likely to speed up bankruptcies and also lead to more “prepacks” (to learn about prepacks, see our nearby *Reality Bytes* box).

One controversial change made by BAPCPA has to do with so-called key employee retention plans or KERPs. Strange as it may sound, bankrupt companies routinely give bonus payments to executives, even though the executives may be the same ones who led the company into bankruptcy in the first place. Such bonuses are intended to keep valuable employees from moving to more successful firms, but critics have argued they are often abused. The new law permits KERPs only if the employee in question actually has a job offer from another company.

Financial Management and the Bankruptcy Process

It may seem a little odd, but the right to go bankrupt is very valuable. There are several reasons why this is true. First of all, from an operational standpoint, when a firm files for bankruptcy, there is an immediate “stay” on creditors, usually meaning that payments to creditors will cease, and creditors will have to await the outcome of the bankruptcy process to find out if and how much they will be paid. This stay gives the firm time to evaluate its options, and it prevents what is usually termed a “race to the courthouse steps” by creditors and others.

Beyond this, some bankruptcy filings are actually strategic actions intended to improve a firm’s competitive position, and firms have filed for bankruptcy even though they were not insolvent at the time. Probably the most famous example is Continental Airlines. In 1983, following deregulation of the airline industry, Continental found itself competing with newly established airlines that had much lower labor costs. In response, Continental filed for reorganization under Chapter 11 even though it was not insolvent.

bankruptcy at
www.bankruptcydata.com.

Bankruptcy, “Prepack” Style

On August 24, 2008, Mrs. Fields Famous Brands, which operated or franchised more than 1,200 Mrs. Fields and TCBY stores, ran out of dough when the company filed for Chapter 11 reorganization under the U.S. bankruptcy code. At the time of the filing, the company had about \$196 million in debt. A firm in this situation could reasonably be expected to spend a year or more in bankruptcy. Not so with Mrs. Fields. The company exited bankruptcy on October 24, 2008. Bondholders received \$90 million in cash, \$50 million in new secured debt, and 87.5 percent of the new common stock. Sometimes that's the way the cookie crumbles. Even though Mrs. Fields had a brief stay in bankruptcy, the all-time record belongs to Blue Bird, maker of the iconic yellow school buses. Blue Bird's stay in bankruptcy was *one day*!

Firms typically file for bankruptcy to seek protection from their creditors, essentially admitting that they cannot meet their financial obligations as they are then structured. Once in bankruptcy, the firm attempts to reorganize its operations and finances so that it can survive. A key to this process is that most of the creditors must ultimately give their approval to the restructuring plan. The time a firm spends in Chapter 11 depends on many things, but it usually depends most on the time it takes to get creditors to agree to a plan of reorganization.

Blue Bird was able to expedite its bankruptcy by filing a presolicited, or prepackaged, bankruptcy, often called a prepack. The idea is simple. Before filing for bankruptcy, the firm approaches its creditors with a plan for reorganization. The two sides negotiate a settlement and agree on the details of how

the firm's finances will be restructured. Then, the firm puts together the necessary paperwork for the bankruptcy court before filing for bankruptcy. A filing is a prepack if the firm essentially walks into court and, at the same time, files a reorganization plan complete with the documentation of its creditors' approval, which is exactly what Blue Bird did.

The key to the prepackaged reorganization process is that both sides have something to gain and something to lose. If bankruptcy is imminent, it may make sense for the creditors to expedite the process even though they are likely to take a financial loss in the restructuring. Blue Bird's bankruptcy was relatively painless for most of its creditors. Several different classes of creditors were involved. Bank loans were converted into senior secured notes and senior bondholders exchanged their bonds for new bonds with the same face value and terms. Of course, the old stockholders received nothing, and, in fact, had their shares canceled.

For a firm, operating in bankruptcy can be a difficult process. The bankruptcy court typically has a great deal of oversight over the firm's day-to-day operations, and putting together a reorganization plan to emerge from bankruptcy can be a tremendous drain on management time, time that would be better spent making the firm profitable again. Also, news that a firm is in bankruptcy can make skittish customers turn to competitors, endangering the future health of the firm. A prepack can't completely eliminate these problems, but by speeding up the bankruptcy process, it can reduce the headaches involved.

Continental argued that, based on pro forma data, it would become insolvent in the future, and a reorganization was therefore necessary. By filing for bankruptcy, Continental was able to terminate its existing labor agreements, lay off large numbers of workers, and slash wages for the remaining employees. In other words, at least in the eyes of critics, Continental essentially used the bankruptcy process as a vehicle for reducing labor costs. Congress has subsequently modified bankruptcy laws to make it more difficult, though not impossible, for companies to abrogate a labor contract through the bankruptcy process. For example, Delta Air Lines filed for bankruptcy in 2005, in part to renegotiate the contracts with its union employees.

Other famous examples of strategic bankruptcies exist. For example, Manville (then known as Johns-Manville) and Dow Corning filed for bankruptcies because of expected future losses resulting from litigations associated with asbestos and silicone breast implants, respectively. Similarly, in the then-largest ever bankruptcy, Texaco filed in 1987 after Pennzoil was awarded a \$10.3 billion judgment against the company. Texaco later settled for \$3.5 billion and emerged from bankruptcy. As of early 2009, the largest bankruptcies ever in terms of assets occurred less than two weeks apart in 2008. On September 15, 2008, the investment bank Lehman Brothers Holdings filed for bankruptcy. The company listed about \$639 billion in assets. Then, on September 26, 2008, the giant savings bank Washington Mutual (or “WaMu” as it was better known) filed for bankruptcy with about \$328 billion in assets. In Lehman's case, for the four-and-one-half month period from September 15, 2008,

to January 31, 2009, one law firm, Weil Gotshal & Manges, requested \$55 million in compensation for its 100,296 hours of labor. The 2003 bankruptcy filing of Italian dairy company Parmalat may have topped them both in terms of relative importance. This company, by itself, represented 1.5 percent of the Italian gross national product!

Agreements to Avoid Bankruptcy

When a firm defaults on an obligation, it can avoid a bankruptcy filing. Because the legal process of bankruptcy can be lengthy and expensive, it is often in everyone's best interest to devise a "workout" that avoids a bankruptcy filing. Much of the time, creditors can work with the management of a company that has defaulted on a loan contract. Voluntary arrangements to restructure, or "reschedule," the company's debt can be and often are made. This may involve *extension*, which postpones the date of payment, or *composition*, which allows a reduced payment.

CONCEPT QUESTIONS

13.8a What is the APR (in connection with bankruptcy proceedings)?

13.8b What is the difference between liquidation and reorganization?

SUMMARY AND CONCLUSIONS

The ideal mixture of debt and equity for a firm—its optimal capital structure—is the one that maximizes the value of the firm and minimizes the overall cost of capital. If we ignore taxes, financial distress costs, and any other imperfections, we find that there is no ideal mixture. Under these circumstances, the firm's capital structure is simply irrelevant.

If we consider the effect of corporate taxes, we find that capital structure matters a great deal. This conclusion is based on the fact that interest is tax deductible and thus generates a valuable tax shield. Unfortunately, we also find that the optimal capital structure is 100 percent debt, which is not something we observe in healthy firms.

We next introduced costs associated with bankruptcy, or, more generally, financial distress. These costs reduce the attractiveness of debt financing. We concluded that an optimal capital structure exists when the net tax saving from an additional dollar in interest just equals the increase in expected financial distress costs. This is the essence of the static theory of capital structure.

When we examine actual capital structures, we find two regularities. First, firms in the United States typically do not use great amounts of debt, but they pay substantial taxes. This suggests that there is a limit to the use of debt financing to generate tax shields. Second, there is wide variation in the use of debt across industries, suggesting that the nature of a firm's assets and operations is an important determinant of its capital structure.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

13.1 EBIT and EPS. Suppose the GNR Corporation has decided in favor of a capital restructuring that involves increasing its existing \$5 million in debt to \$25 million. The interest rate on the debt is 12 percent and is not expected to change. The firm

currently has one million shares outstanding, and the price per share is \$40. If the restructuring is expected to increase the ROE, what is the minimum level for EBIT that GNR's management must be expecting? Ignore taxes in your answer.

- 13.2 M&M Proposition II (no taxes).** The Pro Bono Corporation has a WACC of 20 percent. Its cost of debt is 12 percent. If Pro Bono's debt-equity ratio is 2, what is its cost of equity capital? Ignore taxes in your answer.

- 13.3 M&M Proposition I (with corporate taxes).** Suppose TransGlobal Co. currently has no debt and its equity is worth \$20,000. If the corporate tax rate is 30 percent, what will the value of the firm be if TransGlobal borrows \$6,000 and uses the proceeds to buy up stock?

■ Answers to Chapter Review and Self-Test Problems

- 13.1** To answer, we can calculate the break-even EBIT. At any EBIT above this, the increased financial leverage will increase EPS. Under the old capital structure, the interest bill is \$5 million \times .12 = **\$600,000**. There are one million shares of stock, so, ignoring taxes, EPS is $(\text{EBIT} - \$600,000)/1$ million.

Under the new capital structure, the interest expense will be \$25 million \times .12 = **\$3 million**. Furthermore, the debt rises by \$20 million. This amount is sufficient to repurchase \$20 million/40 = **500,000** shares of stock, leaving 500,000 outstanding. EPS is thus $(\text{EBIT} - \$3 \text{ million})/500,000$.

Now that we know how to calculate EPS under both scenarios, we set the two expressions for EPS equal to each other and solve for the break-even EBIT:

$$\begin{aligned} (\text{EBIT} - \$600,000)/1 \text{ million} &= (\text{EBIT} - \$3 \text{ million})/500,000 \\ \text{EBIT} - \$600,000 &= 2 \times (\text{EBIT} - \$3 \text{ million}) \\ \text{EBIT} &= \mathbf{\$5,400,000} \end{aligned}$$

Verify that, in either case, EPS is \$4.80 when EBIT is \$5.4 million.

- 13.2** According to M&M Proposition II (no taxes), the cost of equity is:

$$\begin{aligned} R_E &= R_A + (R_A - R_D) \times (D/E) \\ &= 20\% + (20\% - 12\%) \times 2 \\ &= \mathbf{36\%} \end{aligned}$$

- 13.3** After the debt issue, TransGlobal will be worth the original \$20,000 plus the present value of the tax shield. According to M&M Proposition I with taxes, the present value of the tax shield is $T_C \times D$, or $.30 \times \$6,000 = \mathbf{\$1,800}$, so the firm is worth $\$20,000 + 1,800 = \mathbf{\$21,800}$.

CRITICAL THINKING AND CONCEPTS REVIEW

L0 1

- 13.1 Business Risk versus Financial Risk.** Explain what is meant by business and financial risk. Suppose Firm A has greater business risk than Firm B. Is it true that Firm A also has a higher cost of equity capital? Explain.

L0 1

- 13.2 M&M Propositions.** How would you answer in the following debate?

Q: Isn't it true that the riskiness of a firm's equity will rise if the firm increases its use of debt financing?

A: Yes, that's the essence of M&M Proposition II.

Q: And isn't it true that, as a firm increases its use of borrowing, the likelihood of default increases, which increases the risk of the firm's debt?

A: Yes.

Q: In other words, increased borrowing increases the risk of the equity *and* the debt?

A: That's right.

Q: Well, given that the firm uses only debt and equity financing, and given that the risk of both is increased by increased borrowing, does it not follow that increasing debt increases the overall risk of the firm and therefore decreases the value of the firm?

A: ??

L0 1 **13.3 Optimal Capital Structure.** Is there an easily identifiable debt-equity ratio that will maximize the value of a firm? Why or why not?

L0 1 **13.4 Observed Capital Structures.** Refer to the observed capital structures given in Table 13.5 of the text. What do you notice about the types of industries with respect to their average debt-equity ratios? Are certain types of industries more likely to be highly leveraged than others? What are some possible reasons for this observed segmentation? Do the operating results and tax history of the firms play a role? How about their future earnings prospects? Explain.

L0 1 **13.5 Financial Leverage.** Why is the use of debt financing referred to as using financial "leverage"?

L0 1 **13.6 Homemade Leverage.** What is homemade leverage?

L0 3 **13.7 Bankruptcy and Corporate Ethics.** As mentioned in the text, some firms have filed for bankruptcy because of actual or likely litigation-related losses. Is this a proper use of the bankruptcy process?

L0 3 **13.8 Bankruptcy and Corporate Ethics.** Firms sometimes use the threat of a bankruptcy filing to force creditors to renegotiate terms. Critics argue that in such cases, the firm is using bankruptcy laws "as a sword rather than a shield." Is this an ethical tactic?

L0 3 **13.9 Bankruptcy and Corporate Ethics.** As mentioned in the text, Continental Airlines filed for bankruptcy, at least in part, as a means of reducing labor costs. Whether this move was ethical, or proper, was hotly debated. Give both sides of the argument.

L0 1 **13.10 Capital Structure Goal.** What is the basic goal of financial management with regard to capital structure?

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

- L0 1** **1. EBIT and Leverage.** Kaelea, Inc., has no debt outstanding and a total market value of \$90,000. Earnings before interest and taxes, EBIT, are projected to be \$8,000 if economic conditions are normal. If there is strong expansion in the economy, then EBIT will be 20 percent higher. If there is a recession, then EBIT will be 35 percent lower. Kaelea is considering a \$34,000 debt issue with a 6 percent interest rate. The proceeds will be used to repurchase shares of stock. There are currently 3,600 shares outstanding. Ignore taxes for this problem.
- Calculate earnings per share, EPS, under each of the three economic scenarios before any debt is issued. Also, calculate the percentage changes in EPS when the economy expands or enters a recession.

Basic
(Questions 1–13)

L0 2

- b. Repeat part (a) assuming that Kaelea goes through with recapitalization. What do you observe?
2. **EBIT, Taxes, and Leverage.** Repeat parts (a) and (b) in Problem 1 assuming Kaelea has a tax rate of 35 percent.

L0 1

L0 2

3. **ROE and Leverage.** Suppose the company in Problem 1 has a market-to-book ratio of 1.0.

- a. Calculate return on equity, ROE, under each of the three economic scenarios before any debt is issued. Also, calculate the percentage changes in ROE for economic expansion and recession, assuming no taxes.
- b. Repeat part (a) assuming the firm goes through with the proposed recapitalization.
- c. Repeat parts (a) and (b) of this problem assuming the firm has a tax rate of 35 percent.

L0 1

4. **Break-Even EBIT.** Kyle Corporation is comparing two different capital structures, an all-equity plan (Plan I) and a levered plan (Plan II). Under Plan I, Kyle would have 700,000 shares of stock outstanding. Under Plan II, there would be 450,000 shares of stock outstanding and \$6 million in debt outstanding. The interest rate on the debt is 10 percent, and there are no taxes.

- a. If EBIT is \$1.3 million, which plan will result in the higher EPS?
- b. If EBIT is \$2.8 million, which plan will result in the higher EPS?
- c. What is the break-even EBIT?

L0 1

5. **M&M and Stock Value.** In Problem 4, use M&M Proposition I to find the price per share of equity under each of the two proposed plans. What is the value of the firm?

L0 1

L0 2

6. **Break-Even EBIT and Leverage.** Blue Stripes Co. is comparing two different capital structures. Plan I would result in 8,500 shares of stock and \$313,500 in debt. Plan II would result in 12,000 shares of stock and \$198,000 in debt. The interest rate on the debt is 10 percent.

- a. Ignoring taxes, compare both of these plans to an all-equity plan assuming that EBIT will be \$53,000. The all-equity plan would result in 18,000 shares of stock outstanding. Which of the three plans has the highest EPS? The lowest?
- b. In part (a), what are the break-even levels of EBIT for each plan as compared to that for an all-equity plan? Is one higher than the other? Why?
- c. Ignoring taxes, when will EPS be identical for Plans I and II?
- d. Repeat parts (a), (b), and (c) assuming that the corporate tax rate is 35 percent. Are the break-even levels of EBIT different from before? Why or why not?

L0 1

7. **Leverage and Stock Value.** Ignoring taxes in Problem 6, what is the price per share of equity under Plan I? Plan II? What principle is illustrated by your answers?

L0 1

8. **Homemade Leverage.** FCOJ, Inc., a prominent consumer products firm, is debating whether or not to convert its all-equity capital structure to one that is 30 percent debt. Currently, there are 6,100 shares outstanding and the price per share is \$55. EBIT is expected to remain at \$19,500 per year forever. The interest rate on new debt is 8 percent, and there are no taxes.

- a. Melanie, a shareholder of the firm, owns 100 shares of stock. What is her cash flow under the current capital structure, assuming the firm has a dividend payout rate of 100 percent?

- b. What will Melanie's cash flow be under the proposed capital structure of the firm? Assume that she keeps all 100 of her shares.
- c. Suppose FCOJ does convert, but Melanie prefers the current all-equity capital structure. Show how she could unlever her shares of stock to recreate the original capital structure.
- d. Using your answer to part (c), explain why FCOJ's choice of capital structure is irrelevant.

L01

9. **Homemade Leverage.** Staal Enterprises is considering a change from its current capital structure. Staal currently has an all-equity capital structure and is considering a capital structure with 25 percent debt. There are currently 4,500 shares outstanding at a price per share of \$60. EBIT is expected to remain constant at \$33,000. The interest rate on new debt is 7 percent and there are no taxes.

- a. Rebecca owns \$18,000 worth of stock in the company. If the firm has a 100 percent payout, what is her cash flow?
- b. What would her cash flow be under the new capital structure assuming that she keeps all of her shares?
- c. Suppose the company does convert to the new capital structure. Show how Rebecca can maintain her current cash flow.
- d. Under your answer to part (c), explain why Staal's choice of capital structure is irrelevant.

L01

10. **Calculating WACC.** Crosby Industries has a debt-equity ratio of 1.5. Its WACC is 9 percent, and its cost of debt is 6 percent. There is no corporate tax.

- a. What is Crosby's cost of equity capital?
- b. What would the cost of equity be if the debt-equity ratio were 2.0? What if it were 0.5? What if it were zero?

L01

11. **Calculating WACC.** Malkin Corp. has no debt but can borrow at 7 percent. The firm's WACC is currently 12 percent, and there is no corporate tax.

- a. What is Malkin's cost of equity?
- b. If the firm converts to 30 percent debt, what will its cost of equity be?
- c. If the firm converts to 60 percent debt, what will its cost of equity be?
- d. What is Malkin's WACC in part (b)? In part (c)?

L02

12. **M&M and Taxes.** Cede & Co. can borrow at 9 percent. Cede currently has no debt, and the cost of equity is 15 percent. The current value of the firm is \$625,000. What will the value be if Cede borrows \$210,000 and uses the proceeds to repurchase shares? The corporate tax rate is 35 percent.

L02

13. **Interest Tax Shield.** Fleury Co. has a 38 percent tax rate. Its total interest payment for the year just ended was \$32 million. What is the interest tax shield? How do you interpret this amount?

L01

14. **M&M.** Guerin Enterprises has no debt. Its current total value is \$70 million. Ignoring taxes, what will the company's value be if it sells \$32 million in debt? Suppose now that the company's tax rate is 40 percent. What will its overall value be if it sells \$32 million in debt? Assume debt proceeds are used to repurchase equity.

L01

15. **M&M.** In the previous question, what is the debt-equity ratio in both cases?

L01

16. **M&M.** Kunitz Co. has no debt. Its cost of capital is 9.3 percent. Suppose Kunitz converts to a debt-equity ratio of 1.0. The interest rate on the debt is 6.4 percent. Ignoring taxes, what is the company's new cost of equity? What is its new WACC?

Intermediate
(Questions 14–16)

Challenge

(Questions 17–20)

L0 2

- 17. Firm Value.** Baker Corporation expects an EBIT of \$43,000 every year forever. Baker currently has no debt, and its cost of equity is 13 percent. The company can borrow at 8 percent. If the corporate tax rate is 38 percent, what is the value of the firm? What will the value be if the company converts to 50 percent debt? To 75 percent debt? To 100 percent debt? What does this tell you about the relationship between the debt-equity ratio and the value of the interest tax shield?

L0 2

- 18. Firm Value.** What is the cost of capital for a firm that is 100 percent debt financed? What is the value of the firm?

L0 2

- 19. Cost of Equity and Leverage.** Assuming a world of corporate taxes only, show that the cost of equity, R_E , is as follows: $R_E = R_U + (R_U - R_D) \times (D/E) \times (1 - T_C)$.

L0 1

- 20. Business and Financial Risk.** Assume a firm's debt is risk-free, so that the cost of debt equals the risk-free rate, R_f . Define β_A as the firm's *asset* beta—that is, the systematic risk of the firm's assets. Define β_E to be the beta of the firm's equity. Use the capital asset pricing model (CAPM) along with M&M Proposition II to show that $\beta_E = \beta_A \times (1 + D/E)$, where D/E is the debt-equity ratio. Assume the tax rate is zero.

WHAT'S ON THE WEB?

- 13.1 Capital Structure.** Go to reuters.com and enter the ticker symbol AMGN for Amgen, a biotechnology company. Find the long-term debt-to-equity and total debt-to-equity ratios. How does Amgen compare to the industry, sector, and S&P 500 in these areas? Now answer the same question for Edison International (EIX), the parent company of Southern California Edison, a utility company. How do the capital structures of Amgen and Edison International compare? Can you think of possible explanations for the difference between these two companies?

- 13.2 Capital Structure.** Go to finance.yahoo.com and find the stock screener. Use the Java stock screener to answer the following questions. How many companies have debt-to-equity ratios greater than 2? Greater than 5? Greater than 10? What company has the highest debt-to-equity ratio? What is the ratio? Now find how many companies have a negative debt-to-equity ratio. What is the lowest debt-to-equity ratio? What does it mean if a company has a negative debt-to-equity ratio?

CHAPTER CASE

STEPHENSON REAL ESTATE RECAPITALIZATION

Stephenson Real Estate Company was founded 25 years ago by the current CEO, Robert Stephenson. The company purchases real estate, including land and buildings, and rents the property to tenants. The company has shown a profit every year for the past 18 years, and the shareholders are satisfied with the company's management. Prior to founding Stephenson Real Estate, Robert was the founder and CEO of a failed alpaca farming operation. The resulting bankruptcy made him extremely averse to debt financing. As a result, the company is entirely equity financed, with 15 million shares of common stock outstanding. The stock currently trades at \$41.50 per share.

Stephenson is evaluating a plan to purchase a huge tract of land in the southeastern United States for \$70 million. The land will subsequently be leased to tenant farmers. This purchase is expected to increase

Stephenson's annual pretax earnings by \$18 million in perpetuity. Kim Weyand, the company's new CFO, has been put in charge of the project. Kim has determined that the company's current cost of capital is 12.5 percent. She feels that the company would be more valuable if it included debt in its capital structure, so she is evaluating whether the company should issue debt to entirely finance the project. Based on some conversations with investment banks, she thinks that the company can issue bonds at par value with an 8 percent coupon rate. From her analysis, she also believes that a capital structure in the range of 70 percent equity/30 percent debt would be optimal. If the company goes beyond 30 percent debt, its bonds would carry a lower rating and a much higher coupon because the possibility of financial distress and the associated costs would rise sharply. Stephenson has a 40 percent corporate tax rate (state and federal).

QUESTIONS

1. If Stephenson wishes to maximize its total market value, would you recommend that it issue debt or equity to finance the land purchase? Explain.
2. Construct Stephenson's market value balance sheet before it announces the purchase.
3. Suppose Stephenson decides to issue equity to finance the purchase.
 - a. What is the net present value of the project?
 - b. Construct Stephenson's market value balance sheet after it announces that the firm will finance the purchase using equity. What would be the new price per share of the firm's stock? How many shares will Stephenson need to issue to finance the purchase?
 - c. Construct Stephenson's market value balance sheet after the equity issue but before the purchase has been made. How many shares of common stock does Stephenson have outstanding? What is the price per share of the firm's stock?
- d. Construct Stephenson's market value balance sheet after the purchase has been made.
4. Suppose Stephenson decides to issue debt to finance the purchase.
 - a. What will the market value of the Stephenson Company be if the purchase is financed with debt?
 - b. Construct Stephenson's market value balance sheet after both the debt issue and the land purchase. What is the price per share of the firm's stock?
5. Which method of financing maximizes the per-share stock price of Stephenson's equity?

Dividends and Dividend Policy

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- L0 1** Discuss dividend types and how dividends are paid.
- L0 2** Explain the issues surrounding dividend policy decisions.
- L0 3** Differentiate between cash and stock dividends.
- L0 4** Explain why share repurchases are an alternative to dividends.

On April 28, 2009, computer services giant IBM, more affectionately known as “Big Blue,” rewarded its shareholders with green when it announced a broad plan to cash in on the company’s recent success. Under the plan, IBM boosted its quarterly dividend by 10 percent from 50 cents per share to 55 cents per share and continued its share buy-back program, with a goal of repurchasing \$3 billion of its stock during 2009. Investors cheered, bidding up the stock price by 2 percent on the day of the announcement. Why were investors pleased? To find out, this chapter explores these actions and their implications for shareholders.

This chapter is about dividend policy. In Chapter 7, we saw that the value of a share of stock depends on all the future dividends that will be paid to shareholders. In that analysis, we took the future stream of dividends as given. What we now examine is how corporations decide on the size and timing of dividend payments. What we would like to find out is how to establish an optimal dividend policy, meaning a dividend policy that maximizes the stock price. What we discover, among other things, is that it is not at all clear how to do this, or even if there is such a thing as an optimal dividend policy!

Visit us at www.mhhe.com/rwj

Dividend policy is an important subject in corporate finance, and dividends are a major cash outlay for many corporations. At first glance, it may seem obvious that a firm would always want to give as much as possible back to its shareholders by paying dividends. It might seem equally obvious, however, that a firm can always invest the money for its shareholders instead of paying it out. The heart of the dividend policy question is just this: Should the firm pay out money to its shareholders, or should the firm take that money and invest it for its shareholders?

It may seem surprising, but much research and economic logic suggest that dividend policy doesn't matter. In fact, it turns out that the dividend policy issue is much like the capital structure question. The important elements are not difficult to identify, but the interactions between those elements are complex and no easy answer exists.

Dividend policy is controversial. Many implausible reasons are given for why dividend policy might be important, and many of the claims made about dividend policy are economically illogical. Even so, in the real world of corporate finance, determining the most appropriate dividend policy is considered an important issue. It could be that financial managers who worry about dividend policy are wasting time, but it could also be true that we are missing something important in our discussions.

In part, all discussions of dividends are plagued by the “two-handed lawyer” problem. President Truman, while discussing the legal implications of a possible presidential decision, asked his staff to set up a meeting with a lawyer. Supposedly, Mr. Truman said, “But I don't want one of those two-handed lawyers.” When asked what a two-handed lawyer was, he replied, “You know, a lawyer who says, ‘On the one hand I recommend you do so and so because of the following reasons, but on the other hand I recommend that you don't do it because of these other reasons.’”

Unfortunately, any sensible treatment of dividend policy will appear to have been written by a two-handed lawyer (or, in fairness, several two-handed financial economists). On the one hand, there are many good reasons for corporations to pay high dividends, but, on the other hand, there are also many good reasons to pay low dividends.

We will cover three broad topics that relate to dividends and dividend policy in this chapter. First, we describe the various kinds of dividends and how dividends are paid. Second, we consider an idealized case in which dividend policy doesn't matter. We then discuss the limitations of this case and present some real-world arguments for both high- and low-dividend payouts. Finally, we conclude the chapter by looking at some strategies that corporations might employ to implement a dividend policy, and we discuss share repurchases as an alternative to dividends.

dividend

Payment made out of a firm's earnings to its owners, in the form of either cash or stock.

CASH DIVIDENDS AND DIVIDEND PAYMENT

14.1

The term **dividend** usually refers to cash paid out of earnings. If a payment is made from sources other than current or accumulated retained earnings, the term **distribution**, rather than *dividend*, is used. However, it is acceptable to refer to a distribution from earnings as a dividend and a distribution from capital as a liquidating dividend. More generally, any direct payment by the corporation to the shareholders may be considered a dividend or a part of dividend policy.

distribution

Payment made by a firm to its owners from sources other than current or accumulated retained earnings.

Dividends come in several different forms. The basic types of cash dividends are:

1. Regular cash dividends
2. Extra dividends
3. Special dividends
4. Liquidating dividends

Later in the chapter, we discuss dividends paid in stock instead of cash, and we also consider an alternative to cash dividends, a stock repurchase.

Cash Dividends

regular cash dividend

Cash payment made by a firm to its owners in the normal course of business, usually made four times per year.

The most common type of dividend is a cash dividend. Commonly, public companies pay **regular cash dividends** four times a year. As the name suggests, these are cash payments made directly to shareholders, and they are made in the regular course of business. In other words, management sees nothing unusual about the dividend and no reason why it won't be continued.

Sometimes firms will pay a regular cash dividend and an *extra cash dividend*. By calling part of the payment “extra,” management is indicating that that part may or may not be repeated in the future. A *special dividend* is similar, but the name usually indicates that this dividend is viewed as a truly unusual or one-time event and it won't be repeated. Finally, the payment of a *liquidating dividend* usually means that some or all of the business has been liquidated, that is, sold off.

However it is labeled, a cash dividend payment reduces corporate cash and retained earnings, except in the case of a liquidating dividend (where paid-in capital may be reduced).

Of course, there are other types of dividends. Companies listed on the Japanese Nikkei stock market have given shareholders alternative dividends in the form of food items, prepaid phone cards, and so forth. For example, McDonald's Holdings Company (Japan) gave its shareholders coupon books for free hamburgers.

Standard Method of Cash Dividend Payment

The decision to pay a dividend rests in the hands of the board of directors of the corporation. When a dividend has been declared, it becomes a liability of the firm and cannot be rescinded easily. Sometime after it has been declared, a dividend is distributed to all shareholders as of some specific date.

Commonly, the amount of the cash dividend is expressed in terms of dollars per share (*dividends per share*). As we have seen in other chapters, it is also expressed as a percentage of the market price (*the dividend yield*) or as a percentage of net income or earnings per share (*the dividend payout*).

declaration date

Date on which the board of directors passes a resolution to pay a dividend.

ex-dividend date

Date two business days before the date of record, establishing those individuals entitled to a dividend.

Dividend Payment: A Chronology

The mechanics of a cash dividend payment can be illustrated by the example in Figure 14.1 and the following description:

1. **Declaration date.** On January 15, the board of directors passes a resolution to pay a dividend of \$1 per share on February 16 to all holders of record as of January 30.
2. **Ex-dividend date.** To make sure that dividend checks go to the right people, brokerage firms and stock exchanges establish an *ex-dividend date*. This date is two

**FIGURE 14.1**

**Example of the
procedure for
dividend payment**

1. **Declaration date:** The board of directors declares a payment of dividends.
2. **Ex-dividend date:** A share of stock goes ex dividend on the date the seller is entitled to keep the dividend; under NYSE rules, shares are traded ex dividend on and after the second business day before the record date.
3. **Record date:** The declared dividends are distributable to those who are shareholders of record as of this specific date.
4. **Payment date:** The dividend checks are mailed to shareholders of record.

business days before the date of record (discussed next). If you buy the stock before this date, then you are entitled to the dividend. If you buy on this date or after, then the previous owner will get the dividend.

In Figure 14.1, Wednesday, January 28, is the ex-dividend date. Before this date, the stock is said to trade “with dividend,” or “cum dividend.” Afterwards, the stock trades “ex dividend.”

The ex-dividend date convention removes any ambiguity about who is entitled to the dividend. Since the dividend is valuable, the stock price will be affected when the stock goes “ex.” We examine this effect below.

3. **Date of record.** Based on its records, the corporation prepares a list on January 30 of all individuals believed to be stockholders. These are the *holders of record*, and January 30 is the *date of record* (or record date). The word *believed* is important here. If you bought the stock just before this date, the corporation’s records might not reflect that fact because of mailing or other delays. Without some modification, some of the dividend checks would get mailed to the wrong people. This is the reason for the ex-dividend day convention.
4. **Date of payment.** The dividend checks are mailed on February 16.

date of record

Date by which holders must be on record to receive a dividend.

date of payment

Date that the dividend checks are mailed.

More on the Ex-Dividend Date

The ex-dividend date is important and is a common source of confusion. We examine what happens to the stock when it goes ex, meaning that the ex-dividend date arrives. To illustrate, suppose we have a stock that sells for \$10 per share. The board of directors declares a dividend of \$1 per share, and the record date is Tuesday, June 12. Based on our discussion above, we know that the ex date will be two business (not calendar) days earlier, on Friday, June 8.

If you buy the stock on Thursday, June 7, right as the market closes, you’ll get the \$1 dividend because the stock is trading cum dividend. If you wait and buy the stock right as the market opens on Friday, you won’t get the \$1 dividend. What will happen to the value of the stock overnight?

If you think about it, the stock is obviously worth about \$1 less on Friday morning, so its price will drop by this amount between close of business on Thursday and the Friday opening. In general, we expect that the value of a share of stock will go down by about the dividend amount when the stock goes ex dividend. The key word here is *about*. Since dividends are taxed, the actual price drop might be closer to some measure of the aftertax

FIGURE 14.2

Price behavior around
the ex-dividend date
for a \$1 cash dividend

The stock price will fall by the amount of the dividend on the ex date (Time 0). If the dividend is \$1 per share, the price will be equal to $\$10 - 1 = \9 on the ex date.

Before ex date (Time -1)	Dividend = \$0	Price = \$10
On ex date (Time 0)	Dividend = \$1	Price = \$9

value of the dividend. Determining this value is complicated because of the different tax rates and tax rules that apply for different buyers. The series of events described here is illustrated in Figure 14.2.

As an example of the price drop on the ex-dividend date, consider the enormous dividend Microsoft paid in November 2004. The special dividend payment totaled a whopping \$32.6 *billion*, the largest corporate cash disbursement in history. What makes the Microsoft special dividend extraordinary is its sheer size. The total dividends paid in 2004 by all the companies in the S&P 500 totaled \$213.6 billion, so Microsoft's special dividend amounted to about 15 percent of the total paid by S&P 500 companies for the year. To give you another idea of the size of the special dividend, consider that, in December, when the dividend was sent to investors, personal income in the United States rose 3.7 percent. Without the dividend, personal income rose only .3 percent; so, the dividend payment accounted for about 3 percent of all personal income in the United States for the month!

What impact did the dividend have on Microsoft's stock price? The stock went ex dividend on November 15, 2004 with a total dividend of \$3.08 per share, consisting of a \$3 special dividend and an \$0.08 regular dividend. The stock price chart below shows the change in Microsoft's stock price on the four days prior to the ex-dividend date and on the ex-dividend date.

The stock closed at \$29.97 on November 12 (a Friday) and opened at \$27.34 on November 15, a drop of \$2.63. With a 15 percent tax rate on dividends, we would have expected a drop of \$2.62, so the actual price drop was almost exactly what we expected (we discuss dividend tax rates in a subsequent section).

“Ex” Marks the Day

EXAMPLE 14.1

The board of directors of Divided Airlines has declared a dividend of \$2.50 per share payable on Tuesday, May 30, to shareholders of record as of Tuesday, May 9. Cal Icon buys 100 shares of Divided on Tuesday, May 2, for \$150 per share. What is the ex date? Describe the events that will occur with regard to the cash dividend and the stock price.

The ex date is two business days before the date of record, Tuesday, May 9, so the stock will go ex on Friday, May 5. Cal buys the stock on Tuesday, May 2, so Cal purchases the stock cum dividend. In other words, Cal will get $\$2.50 \times 100 = \250 in dividends. The check will be mailed on Tuesday, May 30. When the stock does go ex on Friday, its value will drop overnight by about \$2.50 per share.

CONCEPT QUESTIONS

- 14.1a** What are the different types of cash dividends?
- 14.1b** What are the mechanics of the cash dividend payment?
- 14.1c** How should the price of a stock change when the stock goes ex dividend?

DOES DIVIDEND POLICY MATTER?

14.2

To decide whether or not dividend policy matters, we first have to define what we mean by dividend *policy*. All other things being the same, of course dividends matter. Dividends are paid in cash, and cash is something that everybody likes. The question we will be discussing here is whether the firm should pay out cash now or invest the cash and pay it out later. Dividend policy, therefore, is the time pattern of dividend payout. In particular, should the firm pay out a large percentage of its earnings now or a small (or even zero) percentage? This is the dividend policy question.

An Illustration of the Irrelevance of Dividend Policy

A powerful argument can be made that dividend policy does not matter. We illustrate this by considering the simple case of Wharton Corporation. Wharton is an all-equity firm that has existed for 10 years. The current financial managers plan to dissolve the firm in two years. The total cash flows the firm will generate, including the proceeds from liquidation, are \$10,000 in each of the next two years.

Current Policy: Dividends Set Equal to Cash Flow At the present time, dividends at each date are set equal to the cash flow of \$10,000. There are 100 shares outstanding, so the dividend per share will be \$100. In Chapter 7, we showed that the value of the stock is

equal to the present value of the future dividends. Assuming a 10 percent required return, the value of a share of stock today, P_0 , is:

$$\begin{aligned} P_0 &= \frac{D_1}{(1 + R)^1} + \frac{D_2}{(1 + R)^2} \\ &= \frac{\$100}{1.10} + \frac{100}{1.10^2} = \$173.55 \end{aligned}$$

The firm as a whole is thus worth $100 \times \$173.55 = \$17,355$.

Several members of the board of Wharton have expressed dissatisfaction with the current dividend policy and have asked you to analyze an alternative policy.

Alternative Policy: Initial Dividend Greater than Cash Flow Another policy is for the firm to pay a dividend of \$110 per share on the first date (Date 1), which is, of course, a total dividend of \$11,000. Because the cash flow is only \$10,000, an extra \$1,000 must somehow be raised. One way to do this is to issue \$1,000 worth of bonds or stock at Date 1. Assume that stock is issued. The new stockholders will desire enough cash flow at Date 2 so that they earn the required 10 percent return on their Date 1 investment.

What is the value of the firm with this new dividend policy? The new stockholders invest \$1,000. They require a 10 percent return, so they will demand $\$1,000 \times 1.10 = \$1,100$ of the Date 2 cash flow, leaving only \$8,900 to the old stockholders. The dividends to the old stockholders will be:

	Date 1	Date 2
Aggregate dividends to old stockholders	\$11,000	\$8,900
Dividends per share	110	89

The present value of the dividends per share is therefore:

$$P_0 = \frac{\$110}{1.10} + \frac{89}{1.10^2} = \$173.55$$

This is the same value we had before.

The value of the stock is not affected by this switch in dividend policy even though we had to sell some new stock just to finance the dividend. In fact, no matter what pattern of dividend payout the firm chooses, the value of the stock will always be the same in this example. In other words, for the Wharton Corporation, dividend policy makes no difference. The reason is simple: Any increase in a dividend at some point in time is exactly offset by a decrease somewhere else, so the net effect, once we account for time value, is zero.

A Test

Our discussion to this point can be summarized by considering the following true-false test questions:

- 1. True or false: Dividends are irrelevant.
- 2. True or false: Dividend policy is irrelevant.

The first statement is surely false, and the reason follows from common sense. Clearly, investors prefer higher dividends to lower dividends at any single date if the dividend level is held constant at every other date. To be more precise regarding the first question, if the dividend per share at a given date is raised, while the dividend per share at every

other date is held constant, the stock price will rise. The reason is that the present value of the future dividends must go up if this occurs. This action can be accomplished by management decisions that improve productivity, increase tax savings, strengthen product marketing, or otherwise improve cash flow.

The second statement is true, at least in the simple case we have been examining. Dividend policy by itself cannot raise the dividend at one date while keeping it the same at all other dates. Rather, dividend policy merely establishes the trade-off between dividends at one date and dividends at another date. Once we allow for time value, the present value of the dividend stream is unchanged. Thus, in this simple world, dividend policy does not matter, because managers choosing either to raise or to lower the current dividend do not affect the current value of their firm. However, we have ignored several real-world factors that might lead us to change our minds; we pursue some of these in subsequent sections.

Some Real-World Factors Favoring a Low Payout

The example we used to illustrate the irrelevance of dividend policy ignored taxes and flotation costs. We will now see that these factors might lead us to prefer a low-dividend payout.

Taxes U.S. tax laws are complex, and they affect dividend policy in a number of ways. The key tax feature has to do with the taxation of dividend income and capital gains. For individual shareholders, *effective* tax rates on dividend income are higher than the tax rates on capital gains. Historically, dividends received have been taxed as ordinary income. Capital gains have been taxed at somewhat lower rates, and the tax on a capital gain is deferred until the stock is sold. This second aspect of capital gains taxation makes the effective tax rate much lower because the present value of the tax is less.¹

A firm that adopts a low-dividend payout will reinvest the money instead of paying it out. This reinvestment increases the value of the firm and of the equity. All other things being equal, the net effect is that the expected capital gains portion of the return will be higher in the future. So the fact that capital gains are taxed favorably may lead us to prefer this approach.

Recent tax law changes have led to a renewed interest in the effect of taxes on corporate dividend policies. As we previously noted, historically dividends have been taxed as ordinary income (at ordinary income tax rates). In 2003, this changed dramatically. The maximum tax rate on dividends was lowered from the 35–39 percent range to 15 percent. The same rate applies to long-term capital gains. The lower tax rate on dividends reduces the tax disincentive to pay dividends, but does not eliminate it. Note that capital gains are still taxed preferentially because of the deferment.

Flotation Costs In our example illustrating that dividend policy doesn't matter, we saw that the firm could sell some new stock if necessary to pay a dividend. As we discuss in our next chapter, selling new stock can be very expensive. If we include the costs of selling stock ("flotation" costs) in our argument, then we will find that the value of the stock decreases if we sell new stock.

More generally, imagine two firms identical in every way except that one pays out a greater percentage of its cash flow in the form of dividends. Since the other firm plows back more, its equity grows faster. If these two firms are to remain identical, then the one with the higher payout will have to periodically sell some stock to catch up. Since this is expensive, a firm might be inclined to have a low payout.

¹ In fact, capital gains taxes can sometimes be avoided altogether. Although we do not recommend this particular tax-avoidance strategy, the capital gains tax may be avoided by dying. Your heirs are not considered to have a capital gain, so the tax liability dies when you do. In this instance, you can take it with you.

Dividend Restrictions In some cases, a corporation may face restrictions on its ability to pay dividends. For example, as we discussed in Chapter 6, a common feature of a bond indenture is a covenant prohibiting dividend payments above some level. Also, a corporation may be prohibited by state law from paying dividends if the dividend amount exceeds the firm's retained earnings.

Some Real-World Factors Favoring a High Payout

In this section, we consider reasons why a firm might pay its shareholders higher dividends even if it means the firm must issue more shares of stock to finance the dividend payments.

Desire for Current Income It has been argued that many individuals desire current income. The classic example is the group of retired people and others living on a fixed income, the proverbial “widows and orphans.” It is argued that this group is willing to pay a premium to get a higher dividend yield.

It is easy to see, however, that this argument is not relevant in our simple case. An individual preferring high current cash flow but holding low-dividend securities could easily sell off shares to provide the necessary funds. Similarly, an individual desiring a low current cash flow but holding high-dividend securities could just reinvest the dividends. Thus, in a world of no transaction costs, a policy of high current dividends would be of no value to the stockholder.

The current-income argument may have relevance in the real world. Here, the sale of low-dividend stocks would involve brokerage fees and other transaction costs. Such a sale might also trigger capital gains taxes. These direct cash expenses could be avoided by an investment in high-dividend securities. In addition, the expenditure of the stockholder's own time when selling securities and the natural (though not necessarily rational) fear of consuming out of principal might further lead many investors to buy high-dividend securities.

Tax and Legal Benefits from High Dividends Earlier we saw that dividends were taxed unfavorably for individual investors. This fact is a powerful argument for a low payout. However, there are a number of other investors who do not receive unfavorable tax treatment from holding high-dividend yield, rather than low-dividend yield, securities.

Corporate investors A significant tax break on dividends occurs when a corporation owns stock in another corporation. A corporate stockholder receiving either common or preferred dividends is granted a 70 percent (or more) dividend exclusion. Since the 70 percent exclusion does not apply to capital gains, this group is taxed unfavorably on capital gains.

As a result of the dividend exclusion, high-dividend, low-capital gains stocks may be more appropriate for corporations to hold. In fact, this is why corporations hold a substantial percentage of the outstanding preferred stock in the economy. This tax advantage of dividends also leads some corporations to hold high-yielding stocks instead of long-term bonds because there is no similar tax exclusion of interest payments to corporate bondholders.

Tax-exempt investors We have pointed out both the tax advantages and the tax disadvantages of a low-dividend payout. Of course, this discussion is irrelevant to those in zero tax brackets. This group includes some of the largest investors in the economy, such as pension funds, endowment funds, and trust funds.

There are some legal reasons for large institutions to favor high-dividend yields. First, institutions such as pension funds and trust funds are often set up to manage money for the benefit of others. The managers of such institutions have a *fiduciary responsibility* to invest the money prudently. It has been considered imprudent in courts of law to buy stock in companies with no established dividend record.

Second, institutions such as university endowment funds and trust funds are frequently prohibited from spending any of the principal. Such institutions might therefore prefer high-dividend yield stocks so they have some ability to spend. Like widows and orphans, this group thus prefers current income. Unlike widows and orphans, this group is very large in terms of the amount of stock owned.

Overall, individual investors (for whatever reason) may have a desire for current income and may thus be willing to pay the dividend tax. In addition, some very large investors such as corporations and tax-free institutions may have a very strong preference for high-dividend payouts.

Clientele Effects: A Resolution of Real-World Factors?

In our earlier discussion, we saw that some groups (wealthy individuals, for example) have an incentive to pursue low-payout (or zero payout) stocks. Other groups (corporations, for example) have an incentive to pursue high-payout stocks. Companies with high payouts will thus attract one group, and low-payout companies will attract another.

These different groups are called *clienteles*, and what we have described is a **clienteles effect**. The clientele effect argument states that different groups of investors desire different levels of dividends. When a firm chooses a particular dividend policy, the only effect is to attract a particular clientele. If a firm changes its dividend policy, then it just attracts a different clientele.

What we are left with is a simple supply and demand argument. Suppose 40 percent of all investors prefer high dividends, but only 20 percent of the firms pay high dividends. Here, the high-dividend firms will be in short supply; thus, their stock prices will rise. Consequently, low-dividend firms will find it advantageous to switch policies until 40 percent of all firms have high payouts. At this point, the *dividend market* is in equilibrium. Further changes in dividend policy are pointless because all of the clienteles are satisfied. The dividend policy for any individual firm is now irrelevant.

To see if you understand the clientele effect, consider the following statement: In spite of the theoretical argument that dividend policy is irrelevant or that firms should not pay dividends, many investors like high dividends; because of this fact, a firm can boost its share price by having a higher dividend payout ratio. True or false?

The answer is “false” if clienteles exist. As long as enough high-dividend firms satisfy the dividend-loving investors, a firm won’t be able to boost its share price by paying high dividends. An unsatisfied clientele must exist for this to happen, and there is no evidence that this is the case.

clienteles effect

Argument that stocks attract particular groups based on dividend yield and the resulting tax effects.

CONCEPT QUESTIONS

14.2a Are dividends irrelevant?

14.2b What are some of the reasons for a low payout?

14.2c What are the implications of dividend clienteles for payout policies?

14.3

STOCK REPURCHASES: AN ALTERNATIVE TO CASH DIVIDENDS

stock repurchase

The purchase, by a corporation, of its own shares of stock; also known as a buyback.

Thus far in our chapter, we have considered cash dividends. However, cash dividends are not the only way corporations distribute cash. Instead, a company can **repurchase** its own stock. Repurchases (or *buybacks*) have become an increasingly popular tool, and the amount spent on repurchases has become huge. For example, in the first quarter of 2008, U.S. companies announced plans to buy back \$76 billion of stock, down from \$121.9 billion in the fourth quarter of 2007 and a record \$174 billion in the third quarter of 2007. Overall, a record \$538 billion of stock buyback plans were announced in 2007.

Another way to see how important repurchases have become is to compare them to cash dividends. Consider Figure 14.3, which shows the average ratios of dividends to earnings, repurchases to earnings, and total payout (both dividends and repurchases) to earnings for U.S. industrial firms over the years from 1984 to 2004. As can be seen, the ratio of repurchases to earnings was far less than the ratio of dividends to earnings in the early years. However, the ratio of repurchases to earnings exceeded the ratio of dividends to earnings by 1998. This trend reversed after 1999, with the ratio of repurchases to earnings falling slightly below the ratio of dividends to earnings by 2004.

Share repurchases are typically accomplished in one of three ways. First, companies may simply purchase their own stock, just as anyone would buy shares of a particular stock. In these *open market purchases*, the firm does not reveal itself as the buyer. Thus, the seller does not know whether the shares were sold back to the firm or to just another investor.

FIGURE 14.3**Ratios of various payouts to earnings**

Source: Brandon Julio and David Ikenberry, "Reappearing Dividends," *Journal of Applied Corporate Finance* 16, Fall 2004. Copyright © 2004 Blackwell Publishers. Used with permission.

The graph shows the average ratios of repurchases, dividends, and total payout (both repurchases and dividends) to earnings for U.S. industrial companies over the years 1984 to 2004. The graph indicates growth in repurchases over much of the sample period.

Second, the firm could institute a *tender offer*. Here, the firm announces to all of its stockholders that it is willing to buy a fixed number of shares at a specific price. For example, suppose Arts and Crafts (A&C), Inc., has 1 million shares of stock outstanding, with a stock price of \$50 per share. The firm makes a tender offer to buy back 300,000 shares at \$60 per share. A&C chooses a price above \$50 to induce shareholders to sell, that is, tender, their shares. In fact, if the tender price is set high enough, shareholders may very well want to sell more than the 300,000 shares. In the extreme case where all outstanding shares are tendered, A&C will buy back 3 out of every 10 shares that a shareholder has.

Finally, firms may repurchase shares from specific individual stockholders. This procedure has been called a *targeted repurchase*. For example, suppose the International Biotechnology Corporation purchased approximately 10 percent of the outstanding stock of the Prime Robotics Company (P-R Co.) in April at around \$38 per share. At that time, International Biotechnology announced to the Securities and Exchange Commission that it might eventually try to take control of P-R Co. In May, P-R Co. repurchased the International Biotechnology holdings at \$48 per share, well above the market price at that time. This offer was not extended to other shareholders.

Cash Dividends versus Repurchase

Imagine an all-equity company with excess cash of \$300,000. The firm pays no dividends, and its net income for the year just ended is \$49,000. The market value balance sheet at the end of the year is represented here:

Market Value Balance Sheet (before paying out excess cash)			
Excess cash	\$ 300,000	Debt	\$ 0
Other assets	700,000	Equity	1,000,000
Total	<u>\$1,000,000</u>	Total	<u>\$1,000,000</u>

There are 100,000 shares outstanding. The total market value of the equity is \$1 million, so the stock sells for \$10 per share. Earnings per share (EPS) are $\$49,000/100,000 = \0.49 , and the price-earnings ratio (PE) is $\$10/\$0.49 = 20.4$.

One option the company is considering is a $\$300,000/100,000 = \3 per share extra cash dividend. Alternatively, the company is thinking of using the money to repurchase $\$300,000/\$10 = 30,000$ shares of stock.

If commissions, taxes, and other imperfections are ignored in our example, the stockholders shouldn't care which option is chosen. Does this seem surprising? It shouldn't, really. What is happening here is that the firm is paying out \$300,000 in cash. The new balance sheet is represented here:

Market Value Balance Sheet (after paying out excess cash)			
Excess cash	\$ 0	Debt	\$ 0
Other assets	700,000	Equity	700,000
Total	<u>\$700,000</u>	Total	<u>\$700,000</u>

If the cash is paid out as a dividend, there are still 100,000 shares outstanding, so each is worth \$7.

The fact that the per-share value fell from \$10 to \$7 is not a cause for concern. Consider a stockholder who owns 100 shares. At \$10 per share before the dividend, the total value is \$1,000.

After the \$3 dividend, this same stockholder has 100 shares worth \$7 each, for a total of \$700, plus $100 \times \$3 = \300 in cash, for a combined total of \$1,000. This just illustrates what we saw early on: A cash dividend doesn't affect a stockholder's wealth if there are no imperfections. In this case, the stock price simply fell by \$3 when the stock went ex dividend.

Also, because total earnings and the number of shares outstanding haven't changed, EPS is still 49 cents. The price-earnings ratio, however, falls to $\$7/.49 = 14.3$. Why we are looking at accounting earnings and PE ratios will be apparent in just a moment.

Alternatively, if the company repurchases 30,000 shares, there are 70,000 left outstanding. The balance sheet looks the same:

Market Value Balance Sheet (after share repurchase)			
Excess cash	\$ 0	Debt	\$ 0
Other assets	700,000	Equity	700,000
Total	<u>\$700,000</u>	Total	<u>\$700,000</u>

The company is worth \$700,000 again, so each remaining share is worth $\$700,000/70,000 = \10 . Our stockholder with 100 shares is obviously unaffected. For example, if she was so inclined, she could sell 30 shares and end up with \$300 in cash and \$700 in stock, just as she has if the firm pays the cash dividend. This is an example of a homemade dividend.

In this second case, EPS goes up because total earnings remain the same while the number of shares goes down. The new EPS is $\$49,000/70,000 = \$.70$. However, the important thing to notice is that the PE ratio is $\$10/.70 = 14.3$, just as it was following the dividend.

This example illustrates the important point that, if there are no imperfections, a cash dividend and a share repurchase are essentially the same thing. This is just another illustration of dividend policy irrelevance when there are no taxes or other imperfections.

Real-World Considerations in a Repurchase

The example we have just described shows that a repurchase and a cash dividend are the same thing in a world without taxes and transaction costs. In the real world, there are some accounting differences between a share repurchase and a cash dividend, but the most important difference is in the tax treatment.

Under current tax law, a repurchase has a significant tax advantage over a cash dividend. A dividend is taxed, and a shareholder has no choice about whether or not to receive the dividend. In a repurchase, a shareholder pays taxes only if (1) the shareholder actually chooses to sell and (2) the shareholder has a capital gain on the sale.

For example, suppose a dividend of \$1 per share is taxed at ordinary rates. Investors in the 28 percent tax bracket who own 100 shares of the security pay $\$100 \times .28 = \28 in taxes. Selling shareholders would pay far lower taxes if \$100 worth of stock were repurchased. This is because taxes are paid only on the profit from a sale. Thus, the gain on a sale would be only \$40 if shares sold at \$100 were originally purchased at \$60. The capital gains tax would be $.28 \times \$40 = \11.20 . Note that the recent reductions in dividend and capital gains tax rates do not change the fact that a repurchase has a potentially large tax edge.

To give a few examples of recent activity, in June 2009, Walmart announced a \$15 billion share repurchase. In the previous five years, the company had repurchased \$21 billion worth of its shares. IBM is another company known for its aggressive repurchasing policies.

Stock Buybacks: No End in Sight

Share repurchases have continued to grow in recent years, but the recession that began in 2008 affected share repurchases. During 2008, U.S. companies announced \$359.2 billion in stock buybacks, which is 58 percent lower than the \$855.2 billion announced in 2007. Even so, for the past several years, share repurchases have been so large that U.S. corporations bought back more shares than they sold. In other words, aggregate net equity raised by U.S. corporations has been negative.

Some companies appear to have become serial repurchasers. Take Microsoft, for example. In September 2008, the company announced a \$40 billion stock “buyback” (another word for a repurchase). At the then-current market value of the stock, this repurchase amounted to about 25 percent of all shares outstanding. Only two years earlier, Microsoft had announced a \$40 billion stock buyback, which had been completed. Another example is General Electric, which had repurchased \$12 billion of its stock in 2007. In the first nine months of 2008, General Electric bought back \$3.1 billion of its stock and then announced it was suspending its repurchase program because of economic conditions.

Stock buybacks have evolved to the point where they are used for other purposes. For example, in January 2005, consumer products giant Procter & Gamble (P&G) announced that it was purchasing razor manufacturer Gillette for \$54 billion. The purchase was paid for entirely with stock in P&G. This is important because if a company acquires another company

for cash, the shareholders of the acquired company may be forced to pay taxes. If shareholders receive stock, no taxes are due. What made the deal unique was that P&G announced at the same time that it would repurchase from \$18 to \$22 billion in stock. Thus, P&G essentially paid about 60 percent in stock and 40 percent in cash, but the way the deal was structured made it look like a 100 percent stock acquisition to Gillette's stockholders.

Stock buybacks can be a large percentage of a company's equity. For example, on May 28, 2008, tractor manufacturer John Deere announced a buyback of \$6.9 billion. While the amount of the buyback may not be as large as some, it represented about 14 percent of the company's outstanding shares. About the same time, insurance company Aetna increased its repurchase plan to account for about 12 percent of its outstanding stock.

We haven't discussed what happens to the stock when a company does a buyback. There are actually several things the company can do. Many companies keep the stock and use the shares for employee stock option plans. When employee stock options are exercised by the employees, new shares are created, which increases the number of shares of stock outstanding. By using the repurchased shares, the company does not need to issue any new shares. A company can also keep the repurchased stock for itself as Treasury stock. Finally, the company can cancel the stock completely. In essence, it destroys the shares repurchased, which reduces the number of shares outstanding.

In 2007, the company set a record by buying back \$15.7 billion worth of its stock in the second quarter alone. From 2005 to 2007, IBM repurchased \$34.3 billion of its stock and, in February 2008, IBM's board of directors announced yet another buyback, this time of \$15 billion. When the company announced the \$3 billion repurchase we mentioned at the beginning of this chapter, it still had \$3.7 billion of the previous \$15 billion buyback to complete.

One cautionary note is in order concerning share repurchases, or buybacks. A company announcing plans to buy back some of its stock has no legal obligation to actually do it, and it turns out that many announced repurchases are never completed. Our nearby *Reality Bytes* discusses some recent events in stock buybacks.

Share Repurchase and EPS

You may read in the popular financial press that a share repurchase is beneficial because it causes earnings per share to increase. As we have seen, this will happen. The reason is simply that a share repurchase reduces the number of outstanding shares, but it has no effect on total earnings. As a result, EPS rises.

However, the financial press may place undue emphasis on EPS figures in a repurchase agreement. In our preceding example, we saw that the value of the stock wasn't affected by the EPS change. In fact, the PE ratio was exactly the same when we compared a cash dividend to a repurchase.

CONCEPT QUESTIONS

14.3a Why might a stock repurchase make more sense than an extra cash dividend?

14.3b What is the effect of a stock repurchase on a firm's EPS? Its PE?

14.4

WHAT WE KNOW AND DO NOT KNOW ABOUT DIVIDEND AND PAYOUT POLICIES

Dividends and Dividend Payers

As we have discussed, there are numerous good reasons favoring a dividend policy of low (or no) payout. Nonetheless, in the U.S., aggregate dividends paid are quite large. For example, in 1978, U.S. industrial firms listed on the major exchanges paid \$31.3 billion in total dividends. By 2000, that number had risen to \$101.6 billion (unadjusted for inflation), an increase of over 200 percent (after adjusting for inflation, the increase is smaller, 22.7 percent, but still substantial).

While we know dividends are large in the aggregate, we also know that the number of companies that pay dividends has declined. Over the same 1978–2000 period, the number of industrial companies paying dividends declined from over 2,000 to just under 1,000, and the percentage of these firms paying dividends declined 65 percent, to just 19 percent.²

The fact that aggregate dividends grew while the number of payers fell so sharply seems a bit paradoxical, but the explanation is straightforward. Dividend payments are heavily concentrated in a relatively small set of large firms. In 2000, for example, about 80 percent of aggregate dividends were paid by just 100 firms. The top 25 payers, which included such well-known giants as ExxonMobil and General Electric, collectively paid about 55 percent of all dividends. In 2008, the top 25 paid about 51 percent of the total. Thus, the reason that dividends grew while dividend payers shrank is that the decline in dividend payers is almost entirely due to smaller firms, which tend to pay smaller dividends in the first place.

One important reason that the percentage of dividend-paying firms has declined is that the population of firms has changed. There has been a huge increase in the number of newly listed firms over the last 25 or so years. Newly listed firms tend to be younger and less profitable. Such firms need their internally generated cash to fund growth and typically do not pay dividends.

Another factor at work is that firms appear to be more likely to begin making payouts using share repurchases, which are flexible, rather than committing to making cash distributions. Such a policy seems quite sensible. However, after controlling for the changing mix of firms and the increase in share repurchasing activity, there still appears to be a decreased propensity to pay dividends among certain types of older, better established firms, though further research is needed on this question.

The fact that the number of dividend-paying firms has declined so sharply is an interesting phenomenon. Making matters even more interesting is evidence showing that the trend may have begun to reverse itself. Take a look at Figure 14.4, which shows the

² These figures and those in the following paragraph are from DeAngelo, DeAngelo, and Skinner, "Are Dividends Disappearing? Dividend Concentration and the Consolidation of Earnings," *Journal of Financial Economics* 72 (2004).

**FIGURE 14.4**

Proportion of dividend payers among all U.S. industrial firms, 1984–2004

percentage of industrial firms paying dividends over the period 1984–2004. As shown, there is a pronounced downward trend, but that trend appears to bottom out in 2000 and then sharply reverse in 2002. So what's going on?

Part of the apparent rebound in Figure 14.4 is probably an illusion. The number of firms listed on the major stock markets dropped sharply, from over 5,000 to under 4,000, during the period 2000–2005. About 2,000 firms delisted over this period, 98 percent of which were not dividend payers. Thus, the percentage of firms paying dividends rose because nonpayers dropped out in large numbers.³

However, once we control for the dropout problem, there is still an increase in the number of dividend payers, but it happens in 2003. As shown in Figure 14.5, the uptick is concentrated in the months following May 2003. What is so special about this month? The answer is that in May 2003, top personal tax rates on dividends were slashed from about 38 to 15 percent. Thus, consistent with our earlier tax arguments, a reduction in personal tax rates led to increases in dividends.

However, it is important not to read too much into Figure 14.5. It seems clear that the reduction in tax rates did have an effect, but, on balance, what we see is a few hundred firms initiating dividends. There are still thousands of firms that did not initiate dividends, even though the tax rate reduction was very large. Thus, the evidence suggests that tax rates matter, but they are not a primary determinant of dividend policy. This interpretation is consistent with the results of a 2005 survey of financial executives, more than 2/3 of whom said that the tax rate cut probably or definitely would not affect their dividend policies.⁴

³ These numbers and this explanation are from Chetty and Saez, "The Effects of the 2003 Dividend Tax Cut on Corporate Behavior: Interpreting the Evidence," *American Economic Review Papers and Proceedings* 96 (2006).

⁴ See Brav, Graham, Harvey, and Michaely, "Managerial Response to the May 2003 Dividend Tax Cut," Duke University working paper (2007).

A second force that may be at work over time is the maturing of many of the (surviving) newly listed firms we mentioned earlier. As these firms have become better established, their profitability has increased (and, potentially, their investment opportunities have decreased), and they have begun to pay dividends.

A third factor that may be contributing to the increase in the number of dividend payers is a little more subtle. The technology-heavy NASDAQ index plummeted in the spring of 2000 (due to the "dot-com" crash), and it became clear that many newly listed companies were likely to fail. Shortly thereafter, major accounting scandals at companies such as Enron and WorldCom left investors unsure of the trustworthiness of reported earnings. In such an environment, companies may have chosen to initiate dividends in an attempt to signal to investors that they had the cash to make dividend payments now and in the future.

The apparent reversal in the decline of dividend payers is a recent phenomenon, so its significance remains to be seen. It may prove to be just a transient event in the middle of a long decline. We will have to wait and see.

Corporations Smooth Dividends

Dividend cuts are frequently viewed as very bad news by market participants. As a result, companies only cut dividends when there is no other acceptable alternative. For the same reason, companies are also reluctant to increase dividends unless they are sure the new dividend level can be sustained.

In practice, what we observe is that dividend-paying companies tend to raise dividends only after earnings have risen, and they don't increase or cut dividends in response to temporary earnings fluctuations. In other words, (1) dividend growth lags earnings growth and (2) dividend growth will tend to be much smoother than earnings growth.

Dividend stability and steady growth are important to financial managers, notwithstanding the 2008 results. In 2008, dividends for the S&P 500 were \$214.7 billion, a 13.3 percent decline from the record \$247.9 billion paid in 2007. A closer examination shows the effect of the beleaguered financial sector. Of the 62 companies in the S&P 500 that decreased dividends, 48 were in the financial sector. The decrease in dividends from the financial sector alone amounted to about \$37 billion, which is actually more than the \$33.2 billion aggregate drop in dividends.

There are companies with extraordinarily long dividend payments. The S&P 500 Dividend Aristocrat list consists of 59 companies that have increased dividends for at least 25 consecutive years. Two companies with long histories of dividend increases are tool manufacturer Stanley Works and Procter & Gamble. At the end of 2008, Stanley Works had paid a dividend each year for the past 132 consecutive years and had increased its dividend in each of the last 41 years. Procter & Gamble had increased its dividend for 53 years.

Putting It All Together

Much of what we have discussed in this chapter (and much of what we know about dividends from decades of research) can be pulled together and summarized in the following five observations:⁵

1. Aggregate dividends and stock repurchases are massive, and they have increased steadily in nominal and real terms over the years.
2. Dividends are heavily concentrated among a relatively small number of large, mature firms.
3. Managers are very reluctant to cut dividends, normally doing so only due to firm-specific problems.
4. Managers smooth dividends, raising them slowly and incrementally as earnings grow.
5. Stock prices react to unanticipated changes in dividends.

The challenge now is to fit these five pieces into a reasonably coherent picture. With regard to payouts in general, meaning the combination of stock repurchases and cash dividends, a simple life cycle theory fits points 1 and 2. The key ideas are straightforward. First, relatively young and less profitable firms generally should not make cash distributions. They need the cash to fund investments (and flotation costs discourage the raising of outside cash).

However, as a firm matures, it begins to generate free cash flow (which, you will recall, is internally generated cash flow beyond that needed to fund profitable investment activities). Significant free cash flow can lead to agency problems if it is not distributed. Managers may become tempted to pursue empire building or otherwise spend the excess cash in ways not in the shareholders' best interests. Thus, firms come under pressure to make distributions rather than hoard cash. And, consistent with what we observe, we expect large firms with a history of profitability to make large distributions.

Thus, the life cycle theory says that firms trade off the agency costs of excess cash retention against the potential future costs of external equity financing. A firm should begin making distributions when it generates sufficient internal cash flow to fund its investment needs now and into the foreseeable future.

⁵ This list is distilled in part from a longer list in DeAngelo and DeAngelo, "Payout Policy Pedagogy: What Matters and Why," *European Financial Management* 13 (2007).

The more complex issue concerns the type of distribution, cash dividends versus repurchase. The tax argument in favor of repurchases is a clear and strong one. Further, repurchases are a much more flexible option (and managers greatly value financial flexibility), so the question is: Why would firms ever choose a cash dividend?

If we are to answer this question, we have to ask a different question. What can a cash dividend accomplish that a share repurchase cannot? One answer is that when a firm makes a commitment to pay a cash dividend now and into the future, it sends a two-part signal to the markets. As we have already discussed, one signal is that the firm anticipates being profitable, with the ability to make the payments on an ongoing basis. Note that a firm cannot benefit by trying to fool the market in this regard because the firm would ultimately be punished when it couldn't make the dividend payment (or couldn't make it without relying on external financing). Thus, a cash dividend may let a firm distinguish itself from less profitable rivals.

A second, and more subtle, signal takes us back to the agency problem of free cash flow. By committing to pay cash dividends now and in the future, the firm signals that it won't be hoarding cash (or at least not as much cash), thereby reducing agency costs and enhancing shareholder wealth.

This two-part signaling story is consistent with points 3–5 above, but an obvious objection remains. Why don't firms just commit to a policy of setting aside whatever money would be used to pay dividends and use it instead to buy back shares? After all, either way, a firm is committing to pay out cash to shareholders.

A fixed repurchase strategy suffers from two drawbacks. The first is verifiability. A firm could announce an open market repurchase and then simply not do it. By suitably fudging its books, it would be some time before the deception was discovered. Thus, it would be necessary for shareholders to develop a monitoring mechanism, meaning some sort of way for stockholders to know for sure that the repurchase was in fact done. Such a mechanism wouldn't be difficult to build (it could be a simple trustee relationship such as we observe in the bond markets), but it currently does not exist. Of course, a tender offer repurchase needs little or no verification, but such offers have expenses associated with them. The beauty of a cash dividend is that it needs no monitoring. A firm is forced to cut and mail checks four times a year, year in and year out.

A second objection to a fixed repurchase strategy is more controversial. Suppose managers, as insiders, are better able than stockholders to judge whether their stock price is too high or too low. (Note that this idea does not conflict with semistrong market efficiency if inside information is the reason.) In this case, a fixed repurchase commitment forces management to buy back stock even in circumstances when the stock is overvalued. In other words, it forces management into making negative NPV investments.

More research on the cash dividend versus share repurchase question is needed, but the historical trend seems to be favoring continued growth in repurchases relative to dividends. Total corporate payouts seem to be relatively stable over time at roughly 20 percent of aggregate earnings (see Figure 14.3), but repurchases are becoming a larger portion of that total. The split reached about 50–50 in the latter part of the 1990s, but it looks like aggregate repurchases have recently passed aggregate dividends.

One aspect of aggregate cash dividends that has not received much attention is that there may be a strong legacy effect. Before 1982, the regulatory status of stock repurchases was somewhat murky, creating a significant disincentive. In 1982, the SEC, after years of debate, created a clear set of guidelines for firms to follow, thereby making repurchases much more attractive.

The legacy effect arises because many of the giant firms that pay such a large portion of aggregate dividends were paying dividends before (and perhaps long before) 1982. To

the extent that these firms are unwilling to cut their dividends, aggregate cash dividends will be large, but only because of a “lock-in” effect for older firms. If locked-in, legacy payers account for much of the aggregate dividend, what we should observe is (1) a sharply reduced tendency for maturing firms to initiate dividends and (2) a growth in repurchases relative to cash dividends over time. We actually do see evidence of both of these trends; however, legacy effects alone can’t account for all cash dividend payers.

The Pros and Cons of Paying Dividends	
Pros	Cons
1. Cash dividends can underscore good results and provide support to the stock price.	1. Dividends are taxed to recipients.
2. Dividends may attract institutional investors who prefer some return in the form of dividends. A mix of institutional and individual investors may allow a firm to raise capital at lower cost because of the ability of the firm to reach a wider market.	2. Dividends can reduce internal sources of financing. Dividends may force the firm to forgo positive NPV projects or to rely on costly external equity financing.
3. Stock price usually increases with the announcement of a new or increased dividend.	3. Once established, dividend cuts are hard to make without adversely affecting a firm’s stock price.
4. Dividends absorb excess cash flow and may reduce agency costs that arise from conflicts between management and shareholders.	

Some Survey Evidence on Dividends

A recent study surveyed a large number of financial executives regarding dividend policy. One of the questions asked was, “Do these statements describe factors that affect your company’s dividend decisions?” Table 14.1 shows some of the results.

As shown in Table 14.1, financial managers are very disinclined to cut dividends. Moreover, they are very conscious of their previous dividends and desire to maintain a relatively steady dividend. In contrast, the cost of external capital and the desire to attract “prudent man” investors (those with fiduciary duties) are less important.

Table 14.2 is drawn from the same survey, but here the responses are to the question, “How important are the following factors to your company’s dividend decision?” Not surprisingly given the responses in Table 14.1 and our earlier discussion, the highest priority is maintaining a consistent dividend policy. The next several items are also consistent with our previous analysis. Financial managers are very concerned about earnings stability and future earnings levels in making dividend decisions, and they consider the availability of good investment opportunities. Survey respondents also believed that attracting both institutional and individual (retail) investors was relatively important.

In contrast to our discussion of taxes and flotation costs in the earlier part of this chapter, the financial managers in this survey did not think that personal taxes paid on dividends by shareholders are very important. And even fewer think that equity flotation costs are relevant.

14.5

STOCK DIVIDENDS AND STOCK SPLITS

stock dividend

Payment made by a firm to its owners in the form of stock, diluting the value of each share outstanding.

Another type of dividend is paid out in shares of stock. This type of dividend is called a **stock dividend**. A stock dividend is not a true dividend because it is not paid in cash. The effect of a stock dividend is to increase the number of shares that each owner holds. Since there are more shares outstanding, each is simply worth less.

A stock dividend is commonly expressed as a percentage; for example, a 20 percent stock dividend means that a shareholder receives one new share for every five currently owned (a 20 percent increase). Since every shareholder owns 20 percent more stock, the total number of shares outstanding rises by 20 percent. As we will see in a moment, the result is that each share of stock is worth about 20 percent less.

A **stock split** is essentially the same thing as a stock dividend, except that a split is expressed as a ratio instead of a percentage. When a split is declared, each share is split up to create additional shares. For example, in a three-for-one stock split, each old share is split into three new shares.

By convention, stock dividends of less than 20 to 25 percent are called *small stock dividends*. A stock dividend greater than this 20 to 25 percent is called a *large stock dividend*. Large stock dividends are not uncommon. For example, in April 2008, mining equipment company Bucyrus International announced a two-for-one stock split in the form of a 100 percent stock dividend. The previous month, Steel Dynamics had announced a similar split. Except for some relatively minor accounting differences, a stock dividend has the same effect as a stock split. In fact, you can see the relationship between the two because both companies announced the stock dividend in the same way a stock split would be announced.

Value of Stock Splits and Stock Dividends

The laws of logic tell us that stock splits and stock dividends can (1) leave the value of the firm unaffected, (2) increase its value, or (3) decrease its value. Unfortunately, the issues are complex enough that one cannot easily determine which of the three relationships holds.

The Benchmark Case A strong case can be made that stock dividends and splits do not change either the wealth of any shareholder or the wealth of the firm as a whole. The reason is that they are just paper transactions and simply alter the number of shares outstanding. For example, if a firm declares a two-for-one split, all that happens is that the number of shares is doubled, with the result that each share is worth half as much. The total value is not affected.

Although this simple conclusion is relatively obvious, there are reasons that are often given to suggest that there may be some benefits to these actions. The typical financial manager is aware of many real-world complexities, and, for that reason, the stock split or stock dividend decision is not treated lightly in practice.

Popular Trading Range Proponents of stock dividends and stock splits frequently argue that a security has a proper **trading range**. When the security is priced above this level, many investors do not have the funds to buy the common trading unit of 100 shares, called a *round lot*. Although securities can be purchased in *odd-lot* form (fewer than 100 shares), the commissions are greater. Thus, firms will split the stock to keep the price in this trading range.

Although this argument is a popular one, its validity is questionable for a number of reasons. Mutual funds, pension funds, and other institutions have steadily increased their trading activity since World War II and now handle a sizable percentage of total trading volume (on the order of 80 percent of NYSE trading volume, for example). Because these institutions buy and sell in huge amounts, the individual share price is of little concern.

Furthermore, we sometimes observe share prices that are quite large without appearing to cause problems. For example, consider the Swiss chocolatier Lindt. In June 2009, Lindt shares were selling for around 24,000 Swiss francs each, or about \$22,100. A round lot would have cost a cool \$2.21 million. This is fairly expensive, but not compared to Berkshire-Hathaway, the U.S. company run by legendary investor Warren Buffett. In June 2009, each share of the company's class A stock sold for about \$90,000, down from

stock split

An increase in a firm's shares outstanding without any change in owners' equity.

Information on upcoming stock splits is available on the splits calendar at www.investmenthouse.com/1stockplits4.htm and finance.yahoo.com.

trading range

Price range between highest and lowest prices at which a stock is traded.

a recent high of \$147,000 in September 2008 (the class B stock was much cheaper at \$2,900 per share).

Finally, there is evidence that stock splits may actually decrease the liquidity of the company's shares. Following a two-for-one split, the number of shares traded should more than double if liquidity is increased by the split. This doesn't appear to happen, and the opposite is sometimes observed.

Reverse Splits

reverse split

Stock split under which a firm's number of shares outstanding is reduced.

A less frequently encountered financial maneuver is the **reverse split**. For example, in May 2009, marine transportation and equipment manufacturer American Commercial Lines underwent a one-for-four reverse stock split, and, in March 2009, Time Warner Cable did a one-for-three reverse stock split. In a one-for-three reverse split, each investor exchanges three old shares for one new share. The par value is tripled in the process. In May 2009, General Motors proposed a whopper, a 1-for-100 reverse split. However, the company filed for bankruptcy a few weeks later, so the reverse split was not executed.

Given real-world imperfections, three related reasons are cited for reverse splits. First, transaction costs to shareholders may be less after the reverse split. Second, the liquidity and marketability of a company's stock might be improved when its price is raised to the popular trading range. Third, stocks selling at prices below a certain level are not considered respectable, meaning that investors underestimate these firms' earnings, cash flow, growth, and stability. Some financial analysts argue that a reverse split can help achieve instant respectability. As was the case with stock splits, none of these reasons is particularly compelling, especially not the third one.

There are two other reasons for reverse splits. First, stock exchanges have minimum price per share requirements. A reverse split may bring the stock price up to such a minimum. For example, NASDAQ delists companies whose stock price drops below \$1 per share for 30 days. Following the collapse of the Internet boom in 2001–2002, a large number of Internet-related companies found themselves in danger of being delisted and used reverse splits to boost their stock prices. Second, companies sometimes perform reverse splits and, at the same time, buy out any stockholders who end up with less than a certain number of shares.

For example, in February 2009, Computer Horizons completed a reverse/forward split. In this case, the company first did a 1-for-500 reverse stock split. The company repurchased all shares held by stockholders with less than one share of stock, thereby eliminating small shareholders (and reducing the total number of shareholders). The purpose of the reverse split was to allow the company to “go dark.” The reverse split and share repurchase left the company with fewer than 300 shareholders, so it would no longer be required to file periodic reports with the SEC. What made the proposal especially imaginative was that immediately after the reverse split, the company did a 500-for-1 ordinary split to restore the stock to its original cost!

CONCEPT QUESTIONS

14.5a What is the effect of a stock split on stockholder wealth?

14.5b What is a reverse split?

SUMMARY AND CONCLUSIONS

In this chapter, we first discussed the types of dividends and how they are paid. We then defined dividend policy and examined whether or not dividend policy matters. Next, we illustrated how a firm might establish a dividend policy and described an important alternative to cash dividends, a share repurchase.

In covering these subjects, we saw that:

1. Dividend policy is irrelevant when there are no taxes or other imperfections.
2. Individual shareholder income taxes and new issue flotation costs are real-world considerations that favor a low-dividend payout. With taxes and new issue costs, the firm should pay out dividends only after all positive NPV projects have been fully financed.
3. There are groups in the economy that may favor a high payout. These include many large institutions such as pension plans. Recognizing that some groups prefer a high payout and some prefer a low payout, the clientele effect supports the idea that dividend policy responds to the needs of stockholders. For example, if 40 percent of the stockholders prefer low dividends and 60 percent of the stockholders prefer high dividends, approximately 40 percent of companies will have a low-dividend payout, while 60 percent will have a high payout. This sharply reduces the impact of any individual firm's dividend policy on its market price.
4. A firm wishing to pursue a strict residual dividend payout will have an unstable dividend. Dividend stability is usually viewed as highly desirable. We therefore discussed a compromise strategy that provides for a stable dividend and appears to be quite similar to the dividend policies many firms follow in practice.
5. A stock repurchase acts much like a cash dividend, but has a significant tax advantage. Stock repurchases are therefore a very useful part of overall dividend policy.

To close out our discussion of dividends, we emphasize one last time the difference between dividends and dividend policy. Dividends are important, because the value of a share of stock is ultimately determined by the dividends that will be paid. What is less clear is whether or not the time pattern of dividends (more now versus more later) matters. This is the dividend policy question, and it is not easy to give a definitive answer to it.

CHAPTER REVIEW AND SELF-TEST PROBLEM

- 14.1 Repurchase versus Cash Dividend.** Trantor Corporation is deciding whether to pay out \$300 in excess cash in the form of an extra dividend or a share repurchase. Current earnings are \$1.50 per share, and the stock sells for \$15. The market value balance sheet before paying out the \$300 is as follows:

Market Value Balance Sheet (before paying out excess cash)			
Excess cash	\$ 300	Debt	\$ 400
Other assets	1,600	Equity	1,500
Total	<u>\$1,900</u>	Total	<u>\$1,900</u>

Evaluate the two alternatives in terms of the effect on the price per share of the stock, the EPS, and the PE ratio.

■ Answer to Chapter Review and Self-Test Problem

- 14.1** The market value of the equity is \$1,500. The price per share is \$15, so there are 100 shares outstanding. The cash dividend would amount to $\$300/100 = \3 per share. When the stock goes ex dividend, the price will drop by \$3 per share to \$12. Put another way, the total assets decrease by \$300, so the equity value goes down by this amount to \$1,200. With 100 shares, the new stock price is \$12 per share. After the dividend, EPS will be the same, \$1.50, but the PE ratio will be $\$12/1.50 = 8$ times.

With a repurchase, $\$300/15 = 20$ shares will be bought up, leaving 80. The equity will again be worth \$1,200 total. With 80 shares, this is $\$1,200/80 = \15 per share, so the price doesn't change. Total earnings for Trantor must be $\$1.50 \times 100 = \150 . After the repurchase, EPS will be higher at $\$150/80 = \1.875 . The PE ratio, however, will still be $\$15/1.875 = 8$ times.

CRITICAL THINKING AND CONCEPTS REVIEW

- L0 2** **14.1 Dividend Policy Irrelevance.** How is it possible that dividends are so important, but, at the same time, dividend policy is irrelevant?
- L0 4** **14.2 Stock Repurchases.** What is the impact of a stock repurchase on a company's debt ratio? Does this suggest another use for excess cash?
- L0 1** **14.3 Life Cycle Theory of Dividends.** Explain the life-cycle theory of dividend payments. How does it explain corporate dividend payments that are seen in the stock market?
- L0 1** **14.4 Dividend Chronology.** On Tuesday, December 8, Hometown Power Co.'s board of directors declares a dividend of 75 cents per share payable on Wednesday, January 17, to shareholders of record as of Wednesday, January 3. When is the ex-dividend date? If a shareholder buys stock before that date, who gets the dividends on those shares, the buyer or the seller?
- L0 1** **14.5 Alternative Dividends.** Some corporations, like one British company that offers its large shareholders free crematorium use, pay dividends in kind (that is, offer their services to shareholders at below-market cost). Should mutual funds invest in stocks that pay these dividends in kind? (The fundholders do not receive these services.)
- L0 2** **14.6 Dividends and Stock Price.** If increases in dividends tend to be followed by (immediate) increases in share prices, how can it be said that dividend policy is irrelevant?
- L0 2** **14.7 Dividends and Stock Price.** Last month, Central Virginia Power Company, which had been having trouble with cost overruns on a nuclear power plant that it had been building, announced that it was "temporarily suspending dividend payments due to the cash flow crunch associated with its investment program." The company's stock price dropped from \$28.50 to \$25 when this announcement was made. How would you interpret this change in the stock price (that is, what would you say caused it)?
- L0 1** **14.8 Dividend Reinvestment Plans.** The DRK Corporation has recently developed a dividend reinvestment plan (DRIP). The plan allows investors to reinvest cash dividends automatically in DRK in exchange for new shares

of stock. Over time, investors in DRK will be able to build their holdings by reinvesting dividends to purchase additional shares of the company.

Over 1,000 companies offer dividend reinvestment plans. Most companies with DRIPs charge no brokerage or service fees. In fact, the shares of DRK will be purchased at a 10 percent discount from the market price.

A consultant for DRK estimates that about 75 percent of DRK's shareholders will take part in this plan. This is somewhat higher than the average.

Evaluate DRK's dividend reinvestment plan. Will it increase shareholder wealth? Discuss the advantages and disadvantages involved here.

L0 2 **14.9 Dividend Policy.** During 2008, only 21 companies went public with common stock offerings, raising a combined total of \$22.8 billion. Relatively few of these 21 companies involved paid cash dividends. Why do you think most chose not to pay dividends?

L0 1 **14.10 Investment and Dividends.** The Phew Charitable Trust pays no taxes on its capital gains or on its dividend income or interest income. Would it be irrational for it to have low-dividend, high-growth stocks in its portfolio? Would it be irrational for it to have municipal bonds in its portfolio? Explain.

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

- L0 2** **1. Dividends and Stock Prices.** Your portfolio is 180 shares of Sunny Morning, Inc. The stock currently sells for \$88 per share. The company has announced a dividend of \$1.90 per share with an ex-dividend date of April 19. Assuming no taxes, how much will your stock be worth on April 19?
- L0 2** **2. Dividends and Stock Prices.** It is April 19. Using the information in the previous problem, what is your total portfolio value?
- L0 2** **3. Dividends and Taxes.** Palmer, Inc., has declared a \$5.80 per share dividend. Suppose capital gains are not taxed, but dividends are taxed at 15 percent. New IRS regulations require that taxes be withheld at the time the dividend is paid. Palmer sells for \$109 per share, and the stock is about to go ex-dividend. What do you think the ex-dividend price will be?
- L0 3** **4. Stock Dividends.** The owners' equity accounts for Trans World International are shown here:

Basic
(Questions 1–11)

Common stock (\$1 par value)	\$ 30,000
Capital surplus	185,000
Retained earnings	610,000
Total owners' equity	<u>\$825,000</u>

- a. If Trans World stock currently sells for \$42 per share and a 10 percent stock dividend is declared, how many new shares will be distributed? Show how the equity accounts would change.
- b. If Trans World declared a 25 percent stock dividend, how would the accounts change?

LO 3

5. **Stock Splits.** For the company in Problem 4, show how the equity accounts will change if:

- Trans World declares a two-for-one stock split. How many shares are outstanding now? What is the new par value per share?
- Trans World declares a one-for-five reverse stock split. How many shares are outstanding now? What is the new par value per share?

LO 3

6. **Stock Splits and Stock Dividends.** Bermuda Triangle Corporation (BTC) currently has 500,000 shares of stock outstanding that sell for \$83 per share. Assuming no market imperfections or tax effects exist, what will the share price be after:

- BTC has a five-for-three stock split?
- BTC has a 15 percent stock dividend?
- BTC has a 42.5 percent stock dividend?
- BTC has a four-for-seven reverse stock split?
- Determine the new number of shares outstanding in parts (a) through (d).

LO 1

7. **Regular Dividends.** The balance sheet for Price Cut, Inc., is shown here in market value terms. There are 25,000 shares of stock outstanding.

Market Value Balance Sheet

Cash	\$110,000	Equity	\$590,000
Fixed assets	480,000	Total	\$590,000
Total	<u>\$590,000</u>		

The company has declared a dividend of \$1.20 per share. The stock goes ex-dividend tomorrow. Ignoring any tax effects, what is the stock selling for today? What will it sell for tomorrow? What will the balance sheet look like after the dividends are paid?

LO 4

8. **Share Repurchase.** In the previous problem, suppose the company has announced it is going to repurchase \$30,000 worth of stock instead of paying a dividend. What effect will this transaction have on the equity of the firm? How many shares will be outstanding? What will the price per share be after the repurchase? Ignoring tax effects, show how the share repurchase is effectively the same as a cash dividend.

LO 3

9. **Stock Dividends.** The market value balance sheet for Tidwell Manufacturing is shown here. Tidwell has declared a 20 percent stock dividend. The stock goes ex-dividend tomorrow (the chronology for a stock dividend is similar to that for a cash dividend). There are 16,000 shares of stock outstanding. What will the ex-dividend price be?

Market Value Balance Sheet

Cash	\$115,000	Debt	\$145,000
Fixed assets	630,000	Equity	600,000
Total	<u>\$745,000</u>	Total	<u>\$745,000</u>

LO 3

10. **Stock Dividends.** The company with the common equity accounts shown here has declared a 10 percent stock dividend at a time when the market value of its

stock is \$64 per share. What effects on the equity accounts will the distribution of the stock dividend have?

Common stock (\$1 par value)	\$ 380,000
Capital surplus	1,570,000
Retained earnings	<u>3,860,000</u>
Total owners' equity	<u>\$5,810,000</u>

L0 3

- 11. Stock Splits.** In the previous problem, suppose the company instead decides on a two-for-one stock split. The firm's 42-cent-per-share cash dividend on the new (postsplit) shares represents an increase of 10 percent over last year's dividend on the presplit stock. What effect does this have on the equity accounts? What was last year's dividend per share?

L0 4

- 12. Stock Repurchase.** Flashback Corporation is evaluating an extra dividend versus a share repurchase. In either case, \$16,320 would be spent. Current earnings are \$3.10 per share, and the stock currently sells for \$85 per share. There are 3,400 shares outstanding. Ignore taxes and other imperfections in answering the first two questions.

- Evaluate the two alternatives in terms of the effect on the price per share of the stock and shareholder wealth.
- What will be the effect on Flashback's EPS and PE ratio under the two different scenarios?
- In the real world, which of these actions would you recommend? Why?

Intermediate
(Question 12)

L0 2

- 13. Expected Return, Dividends, and Taxes.** The Gecko Company and the Gordon Company are two firms whose business risk is the same but that have different dividend policies. Gecko pays no dividend, whereas Gordon has an expected dividend yield of 4 percent. Suppose the capital gains tax rate is zero, whereas the income tax rate is 35 percent. Gecko has an expected earnings growth rate of 13 percent annually, and its stock price is expected to grow at this same rate. If the aftertax expected returns on the two stocks are equal (because they are in the same risk class), what is the pretax required return on Gordon's stock?

Challenge
(Questions 13–14)

L0 2

- 14. Dividends and Taxes.** As discussed in the text, in the absence of market imperfections and tax effects, we would expect the share price to decline by the amount of the dividend payment when the stock goes ex dividend. Once we consider the role of taxes, however, this is not necessarily true. One model has been proposed that incorporates tax effects into determining the ex-dividend price:

$$(P_0 - P_x)/D = (1 - T_p)/(1 - T_G)$$

where P_0 is the price just before the stock goes ex, P_x is the ex-dividend share price, D is the amount of the dividend per share, T_p is the relevant marginal personal tax rate on dividends, and T_G is the effective marginal tax rate on capital gains.

- If $T_p = T_G = 0$, how much will the share price fall when the stock goes ex?
- If $T_p = 15$ percent and $T_G = 0$, how much will the share price fall?
- If $T_p = 15$ percent and $T_G = 30$ percent, how much will the share price fall?

- d. Suppose the only owners of stock are corporations. Recall that corporations get at least a 70 percent exemption from taxation on the dividend income they receive, but they do not get such an exemption on capital gains. If the corporation's income and capital gains tax rates are both 35 percent, what does this model predict the ex-dividend share price will be?
- e. What does this problem tell you about real-world tax considerations and the dividend policy of the firm?

WHAT'S ON THE WEB?

- 14.1 Dividend Reinvestment Plans.** Dividend reinvestment plans (DRIPs) permit shareholders to automatically reinvest cash dividends in the company. To find out more about DRIPs, go to www.fool.com and answer the following questions about DRIPs. What are the advantages Motley Fool lists for DRIPs? What are the different types of DRIPs? What is a direct purchase plan? How does a direct purchase plan differ from a DRIP?
- 14.2 Dividends.** Go to www.earnings.com and find the list of dividends. How many companies went "ex" today? What is the largest declared dividend? For the stocks going "ex" today, what is the longest time until the payable date?
- 14.3 Stock Splits.** Go to www.earnings.com and find the stock splits. How many stock splits are listed? How many are reverse splits? What is the largest split and the largest reverse split in terms of shares? Pick a company and follow the link. What type of information do you find?
- 14.4 Stock Splits.** How many times has Procter & Gamble stock split? Go to P&G's Web page at www.pg.com and find the history of the company's stock splits. When did Procter & Gamble stock first split? What was the split? When was the most recent stock split? If you owned 100 shares of Procter & Gamble on January 1, 1950, and never sold any shares, how many shares would you own today?

CHAPTER CASE

ELECTRONIC TIMING, INC.

Electronic Timing, Inc. (ETI), is a small company founded 15 years ago by electronics engineers Tom Miller and Jessica Kerr. ETI manufactures integrated circuits to capitalize on the complex mixed-signal design technology and has recently entered the market for frequency timing generators, or silicon timing devices, which provide the timing signals or “clocks” necessary to synchronize electronic systems. Its clock products originally were used in PC video graphics applications, but the market subsequently expanded to include motherboards, PC peripheral devices, and other digital consumer electronics, such as digital television boxes and game consoles. ETI also designs and markets custom application-specific integrated circuits (ASICs) for industrial customers. The ASIC’s design combines analog and digital, or mixed-signal, technology. In addition to Tom and Jessica, Nolan Pittman,

who provided capital for the company, is the third primary owner. Each owns 25 percent of the 1 million shares outstanding. The company has several other individuals, including current employees, who own the remaining shares.

Recently, the company designed a new computer motherboard. The company’s design is both more efficient and less expensive to manufacture, and the ETI design is expected to become standard in many personal computers. After investigating the possibility of manufacturing the new motherboard, ETI determined that the costs involved in building a new plant would be prohibitive. The owners also decided that they were unwilling to bring in another large outside owner. Instead, ETI sold the design to an outside firm. The sale of the motherboard design was completed for an aftertax payment of \$30 million. ■

QUESTIONS

1. Tom believes the company should use the extra cash to pay a special one-time dividend. How will this proposal affect the stock price? How will it affect the value of the company?
2. Jessica believes the company should use the extra cash to pay off debt and upgrade and expand its existing manufacturing capability. How would Jessica’s proposals affect the company?
3. Nolan favors a share repurchase. He argues that a repurchase will increase the company’s P/E ratio, return on assets, and return on equity. Are his arguments correct? How will a share repurchase affect the value of the company?
4. Another option discussed by Tom, Jessica, and Nolan would be to begin a regular dividend payment to shareholders. How would you evaluate this proposal?
5. One way to value a share of stock is the dividend growth, or growing perpetuity, model. Consider the

following: The dividend payout ratio is 1 minus b , where b is the “retention” or “plowback” ratio. So, the dividend next year will be the earnings next year, E_1 , times 1 minus the retention ratio. The most commonly used equation to calculate the sustainable growth rate is the return on equity times the retention ratio. Substituting these relationships into the dividend growth model, we get the following equation to calculate the price of a share of stock today:

$$P_0 = \frac{E_1(1 - b)}{R_s - \text{ROE} \times b}$$

What are the implications of this result in terms of whether the company should pay a dividend or upgrade and expand its manufacturing capability? Explain.

6. Does the question of whether the company should pay a dividend depend on whether the company is organized as a corporation or an LLC?

Raising Capital

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Explain the venture capital market and its role in the financing of new, high-risk ventures.
- LO 2** Describe how securities are sold to the public and the role of investment banks in the process.
- LO 3** Explain initial public offerings and identify some of the costs of going public.

In an eagerly awaited initial public offering (IPO), credit card giant Visa went public on March 19, 2008. Assisted by J. P. Morgan, Goldman Sachs, and Bank of America, Visa sold about 447 million shares of stock to the public at a price of \$44. In a nod to the public's unfortunate fascination with credit, the stock price jumped to \$56.50 at the end of the day, a 28 percent increase. The Visa offer raised a total of \$19.67 billion, easily the largest IPO in U.S. history. The previous recordholder was the AT&T Wireless offering in 2000, which

raised \$10.6 billion. In this chapter, we will examine the process by which companies such as Visa sell stock to the public, the costs of doing so, and the role of investment banks in the process.

Businesses large and small have one thing in common: They need long-term capital. This chapter describes how they get it. We pay particular attention to what is probably the most important stage in a company's financial life cycle, the initial public offering. Such offerings are the process by which companies convert from being privately owned to being publicly owned. For many, starting a company, growing it, and taking it public is the ultimate entrepreneurial dream.

Visit us at www.mhhe.com/rwj

All firms must, at varying times, obtain capital. To do so, a firm must either borrow the money (debt financing), sell a portion of the firm (equity financing), or both. How a firm raises capital depends a great deal on the size of the firm, its life cycle stage, and its growth prospects.

In this chapter, we examine some of the ways in which firms actually raise capital. We begin by looking at companies in the early stages of their lives and the importance of

venture capital for such firms. We then look at the process of going public and the role of investment banks. Along the way, we discuss many of the issues associated with selling securities to the public and their implications for all types of firms. We close the chapter with a discussion of sources of debt capital.¹

THE FINANCING LIFE CYCLE OF A FIRM: EARLY-STAGE FINANCING AND VENTURE CAPITAL

15.1

One day, you and a friend have a great idea for a new computer software product that helps users communicate using the next generation Meganet. Filled with entrepreneurial zeal, you christen the product MegaComm and set about bringing it to market.

Working nights and weekends, you are able to create a prototype of your product. It doesn't actually work, but at least you can show it around to illustrate your idea. To actually develop the product, you need to hire programmers, buy computers, rent office space, and so on. Unfortunately, because you are both college students, your combined assets are not sufficient to fund a pizza party, much less a start-up company. You need what is often referred to as OPM—other people's money.

Your first thought might be to approach a bank for a loan. You would probably discover, however, that banks are generally not interested in making loans to start-up companies with no assets (other than an idea) run by fledgling entrepreneurs with no track record. Instead, your search for capital would very likely lead you to the **venture capital (VC)** market.

Venture Capital

The term *venture capital* does not have a precise meaning, but it generally refers to financing for new, often high-risk ventures. For example, before it went public, Internet auctioneer eBay was venture capital financed. Individual venture capitalists invest their own money, whereas venture capital firms specialize in pooling funds from various sources and investing them. The underlying sources of funds for such firms include individuals, pension funds, insurance companies, large corporations, and even university endowment funds. The broad term *private equity* is often used to label the rapidly growing area of equity financing for nonpublic companies.²

Venture capitalists and venture capital firms recognize that many, or even most, new ventures will not fly, but the occasional one will. The potential profits are enormous in such cases. To limit their risk, venture capitalists generally provide financing in stages. At each stage, enough money is invested to reach the next milestone or planning stage. For example, the *first-stage* (or first “round”) *financing* might be enough to get a prototype built and a manufacturing plan completed. Based on the results, the *second-stage financing* might be a major investment needed to actually begin manufacturing, marketing, and

venture capital (VC)

Financing for new, often high-risk ventures.

For a list of well-known VC firms, see www.vfinance.com.

¹ We are indebted to Jay R. Ritter of the University of Florida for helpful comments and suggestions on this chapter.

² So-called “vulture” capitalists specialize in high-risk investments in established, but financially distressed, firms.

distribution. There might be many such stages, each of which represents a key step in the process of growing the company.

Venture capital firms often specialize in different stages. Some specialize in very early “seed money,” or ground floor, financing. In contrast, financing in the later stages might come from venture capitalists specializing in so-called mezzanine level financing, where *mezzanine level* refers to the level just above the ground floor.

The fact that financing is available in stages and is contingent on specified goals being met is a powerful motivating force for the firm’s founders. Often, the founders receive relatively little in the way of salary and have substantial portions of their personal assets tied up in the business. At each stage of financing, the value of the founder’s stake grows and the probability of success rises. If goals are not met, the venture capitalist will withhold further financing, thereby limiting future losses.

In addition to providing financing, venture capitalists generally will actively participate in running the firm, providing the benefit of experience with previous start-ups as well as general business expertise. This is especially true when the firm’s founders have little or no hands-on experience running a company.

The Internet is a tremendous source of venture capital information, both for suppliers and demanders of capital. For example, the site at www.dealflow.com prompts you to search the firm’s database as either an entrepreneur or a venture capitalist (i.e., angel investor).

Some Venture Capital Realities

Although there is a large venture capital market, the truth is that access to venture capital is really very limited. Venture capital companies receive huge numbers of unsolicited proposals, the vast majority of which end up in the circular file (the waste basket). Venture capitalists rely heavily on informal networks of engineers, scientists, lawyers, accountants, bankers, and other venture capitalists to help identify potential investments. As a result, personal contacts are important in gaining access to the venture capital market; it is very much an “introduction” market.

Another simple fact about venture capital is that it is incredibly expensive. In a typical deal, the venture capitalist will demand (and get) 40 percent or more of the equity in the company. The venture capitalist will frequently hold voting convertible preferred stock, which gives various priorities in the event that the company is sold or liquidated. The venture capitalist will typically demand (and get) several seats on the company’s board of directors and may even appoint one or more members of senior management.

Choosing a Venture Capitalist

Some start-up companies, particularly those headed by experienced, previously successful entrepreneurs, will be in such demand that they will have the luxury of looking beyond the money in choosing a venture capitalist. There are some key considerations in such a case, some of which can be summarized as follows:

1. Financial strength is important. The venture capitalist needs to have the resources and financial reserves for additional financing stages should they become necessary. This doesn’t mean that bigger is necessarily better, however, because of our next consideration.
2. Style is important. Some venture capitalists will wish to be very much involved in day-to-day operations and decision making, whereas others will be content with monthly reports. Which is better depends on the firm and also on the venture capitalists’ business skills. In addition, a large venture capital firm may be less flexible and more bureaucratic than a smaller “boutique” firm.

3. References are important. Has the venture capitalist been successful with similar firms? Of equal importance, how has the venture capitalist dealt with situations that didn't work out?
4. Contacts are important. A venture capitalist may be able to help the business in ways other than helping with financing and management by providing introductions to potentially important customers, suppliers, and other industry contacts. Venture capitalist firms frequently specialize in a few particular industries, and such specialization could prove quite valuable.
5. Exit strategy is important. Venture capitalists are generally not long-term investors. How and under what circumstances the venture capitalist will "cash out" of the business should be carefully evaluated.

Conclusion

If a start-up succeeds, the big payoff frequently comes when the company is sold to another company or goes public. Either way, investment bankers are often involved in the process.

CONCEPT QUESTIONS

15.1a What is venture capital?

15.1b Why is venture capital often provided in stages?

SELLING SECURITIES TO THE PUBLIC: THE BASIC PROCEDURE

15.2

We discuss the process of selling securities to the public in the next several sections, paying particular attention to the process of going public.

There are many rules and regulations surrounding the process of selling securities. The Securities Act of 1933 is the origin of federal regulations for all new interstate securities issues. The Securities Exchange Act of 1934 is the basis for regulating securities already outstanding. The Securities and Exchange Commission, or SEC, administers both acts.

There is a series of steps involved in issuing securities to the public. In general terms, the basic procedure is as follows:

1. Management's first step in issuing any securities to the public is to obtain approval from the board of directors. In some cases, the number of authorized shares of common stock must be increased. This requires a vote of the shareholders.
2. The firm must prepare a **registration statement** and file it with the SEC. With just a few exceptions, the registration statement is required for all public, interstate issues of securities.

Normally, a registration statement contains many pages of financial information, including a financial history, details of the existing business, proposed financing, and plans for the future.

3. The SEC examines the registration statement during a waiting period. During this time, the firm may distribute copies of a preliminary **prospectus**. The prospectus contains much of the information put into the registration statement, and it is given to

Find out what firms are going public this week at marketwatch.com.

registration statement

A statement filed with the SEC that discloses all material information concerning the corporation making a public offering.

prospectus

A legal document describing details of the issuing corporation and the proposed offering to potential investors.

red herring

A preliminary prospectus distributed to prospective investors in a new issue of securities.

potential investors by the firm. The preliminary prospectus is sometimes called a **red herring**, in part because bold red letters are printed on the cover.

A registration statement becomes effective on the twentieth day after its filing unless the SEC sends a *letter of comment* suggesting changes. In that case, after the changes are made, the 20-day waiting period starts again. It is important to note that the SEC does not consider the economic merits of the proposed sale; it merely makes sure that various rules and regulations are followed. Also, the SEC generally does not check the accuracy or truthfulness of information in the prospectus.

The registration statement does not initially contain the price of the new issue. Usually, a price amendment is filed at or near the end of the waiting period, and the registration becomes effective.

4. The company cannot sell the securities during the waiting period. However, oral offers can be made.
5. On the effective date of the registration statement, a price is determined and a full-fledged selling effort gets under way. A final prospectus must accompany the delivery of securities or confirmation of sale, whichever comes first.

tombstone

An advertisement announcing a public offering.

Tombstone advertisements (or, simply, tombstones) are used by underwriters after the waiting period. An example is reproduced in Figure 15.1. The tombstone contains the name of the issuer (the World Wrestling Federation, or WWF, in this case). It provides some information about the issue, and it lists the investment banks (the underwriters) that are involved with selling the issue. The role of the investment banks in selling securities is discussed more fully in the following pages.

The investment banks are divided into groups called *brackets* on the tombstone, based on their participation in the issue, and the names of the banks are listed alphabetically within each bracket. The brackets are often viewed as a kind of pecking order. In general, the higher the bracket, the greater is the underwriter's prestige.

CONCEPT QUESTIONS

15.2a What are the basic procedures in selling a new issue?

15.2b What is a registration statement?

15.3**ALTERNATIVE ISSUE METHODS****general cash offer**

An issue of securities offered for sale to the general public on a cash basis.

rights offer

A public issue of securities in which securities are first offered to existing shareholders. Also called a rights offering.

When a company decides to issue a new security, it can sell it as a public issue or a private issue. In the case of a public issue, the firm is required to register the issue with the SEC. However, if the issue is to be sold to fewer than 35 investors, the sale can be carried out privately. In this case, a registration statement is not required.³

For equity sales, there are two kinds of public issues: a **general cash offer** and a **rights offer** (or *rights offering*). With a cash offer, securities are offered to the general public on a “first come, first served” basis. With a rights offer, securities are initially offered only to

³ A variety of different arrangements can be made for private equity issues. Selling unregistered securities avoids the costs of complying with the Securities Exchange Act of 1934. Regulation significantly restricts the resale of unregistered equity securities. For example, the purchaser may be required to hold the securities for at least two years. Many of the restrictions were significantly eased in 1990 for very large institutional investors, however. The private placement of bonds is discussed in a later section.

This announcement is neither an offer to sell nor a solicitation of an offer to buy any of these securities.
The offering is made only by the Prospectus.

New Issue

11,500,000 Shares

World Wrestling Federation Entertainment, Inc.

Class A Common Stock

Price \$17.00 Per Share

Copies of the Prospectus may be obtained in any State in which this announcement is circulated from only such of the Underwriters, including the undersigned, as may lawfully offer these securities in such State.

U.S. Offering

9,200,000 Shares

This portion of the underwriting is being offered in the United States and Canada.

existing owners. Rights offers are fairly common in other countries, but they are relatively rare in the United States, particularly in recent years. We therefore focus on cash offers in this chapter.

initial public offering

A company's first equity issue made available to the public. Also called an unseasoned new issue or an IPO.

seasoned equity offering (SEO)

A new equity issue of securities by a company that has previously issued securities to the public.

The first public equity issue that is made by a company is referred to as an **initial public offering**, an IPO, or an *unseasoned new issue*. This issue occurs when a company decides to go public. Obviously, all initial public offerings are cash offers. If the firm's existing shareholders wanted to buy the shares, the firm wouldn't have to sell them publicly in the first place.

A **seasoned equity offering (SEO)** is a new issue for a company with securities that have been previously issued. The terms *secondary* and *follow-on offering* are also commonly used. A seasoned equity offering of common stock can be made by using a cash offer or a rights offer.

These methods of issuing new securities are shown in Table 15.1. They are discussed in sections 15.4 through 15.9.

CONCEPT QUESTIONS	
15.3a	Why is an initial public offering necessarily a cash offer?
15.3b	What is the difference between a rights offer and a cash offer?

TABLE 15.1	Method	Type	Definition
The methods of issuing new securities	Public Traditional negotiated cash offer	Firm commitment cash offer	Company negotiates an agreement with an investment banker to underwrite and distribute the new shares. A specified number of shares are bought by underwriters and sold at a higher price.
		Best efforts cash offer	Company has investment bankers sell as many of the new shares as possible at the agreed-upon price. There is no guarantee concerning how much cash will be raised. Some best efforts offerings do not use an underwriter.
		Dutch auction cash offer	Company has investment bankers auction shares to determine the highest offer price obtainable for a given number of shares to be sold.
	Privileged subscription	Direct rights offer	Company offers the new stock directly to its existing shareholders.
		Standby rights offer	Like the direct rights offer, this contains a privileged subscription arrangement with existing shareholders. The net proceeds are guaranteed by the underwriters.
	Nontraditional cash offer	Shelf cash offer	Qualifying companies can authorize all the shares they expect to sell over a two-year period and sell them when needed.
		Competitive firm cash offer	Company can elect to award the underwriting contract through a public auction instead of negotiation.
	Private	Direct placement	Securities are sold directly to the purchaser, who, at least until recently, generally could not resell the securities for at least two years.

UNDERWRITERS

If the public issue of securities is a cash offer, **underwriters** are usually involved. Underwriting is an important line of business for large investment firms such as Merrill Lynch. Underwriters perform services such as the following for corporate issuers:

1. Formulating the method used to issue the securities.
2. Pricing the new securities.
3. Selling the new securities.

Typically, the underwriter buys the securities for less than the offering price and accepts the risk of not being able to sell them. The difference between the underwriter's buying price and the offering price is called the **spread**, or discount. It is the basic compensation received by the underwriter. Sometimes the underwriter will get noncash compensation in the form of warrants and stock in addition to the spread.⁴

Underwriters combine to form an underwriting group called a **syndicate** to share the risk and to help sell the issue. In a syndicate, one or more managers arrange the offering. This manager is designated as the lead manager, or principal manager. The lead manager typically has the responsibility of pricing the securities. The other underwriters in the syndicate serve primarily to distribute the issue.

Choosing an Underwriter

A firm can offer its securities to the highest bidding underwriter on a *competitive offer* basis, or it can negotiate directly with an underwriter. In most cases, companies usually do new issues of debt and equity on a *negotiated offer* basis.

There is evidence that competitive underwriting is cheaper to use than negotiated underwriting, and the underlying reasons for the dominance of negotiated underwriting in the United States are the subject of ongoing debate.

Types of Underwriting

Two basic types of underwriting are involved in a cash offer: firm commitment and best efforts.

Firm Commitment Underwriting In **firm commitment underwriting**, the issuer sells the entire issue to the underwriters, who then attempt to resell it. This is the most prevalent type of underwriting in the United States. This is really just a purchase-resale arrangement, and the underwriter's fee is the spread. For a new issue of seasoned equity, the underwriters can look at the market price to determine what the issue should sell for, and 95 percent of all such new issues are firm commitments.

If the underwriter cannot sell all of the issue at the agreed-upon offering price, it may have to lower the price on the unsold shares. Nonetheless, with firm commitment underwriting, the issuer receives the agreed-upon amount, and all the risk associated with selling the issue is transferred to the underwriter.

Because the offering price usually isn't set until the underwriters have investigated how receptive the market is to the issue, this risk is usually minimal. Also, because the offering price usually is not set until just before selling commences, the issuer doesn't know precisely what its net proceeds will be until that time.

15.4

underwriters

Investment firms that act as intermediaries between a company selling securities and the investing public.

spread

Compensation to the underwriter, determined by the difference between the underwriter's buying price and offering price.

syndicate

A group of underwriters formed to share the risk and to help sell an issue.

firm commitment underwriting

The type of underwriting in which the underwriter buys the entire issue, assuming full financial responsibility for any unsold shares.

⁴ Warrants are essentially options to buy stock at a fixed price for some fixed period of time.

best efforts underwriting

The type of underwriting in which the underwriter sells as much of the issue as possible, but can return any unsold shares to the issuer without financial responsibility.

Dutch auction underwriting

The type of underwriting in which the offer price is set based on competitive bidding by investors. Also known as a *uniform price auction*.

Best Efforts Underwriting In **best efforts underwriting**, the underwriter is legally bound to use “best efforts” to sell the securities at the agreed-upon offering price. Beyond this, the underwriter does not guarantee any particular amount of money to the issuer. This form of underwriting has become very uncommon in recent years; firm commitments are now the dominant form.

Dutch Auction Underwriting With **Dutch auction underwriting**, the underwriter does not set a fixed price for the shares to be sold. Instead, the underwriter conducts an auction in which investors bid for shares. The offer price is determined based on the submitted bids. A Dutch auction is also known by the more descriptive name *uniform price auction*. This approach to selling securities to the public is relatively new in the IPO market and has not been widely used there, but it is very common in the bond markets. For example, it is the sole procedure used by the U.S. Treasury to sell enormous quantities of notes, bonds, and bills to the public.

Dutch auction underwriting was much in the news in 2004 because Web search company Google elected to use this approach. The best way to understand a Dutch or uniform price auction is to consider a simple example. Suppose the Rial Company wants to sell 400 shares to the public. The company receives five bids as follows:

Bidder	Quantity	Price
A	100 shares	\$16
B	100 shares	14
C	200 shares	12
D	100 shares	12
E	200 shares	10

Learn all about Dutch auction IPOs at www.wrhambrecht.com.

Thus, bidder A is willing to buy 100 shares at \$16 each, bidder B is willing to buy 100 shares at \$14, and so on. The Rial Company examines the bids to determine the highest price that will result in all 400 shares being sold. So, for example, at \$14, A and B would buy only 200 shares, so that price is too high. Working our way down, all 400 shares won’t be sold until we hit a price of \$12, so \$12 will be the offer price in the IPO. Bidders A through D will receive shares; bidder E will not.

There are two additional important points to observe in our example: First, all the winning bidders will pay \$12, even bidders A and B, who actually bid a higher price. The fact that all successful bidders pay the same price is the reason for the name “uniform price auction.” The idea in such an auction is to encourage bidders to bid aggressively by providing some protection against bidding a price that is too high.

Second, notice that at the \$12 offer price, there are actually bids for 500 shares, which exceeds the 400 shares Rial wants to sell. Thus, there has to be some sort of allocation. How this is done varies a bit, but, in the IPO market, the approach has been to simply compute the ratio of shares offered to shares bid at the offer price or better, which, in our example, is $400/500 = .8$, and allocate bidders that percentage of their bids. In other words, bidders A through D would each receive 80 percent of the shares they bid at a price of \$12 per share.

Green Shoe provision

A contract provision giving the underwriter the option to purchase additional shares from the issuer at the offering price. Also called the over-allotment option.

The Green Shoe Provision

Many underwriting contracts contain a **Green Shoe provision** (sometimes called the *over-allotment option*), which gives the members of the underwriting group the option to

purchase additional shares from the issuer at the offering price.⁵ Essentially all IPOs and SEOs include this provision, but ordinary debt offerings generally do not. The stated reason for the Green Shoe option is to cover excess demand and oversubscriptions. Green Shoe options usually last for about 30 days and involve no more than 15 percent of the newly issued shares.

The Aftermarket

The period after a new issue is initially sold to the public is referred to as the *aftermarket*. The lead underwriter frequently will “stabilize,” or support, the market price for a relatively short time following the offering. This is done by actually selling 115 percent of the issue. If the price rises in the aftermarket, the underwriter will exercise the Green Shoe option to purchase the extra 15 percent needed. If the price declines, however, the underwriter will step in and buy the stock in the open market, thereby supporting the price. In this second case, the underwriter allows the Green Shoe option to expire.⁶

Lockup Agreements

Although they are not required by law, almost all underwriting contracts contain so-called **lockup agreements**. Such agreements specify how long insiders must wait after an IPO before they can sell some or all of their stock. Lockup periods have become fairly standardized in recent years at 180 days. Thus, following an IPO, insiders can’t cash out until six months have gone by, which ensures that they maintain a significant economic interest in the company going public.

Lockup periods are also important because it is not unusual for the number of locked-up shares to exceed the number of shares held by the public, sometimes by a substantial multiple. On the day the lockup period expires, there is the possibility that a large number of shares will hit the market on the same day and thereby depress values. The evidence suggests that, on average, venture capital–backed companies are particularly likely to experience a loss in value on the lockup expiration day.

The Quiet Period

For 40 calendar days following an IPO, the SEC requires that a firm and its managing underwriters observe a “quiet period.” This means that all communications with the public must be limited to ordinary announcements and other purely factual matters. The SEC’s logic is that all relevant information should be contained in the prospectus. An important result of this requirement is that the underwriter’s analysts are prohibited from making recommendations to investors. As soon as the quiet period ends, however, the managing underwriters typically publish research reports, usually accompanied by a favorable “buy” recommendation.

Firms that don’t stay quiet can have their IPOs delayed. For example, just before Google’s IPO, an interview with cofounders Sergey Brin and Larry Page appeared in *Playboy*. The interview almost caused a postponement of the IPO, but Google was able to amend its prospectus in time (by including the article!). However, in May 2004, Salesforce.com’s IPO was delayed because an interview with CEO Marc Benioff appeared in *The New York Times*. Salesforce.com finally went public two months later.

lockup agreement

The part of the underwriting contract that specifies how long insiders must wait after an IPO before they can sell stock.

Learn more about investment banks at Merrill Lynch’s Web site: www.ml.com.

⁵ The term *Green Shoe provision* sounds quite exotic, but the origin is relatively mundane. The term comes from the name of the Green Shoe Manufacturing Company, which, in 1963, was the first issuer to grant such an option.

⁶ Occasionally, the price of a security falls dramatically when the underwriter ceases to stabilize the price. In such cases, Wall Street humorists (the ones who didn’t buy any of the stock) have referred to the period following the aftermarket as the aftermath.

CONCEPT QUESTIONS

15.4a What do underwriters do?

15.4b What is the Green Shoe provision?

15.5

IPOS AND UNDERPRICING

Determining the correct offering price is the most difficult thing an underwriter must do for an initial public offering. The issuing firm faces a potential cost if the offering price is set too high or too low. If the issue is priced too high, it may be unsuccessful and have to be withdrawn. If the issue is priced below the true market value, the issuer's existing shareholders will experience an opportunity loss when they sell their shares for less than they are worth.

Underpricing is fairly common. It obviously helps new shareholders earn a higher return on the shares they buy. However, the existing shareholders of the issuing firm are not helped by underpricing. To them, it is an indirect cost of issuing new securities. For example, consider the Visa IPO we discussed at the beginning of the chapter. The stock opened at \$44 and rose to a first-day high of \$69, before closing at \$56.50, a gain of about 28 percent. On the basis of these numbers, Visa was underpriced by about \$12.50 per share, which means the company missed out on an additional \$5.6 billion or so, the largest dollar amount "left on the table" in history.

Dutch auctions are supposed to eliminate this kind of "pop" in first day prices. As we previously discussed, Google sold 19.6 million shares at a price of \$85 in a Dutch auction IPO. However, the stock closed at \$100.34 on the first day, an increase of 18 percent, so Google missed out on an additional \$300 million.

One of the biggest dollar amounts "left on the table" occurred in 1999 when eToys went public, offering 8.2 million shares. The stock jumped \$57 dollars above the offer price on the first day, which meant eToys left about half a billion dollars on the table! eToys could have used the money; it filed for bankruptcy less than two years later. In May 2002, the company sued its lead underwriter, claiming the offer price was deliberately set too low.

Of course, not all IPOs increase in price on the first day. On May 24, 2006, Vonage Holdings Corp., provider of Voice over Internet Protocol (VoIP) phone service, went public. The company sold 31.3 million shares to the public at a price of \$17 per share. Unfortunately for the shareholders, the stock price closed the day at \$14.85, a loss of almost 13 percent. For Vonage, the problems weren't over. In the IPO, Vonage had taken an unusual step and permitted its customers to buy 4.2 million shares of stock, but, following the offering, many customers refused to pay for the shares they had requested. Since Vonage had guaranteed payment to its underwriters for the shares purchased by its customers, the company was liable for the purchase price.

Evidence on Underpricing

Figure 15.2 provides a more general illustration of the underpricing phenomenon. What is shown is the month-by-month history of underpricing for SEC-registered IPOs.⁷ The

IPO information is ubiquitous on the World Wide Web. Two sites of interest are www.ipohome.com and IPO Central at www.hoovers.com.

⁷ The discussion in this section draws on Jay R. Ritter, "Initial Public Offerings," *Contemporary Finance Digest* 2 (Spring 1998).

period covered is 1960 through 2008. Figure 15.3 presents the number of offerings in each month for the same period.

Figure 15.2 shows that underpricing can be quite dramatic, exceeding 100 percent in some months. In such months, the average IPO more than doubled in value, sometimes in a matter of hours. Also, the degree of underpricing varies through time, and periods of severe underpricing ("hot issue" markets) are followed by periods of little underpricing ("cold issue" markets). For example, in the 1960s, the average IPO was underpriced by 21.25 percent. In the 1970s, the average underpricing was much smaller (8.95 percent), and the amount of underpricing was actually very small or even negative for much of that time. For 1990–1999, IPOs were underpriced by 21.1 percent on average, and for 2000–2008, average underpricing was 24.5 percent.

From Figure 15.3, it is apparent that the number of IPOs is also highly variable through time. Further, there are pronounced cycles in both the degree of underpricing and

the number of IPOs. Comparing Figures 15.2 and 15.3, we see that increases in the number of new offerings tend to follow periods of significant underpricing by roughly 6 to 12 months. This probably occurs because companies decide to go public when they perceive that the market is highly receptive to new issues.

Table 15.2 contains a year-by-year summary of underpricing for the years 1975 to 2008. As is indicated, a grand total of 7,942 companies were included in this analysis. The

TABLE 15.2				
	Year	Number of Offerings*	Average First-Day Return, %†	Gross Proceeds, \$ Millions‡
Number of offerings, average first-day returns, and gross proceeds of initial public offerings: 1975–2008	1975	12	–1.5	262

IPO Underpricing around the World

The United States is not the only country in which initial public offerings (IPOs) of common stock are underpriced. The phenomenon exists in every country with a stock market, although the extent of underpricing varies from country to country.

In general, countries with developed capital markets have more moderate underpricing than in emerging markets. During the Internet bubble of 1999–2000, however, underpricing in the developed capital markets increased dramatically. In the United States, for example, the average first-day return during 1999–2000 was 65 percent. At the same time that underpricing

in the developed capital markets increased, the underpricing of IPOs sold to residents of China moderated. The Chinese average has come down to a mere 164 percent, which is lower than it had been in the early and mid-1990s. After the bursting of the Internet bubble in mid-2000, the level of underpricing in the United States, Germany, and other developed capital markets has returned to more traditional levels.

The table below gives a summary of the average first-day returns on IPOs in a number of countries around the world, with the figures collected from a number of studies by various authors.

Country	Sample Size	Time Period	Avg. Initial Return	Country	Sample Size	Time Period	Avg. Initial Return
Argentina	20	1991–1994	4.4%	Korea	1,417	1980–2007	57.4%
Australia	1,103	1976–2006	19.8	Malaysia	350	1980–2006	69.6

Japan	2,579	1970–2007	40.5				

Source: Jay R. Ritter, Cordell Professor of Finance, University of Florida.

degree of underpricing averaged 17.2 percent overall for the 34 years examined. Securities were overpriced on average in only 1 of the 34 years; in 1975 the average decrease in value was –1.5 percent. At the other extreme, in 1999, the 487 issues were underpriced, on average, by a remarkable 69.6 percent. The nearby *Reality Bytes* box shows that IPO underpricing is not just confined to the United States; instead, it seems to be a global phenomenon.

IPO Underpricing: The 1999–2000 Experience

Table 15.2, along with Figures 15.2 and 15.3, show that 1999 and 2000 were extraordinary years in the IPO market. Almost 900 companies went public, and the average first-day

return across the two years was about 65 percent. During this time, 194 IPOs doubled, or more than doubled, in value on the first day. In contrast, only 39 did so in the preceding 24 years combined. One company, VA Linux, shot up 698 percent!

The dollar amount raised in 2000, \$66 billion, was a record, followed closely by 1999 at \$65 billion. The underpricing was so severe in 1999 that companies left another \$36 billion “on the table,” which was substantially more than in 1990 through 1998 combined, and, in 2000, the amount was at least \$27 billion. In other words, over the two-year period, companies missed out on \$63 billion because of underpricing.

October 19, 1999, was one of the more memorable days during this time. The World Wrestling Federation (WWF) (now known as World Wrestling Entertainment, or WWE) and Martha Stewart Omnimedia both went public, so it was Martha Stewart versus “Stone Cold” Steve Austin in a Wall Street version of MTV’s *Celebrity Deathmatch*. When the closing bell rang, it was a clear smackdown as Martha Stewart gained 98 percent on the first day compared to 48 percent for the WWF. If you’re interested in finding out how IPOs have done recently, check out our nearby *Work the Web* box.

The IPO market cooled off considerably in 2001. Many observers now refer to the 1999–2000 period as the Internet “bubble” period. The word *bubble* in this context refers to a situation in which prices are bid up to irrational, and unsustainable, levels. During 1999,

WORK THE WEB

So, do the high returns IPOs sometimes earn have you excited? Do you wonder how recent IPOs have performed? You can find out at www.hoovers.com. We went to the Web site and looked in the IPO area. Here is part of what we found:

Biggest First-Day Gains

Company Name	Offer Price	Close Price (First Day)	Percent Change
NIVS IntelliMedia Technology Group, Inc.	\$3.50	\$4.15	19%
Mead Johnson Nutrition Company	\$24.00	\$26.43	10%

As you can see, NIVS and Mead Johnson had the largest first-day returns.

Questions

1. Go to www.hoovers.com and find the companies that have had the biggest first-day gains in the most recent quarter. How do the most recent gains compare with the gains shown above? Which companies had the biggest first-day drops?
2. Go to www.hoovers.com and find out which companies have filed for an IPO but have yet to start trading.

The (Mis)-Pricing of Palm, Inc.

At one time, Palm was entirely owned by 3Com, Inc., a profitable provider of computer networking products and services. On March 2, 2000, 3Com sold 5 percent of its stake in Palm to the public via an IPO. This type of IPO, in which a company sells a part of its stock (usually a minority share) in a subsidiary, is called an equity “carve-out,” and such carve-outs are not uncommon events.

At some point following a carve-out, the parent company will often distribute the remaining shares in the subsidiary to its stockholders. This transaction is called a spin-off. In Palm’s case, 3Com planned to spin off its remaining shares to 3Com’s shareholders before the end of the year. Under the plan, 3Com shareholders would receive about 1.5 shares of Palm for every share of 3Com that they owned. Thus, after the IPO, investors could buy shares in Palm directly, or they could buy shares indirectly by purchasing stock in 3Com and waiting a little while.

Here is where it gets interesting. Because the owner of a share of 3Com will ultimately get 1.5 shares of Palm, each share of 3Com has to be worth at least as much as 1.5 shares of Palm, right? In fact, given that 3Com’s other businesses were profitable, 3Com’s stock price should be well above 1.5 times that of Palm.

It didn’t happen that way. The day before the Palm IPO, 3Com closed at \$104.13 per share. After the first day of trading, Palm closed at \$95.06 per share, implying that the price of 3Com should have jumped to at least \$145. Instead, 3Com fell to \$81.81. The next day, the wacky pricing was prominently discussed in *The Wall Street Journal* and elsewhere, so it wasn’t a secret. It was easy to see, yet it persisted for months.

Based on these prices, the stock market was placing a negative value on 3Com’s non-Palm businesses. Since the stock sold for about \$82 per share when it should have sold for at least \$145, the market was valuing all of 3Com’s non-Palm operations at $\$82 - \$145 = -\$63$ per share, or about $-\$22$ billion in all! Of course, stock prices can’t be negative, so a reasonable interpretation would be that Palm’s stock price was far too high relative to 3Com’s.

Episodes like that of Palm are rare, but there were at least five other cases of clear negative valuations in roughly the same time period as Palm’s IPO. In all cases, the negative values gradually disappeared, so the misvaluations were corrected, but it took time in each case.

for example, 323 of the companies that went public were considered Internet IPOs, meaning companies that did most (or all) of their business on the Internet, or companies whose products were used for computers or networks. By April 2001, of the 1999 Internet IPOs, only 12, or 4 percent, were trading above their offer price, and only 4, or 1 percent, were trading above their first-day close. Was it really a bubble? Let us say that, at a minimum, there were instances of valuations that are very hard to reconcile with economic reality. A nearby *Reality Bytes* box discusses one of the most notorious, the case of Palm, Inc., maker of handheld computers.

Why Does Underpricing Exist?

Based on the evidence we’ve examined, an obvious question is why does underpricing continue to exist? As we discuss, there are various explanations, but, to date, there is a lack of complete agreement among researchers as to which is correct.

We present some pieces of the underpricing puzzle by stressing two important caveats to our preceding discussion. First, the average figures we have examined tend to obscure the fact that much of the apparent underpricing is attributable to the smaller, more highly speculative issues. This point is illustrated in Table 15.3, which shows the extent of underpricing for over 7,300 firms over the period from 1980 through 2008. Here, the firms are grouped based on their total sales in the 12 months prior to the IPO.

As illustrated in Table 15.3, there is a tendency for underpricing to be more pronounced for firms with relatively small pre-IPO sales. These firms tend to be young firms, and such young firms can be very risky investments. Arguably, they must be significantly underpriced, on average, just to attract investors, and this is one explanation for the underpricing phenomenon.

TABLE 15.3**Average first-day returns, categorized by sales, for IPOs: 1980–2008***

Annual Sales of Issuing Firms	1980–1989		1990–1998		1999–2000		2001–2008	
	Number of Firms	First-Day Average Return	Number of Firms	First-Day Average Return	Number of Firms	First-Day Average Return	Number of Firms	First-Day Average Return
\$0 ≤ sales < \$10m	416	10.3%	716	17.3%	334	68.8%	135	6.4%
\$10m ≤ sales < \$20m	252	8.5%	388	18.4%	139	80.1%	41	8.4%
\$20m ≤ sales < \$50m	497	7.7%	783	18.8%	152	75.9%	126	13.4%
\$50m ≤ sales < \$100m	352	6.6%	583	12.9%	89	60.4%	137	16.9%
\$100m ≤ sales < \$200m	238	4.8%	446	11.8%	57	34.9%	120	15.1%
\$200m ≤ sales	287	3.5%	630	8.6%	88	25.5%	322	11.0%
All	2,042	7.2%	3,546	14.8%	859	64.3%	881	11.9%

*Sales, measured in millions, are for the last 12 months prior to going public. All sales have been converted into dollars of 2003 purchasing power, using the Consumer Price Index. There are 7,328 IPOs, after excluding IPOs with an offer price of less than \$5.00 per share, units, REITs, ADRs, closed-end funds, banks and S&Ls, firms not listed on CRSP within six months of the offer date, and 146 firms with missing sales. The average first-day return is 18.1 percent.

Source: Professor Jay R. Ritter, University of Florida.

The second caveat is that relatively few IPO buyers will actually get the initial high average returns observed in IPOs, and many will actually lose money. Although it is true that, on average, IPOs have positive initial returns, a significant fraction of them have price drops. Furthermore, when the price is too low, the issue is often “oversubscribed.” This means investors will not be able to buy all of the shares they want, and the underwriters will allocate the shares among investors.

The average investor will find it difficult to get shares in a “successful” offering (one in which the price increases) because there will not be enough shares to go around. On the other hand, an investor blindly submitting orders for IPOs tends to get more shares in issues that go down in price.

To illustrate, consider this tale of two investors. Smith knows very accurately what the Bonanza Corporation is worth when its shares are offered. She is confident that the shares are underpriced. Jones knows only that IPOs are usually underpriced. Armed with this information, Jones decides to buy 1,000 shares of every IPO. Does he actually earn an abnormally high return on the initial offering?

The answer is no, and at least one reason is Smith. Knowing about the Bonanza Corporation, Smith invests all her money in its IPO. When the issue is oversubscribed, the underwriters have to somehow allocate the shares between Smith and Jones. The net result is that when an issue is underpriced, Jones doesn’t get to buy as much of it as he wanted.

Smith also knows that the Blue Sky Corporation IPO is overpriced. In this case, she avoids its IPO altogether, and Jones ends up with a full 1,000 shares. To summarize this tale, Jones gets fewer shares when more knowledgeable investors swarm to buy an underpriced issue and gets all he wants when the smart money avoids the issue.

This is an example of a “winner’s curse,” and it is thought to be another reason why IPOs have such a large average return. When the average investor “wins” and gets the entire allocation, it may be because those who knew better avoided the issue. The only way underwriters can counteract the winner’s curse and attract the average investor is to underprice new issues (on average) so that the average investor still makes a profit.

A final reason for underpricing is that the underpricing is a kind of insurance for the investment banks. Conceivably, an investment bank could be sued successfully by angry customers if it consistently overpriced securities. Underpricing guarantees that, at least on average, customers will come out ahead.

CONCEPT QUESTIONS

15.5a Why is underpricing a cost to the issuing firm?

15.5b Suppose a stockbroker calls you up out of the blue and offers to sell you “all the shares you want” of a new issue. Do you think the issue will be more or less underpriced than average?

NEW EQUITY SALES AND THE VALUE OF THE FIRM

15.6

We now turn to a consideration of seasoned equity offerings (SEOs), which, as we discussed earlier, are offerings by firms that already have outstanding securities. It seems reasonable to believe that new long-term financing is arranged by firms after positive net present value projects are put together. As a consequence, when the announcement of external financing is made, the firm's market value should go up. Interestingly, this is not what happens. Stock prices tend to decline following the announcement of a new equity issue, although they tend to not change much following a debt announcement. A number of researchers have studied this issue. Plausible reasons for this strange result include the following:

1. **Managerial information.** If management has superior information about the market value of the firm, it may know when the firm is overvalued. If it does, it will attempt to issue new shares of stock when the market value exceeds the correct value. This will benefit existing shareholders. However, the potential new shareholders are not stupid, and they will anticipate this superior information and discount it in lower market prices at the new issue date.
2. **Debt usage.** A company's issuing new equity may reveal that the company has too much debt or too little liquidity. One version of this argument says that the equity issue is a bad signal to the market. After all, if the new projects are favorable ones, why should the firm let new shareholders in on them? It could just issue debt and let the existing shareholders have all the gain.
3. **Issue costs.** As we discuss next, there are substantial costs associated with selling securities.

The drop in value of the existing stock following the announcement of a new issue is an example of an indirect cost of selling securities. This drop might typically be on the order of 3 percent for an industrial corporation (and somewhat smaller for a public utility), so, for a large company, it can represent a substantial amount of money. We label this drop the *abnormal return* in our discussion of the costs of new issues that follows.

CONCEPT QUESTIONS

15.6a What are some possible reasons why the price of stock drops on the announcement of a new equity issue?

15.6b Explain why we might expect a firm with a positive NPV investment to finance it with debt instead of equity.

15.7

THE COST OF ISSUING SECURITIES

Issuing securities to the public isn't free, and the costs of different methods are important determinants of which is used. These costs associated with *floating* a new issue are generically called *flotation costs*. In this section, we take a closer look at the flotation costs associated with equity sales to the public.

The costs of selling stock are classified in the following table and fall into six categories: (1) the spread, (2) other direct expenses, (3) indirect expenses, (4) abnormal returns (discussed previously), (5) underpricing, and (6) the Green Shoe option.

The Costs of Issuing Securities	
1. Spread	The spread consists of direct fees paid by the issuer to the underwriting syndicate—the difference between the price the issuer receives and the offer price.
2. Other direct expenses	These are direct costs incurred by the issuer that are not part of the compensation to underwriters. These costs include filing fees, legal fees, and taxes—all reported on the prospectus.
3. Indirect expenses	These costs are not reported on the prospectus and include the cost of management time spent working on the new issue.
4. Abnormal returns	In a seasoned issue of stock, the price of the existing stock drops on average by 3 percent upon the announcement of the issue. This drop is called the abnormal return.
5. Underpricing	For initial public offerings, losses arise from selling the stock below the true value.
6. Green Shoe option	The Green Shoe option gives the underwriters the right to buy additional shares at the offer price to cover overallocments.

Table 15.4 reports direct costs as a percentage of the gross amount raised for IPOs, SEOs, straight (ordinary) bonds, and convertible bonds sold by U.S. companies over the nineteen-year period from 1990 through 2008. These are direct costs only. Not included are indirect expenses, the cost of the Green Shoe provision, underpricing (for IPOs), and abnormal returns (for SEOs).

As Table 15.4 shows, the direct costs alone can be very large, particularly for smaller issues (less than \$10 million). On a smaller IPO, for example, the total direct costs amount to 25.22 percent of the amount raised. This means that if a company sells \$10 million in stock, it will only net about \$7.5 million; the other \$2.5 million goes to cover the underwriter spread and other direct expenses. Typical underwriter spreads on an IPO range from about 5 percent for large offerings to 10 percent for small offerings, but, for about half of the IPOs in Table 15.4, the spread is exactly 7 percent, so this is, by far, the most common spread. The *Reality Bytes* box on page 488 provides a detailed example for a particular company.

Overall, four clear patterns emerge from Table 15.4. First of all, with the possible exception of straight debt offerings (about which we will have more to say later), there are substantial economies of scale. The underwriter spreads are smaller on larger issues, and the other direct costs fall sharply as a percentage of the amount raised, a reflection of the mostly fixed nature of such costs. Second, the costs associated with selling debt are substantially less than the costs of selling equity. Third, IPOs have higher expenses than SEOs, but the difference is not as great as might originally be guessed. Finally, straight bonds are cheaper to float than convertible bonds.

As we have discussed, the underpricing of IPOs is an additional cost to the issuer. To give a better idea of the total cost of going public, Table 15.5 combines the information in Table 15.4 for IPOs with data on the underpricing experienced by these firms. Comparing

TABLE 15.4

Direct costs as a percentage of gross proceeds for equity (IPOs and SEOs) and straight and convertible bonds offered by domestic operating companies: 1990–2008

Proceeds (\$ millions)	IPOs			SEOs

Anatomy of an IPO

On February 6, 2004, Symbion, Inc., the Nashville-based owner and operator of outpatient surgery centers, went public via an IPO. Symbion issued 7.2 million shares of stock at a price of \$15.00 each, 2,584,000 of which were underwritten by Symbion's lead investment bank, Credit Suisse First Boston LLC, with the remaining 4,616,000 underwritten by a syndicate made up of seven other investment banks.

Even though the IPO raised a gross sum of \$108 million, Symbion only got to keep about \$96 million after expenses. The biggest expense was the 7 percent underwriter spread, which is very standard for an offering of this size. Symbion sold each of the 7.2 million shares to the underwriters for \$13.95, and the underwriters in turn sold the shares to the public for \$15.00 each. Thus, of the \$108 million investors paid for the shares, Symbion received \$100,440,000.

But wait, there's more. Symbion spent \$10,048 in SEC registration fees, \$12,000 in other filing fees, and \$100,000 to

be listed on the NASDAQ. The company also spent \$1.29 million on accounting to obtain the necessary audits, \$5,250 for a transfer agent to physically transfer the shares and maintain a list of shareholders, \$565,000 for printing and engraving expenses, \$1.16 million for legal fees and expenses, and, finally, \$67,702 in miscellaneous expenses.

As Symbion's outlays show, an IPO can be a costly undertaking! In the end, Symbion's expenses totaled \$10,770,000, of which \$7,560,000 went to the underwriters and \$3,210,000 went to other parties. The total cost to Symbion was 11 percent of the issue proceeds, which is a little higher than might be expected. At least part of the reason is that the company had filed to go public in 2003. Midway through the process, the company and its underwriters determined that the market conditions were not favorable for an IPO, so the company withdrew its registration. The costs for this previous registration were included in the 2004 IPO.

the total direct costs (in the fifth column) to the underpricing (in the sixth column), we see that they tend to be similar in size, so the direct costs are only about half of the total for small issues. Overall, across all size groups, the total direct costs amount to 10 percent of the amount raised and the underpricing amounts to 19 percent.

Finally, with regard to debt offerings, there is a general pattern in issue costs that is somewhat obscured in Table 15.4. Recall from Chapter 6 that bonds carry different credit ratings. Higher-rated bonds are said to be investment grade, whereas lower-rated bonds are noninvestment grade. Table 15.6 contains a breakdown of direct costs for bond issues after the investment and noninvestment grades have been separated.

Table 15.6 clarifies three things regarding debt issues. First, there are substantial economies of scale here as well. Second, investment-grade issues have much lower direct costs, particularly for straight bonds. Finally, there are relatively few noninvestment-grade issues in the smaller size categories, reflecting the fact that such issues are more commonly handled as private placements, which we discuss in our next section.

TABLE 15.5

Direct and indirect costs, in percentages, of equity IPOs: 1990–2008

Proceeds (\$ in millions)	Number of Issues	Gross Spread	Other Direct Expense	Total Direct Cost	Underpricing

CONCEPT QUESTIONS

15.7a What are the different costs associated with security offerings?

15.7b What lessons do we learn from studying issue costs?

15.8

ISSUING LONG-TERM DEBT

The general procedures followed in a public issue of bonds are the same as those for stocks. The issue must be registered with the SEC, there must be a prospectus, and so on. The registration statement for a public issue of bonds, however, is different from the one for common stock. For bonds, the registration statement must indicate an indenture.

Another important difference is that more than 50 percent of all debt is issued privately. There are two basic forms of direct private long-term financing: term loans and private placement.

term loans

Direct business loans of, typically, one to five years.

private placements

Loans, usually long-term in nature, provided directly by a limited number of investors.

Term loans are direct business loans. These loans have maturities of between one year and five years. Most term loans are repayable during the life of the loan. The lenders include commercial banks, insurance companies, and other lenders that specialize in corporate finance. **Private placements** are very similar to term loans except that the maturities are longer.

The important differences between direct private long-term financing and public issues of debt are:

1. A direct long-term loan avoids the cost of Securities and Exchange Commission registration.
2. Direct placement is likely to have more restrictive covenants.
3. It is easier to renegotiate a term loan or a private placement in the event of a default. It is harder to renegotiate a public issue because hundreds of holders are usually involved.
4. Life insurance companies and pension funds dominate the private-placement segment of the bond market. Commercial banks are significant participants in the term-loan market.
5. The costs of distributing bonds are lower in the private market.

The interest rates on term loans and private placements are often higher than those on an equivalent public issue. This difference may reflect the trade-off between a higher interest rate and more flexible arrangements in the event of financial distress, as well as the lower costs associated with private placements.

An additional, and very important, consideration is that the flotation costs associated with selling debt are much less than the comparable costs associated with selling equity.

CONCEPT QUESTIONS

15.8a What is the difference between private and public bond issues?

15.8b A private placement is likely to have a higher interest rate than a public issue. Why?

SHELF REGISTRATION

15.9

To simplify the procedures for issuing securities, in March 1982, the SEC adopted Rule 415 on a temporary basis, and it was made permanent in November 1983. Rule 415 allows shelf registration. Both debt and equity securities can be shelf registered.

Shelf registration permits a corporation to register an offering that it reasonably expects to sell within the next two years and then sell the issue whenever it wants during that two-year period. For example, in February 2009, Intel announced a shelf registration to sell up to \$1 billion in stock. According to the registration documents filed by the company, the proceeds were to be used for future acquisitions of other businesses, assets, or securities.

Not all companies can use Rule 415. The primary qualifications are:

1. The company must be rated investment grade.
2. The firm cannot have defaulted on its debt in the past three years.
3. The aggregate market value of the firm's outstanding stock must be more than \$150 million.
4. The firm must not have had a violation of the Securities Act of 1934 in the past three years.

The rule has been controversial. Arguments have been constructed against shelf registration:

1. The costs of new issues might go up because underwriters might not be able to provide as much current information to potential investors as they would otherwise, so investors would pay less. The expense of selling the issue piece by piece might therefore be higher than that of selling it all at once.
2. Some investment bankers have argued that shelf registration will cause a “market overhang” that will depress market prices. In other words, the possibility that the company could increase the supply of stock at any time will have a negative impact on the current stock price. There is little evidence to support this position, however.

In addition to shelf registrations, companies also sell stock through continuous equity offerings, or “dribble” programs. In a dribble program, the company registers the stock with the SEC through a variety of different methods and sells the shares in dribbles as it sees fit. In other words, the company sells the stock on the secondary market like any other investor would. In 2008, fifty dribble programs were announced, ranging from a \$1 billion registration from Chesapeake Energy Corp. to a \$2.4 million filing from CapitaRetail China Trust.

shelf registration

Registration permitted by SEC Rule 415, which allows a company to register all issues it expects to sell within two years at one time, with subsequent sales at any time within those two years.

CONCEPT QUESTIONS

15.9a What is shelf registration?

15.9b What are the arguments against shelf registration?

SUMMARY AND CONCLUSIONS

This chapter has looked at how corporate securities are issued. The following are the main points:

1. The venture capital market is a primary source of financing for new high-risk companies.
2. The costs of issuing securities can be quite large. They are much lower (as a percentage) for larger issues.
3. Firm commitment underwriting is far more prevalent for large issues than best efforts underwriting. This is probably connected to the uncertainty of smaller issues. For a given size offering, the direct expenses of best efforts underwriting and firm commitment underwriting are of the same magnitude.
4. The direct and indirect costs of going public can be substantial. However, once a firm is public, it can raise additional capital with much greater ease.

CHAPTER REVIEW AND SELF-TEST PROBLEM

15.1 Flotation Costs. The L5 Corporation is considering an equity issue to finance a new space station. A total of \$10 million in new equity is needed. If the direct costs are estimated at 6 percent of the amount raised, how large does the issue need to be? What is the dollar amount of the flotation cost?

Answer to Chapter Review and Self-Test Problem

15.1 The firm needs to net \$10 million after paying the 6 percent flotation costs. So, the amount raised is given by:

$$\text{Amount raised} \times (1 - .06) = \$10 \text{ million}$$

$$\text{Amount raised} = \$10 / .94 = \$10.638 \text{ million}$$

The total flotation cost is thus \$638,000.

CRITICAL THINKING AND CONCEPTS REVIEW

- L0 2** **15.1 Debt versus Equity Offering Size.** In the aggregate, debt offerings are much more common than equity offerings and typically much larger as well. Why?
- L0 2** **15.2 Debt versus Equity Flotation Costs.** Why are the costs of selling equity so much larger than the costs of selling debt?
- L0 2** **15.3 Bond Ratings and Flotation Costs.** Why do noninvestment-grade bonds have much higher direct costs than investment-grade issues?
- L0 2** **15.4 Underpricing in Debt Offerings.** Why is underpricing not a great concern with bond offerings?

Use the following information to answer the next three questions. Eyetech Pharmaceuticals, Inc., a company that develops treatments for eye problems, went public in January 2004. Assisted by the investment bank Merrill Lynch, Eyetech

sold 6.5 million shares at \$21 each, thereby raising a total of \$136.5 million. At the end of the first day of trading, the stock sold for \$32.40 per share, down slightly from a high of \$33.00. Based on the end-of-day numbers, Eyetech shares were apparently underpriced by about \$11 each, meaning that the company missed out on an additional \$74 million.

L03 15.5 IPO Pricing. The Eyetech IPO was underpriced by about 54 percent. Should Eyetech be upset at Merrill Lynch over the underpricing?

L03 15.6 IPO Pricing. In the previous question, would it affect your thinking to know that the company was incorporated less than four years earlier, had only \$30 million in revenues for the first nine months of 2003, and had never earned a profit? Additionally, the company had only one product, Macugen, which had won fast-track status from the FDA, but still did not have approval to be sold.

L03 15.7 IPO Pricing. In the previous two questions, how would it affect your thinking to know that in addition to the 6.5 million shares offered in the IPO, Eyetech had an additional 32 million shares outstanding? Of those 32 million shares, 10 million shares were owned by pharmaceutical giant Pfizer, and 12 million shares were owned by the 13 directors and executive officers.

L03 15.8 IPO Underpricing. In 1980, a certain assistant professor of finance bought 12 initial public offerings of common stock. He held each of these for approximately one month and then sold. The investment rule he followed was to submit a purchase order for every firm commitment initial public offering of oil and gas exploration companies. There were 22 of these offerings, and he submitted a purchase order for approximately \$1,000 in stock for each of the companies. With 10 of these, no shares were allocated to this assistant professor. With 5 of the 12 offerings that were purchased, fewer than the requested number of shares were allocated.

The year 1980 was very good for oil and gas exploration company owners: On average, for the 22 companies that went public, the stocks were selling for 80 percent above the offering price a month after the initial offering date. The assistant professor looked at his performance record and found that the \$8,400 invested in the 12 companies had grown to \$10,000, representing a return of only about 20 percent (commissions were negligible). Did he have bad luck, or should he have expected to do worse than the average initial public offering investor? Explain.

L03 15.9 IPO Pricing. The following material represents the cover page and summary of the prospectus for the initial public offering of the Pest Investigation Control Corporation (PICC), which is going public tomorrow with a firm commitment initial public offering managed by the investment banking firm of Erlanger and Ritter. Answer the following questions:

- a. Assume that you know nothing about PICC other than the information contained in the prospectus. Based on your knowledge of finance, what is your prediction for the price of PICC tomorrow? Provide a short explanation of why you think this will occur.
- b. Assume that you have several thousand dollars to invest. When you get home from class tonight, you find that your stockbroker, whom you have not talked to for weeks, has called. She has left a message that PICC is going public tomorrow and that she can get you several hundred shares at the offering price if you call her back first thing in the morning. Discuss the merits of this opportunity.

PROSPECTUS

PICC

200,000 shares
PEST INVESTIGATION CONTROL CORPORATION

Of the shares being offered hereby, all 200,000 are being sold by the Pest Investigation Control Corporation, Inc. ("the Company"). Before the offering there has been no public market for the shares of PICC, and no guarantee can be given that any such market will develop.

These securities have not been approved or disapproved by the SEC nor has the commission passed upon the accuracy or adequacy of this prospectus. Any representation to the contrary is a criminal offense.

	Price to Public	Underwriting Discount	Proceeds to Company*
Per share	\$11.00	\$1.10	\$9.90
Total	\$2,200,000	\$220,000	\$1,980,000

*Before deducting expenses estimated at \$27,000 and payable by the Company.

This is an initial public offering. The common shares are being offered, subject to prior sale, when, as, and if delivered to and accepted by the Underwriters and subject to approval of certain legal matters by their Counsel and by Counsel for the Company. The Underwriters reserve the right to withdraw, cancel, or modify such offer and to reject offers in whole or in part.

Prospectus Summary

The Company	The Pest Investigation Control Corporation (PICC) breeds and markets toads and tree frogs as ecologically safe insect-control mechanisms.
The Offering	200,000 shares of common stock, no par value.
Listing	The Company will seek listing on NASDAQ and will trade over the counter.
Shares Outstanding	As of June 30, 2010, 400,000 shares of common stock were outstanding. After the offering, 600,000 shares of common stock will be outstanding.
Use of Proceeds	To finance expansion of inventory and receivables and general working capital, and to pay for country club memberships for certain finance professors.

Selected Financial Information
(amounts in thousands except per-share data)

	<i>Fiscal Year Ended June 30</i>		
	2008	2009	2010
Revenues	\$60.00	\$120.00	\$240.00
Net earnings	3.80	15.90	36.10

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

Basic

(Questions 1–7)

L0 3

- 1. IPO Underpricing.** The Sun Co. and the Moon Co. have both announced IPOs at \$40 per share. One of these is undervalued by \$9, and the other is overvalued by \$4.25, but you have no way of knowing which is which. You plan on buying 1,000 shares of each issue. If an issue is underpriced, it will be rationed, and only half your order will be filled. If you *could* get 1,000 shares in Sun and 1,000 shares in Moon, what would your profit be? What profit do you actually expect? What principle have you illustrated?

L0 3

- 2. Calculating Flotation Costs.** The IBBS Co. needs to raise \$65 million to finance its expansion into new markets. The company will sell new shares of equity via a general cash offering to raise the needed funds. If the offer price is \$50 per share and the company's underwriters charge an 8 percent spread, how many shares need to be sold?

L0 3

- 3. Calculating Flotation Costs.** In the previous problem, if the SEC filing fee and associated administrative expenses of the offering are \$450,000, how many shares need to be sold now?

L0 3

- 4. Calculating Flotation Costs.** The Bostitch Co. has just gone public. Under a firm commitment agreement, Bostitch received \$32 for each of the 4.1 million shares sold. The initial offering price was \$34.40 per share, and the stock rose to \$41 per share in the first few minutes of trading. Bostitch paid \$905,000 in legal and other direct costs and \$250,000 in indirect costs. What was the flotation cost as a percentage of funds raised?

L0 3

- 5. Calculating Flotation Costs.** The Hootenanny Corporation needs to raise \$51 million to finance its expansion into new markets. The company will sell new shares of equity via a general cash offering to raise the needed funds. If the offer price is \$26 per share and the company's underwriters charge a 7 percent spread, how many shares need to be sold?

L0 3

- 6. Calculating Flotation Costs.** In the previous problem, if the SEC filing fee and associated administrative expenses of the offering are \$1,450,000, how many shares need to be sold now?

L0 3

- 7. Calculating Flotation Costs.** The Verbatim Co. has just gone public. Under a firm commitment agreement, Verbatim received \$20.15 for each of the 6.5 million shares sold. The initial offering price was \$22 per share, and the stock rose to \$28.51 per share in the first few minutes of trading. Verbatim paid \$900,000 in legal and other direct costs and \$175,000 in indirect costs. What was the flotation cost as a percentage of funds raised?

- 15.1 IPO Filings.** Go to www.hoovers.com and find the most recent IPO. Now go to the SEC Web site at www.sec.gov and look up the company's filings with the SEC. What is the name of the filing the company made to sell stock to the public? Look at the filing. What does this company do? How does the company propose to use the funds raised by the IPO?

- 15.2 Secondary Offerings.** Go to www.hoovers.com and find the most recent secondary stock offering. At what price was the stock offered for sale to the public? How does this offer price compare to the market price of the stock on the same day?

- 15.3 Initial Public Offerings.** What was the largest IPO? Go to www.hoovers.com and find out. In what country was the company located? What was the largest IPO in the United States?

**WHAT'S ON
THE WEB?**

CHAPTER CASE

S&S AIR GOES PUBLIC

Mark Sexton and Todd Story have been discussing the future of S&S Air. The company has been experiencing fast growth, and the two see only clear skies in the company's future. However, the fast growth can no longer be funded by internal sources, so Mark and Todd have decided the time is right to take the company public. To this end, they have entered into discussions with the investment bank of Crowe & Mallard. The company has a working relationship with Renata Harper, the underwriter who assisted with the company's previous bond offering. Crowe & Mallard have assisted numerous small companies in the IPO process, so Mark and Todd feel confident with this choice.

Renata begins by telling Mark and Todd about the process. Although Crowe & Mallard charged an underwriter fee of 4 percent on the bond offering, the

underwriter fee is 7 percent on all initial stock offerings of the size of S&S Air's offering. Renata tells Mark and Todd that the company can expect to pay about \$1,200,000 in legal fees and expenses, \$12,000 in SEC registration fees, and \$15,000 in other filing fees. Additionally, to be listed on the NASDAQ, the company must pay \$100,000. There are also transfer agent fees of \$6,500 and engraving expenses of \$450,000. The company should also expect to pay \$75,000 for other expenses associated with the IPO.

Finally, Renata tells Mark and Todd that to file with the SEC, the company must provide three years' audited financial statements. She is unsure about the costs of the audit. Mark tells Renata that the company provides audited financial statements as part of the bond covenant, and the company pays \$300,000 per year for the outside auditor. ■

QUESTIONS

- At the end of the discussion, Mark asks Renata about the Dutch auction IPO process. What are the differences in the expenses to S&S Air if it uses a Dutch auction IPO versus a traditional IPO? Should the company go public through a Dutch auction or use a traditional underwritten offering?
- During the discussion of the potential IPO and S&S Air's future, Mark states that he feels the company should raise \$50 million. However, Renata points out that if the company needs more cash in the near future, a secondary offering close to the IPO would be problematic. Instead, she suggests that the company should raise \$80 million in the IPO. How can we calculate the optimal size of the IPO? What are the advantages and disadvantages of increasing the size of the IPO to \$80 million?
- After deliberation, Mark and Todd have decided that the company should use a firm commitment offering with Crowe & Mallard as the lead underwriter. The IPO will be for \$60 million. Ignoring underpricing, how much will the IPO cost the company as a percentage of the funds received?
- Many employees of S&S Air have shares of stock in the company because of an existing employee stock purchase plan. To sell the stock, the employees can tender their shares to be sold in the IPO at the offering price, or the employees can retain their stock and sell it in the secondary market after S&S Air goes public. Todd asks you to advise the employees about which option is best. What would you suggest to the employees?

Short-Term Financial Planning

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Discuss operating and cash cycles and why they are important.
- LO 2** Differentiate between the types of short-term financial policy.
- LO 3** Identify the essentials of short-term financial planning.

With gasoline passing \$4 per gallon in mid-2008, sales of hybrid automobiles really began to pick up. For example, during 2007, the hybrid version of the Saturn Vue sat on dealer lots for 63 days, on average, before selling. By the summer of 2008, this period had fallen to 17 days. Overall, hybrids sat for 23 days during April and May 2008, which is considerably less than the auto industry's average of 60 days. And the Saturn Vue wasn't the fastest-moving car. While Honda does not release precise data, the company re-

ported that the inventory period for the Honda Civic hybrid was a "few days." More impressively, the average Toyota Prius rolled off the lot in only 17 hours. Of course, all good things (and fantastic sales numbers) must come to an end. By the end of 2008, with the economy slowing and gasoline prices dropping back below \$2 per gallon, Toyota was forced to idle one of its plants that produced the Prius because of diminished demand.

Short-term financial planning is one activity that concerns everyone in business. As this chapter illustrates, such planning requires, among other things, sales projections from marketing, cost numbers from accounting, and inventory requirements from operations. Perhaps a particularly good reason to study this chapter for many is that short-term planning and management are frequently where new hires start out in a corporation, especially in finance and accounting. Also, such planning is especially important for small businesses, and a lack of adequate short-term financial resources is a frequently cited reason for small business failure.

Visit us at www.mhhe.com/rwj

To this point, we have described many of the decisions of long-term finance, for example, capital budgeting, dividend policy, and financial structure. In this chapter, we begin to discuss short-term finance. Short-term finance is primarily concerned with the analysis of decisions that affect current assets and current liabilities.

Frequently, the term *net working capital* is associated with short-term financial decision making. As we describe in Chapter 2 and elsewhere, net working capital is the difference between current assets and current liabilities. Often, short-term financial management is called *working capital management*. These mean the same thing. Working capital management can be critical for a company. According to a 2008 survey, if an average company with \$10 billion in sales could match the best working capital management company, it could reduce working capital by \$1.4 billion, or 14 percent of sales.

There is no universally accepted definition of short-term finance. The most important difference between short-term and long-term finance is the timing of cash flows. Short-term financial decisions typically involve cash inflows and outflows that occur within a year or less. For example, short-term financial decisions are involved when a firm orders raw materials, pays in cash, and anticipates selling finished goods in one year for cash. In contrast, long-term financial decisions are involved when a firm purchases a special machine that will reduce operating costs over, say, the next five years.

What types of questions fall under the general heading of short-term finance? To name just a very few:

1. What is a reasonable level of cash to keep on hand (in a bank) to pay bills?
2. How much should the firm borrow in the short term?
3. How much credit should be extended to customers?

This chapter introduces the basic elements of short-term financial decisions. First, we discuss the short-term operating activities of the firm. We then identify some alternative short-term financial policies. Finally, we outline the basic elements in a short-term financial plan and describe short-term financing instruments.

16.1

TRACING CASH AND NET WORKING CAPITAL

In this section, we examine the components of cash and net working capital as they change from one year to the next. We have already discussed various aspects of this subject in Chapters 2 and 3. We briefly review some of that discussion as it relates to short-term financing decisions. Our goal is to describe the short-term operating activities of the firm and their impact on cash and working capital.

To begin, recall that *current assets* are cash and other assets that are expected to convert to cash within the year. Current assets are presented on the balance sheet in order of their liquidity—the ease with which they can be converted to cash and the time it takes to convert them. Four of the most important items found in the current asset section of a balance sheet are cash and cash equivalents, marketable securities, accounts receivable, and inventories.

Analogous to their investment in current assets, firms use several kinds of short-term debt, called *current liabilities*. Current liabilities are obligations that are expected

to require cash payment within one year. Three major items found as current liabilities are accounts payable; expenses payable, including accrued wages and taxes; and notes payable.

Because we want to focus on changes in cash, we start off by defining cash in terms of the other elements of the balance sheet. This lets us isolate the cash account and explore the impact on cash from the firm's operating and financing decisions. The basic balance sheet identity can be written as:

$$\text{Net working capital} + \text{Fixed assets} = \text{Long-term debt} + \text{Equity} \quad [16.1]$$

Net working capital is cash plus other current assets, less current liabilities; that is,

$$\begin{aligned} \text{Net working capital} = & (\text{Cash} + \text{Other current assets}) \\ & - \text{Current liabilities} \end{aligned} \quad [16.2]$$

If we substitute this for net working capital in the basic balance sheet identity and rearrange things a bit, we see that cash is:

$$\begin{aligned} \text{Cash} = & \text{Long-term debt} + \text{Equity} + \text{Current liabilities} \\ & - \text{Current assets other than cash} - \text{Fixed assets} \end{aligned} \quad [16.3]$$

This tells us in general terms that some activities naturally increase cash and some activities decrease it. We can list these along with an example of each as follows:

Activities That Increase Cash

- Increasing long-term debt (borrowing over the long term)
- Increasing equity (selling some stock)
- Increasing current liabilities (getting a 90-day loan)
- Decreasing current assets other than cash (selling some inventory for cash)
- Decreasing fixed assets (selling some property)

Activities That Decrease Cash

- Decreasing long-term debt (paying off a long-term debt)
- Decreasing equity (repurchasing some stock)
- Decreasing current liabilities (paying off a 90-day loan)
- Increasing current assets other than cash (buying some inventory for cash)
- Increasing fixed assets (buying some property)

Notice that our two lists are exact opposites. For example, floating a long-term bond issue increases cash (at least until the money is spent). Paying off a long-term bond issue decreases cash.

Activities that increase cash are called *sources of cash*. Those activities that decrease cash are called *uses of cash*. Looking back at our list, we see that sources of cash always involve increasing a liability (or equity) account or decreasing an asset account. This makes sense because increasing a liability means we have raised money by borrowing it or by selling an ownership interest in the firm. A decrease in an asset means that we have sold or otherwise liquidated an asset. In either case, there is a cash inflow.

Uses of cash are just the reverse. A use of cash involves decreasing a liability by paying it off, perhaps, or increasing assets by purchasing something. Both of these activities require that the firm spend some cash.

EXAMPLE 16.1

Sources and Uses

Here is a quick check of your understanding of sources and uses: If accounts payable go up by \$100, is this a source or a use? If accounts receivable go up by \$100, is this a source or a use?

Accounts payable are what we owe our suppliers. This is a short-term debt. If it rises by \$100, we have effectively borrowed the money, so this is a *source* of cash. Receivables are what our customers owe to us, so an increase of \$100 in accounts receivable means that we have loaned the money; this is a *use* of cash.

CONCEPT QUESTIONS

16.1a

What is the difference between net working capital and cash?

16.1b

Will net working capital always increase when cash increases?

16.1c

List five potential uses of cash.

16.1d

List five potential sources of cash.

16.2

THE OPERATING CYCLE AND THE CASH CYCLE

The primary concerns in short-term finance are the firm’s short-run operating and financing activities. For a typical manufacturing firm, these short-run activities might consist of the following sequence of events and decisions:

Events	Decisions
1. Buying raw materials	1. How much inventory to order
2. Paying cash	2. Whether to borrow or draw down cash balances
3. Manufacturing the product	3. What choice of production technology to use
4. Selling the product	4. Whether credit should be extended to a particular customer
5. Collecting cash	5. How to collect

These activities create patterns of cash inflows and cash outflows. These cash flows are both unsynchronized and uncertain. They are unsynchronized because, for example, the payment of cash for raw materials does not happen at the same time as the receipt of cash from selling the product. They are uncertain because future sales and costs cannot be precisely predicted.

Defining the Operating and Cash Cycles

We can start with a simple case. One day, call it Day 0, you purchase \$1,000 worth of inventory on credit. You pay the bill 30 days later, and, after 30 more days, someone buys the \$1,000 in inventory for \$1,400. Your buyer does not actually pay for another 45 days. We can summarize these events chronologically as follows:

Day	Activity	Cash Effect
0	Acquire inventory on credit	None
30	Pay for inventory	−\$1,000
60	Sell inventory on credit	None
105	Collect on sale	+\$1,400

The Operating Cycle There are several things to notice in our example. First, the entire cycle, from the time we acquire some inventory to the time we collect the cash, takes 105 days. This is called the **operating cycle**.

As we illustrate, the operating cycle is the length of time it takes to acquire inventory, sell it, and collect for it. This cycle has two distinct components. The first part is the time it takes to acquire and sell the inventory. This period, a 60-day span in our example, is called the **inventory period**. The second part is the time it takes to collect on the sale, 45 days in our example. This is called the **accounts receivable period**, or, simply, the receivables period.

Based on our definitions, the operating cycle is obviously just the sum of the inventory and receivables periods:

$$\begin{aligned}\text{Operating cycle} &= \text{Inventory period} + \text{Accounts receivable period} \\ 105 \text{ days} &= 60 \text{ days} + 45 \text{ days}\end{aligned}\quad [16.4]$$

What the operating cycle describes is how a product moves through the current asset accounts. It begins life as inventory, it is converted to a receivable when it is sold, and it is finally converted to cash when we collect from the sale. Notice that, at each step, the asset is moving closer to cash.

The Cash Cycle The second thing to notice is that the cash flows and other events that occur are not synchronized. For example, we don't actually pay for the inventory until 30 days after we acquire it. The intervening 30-day period is called the **accounts payable period**. Next, we spend cash on Day 30, but we don't collect until Day 105. Somehow, we have to arrange to finance the \$1,000 for $105 - 30 = 75$ days. This period is called the **cash cycle**.

The cash cycle, therefore, is the number of days that pass until we collect the cash from a sale, measured from when we actually pay for the inventory. Notice that, based on our definitions, the cash cycle is the difference between the operating cycle and the accounts payable period:

$$\begin{aligned}\text{Cash cycle} &= \text{Operating cycle} - \text{Accounts payable period} \\ 75 \text{ days} &= 105 \text{ days} - 30 \text{ days}\end{aligned}\quad [16.5]$$

Figure 16.1 depicts the short-term operating activities and cash flows for a typical manufacturing firm by looking at the cash flow time line. As is shown, the **cash flow time line** is made up of the operating cycle and the cash cycle. In Figure 16.1, the need for short-term financial management is suggested by the gap between the cash inflows and the cash outflows. This is related to the length of the operating cycle and the accounts payable period.

The gap between short-term inflows and outflows can be filled either by borrowing or by holding a liquidity reserve in the form of cash or marketable securities. Alternatively, the gap can be shortened by changing the inventory, receivable, and payable periods. These are all managerial options that we discuss below and in subsequent chapters.

operating cycle

The time period between the acquisition of inventory and the collection of cash from receivables.

inventory period

The time it takes to acquire and sell inventory.

accounts receivable period

The time between sale of inventory and collection of the receivable.

accounts payable period

The time between receipt of inventory and payment for it.

cash cycle

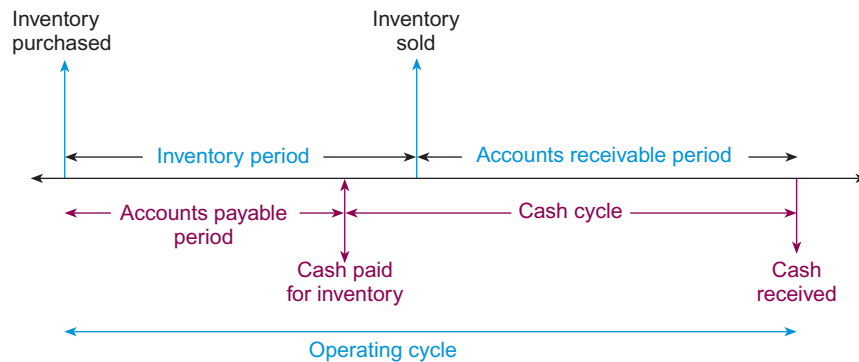

The time between cash disbursement and cash collection.

cash flow time line

Graphical representation of the operating cycle and the cash cycle.

FIGURE 16.1

Cash flow time line and the short-term operating activities of a typical manufacturing firm

The operating cycle is the time period from inventory purchase until the receipt of cash. The cash cycle is the time period from when cash is paid out to when cash is received.

The Operating Cycle and the Firm's Organizational Chart

Before we examine the operating and cash cycles in greater detail, it is useful to take a look at the people involved in managing a firm's current assets and liabilities. As Table 16.1 illustrates, short-term financial management in a large corporation involves a number of different financial and nonfinancial managers. Examining Table 16.1, we see that selling on credit involves at least three different individuals: the credit manager, the marketing manager, and the controller. Of these three, only two are responsible to the vice president of finance (the marketing function is usually associated with the vice president of marketing). Thus, there is the potential for conflict, particularly if different managers only concentrate on part of the picture. For example, if marketing is trying to

TABLE 16.1**Managers who deal with short-term financial problems**

Title of Manager	Duties Related to Short-Term Financial Management	Assets/Liabilities Influenced
Cash manager	Collection, concentration, disbursement; short-term investments; short-term borrowing; banking relations	Cash, marketable securities, short-term loans
Credit manager	Monitoring and control of accounts receivable; credit policy decisions	Accounts receivable
Marketing manager	Credit policy decisions	Accounts receivable
Purchasing manager	Decisions on purchases, suppliers; may negotiate payment terms	Inventory, accounts payable
Production manager	Setting of production schedules and materials requirements	Inventory, accounts payable
Payables manager	Decisions on payment policies and on whether to take discounts	Accounts payable
Controller	Accounting information on cash flows; reconciliation of accounts payable; application of payments to accounts receivable	Accounts receivable, accounts payable

land a new account, it may seek more liberal credit terms as an inducement. However, this may increase the firm's investment in receivables or its exposure to bad-debt risk, and conflict can result.

Calculating the Operating and Cash Cycles

In our example, the lengths of time that made up the different periods were obvious. If all we have is financial statement information, we will have to do a little more work. We illustrate these calculations next.

To begin, we need to determine various things such as how long it takes, on average, to sell inventory and how long it takes, on average, to collect. We start by gathering some balance sheet information such as the following (in thousands):

Item	Beginning	Ending	Average
Inventory	\$2,000	\$3,000	\$2,500
Accounts receivable	1,600	2,000	1,800
Accounts payable	750	1,000	875

Also, from the most recent income statement, we might have the following figures (in thousands):

Net sales	\$11,500
Cost of goods sold	8,200

We now need to calculate some financial ratios. We discussed these in some detail in Chapter 3; here we just define them and use them as needed.

The Operating Cycle First of all, we need the inventory period. We spent \$8.2 million on inventory (our cost of goods sold). Our average inventory was \$2.5 million. We thus turned our inventory over $\$8.2 / \2.5 times during the year:¹

$$\begin{aligned}\text{Inventory turnover} &= \frac{\text{Cost of goods sold}}{\text{Average inventory}} \\ &= \frac{\$8.2 \text{ million}}{\$2.5 \text{ million}} = 3.28 \text{ times}\end{aligned}$$

Loosely speaking, this tells us that we bought and sold off our inventory 3.28 times during the year. This means that, on average, we held our inventory for:

$$\begin{aligned}\text{Inventory period} &= \frac{365 \text{ days}}{\text{Inventory turnover}} \\ &= \frac{365}{3.28} = 111.3 \text{ days}\end{aligned}$$

So, the inventory period is about 111 days. On average, in other words, inventory sat for about 111 days before it was sold.²

¹ Notice that in calculating inventory turnover here, we used the *average* inventory instead of using the ending inventory as we did in Chapter 3. Both approaches are used in the real world. To gain some practice using average figures, we will stick with this approach in calculating various ratios throughout this chapter.

² This measure is conceptually identical to the days' sales in inventory we discussed in Chapter 3.

Similarly, receivables averaged \$1.8 million, and sales were \$11.5 million. Assuming that all sales were credit sales, the receivables turnover is:³

$$\begin{aligned}\text{Receivables turnover} &= \frac{\text{Credit sales}}{\text{Average accounts receivable}} \\ &= \frac{\$11.5 \text{ million}}{1.8 \text{ million}} = 6.4 \text{ times}\end{aligned}$$

If we turn over our receivables 6.4 times, then the receivables period is:

$$\begin{aligned}\text{Receivables period} &= \frac{365 \text{ days}}{\text{Receivables turnover}} \\ &= \frac{365}{6.4} = 57 \text{ days}\end{aligned}$$

The receivables period is also called the *days' sales in receivables* or the *average collection period*. Whatever it is called, it tells us that our customers took an average of 57 days to pay.

The operating cycle is the sum of the inventory and receivables periods:

$$\begin{aligned}\text{Operating cycle} &= \text{Inventory period} + \text{Accounts receivable period} \\ &= 111 \text{ days} + 57 \text{ days} = 168 \text{ days}\end{aligned}$$

This tells us that, on average, 168 days elapse between the time we acquire inventory and, having sold it, collect for the sale.

The Cash Cycle We now need the payables period. From the information given above, average payables were \$875,000, and cost of goods sold was again \$8.2 million. Our payables turnover is:

$$\begin{aligned}\text{Payables turnover} &= \frac{\text{Cost of goods sold}}{\text{Average payables}} \\ &= \frac{\$8.2 \text{ million}}{.875 \text{ million}} = 9.4 \text{ times}\end{aligned}$$

The payables period is:

$$\begin{aligned}\text{Payables period} &= \frac{365 \text{ days}}{\text{Payables turnover}} \\ &= \frac{365}{9.4} = 39 \text{ days}\end{aligned}$$

Thus, we took an average of 39 days to pay our bills.

Finally, the cash cycle is the difference between the operating cycle and the payables period:

$$\begin{aligned}\text{Cash cycle} &= \text{Operating cycle} - \text{Accounts payable period} \\ &= 168 \text{ days} - 39 \text{ days} = 129 \text{ days}\end{aligned}$$

So, on average, there is a 129-day delay from the time we pay for merchandise to the time we collect on the sale.

³ If less than 100 percent of our sales are credit sales, then we just need a little more information, namely, credit sales for the year. See Chapter 3 for more discussion of this measure.

The Operating and Cash Cycles

EXAMPLE 16.2

You have collected the following information for the Slowpay Company:

Item	Beginning	Ending
Inventory	\$5,000	\$7,000
Accounts receivable	1,600	2,400
Accounts payable	2,700	4,800

Credit sales for the year just ended were \$50,000, and cost of goods sold was \$30,000. How long does it take Slowpay to collect on its receivables? How long does merchandise stay around before it is sold? How long does Slowpay take to pay its bills?

We can first calculate the three turnover ratios:

$$\text{Inventory turnover} = \$30,000 / 6,000 = 5 \text{ times}$$

$$\text{Receivables turnover} = \$50,000 / 2,000 = 25 \text{ times}$$

$$\text{Payables turnover} = \$30,000 / 3,750 = 8 \text{ times}$$

We use these to get the various periods:

$$\text{Inventory period} = 365 / 5 = 73 \text{ days}$$

$$\text{Receivables period} = 365 / 25 = 14.6 \text{ days}$$

$$\text{Payables period} = 365 / 8 = 45.6 \text{ days}$$

All told, Slowpay collects on a sale in 14.6 days, inventory sits around for 73 days, and bills get paid after about 46 days. The operating cycle here is the sum of the inventory and receivables periods: $73 + 14.6 = 87.6$ days. The cash cycle is the difference between the operating cycle and the payables period: $87.6 - 45.6 = 42$ days.

Interpreting the Cash Cycle

Our examples show that the cash cycle depends on the inventory, receivables, and payables periods. The cash cycle increases as the inventory and receivables periods get longer. It decreases if the company is able to defer payment of payables and thereby lengthen the payables period.

Most firms have a positive cash cycle, and they thus require financing for inventories and receivables. The longer the cash cycle, the more financing is required. Also, changes in the firm's cash cycle are often monitored as an early-warning measure. A lengthening cycle can indicate that the firm is having trouble moving inventory or collecting on its receivables. Such problems can be masked, at least partially, by an increased payables cycle, so both should be monitored.

We can easily see the link between the firm's cash cycle and its profitability by recalling that one of the basic determinants of profitability and growth for a firm is its total asset turnover, which is defined as $\text{Sales} / \text{Total assets}$. In Chapter 3, we saw that the higher this ratio is, the greater are the firm's accounting return on assets, ROA, and return on equity, ROE. Thus, all other things being the same, the shorter the cash cycle is, the lower is the firm's investment in inventories and receivables. As a result, the firm's total assets are lower, and total turnover is higher.

Cash Cycle Comparison

In 2008, *CFO* magazine published its annual survey of working capital for various industries. The results of this survey highlight the differences in cash and operating cycles across industries. The table below shows four different industries and the operating and cash cycles for each. Of these, the computer industry has the shortest operating cycle and cash cycle. Looking at the components, this industry has the shortest inventory period for all of the industries shown. Although it is not shown here, the company with the best working capital management in the computer industry is Apple,

with an operating cycle of 30 days and a cash cycle of *negative* 46 days.

In contrast to the computer industry, the health-care equipment industry has a much longer operating cycle; the long receivables period is the major cause. However, this does not necessarily mean the health-care equipment industry is less efficient. Most, if not all, of the receivables in this industry will be paid by medical insurance companies and government medical insurers such as Medicare, but these entities have relatively long payables periods.

	Receivables Period (days)	Inventory Period (days)	Operating Cycle (days)	Payables Period (days)	Cash Cycle (days)
Auto components	53	31	84	47	37
Computers & peripherals	52	17	69	41	28
Health-care equipment	66	46	112	17	95
Tobacco industry	26	109	135	15	120

We've seen that operating and cash cycles can vary quite a bit across industries, but these cycles can also be different for companies within the same industry. Below you will find the operating and cash cycles for selected companies within the food industry. As you can see, there are major

differences. Chiquita Brands and Flowers Foods have the best operating and cash cycles in the industry. Both McCormick and Del Monte have longer inventory periods than their peers. These companies have inventory periods three to five times as long.

	Receivables Period (days)	Inventory Period (days)	Operating Cycle (days)	Payables Period (days)	Cash Cycle (days)
Chiquita Brands	35	17	52	34	18
Flowers Foods	23	14	37	19	18
McCormick	57	54	111	30	81
Del Monte Foods	28	87	115	21	94

By examining all parts of the cash cycle, you can see where a company is performing well or poorly, as the case may be. Looking at the operating cycle for McCormick and Del Monte Foods, both have much longer inventory periods. But, when we dig deeper, the reason becomes more apparent. McCormick is known for its dried seasonings and flavorings, while Del Monte

sells canned foods. So, both companies sell food products with a relatively long shelf life. In contrast, Chiquita Brands, known for its famous bananas, sells food with a much shorter shelf life. Thus, a long inventory period for Chiquita Brands results in spoilage, while McCormick and Del Monte Foods do not have this problem.

To see how important the cash cycle is, consider the case of semiconductor manufacturer MEMC. At the end of 2008, the company had an operating cycle of 45 days, down from 81 days two years earlier. As a result, the company freed up \$340 million in cash. At an interest rate of 5 percent, this represents an interest cash flow of \$17 million per year. The above *Reality Bytes* box discusses the cash cycles and operating cycles for several industries, as well as for some specific companies.

CONCEPT QUESTIONS

- 16.2a** What does it mean to say that a firm has an inventory turnover ratio of 4?
- 16.2b** Describe the operating cycle and cash cycle. What are the differences?
- 16.2c** Explain the connection between a firm's accounting-based profitability and its cash cycle.

SOME ASPECTS OF SHORT-TERM FINANCIAL POLICY

16.3

The short-term financial policy that a firm adopts will be reflected in at least two ways:

1. *The size of the firm's investment in current assets.* This is usually measured relative to the firm's level of total operating revenues. A *flexible*, or accommodative, short-term financial policy would maintain a relatively high ratio of current assets to sales. A *restrictive* short-term financial policy would entail a low ratio of current assets to sales.⁴
2. *The financing of current assets.* This is measured as the proportion of short-term debt (that is, current liabilities) and long-term debt used to finance current assets. A restrictive short-term financial policy means a high proportion of short-term debt relative to long-term financing, and a flexible policy means less short-term debt and more long-term debt.

If we take these two areas together, we see that a firm with a flexible policy would have a relatively large investment in current assets. It would finance this investment with relatively less in short-term debt. The net effect of a flexible policy is thus a relatively high level of net working capital. Put another way, with a flexible policy, the firm maintains a larger overall level of liquidity.

The Size of the Firm's Investment in Current Assets

Flexible short-term financial policies with regard to current assets include such actions as:

1. Keeping large balances of cash and marketable securities.
2. Making large investments in inventory.
3. Granting liberal credit terms, which results in a high level of accounts receivable.

Restrictive short-term financial policies would be just the opposite of the ones above:

1. Keeping low cash balances and little investment in marketable securities.
2. Making small investments in inventory.
3. Allowing few or no credit sales, thereby minimizing accounts receivable.

Determining the optimal level of investment in short-term assets requires an identification of the different costs of alternative short-term financing policies. The objective is to

⁴ Some people use the term *conservative* in place of *flexible* and the term *aggressive* in place of *restrictive*.

trade off the cost of a restrictive policy against the cost of a flexible one to arrive at the best compromise.

Current asset holdings are highest with a flexible short-term financial policy and lowest with a restrictive policy. So, flexible short-term financial policies are costly in that they require a greater investment in cash and marketable securities, inventory, and accounts receivable. However, we expect that future cash inflows will be higher with a flexible policy. For example, sales are stimulated by the use of a credit policy that provides liberal financing to customers. A large amount of finished inventory on hand (“on the shelf”) provides a quick delivery service to customers and may increase sales. Similarly, a large inventory of raw materials may result in fewer production stoppages because of inventory shortages.

A more restrictive short-term financial policy probably reduces future sales levels below those that would be achieved under flexible policies. It is also possible that higher prices can be charged to customers under flexible working capital policies. Customers may be willing to pay higher prices for the quick delivery service and more liberal credit terms implicit in flexible policies.

Managing current assets can be thought of as involving a trade-off between costs that rise and costs that fall with the level of investment. Costs that rise with increases in the level of investment in current assets are called **carrying costs**. The larger the investment a firm makes in its current assets, the higher its carrying costs will be. Costs that fall with increases in the level of investment in current assets are called **shortage costs**.

carrying costs

Costs that rise with increases in the level of investment in current assets.

shortage costs

Costs that fall with increases in the level of investment in current assets.

In a general sense, carrying costs are the opportunity costs associated with current assets. The rate of return on current assets is very low when compared to that on other assets. For example, the rate of return on U.S. Treasury bills is usually well below 10 percent. This is very low compared to the rate of return firms would like to achieve overall. (U.S. Treasury bills are an important component of cash and marketable securities.)

Shortage costs are incurred when the investment in current assets is low. If a firm runs out of cash, it will be forced to sell marketable securities. Of course, if a firm runs out of cash and cannot readily sell marketable securities, it may have to borrow or default on an obligation. This situation is called a *cash-out*. A firm may lose customers if it runs out of inventory (a *stock-out*) or if it cannot extend credit to customers.

More generally, there are two kinds of shortage costs:

1. *Trading, or order, costs.* Order costs are the costs of placing an order for more cash (brokerage costs, for example) or more inventory (production setup costs, for example).
2. *Costs related to lack of safety reserves.* These are costs of lost sales, lost customer goodwill, and disruption of production schedules.

The top part of Figure 16.2 illustrates the basic trade-off between carrying costs and shortage costs. On the vertical axis, we have costs measured in dollars, and, on the horizontal axis, we have the amount of current assets. Carrying costs start out at zero when current assets are zero and then climb steadily as current assets grow. Shortage costs start out very high and then decline as we add current assets. The total cost of holding current assets is the sum of the two. Notice how the combined costs reach a minimum at CA*. This is the optimal level of current assets.

Optimal current asset holdings are highest under a flexible policy. This policy is one in which the carrying costs are perceived to be low relative to shortage costs. This is Case A in Figure 16.2. In comparison, under restrictive current asset policies, carrying costs are perceived to be high relative to shortage costs, resulting in lower current asset holdings. This is Case B in Figure 16.2.

FIGURE 16.2**Carrying costs and shortage costs****Short-term financial policy: the optimal investment in current assets**

CA* represents the optimal amount of current assets. Holding this amount minimizes total costs.

Carrying costs increase with the level of investment in current assets. They include the costs of maintaining economic value and opportunity costs. Shortage costs decrease with increases in the level of investment in current assets. They include trading costs and the costs related to being short of the current asset (for example, being short of cash). The firm's policy can be characterized as flexible or restrictive.

A flexible policy is most appropriate when carrying costs are low relative to shortage costs.

A restrictive policy is most appropriate when carrying costs are high relative to shortage costs.

Alternative Financing Policies for Current Assets

In previous sections, we looked at the basic determinants of the level of investment in current assets, and we thus focused on the asset side of the balance sheet. Now we turn to the financing side of the question. Here we are concerned with the relative amounts of short-term and long-term debt, assuming the investment in current assets is constant.

A growing firm can be thought of as having a total asset requirement consisting of the current assets and long-term assets needed to run the business efficiently. The total asset requirement may exhibit change over time for many reasons, including (1) a general growth trend, (2) seasonal variation around the trend, and (3) unpredictable day-to-day and month-to-month fluctuations. This situation is depicted in Figure 16.3. (We have not

FIGURE 16.3

The total asset requirement over time

**FIGURE 16.4**

Alternative asset financing policies

Policy F always implies a short-term cash surplus and a large investment in cash and marketable securities.

Policy R uses long-term financing for permanent asset requirements only and short-term borrowing for seasonal variations.

tried to show the unpredictable day-to-day and month-to-month variations in the total asset requirement.)

The peaks and valleys in Figure 16.3 represent the firm's total asset needs through time. For example, for a lawn and garden supply firm, the peaks might represent inventory buildups prior to the spring selling season. The valleys come about because of lower off-season inventories. There are two strategies such a firm might consider to meet its cyclical needs. First, the firm could keep a relatively large pool of marketable securities. As the need for inventory and other current assets begins to rise, the firm sells off marketable securities and uses the cash to purchase whatever is needed. Once the inventory is sold and inventory holdings begin to decline, the firm reinvests in marketable securities. This approach is the flexible policy illustrated in Figure 16.4 as Policy F. Notice that the firm essentially uses a pool of marketable securities as a buffer against changing current asset needs.

At the other extreme, the firm could keep relatively little in marketable securities. As the need for inventory and other assets begins to rise, the firm simply borrows the needed cash on a short-term basis. The firm repays the loans as the need for assets cycles back down. This approach is the restrictive policy illustrated in Figure 16.4 as Policy R.

In comparing the two strategies illustrated in Figure 16.4, notice that the chief difference is the way in which the seasonal variation in asset needs is financed. In the flexible case, the firm finances internally, using its own cash and marketable securities. In the restrictive case, the firm finances externally, borrowing the needed funds on a short-term basis. As we discussed above, all else being the same, a firm with a flexible policy will have a greater investment in net working capital.

Which Financing Policy Is Best?

What is the most appropriate amount of short-term borrowing? There is no definitive answer. Several considerations must be included in a proper analysis:

1. *Cash reserves.* The flexible financing policy implies surplus cash and little short-term borrowing. This policy reduces the probability that a firm will experience financial distress. Firms may not have to worry as much about meeting recurring short-run obligations. However, investments in cash and marketable securities are zero net present value investments at best.
2. *Maturity hedging.* Most firms attempt to match the maturities of assets and liabilities. They finance inventories with short-term bank loans and fixed assets with long-term financing. Firms tend to avoid financing long-lived assets with short-term borrowing. This type of maturity mismatching would necessitate frequent refinancing and is inherently risky because short-term interest rates are more volatile than longer-term rates.
3. *Relative interest rates.* Short-term interest rates are usually lower than long-term rates. This implies that it is, on average, more costly to rely on long-term borrowing as compared to short-term borrowing.

The two policies, F and R, that we discuss above are, of course, extreme cases. With F, the firm never does any short-term borrowing, and, with R, the firm never has a cash reserve (an investment in marketable securities). Figure 16.5 illustrates these two policies along with a compromise, Policy C.

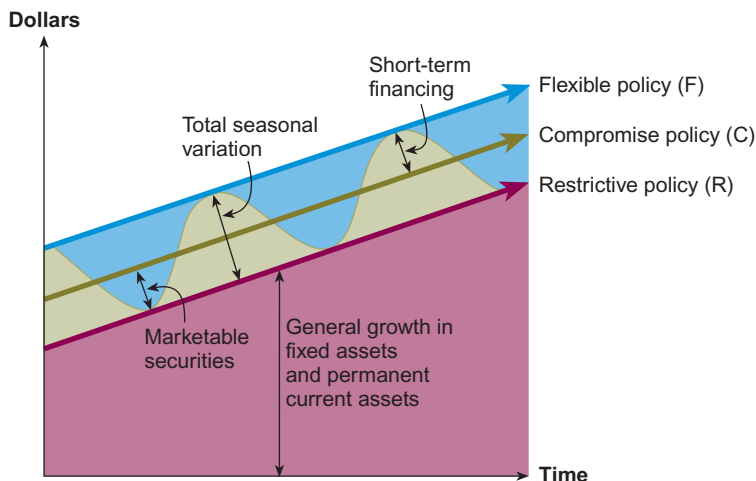

FIGURE 16.5

A compromise financing policy

With a compromise policy, the firm keeps a reserve of liquidity that it uses to initially finance seasonal variations in current asset needs. Short-term borrowing is used when the reserve is exhausted.

TABLE 16.2

Current assets and current liabilities as a percentage of total assets for selected companies: 2008

	Amazon.com	Boeing	Dell	Walmart
Cash and near cash	33.63%	6.08%	31.52%	3.53%
Marketable securities	11.52	0.81	9.25	0.00
Accounts receivable	12.40	12.36	17.85	1.94
Inventories	16.83	29.03	3.27	24.08
Other current assets	0.00	0.00	14.15	1.95
Total current assets	<u>74.38%</u>	<u>48.28%</u>	<u>76.04%</u>	<u>31.49%</u>
Accounts payable	56.37%	43.01%	31.38%	28.28%
Short-term borrowings	0.71	1.04	0.43	7.74
Other short-term liabilities	0.00	13.46	24.27	0.08
Total current liabilities	<u>57.08%</u>	<u>57.50%</u>	<u>56.07%</u>	<u>36.11%</u>

With this compromise approach, the firm borrows in the short term to cover peak financing needs, but it maintains a cash reserve in the form of marketable securities during slow periods. As current assets build up, the firm draws down this reserve before doing any short-term borrowing. This allows for some run-up in current assets before the firm has to resort to short-term borrowing.

Current Assets and Liabilities in Practice

Short-term assets represent a significant portion of a typical firm's overall assets. For U.S. manufacturing, mining, and trade corporations, current assets were about 50 percent of total assets in the 1960s. Today, this figure is closer to 40 percent. Most of the decline is due to more efficient cash and inventory management. Over this same period, current liabilities rose from about 20 percent of total liabilities and equity to almost 30 percent. The result is that liquidity (as measured by the ratio of net working capital to total assets) has declined, signaling a move to more restrictive short-term policies.

The cash cycle is longer in some industries than in others because of different products and industry practices. Table 16.2 illustrates this point by comparing the current asset and liability percentages for four different companies. Of the four, Boeing has the highest level of inventories. Does this mean Boeing is less efficient? Probably not; instead, the relatively high inventory levels are consistent with the industry. Boeing manufactures airplanes, and manufacturing a jetliner can take one to two years. During this time, the partially completed plane is on Boeing's balance sheet as inventory. Walmart also needs a higher level of inventory on hand to satisfy customers who walk into its stores. In contrast, Dell mostly makes products to order, so its inventory levels are lower. Notice also that Walmart and Boeing have the lowest levels of current assets to total assets, implying that fixed assets are large, as you would expect from such capital-intensive companies. Walmart and Boeing also share another similarity. In both cases, current liabilities exceed current assets, so both companies have a negative net working capital.

CONCEPT QUESTIONS

16.3a What considerations determine the optimal size of the firm's investment in current assets?

16.3b What considerations determine the optimal compromise between flexible and restrictive net working capital policies?

THE CASH BUDGET

The **cash budget** is a primary tool in short-run financial planning. It allows the financial manager to identify short-term financial needs and opportunities. Importantly, the cash budget will help the manager explore the need for short-term borrowing. The idea of the cash budget is simple: It records estimates of cash receipts (cash in) and disbursements (cash out). The result is an estimate of the cash surplus or deficit.

16.4

cash budget

A forecast of cash receipts and disbursements for the next planning period.

Sales and Cash Collections

We start with an example for the Fun Toys Corporation. We will prepare a quarterly cash budget. We could just as well use a monthly, weekly, or even daily basis. We choose quarters for convenience and also because a quarter is a common short-term business planning period.

All of Fun Toys's cash inflows come from the sale of toys. Cash budgeting for Fun Toys must therefore start with a sales forecast for the coming year, by quarter:

	Q1	Q2	Q3	Q4
Sales (in millions)	\$200	\$300	\$250	\$400

Note that these are predicted sales, so there is forecasting risk here; actual sales could be more or less. Also, Fun Toys started the year with accounts receivable equal to \$120.

Fun Toys has a 45-day receivables, or average collection, period. This means that half of the sales in a given quarter will be collected the following quarter. This happens because sales made during the first 45 days of a quarter will be collected in that quarter. Sales made in the second 45 days will be collected in the next quarter. Note that we are assuming that each quarter has 90 days, so the 45-day collection period is the same as a half-quarter collection period.

Based on the sales forecasts, we now need to estimate Fun Toys's projected cash collections. First, any receivables that we have at the beginning of a quarter will be collected within 45 days, so all of them will be collected sometime during the quarter. Second, as we discussed, any sales made in the first half of the quarter will be collected, so total cash collections are:

$$\text{Cash collections} = \text{Beginning accounts receivable} + \frac{1}{2} \times \text{Sales} \quad [16.6]$$

For example, in the first quarter, cash collections would be the beginning receivables of \$120 plus half of sales, $\frac{1}{2} \times \$200 = \100 , for a total of **\$220**.

Since beginning receivables are all collected along with half of sales, ending receivables for a particular quarter would be the other half of sales. First-quarter sales are projected at \$200, so ending receivables will be \$100. This will be the beginning receivables in the second quarter. Cash collections in the second quarter will thus be \$100 plus half of the projected \$300 in sales, or \$250 total.

Continuing this process, we can summarize Fun Toys's projected cash collections as shown in Table 16.3.

In Table 16.3, collections are shown as the only source of cash. Of course, this might not be the case. Other sources of cash could include asset sales, investment income, and receipts from planned long-term financing.

TABLE 16.3**Cash collections for Fun Toys (in millions)**

	Q1	Q2	Q3	Q4
Beginning receivables	\$120	\$100	\$150	\$125
Sales	200	300	250	400
Cash collections	220	250	275	325
Ending receivables	100	150	125	200

$$\text{Collections} = \text{Beginning receivables} + \frac{1}{2} \times \text{Sales}$$

$$\text{Ending receivables} = \text{Beginning receivables} + \text{Sales} - \text{Collections}$$

$$= \frac{1}{2} \times \text{Sales}$$

TABLE 16.4**Cash disbursements for Fun Toys (in millions)**

	Q1	Q2	Q3	Q4
Payment of accounts (60% of sales)	\$120	\$180	\$150	\$240
Wages, taxes, other expenses	40	60	50	80
Capital expenditures	0	100	0	0
Long-term financing expenses (interest and dividends)	20	20	20	20
Total cash disbursements	\$180	\$360	\$220	\$340

Cash Outflows

Next, we consider the cash disbursements, or payments. These come in four basic categories:

1. *Payments of accounts payable.* These are payments for goods or services rendered by suppliers, such as raw materials. Generally, these payments will be made sometime after purchases.
2. *Wages, taxes, and other expenses.* This category includes all other regular costs of doing business that require actual expenditures. Depreciation, for example, is often thought of as a regular cost of business, but it requires no cash outflow and is not included.
3. *Capital expenditures.* These are payments of cash for long-lived assets.
4. *Long-term financing expenses.* This category, for example, includes interest payments on long-term debt outstanding and dividend payments to shareholders.

Fun Toys's purchases from suppliers (in dollars) in a quarter are equal to 60 percent of the next quarter's predicted sales. Fun Toys's payments to suppliers are equal to the previous quarter's purchases, so the accounts payable period is 90 days. For example, in the quarter just ended, Fun Toys ordered $.60 \times \$200 = \120 in supplies. This will actually be paid in the first quarter (Q1) of the coming year.

Wages, taxes, and other expenses are routinely 20 percent of sales; interest and dividends are currently \$20 per quarter. In addition, Fun Toys plans a major plant expansion (a capital expenditure) of \$100 in the second quarter. If we put all this information together, the cash outflows are as shown in Table 16.4.

The Cash Balance

The predicted *net cash inflow* is the difference between cash collections and cash disbursements. The net cash inflow for Fun Toys is shown in Table 16.5. What we see immediately is that there is a net cash inflow in the first and third quarters and a net outflow in the second and fourth.

	Q1	Q2	Q3	Q4	TABLE 16.5
Total cash collections	\$220	\$250	\$275	\$325	Net cash inflow for Fun Toys (in millions)
Total cash disbursements	180	360	220	340	
Net cash inflow	\$ 40	−\$110	\$ 55	−\$ 15	

	Q1	Q2	Q3	Q4	TABLE 16.6
Beginning cash balance	\$20	\$ 60	−\$50	\$ 5	Cash balance for Fun Toys (in millions)
Net cash inflow	40	− 110	55	− 15	
Ending cash balance	\$60	−\$ 50	\$ 5	−\$10	
Minimum cash balance	− 10	− 10	− 10	− 10	
Cumulative surplus (deficit)	\$50	−\$ 60	−\$ 5	−\$20	

We will assume that Fun Toys starts the year with a \$20 cash balance. Furthermore, Fun Toys maintains a \$10 minimum cash balance to guard against unforeseen contingencies and forecasting errors. So, we start the first quarter with \$20 in cash. This rises by \$40 during the quarter, and the ending balance is \$60. Of this, \$10 is reserved as a minimum, so we subtract it out and find that the first-quarter surplus is $\$60 - \$10 = \$50$.

Fun Toys starts the second quarter with \$60 in cash (the ending balance from the previous quarter). There is a net cash inflow of $-\$110$, so the ending balance is $\$60 - \$110 = -\$50$. We need another \$10 as a buffer, so the total deficit is $-\$60$. These calculations and those for the last two quarters are summarized in Table 16.6.

Beginning in the second quarter, Fun Toys has a cash shortfall of \$60. This occurs because of the seasonal pattern of sales (higher towards the end of the second quarter), the delay in collections, and the planned capital expenditure.

The cash situation at Fun Toys is projected to improve to a \$5 deficit in the third quarter, but, by year's end, Fun Toys is showing a \$20 deficit. Without some sort of financing, this deficit will carry over into the next year. We explore this subject in the next section.

For now, we can make the following general comments on Fun Toys's cash needs:

1. Fun Toys's large outflow in the second quarter is not necessarily a sign of trouble. It results from delayed collections on sales and a planned capital expenditure (presumably a worthwhile one).
2. The figures in our example are based on a forecast. Sales could be much worse (or better) than the forecast figures.

CONCEPT QUESTIONS

16.4a How would you do a sensitivity analysis (discussed in Chapter 9) for Fun Toys's net cash balance?

16.4b What could you learn from such an analysis?

16.5

SHORT-TERM BORROWING

Fun Toys has a short-term financing problem. It cannot meet the forecast cash outflows in the second quarter from internal sources. How it will finance the shortfall depends on its financial policy. With a very flexible policy, Fun Toys might seek up to \$60 million in long-term debt financing.

In addition, note that much of the cash deficit comes from the large capital expenditure. Arguably, this is a candidate for long-term financing. Nonetheless, because we have discussed long-term financing elsewhere, we will concentrate here on two short-term borrowing options: (1) unsecured borrowing and (2) secured borrowing.

Unsecured Loans

The most common way to finance a temporary cash deficit is to arrange a short-term, unsecured bank loan. Firms that use short-term bank loans often arrange a line of credit. A **line of credit** is an agreement under which a firm is authorized to borrow up to a specified amount. To ensure that the line is used for short-term purposes, the borrower will sometimes be required to pay the line down to zero and keep it there for some period during the year, typically 60 days (called a *cleanup period*).

Short-term lines of credit are classified as either *committed* or *noncommitted*. The latter is an informal arrangement that allows firms to borrow up to a previously specified limit without going through the normal paperwork (much as you would with a credit card). A *revolving credit arrangement* (or just *revolver*) is similar to a line of credit, but it is usually open for two or more years, whereas a line of credit would usually be evaluated on an annual basis.

Committed lines of credit are more formal legal arrangements and often involve a commitment fee paid by the firm to the bank. The interest rate on the line of credit will usually float. A firm that pays a commitment fee for a committed line of credit is essentially buying insurance to guarantee that the bank can't back out of the agreement (absent some material change in the borrower's status).

Secured Loans

Banks and other finance companies often require security for a short-term loan just as they do for a long-term loan. Security for short-term loans usually consists of accounts receivable, inventories, or both.

line of credit

A formal (committed) or informal (noncommitted) prearranged, short-term bank loan.

accounts receivable financing

A secured short-term loan that involves either the assignment or factoring of receivables.

Accounts Receivable Financing **Accounts receivable financing** involves either *assigning* receivables or *factoring* receivables. Under assignment, the lender has the receivables as security, but the borrower is still responsible if a receivable can't be collected. With *conventional factoring*, the receivable is discounted and sold to the lender (the factor). Once it is sold, collection is the factor's problem, and the factor assumes the full risk of default on bad accounts. With *maturity factoring*, the factor forwards the money on an agreed-upon future date.

EXAMPLE 16.3**Cost of Factoring**

For the year just ended, LuLu's Pies had an average of \$50,000 in accounts receivable. Credit sales were \$500,000. LuLu's factors its receivables by discounting them 3 percent, in other words, by selling them for 97 cents on the dollar. What is the effective interest rate on this source of short-term financing?

(continued)

To determine the interest rate, we first have to know the accounts receivable, or average collection, period. During the year, LuLu's turned over its receivables $\$500,000/50,000 = 10$ times. The average collection period is therefore $365/10 = 36.5$ days.

The interest paid here is a form of "discount interest." In this case, LuLu's is paying 3 cents in interest on every 97 cents of financing. The interest rate per 36.5 days is thus $.03/.97 = 3.09\%$. The APR is $10 \times 3.09\% = 30.9\%$, but the effective annual rate is:

$$\text{EAR} = 1.0309^{10} - 1 = 35.6\%$$

The factoring is a relatively expensive source of money in this case.

We should note that if the factor takes on the risk of default by a buyer, then the factor is providing insurance as well as immediate cash. More generally, the factor essentially takes over the firm's credit operations. This can result in a significant saving. The interest rate we calculated is therefore overstated, particularly if default is a significant possibility.

Inventory Loans **Inventory loans**, short-term loans to purchase inventory, come in three basic forms: blanket inventory liens, trust receipts, and field warehouse financing:

1. *Blanket inventory lien.* A blanket lien gives the lender a lien against all the borrower's inventories (the blanket "covers" everything).
2. *Trust receipt.* A trust receipt is a device by which the borrower holds specific inventory in "trust" for the lender. Automobile dealer financing, for example, is done by use of trust receipts. This type of secured financing is also called *floor planning*, in reference to inventory on the showroom floor. However, it is somewhat cumbersome to use trust receipts for, say, wheat grain.
3. *Field warehouse financing.* In field warehouse financing, a public warehouse company (an independent company that specializes in inventory management) acts as a control agent to supervise the inventory for the lender.

inventory loan

A secured short-term loan to purchase inventory.

Other Sources

There are a variety of other sources of short-term funds employed by corporations. Two of the most important are *commercial paper* and *trade credit*.

Commercial paper consists of short-term notes issued by large and highly rated firms. Typically, these notes are of short maturity, ranging up to 270 days (beyond that limit, the firm must file a registration statement with the SEC). Because the firm issues these directly, the interest rate the borrowing firm obtains can be significantly below the rate a bank would charge for a direct loan.

Another option available to a firm is to increase the accounts payable period; in other words, it may take longer to pay its bills. This amounts to borrowing from suppliers in the form of trade credit. This is an extremely important form of financing for smaller businesses in particular. As we discuss in Chapter 17, a firm using trade credit may end up paying a much higher price for what it purchases, so this can be a very expensive source of financing.

CONCEPT QUESTIONS

16.5a What are the two basic forms of short-term financing?

16.5b Describe two types of secured loans.

16.6

A SHORT-TERM FINANCIAL PLAN

To illustrate a completed short-term financial plan, we will assume that Fun Toys arranges to borrow any needed funds on a short-term basis. The interest rate is 20 percent APR, and it is calculated on a quarterly basis. From Chapter 5, we know that the rate is $20\%/4 = 5\%$ per quarter. We will assume that Fun Toys starts the year with no short-term debt.

From Table 16.6, we see that Fun Toys has a second-quarter deficit of \$60 million. We will have to borrow this amount. Net cash inflow in the following quarter is \$55 million. We now have to pay $\$60 \times .05 = \3 million in interest out of that, leaving \$52 million to reduce the borrowing.

We still owe $\$60 - \$52 = \$8$ million at the end of the third quarter. Interest in the last quarter will thus be $\$8 \times .05 = \4 million. In addition, net inflows in the last quarter are $-\$15$ million, so we have to borrow a total of \$15.4 million, bringing our total borrowing up to $\$15.4 + 8 = \23.4 million. Table 16.7 extends Table 16.6 to include these calculations.

Notice that the ending short-term debt is just equal to the cumulative deficit for the entire year, \$20 million, plus the interest paid during the year, $\$3 + .4 = \3.4 million, for a total of \$23.4 million.

Our plan is very simple. For example, we ignored the fact that the interest paid on the short-term debt is tax deductible. We also ignored the fact that the cash surplus in the first quarter would earn some interest (which would be taxable). We could add on a number of refinements. Even so, our plan highlights the fact that in about 90 days Fun Toys will need to borrow \$60 million or so on a short-term basis. It's time to start lining up the source of the funds.

Our plan also illustrates that financing the firm's short-term needs will cost about \$3.4 million in interest (before taxes) for the year. This is a starting point for Fun Toys to begin evaluating alternatives to reduce this expense. For example, can the \$100 million planned expenditure be postponed or spread out? At 5 percent per quarter, short-term credit is expensive.

Also, if Fun Toys's sales are expected to keep growing, then the \$20 million plus deficit will probably also keep growing, and the need for additional financing is permanent. Fun Toys may wish to think about raising money on a long-term basis to cover this need.

TABLE 16.7

**Short-term financial
plan for Fun Toys
(in millions)**

	Q1	Q2	Q3	Q4
Beginning cash balance	\$20	\$60	\$10	\$10.0
Net cash inflow	40	-110	55	-15.0
New short-term borrowing	—	60	—	15.4
Interest on short-term borrowing	—	—	-3	-.4
Short-term borrowing repaid	—	—	-52	—
Ending cash balance	\$60	\$10	\$10	\$10.0
Minimum cash balance	-10	-10	-10	-10.0
Cumulative surplus (deficit)	\$50	\$0	\$0	\$0
Beginning short-term borrowing	0	0	60	8.0
Change in short-term debt	0	60	-52	15.4
Ending short-term debt	\$0	\$60	\$8	\$23.4

CONCEPT QUESTIONS

- 16.6a** In Table 16.7, does Fun Toys have a projected deficit or surplus?
- 16.6b** In Table 16.7, what would happen to Fun Toys's deficit or surplus if the minimum cash balance was reduced to \$5?

SUMMARY AND CONCLUSIONS

1. This chapter has introduced the management of short-term finance. Short-term finance involves short-lived assets and liabilities. We traced and examined the short-term sources and uses of cash as they appear on the firm's financial statements. We saw how current assets and current liabilities arise in the short-term operating activities and the cash cycle of the firm.
2. Managing short-term cash flows involves the minimizing of costs. The two major costs are carrying costs, the returns foregone by keeping too much invested in short-term assets such as cash, and shortage costs, the costs of running out of short-term assets. The objective of managing short-term finance and doing short-term financial planning is to find the optimal trade-off between these two costs.
3. In an "ideal" economy, the firm could perfectly predict its short-term uses and sources of cash, and net working capital could be kept at zero. In the real world we live in, cash and net working capital provide a buffer that lets the firm meet its ongoing obligations. The financial manager seeks the optimal level of each of the current assets.
4. The financial manager can use the cash budget to identify short-term financial needs. The cash budget tells the manager what borrowing is required or what lending will be possible in the short run. The firm has available to it a number of possible ways of acquiring funds to meet short-term shortfalls, including the use of unsecured and secured loans.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

- 16.1 The Operating and Cash Cycles.** Consider the following financial statement information for the Glory Road Company:

Item	Beginning	Ending
Inventory	\$1,543	\$1,669
Accounts receivable	4,418	3,952
Accounts payable	2,551	2,673
Net sales		\$11,500
Cost of goods sold		8,200

Calculate the operating and cash cycles.

- 16.2 Cash Balance for Masson Corporation.** The Masson Corporation has a 60-day average collection period and wishes to maintain a \$5 million minimum

cash balance. Based on this and the information below, complete the following cash budget. What conclusions do you draw?

MASSON CORPORATION Cash Budget (in millions)				
	Q1	Q2	Q3	Q4
Beginning receivables	\$120			
Sales	90	\$120	\$150	\$120
Cash collections				
Ending receivables				
Total cash collections				
Total cash disbursements	80	160	180	160
Net cash inflow				
Beginning cash balance	\$ 5			
Net cash inflow				
Ending cash balance				
Minimum cash balance				
Cumulative surplus (deficit)				

■ Answers to Chapter Review and Self-Test Problems

- 16.1** We first need the turnover ratios. Note that we use the average values for all balance sheet items and that we base the inventory and payables turnover measures on cost of goods sold.

$$\begin{aligned}\text{Inventory turnover} &= \$8,200 / [(1,543 + 1,669) / 2] \\ &= 5.11 \text{ times}\end{aligned}$$

$$\begin{aligned}\text{Receivables turnover} &= \$11,500 / [(4,418 + 3,952) / 2] \\ &= 2.75 \text{ times}\end{aligned}$$

$$\begin{aligned}\text{Payables turnover} &= \$8,200 / [(2,551 + 2,673) / 2] \\ &= 3.14 \text{ times}\end{aligned}$$

We can now calculate the various periods:

$$\begin{aligned}\text{Inventory period} &= 365 \text{ days} / 5.11 \text{ times} = 71.43 \text{ days} \\ \text{Receivables period} &= 365 \text{ days} / 2.75 \text{ times} = 132.73 \text{ days} \\ \text{Payables period} &= 365 \text{ days} / 3.14 \text{ times} = 116.24 \text{ days}\end{aligned}$$

So, the time it takes to acquire inventory and sell it is about 71 days. Collection takes another 133 days, so the operating cycle is thus $71 + 133 = 204$ days. The cash cycle is this 204 days less the payables period, $204 - 116 = 88$ days.

- 16.2** Since Masson has a 60-day collection period, only those sales made in the first 30 days of the quarter will be collected in the same quarter. Total cash collections in the first quarter will thus equal $30/90 = \frac{1}{3}$ of sales plus beginning receivables, or $\$120 + \frac{1}{3} \times 90 = \150 . Ending receivables for the first quarter (and the second-quarter beginning receivables) are the other $\frac{2}{3}$ of sales, or $\frac{2}{3} \times \$90 = \60 . The remaining calculations are straightforward, and the completed budget follows.

MASSON CORPORATION Cash Budget (in millions)				
	Q1	Q2	Q3	Q4
Beginning receivables	\$120	\$ 60	\$ 80	\$100
Sales	90	120	150	120
Cash collections	150	100	130	140
Ending receivables	\$ 60	\$ 80	\$100	\$ 80
Total cash collections	\$150	\$100	\$130	\$140
Total cash disbursements	80	160	180	160
Net cash inflow	\$ 70	-\$ 60	-\$ 50	-\$ 20
Beginning cash balance	\$ 5	\$ 75	\$ 15	-\$ 35
Net cash inflow	70	- 60	- 50	- 20
Ending cash balance	\$ 75	\$ 15	-\$ 35	-\$ 55
Minimum cash balance	-\$ 5	-\$ 5	-\$ 5	-\$ 5
Cumulative surplus (deficit)	\$ 70	\$ 10	-\$ 40	-\$ 60

The primary conclusion from this schedule is that, beginning in the third quarter, Masson's cash surplus becomes a cash deficit. By the end of the year, Masson will need to arrange for \$60 million in cash beyond what will be available.

CRITICAL THINKING AND CONCEPTS REVIEW

- L0 1** **16.1 Operating Cycle.** What are some of the characteristics of a firm with a long operating cycle?
- L0 1** **16.2 Cash Cycle.** What are some of the characteristics of a firm with a long cash cycle?
- L0 3** **16.3 Sources and Uses.** For the year just ended, you have gathered the following information on the Holly Corporation:
- A \$200 dividend was paid.
 - Accounts payable increased by \$500.
 - Fixed asset purchases were \$900.
 - Inventories increased by \$625.
 - Long-term debt decreased by \$1,200.
- Label each item as a source or use of cash and describe its effect on the firm's cash balance.
- L0 2** **16.4 Cost of Current Assets.** Kane Manufacturing, Inc., has recently installed a just-in-time (JIT) inventory system. Describe the effect this is likely to have on the company's carrying costs, shortage costs, and operating cycle.
- L0 1** **16.5 Cycles.** Is it possible for a firm's cash cycle to be longer than its operating cycle? Explain why or why not.

Use the following information to answer Questions 16.6–16.10. Last month, BlueSky Airline announced that it would stretch out its bill payments to 45 days from 30 days. The reason given was that the company wanted to “control costs and optimize cash flow.” The increased payables period will be in effect for all of the company's 4,000 suppliers.

- L0 1** 16.6 **Operating and Cash Cycles.** What impact did this change in payables policy have on BlueSky's operating cycle? Its cash cycle?
- L0 1** 16.7 **Operating and Cash Cycles.** What impact did the announcement have on BlueSky's suppliers?
- L0 1** 16.8 **Corporate Ethics.** Is it ethical for large firms to unilaterally lengthen their payables periods, particularly when dealing with smaller suppliers?
- L0 1** 16.9 **Payables Period.** Why don't all firms simply increase their payables periods to shorten their cash cycles?
- L0 1** 16.10 **Payables Period.** BlueSky lengthened its payables period to "control costs and optimize cash flow." Exactly what is the cash benefit to BlueSky from this change?

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

Basic

(Questions 1–12)

- L0 3** 1. **Changes in the Cash Account.** Indicate the impact of the following corporate actions on cash, using the letter *I* for an increase, *D* for a decrease, or *N* when no change occurs.
- A dividend is paid with funds received from a sale of debt.
 - Real estate is purchased and paid for with short-term debt.
 - Inventory is bought on credit.
 - A short-term bank loan is repaid.
 - Next year's taxes are prepaid.
 - Preferred stock is repurchased.
 - Sales are made on credit.
 - Interest on long-term debt is paid.
 - Payments for previous sales are collected.
 - The accounts payable balance is reduced.
 - A dividend is paid.
 - Production supplies are purchased and paid for with a short-term note.
 - Utility bills are paid.
 - Cash is paid for raw materials purchased for inventory.
 - Marketable securities are purchased.
- L0 3** 2. **Cash Equation.** Kings of Leon, Inc., has a book value of equity of \$62,000. Long-term debt is \$55,000. Net working capital, other than cash, is \$21,800. Fixed assets are \$91,600. How much cash does the company have? If current liabilities are \$6,800, what are current assets?
- L0 1** 3. **Changes in the Operating Cycle.** Indicate the effect that the following will have on the operating cycle. Use the letter *I* to indicate an increase, the letter *D* for a decrease, and the letter *N* for no change.
- Average receivables go up.
 - Credit payment times for customers are increased.
 - Inventory turnover goes from 3 times to 7 times.
 - Payables turnover goes from 6 times to 11 times.
 - Receivables turnover goes from 7 times to 9 times.
 - Payments to suppliers are accelerated.

L0 1

4. **Changes in Cycles.** Indicate the impact of the following on the cash and operating cycles, respectively. Use the letter *I* to indicate an increase, the letter *D* for a decrease, and the letter *N* for no change.
- The terms of cash discounts offered to customers are made less favorable.
 - The cash discounts offered by suppliers are increased; thus, payments are made earlier.
 - An increased number of customers begin to pay in cash instead of with credit.
 - Fewer raw materials than usual are purchased.
 - A greater percentage of raw material purchases are paid for with credit.
 - More finished goods are produced for inventory instead of for order.

L0 3

5. **Calculating Cash Collections.** The Maynard Company has projected the following quarterly sales amounts for the coming year:

	Q1	Q2	Q3	Q4
Sales	\$480	\$520	\$610	\$760

- a. Accounts receivable at the beginning of the year are \$240. Maynard has a 45-day collection period. Calculate cash collections in each of the four quarters by completing the following:

	Q1	Q2	Q3	Q4
Beginning receivables				
Sales				
Cash collections				
Ending receivables				

- b. Rework (a) assuming a collection period of 60 days.
 c. Rework (a) assuming a collection period of 30 days.

L0 1

6. **Calculating Cycles.** Consider the following financial statement information for the Keenan Corporation:

Item	Beginning	Ending
Inventory	\$9,582	\$10,380
Accounts receivable	4,851	5,381
Accounts payable	5,152	5,493
Net sales		\$138,503
Cost of goods sold		86,313

Assume all sales are on credit. Calculate the operating and cash cycles. How do you interpret your answer?

L0 3

7. **Factoring Receivables.** Your firm has an average collection period of 47 days. Current practice is to factor all receivables immediately at a 2 percent discount. What is the effective cost of borrowing in this case? Assume that default is extremely unlikely.

L0 3

8. **Calculating Payments.** Confusion Products has projected the following sales for the coming year:

	Q1	Q2	Q3	Q4
Sales	\$620	\$690	\$860	\$780

Sales in the year following this one are projected to be 15 percent greater in each quarter.

- a. Calculate payments to suppliers assuming that the company places orders during each quarter equal to 30 percent of projected sales for the next quarter. Assume that the company pays immediately. What is the payables period in this case?

	Q1	Q2	Q3	Q4
Payment of accounts				

- b. Rework (a) assuming a 90-day payables period.
c. Rework (a) assuming a 60-day payables period.

L0 3

9. **Calculating Payments.** The Bruin Corporation's purchases from suppliers in a quarter are equal to 75 percent of the next quarter's forecast sales. The payables period is 60 days. Wages, taxes, and other expenses are 30 percent of sales, and interest and dividends are \$110 per quarter. No capital expenditures are planned. Projected quarterly sales are:

	Q1	Q2	Q3	Q4
Sales	\$1,380	\$1,530	\$1,610	\$1,830

Sales for the first quarter of the following year are projected at \$1,500. Calculate Bruin's cash outlays by completing the following:

	Q1	Q2	Q3	Q4
Payment of accounts				
Wages, taxes, other expenses				
Long-term financing expenses (interest and dividends)				
Total				

L0 3

10. **Calculating Cash Collections.** The following is the sales budget for Segura, Inc., for the first quarter of 2010:

	January	February	March
Sales budget	\$129,000	\$146,000	\$161,000

Credit sales are collected as follows:

65 percent in the month of the sale

20 percent in the month after the sale

15 percent in the second month after the sale

The accounts receivable balance at the end of the previous quarter was \$92,000 (\$67,000 of which was uncollected December sales).

- a. Compute the sales for November.
- b. Compute the sales for December.
- c. Compute the cash collections from sales for each month from January through March.

L03

- 11. Calculating the Cash Budget.** Here are some important figures from the budget of Red Barchetta, Inc., for the second quarter of 2010:

	April	May	June
Credit sales	\$398,000	\$347,000	\$435,000
Credit purchases	175,000	163,000	196,000
Cash disbursements			
Wages, taxes, and expenses	79,300	74,800	103,500
Interest	9,000	9,000	9,000
Equipment purchases	31,000	3,500	143,000

The company predicts that 5 percent of its credit sales will never be collected, 35 percent of its sales will be collected in the month of the sale, and the remaining 60 percent will be collected in the following month. Credit purchases will be paid in the month following the purchase.

In March 2010, credit sales were \$325,000. Using this information, complete the following cash budget:

	April	May	June
Beginning cash balance	\$105,000		
Cash receipts			
Cash collections from credit sales			
Total cash available			
Cash disbursements			
Purchases	167,000		
Wages, taxes, and expenses			
Interest			
Equipment purchases			
Total cash disbursements			
Ending cash balance			

L03

- 12. Calculating Cash Collections.** The Coba Company has projected the following quarterly sales amounts for the coming year:

	Q1	Q2	Q3	Q4
Sales	\$8,100	\$9,800	\$9,200	\$7,600

- a. Accounts receivable at the beginning of the year are \$3,700. The company has a 45-day collection period. Calculate cash collections in each of the four quarters by completing the following:

	Q1	Q2	Q3	Q4
Beginning receivables				
Sales				
Cash collections				
Ending receivables				

- b. Rework (a) assuming a collection period of 60 days.
 c. Rework (a) assuming a collection period of 30 days.
- 13. Costs of Borrowing.** You've worked out a line of credit arrangement that allows you to borrow up to \$60 million at any time. The interest rate is .573 percent per month. In addition, 4 percent of the amount that you borrow must be deposited in a noninterest-bearing account. Assume that your bank uses compound interest on its line-of-credit loans.
- a. What is the effective annual interest rate on this lending arrangement?
 b. Suppose you need \$15 million today and you repay it in six months. How much interest will you pay?

- 14. Costs of Borrowing.** A bank offers your firm a revolving credit arrangement for up to \$75 million at an interest rate of 1.34 percent per quarter. The bank also requires you to maintain a compensating balance of 4 percent against the *unused* portion of the credit line, to be deposited in a noninterest-bearing account. Assume you have a short-term investment account at the bank that pays 0.75 percent per quarter, and assume that the bank uses compound interest on its revolving credit loans.
- a. What is your effective annual interest rate (an opportunity cost) on the revolving credit arrangement if your firm does not use it during the year?
 b. What is your effective annual interest rate on the lending arrangement if you borrow \$40 million immediately and repay it in one year?
 c. What is your effective annual interest rate if you borrow \$75 million immediately and repay it in one year?

- 15. Cash and Operating Cycles.** Coley, Inc., has a cash cycle of 42.5 days, an operating cycle of 61 days, and an inventory period of 26 days. The company reported cost of goods sold in the amount of \$340,000, and credit sales were \$563,000. What is the company's average balance in accounts payable and accounts receivable?

- 16. Cash Budget.** Piano Man, Inc., has a 40-day average collection period and wants to maintain a minimum cash balance of \$25 million, which is what the company currently has on hand. The company currently has a receivables balance of \$182 million and has developed the following sales and cash disbursement budgets in millions:

	Q1	Q2	Q3	Q4
Sales	\$315	\$390	\$475	\$435
Total cash disbursement	265	340	560	375

Intermediate

(Questions 13–16)

L0 3

L0 3

L0 3

Complete the following cash budget for the company. What conclusions do you draw?

PIANO MAN, INC. Cash Budget (in millions)				
	Q1	Q2	Q3	Q4
Beginning receivables				
Sales				
Cash collections				
Ending receivables				
Total cash collections				
Total cash disbursements				
Net cash inflow				
Beginning cash balance				
Net cash inflow				
Ending cash balance				
Minimum cash balance				
Cumulative surplus (deficit)				

L0 3

- 17. Costs of Borrowing.** In exchange for a \$400 million fixed commitment line of credit, your firm has agreed to do the following:

1. Pay 1.8 percent per quarter on any funds actually borrowed.
2. Maintain a 4 percent compensating balance on any funds actually borrowed.
3. Pay an up-front commitment fee of .25 percent of the amount of the line.

Based on this information, answer the following:

- a. Ignoring the commitment fee, what is the effective annual interest rate on this line of credit?
- b. Suppose your firm immediately uses \$210 million of the line and pays it off in one year. What is the effective annual interest rate on this \$210 million loan?

L0 3

- 18. Costs of Borrowing.** Come and Go Bank offers your firm an 8 percent *discount* interest loan for up to \$20 million, and in addition requires you to maintain a 3 percent compensating balance against the face amount borrowed. What is the effective annual interest rate on this lending arrangement?

Challenge

(Questions 17–18)

- 16.1 Cash Cycle.** Go to www.reuters.com. You will need to find the most recent annual income statement and the two most recent balance sheets for McKesson (MCK) and Newmont Mining (NEM). MCK is involved in pharmaceuticals and consumer health care, while Newmont Mining is a leading gold mining company. Calculate the cash cycle for each company and comment on any similarities or differences.
- 16.2 Operating Cycle.** Using the information you gathered in the previous problem, calculate the operating cycle for each company. What are the similarities or differences? Is this what you would expect from companies in each of these industries?
- 16.3 Sources and Uses of Cash.** Find the two most recent balance sheets for 3M at the “Investor Relations” link on the Web site www.mmm.com. For each account in the balance sheet, show the change during the most recent year and note whether this was a source or use of cash. Do your numbers add up and make sense? Explain your answer for total assets as compared to your answer for total liabilities and owners’ equity.

**WHAT’S ON
THE WEB?**

CHAPTER CASE

PIEPKORN MANUFACTURING WORKING CAPITAL MANAGEMENT, PART 1

You have recently been hired by Piepkorn Manufacturing to work in its newly established treasury department. Piepkorn Manufacturing is a small company that produces cardboard boxes in a variety of sizes. Gary Piepkorn, the owner of the company, works primarily in the sales and production areas. Currently, the company puts all receivables in one shoe box and all payables in another. Because of the disorganized system, the finance area needs work, and that's what you've been brought in to do.

The company currently has a cash balance of \$154,000 and plans to purchase new box folding machinery in the fourth quarter at a cost of \$260,000. The purchase of the machinery will be made with cash because of the discount offered. The company's policy is to maintain a target cash balance of \$100,000. All sales and all purchases are made on credit.

Gary Piepkorn has projected the following gross sales for each of the next four quarters:

	Q1	Q2	Q3	Q4
Gross sales	\$785,000	\$835,000	\$905,000	\$840,000

Gross sales for the first quarter of next year are projected at \$825,000.

Piepkorn typically orders 50 percent of next quarter's projected gross sales in the current quarter, and suppliers are typically paid in 53 days. Wages, taxes, and other costs run about 30 percent of gross sales. The company has a quarterly interest payment of \$115,000 on its long-term debt.

The company uses a local bank for its short-term financial needs. It pays 1.5 percent per quarter on all short-term borrowing and maintains a money market account that pays 1 percent per quarter on all short-term deposits.

Gary has asked you to prepare a cash budget and short-term financial plan for the company under the current policies. He has also asked you to prepare additional plans based on changes in several inputs. ■

QUESTIONS

1. Use the numbers given to complete the cash budget and short-term financial plan.
2. Rework the cash budget and short-term financial plan assuming Piepkorn changes to a target balance of \$80,000.

Working Capital Management

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Explain how firms manage their cash and identify some of the collection, concentration, and disbursement techniques used.
- LO 2** Analyze how firms manage their receivables and the basic components of a firm's credit policies.
- LO 3** Differentiate between the types of inventory and inventory management systems used by firms and explain what determines the optimal inventory level.

Most often, when news breaks about a firm's bank accounts, it's because the company is running low on cash. However, that wasn't the case for many companies in late 2008. For example, in December 2008, carmaker Ford had a cash balance of \$28.2 billion, or \$11.75 per share. What's so striking about that amount is that the stock was trading for only about \$5 per share, so Ford's cash per share was much larger than its stock price, normally not a good sign. Other companies with healthier operations also had large amounts of cash. For example, Microsoft had a cash hoard of about \$21 billion, while General Electric had about \$60 billion. Why

would firms such as these hold such large quantities of cash? We examine cash management in this chapter to find out.

This chapter considers various aspects of working capital management. Commonly, responsibility for working capital is spread across several different disciplines. Accounting is frequently responsible for payables and receivables; operations is in charge of inventory; and finance handles cash management. Marketing also plays a key role because sales forecasts are a key determinant of working capital needs. So, an understanding of working capital management is important for just about everyone in the firm.

Visit us at www.mhhe.com/rwj

This chapter examines working capital management. Recall from Chapter 1 that working capital management deals with a firm's short-term, or current, assets and liabilities. A firm's current liabilities consist largely of short-term borrowing. We discussed short-term borrowing in our previous chapter, so this chapter mainly focuses on current assets, in particular, cash, accounts receivable, and inventory.

17.1

FLOAT AND CASH MANAGEMENT

We begin our analysis of working capital management by looking at how firms manage cash. The basic objective in cash management is to keep the investment in cash as low as possible while still operating the firm's activities efficiently and effectively. This goal usually reduces to the dictum "Collect early and pay late." Accordingly, we discuss ways of accelerating collections and managing disbursements.

In addition, firms must invest temporarily idle cash in short-term marketable securities. As we discuss in various places, these securities can be bought and sold in the financial markets. As a group, they have very little default risk, and most are highly liquid. There are different types of these so-called money market securities, and we discuss a few of the most important ones a bit later.

Reasons for Holding Cash

John Maynard Keynes, in his great work *The General Theory of Employment, Interest, and Money*, identified three reasons why liquidity is important: the speculative motive, the precautionary motive, and the transaction motive. We discuss these next.

speculative motive

The need to hold cash to take advantage of additional investment opportunities, such as bargain purchases.

precautionary motive

The need to hold cash as a safety margin to act as a financial reserve.

transaction motive

The need to hold cash to satisfy normal disbursement and collection activities associated with a firm's ongoing operations.

The Speculative and Precautionary Motives The **speculative motive** is the need to hold cash in order to be able to take advantage of, for example, bargain purchase opportunities that might arise, attractive interest rates, and (in the case of international firms) favorable exchange rate fluctuations.

For most firms, reserve borrowing ability and marketable securities can be used to satisfy speculative motives. Thus, for a modern firm, there might be a speculative motive for liquidity, but not necessarily for cash per se. Think of it this way: If you have a credit card with a very large credit limit, then you can probably take advantage of any unusual bargains that come along without carrying any cash.

This is also true, to a lesser extent, for precautionary motives. The **precautionary motive** is the need for a safety supply to act as a financial reserve. Once again, there probably is a precautionary motive for liquidity. However, given that the value of money market instruments is relatively certain and that instruments such as T-bills are extremely liquid, there is no real need to hold substantial amounts of cash for precautionary purposes.

The Transaction Motive Cash is needed to satisfy the **transaction motive**, the need to have cash on hand to pay bills. Transaction-related needs come from the normal disbursement and collection activities of the firm. The disbursement of cash includes the payment of wages and salaries, trade debts, taxes, and dividends.

Cash is collected from sales, the selling of assets, and new financing. The cash inflows (collections) and outflows (disbursements) are not perfectly synchronized, and some level of cash holdings is necessary to serve as a buffer. Perfect liquidity is the characteristic of cash that allows it to satisfy the transaction motive.

As electronic funds transfers and other high-speed, "paperless" payment mechanisms continue to develop, even the transaction demand for cash may all but disappear. Even if it does, however, there will still be a demand for liquidity and a need to manage it efficiently.

Benefits of Holding Cash When a firm holds cash in excess of some necessary minimum, it incurs an opportunity cost. The opportunity cost of excess cash (held in currency or bank deposits) is the interest income that could be earned in the next best use, such as investing in marketable securities.

Given the opportunity cost of holding cash, why would a firm hold excess cash? The answer is that a cash balance must be maintained to provide the liquidity necessary for transaction needs—paying bills. If the firm maintains too small a cash balance, it may run out of cash. If this happens, the firm may have to raise cash on a short-term basis. This could involve, for example, selling marketable securities or borrowing.

Activities such as selling marketable securities and borrowing involve various costs. As we've discussed, holding cash has an opportunity cost. To determine the appropriate cash balance, the firm must weigh the benefits of holding cash against these costs. We discuss this subject in more detail in the sections that follow.

Understanding Float

As you no doubt know, the amount of money you have according to your checkbook can be very different from the amount of money that your bank thinks you have. The reason is that some of the checks you have written haven't yet been presented to the bank for payment. The same thing is true for a business. The cash balance that a firm shows on its books is called the firm's *book*, or *ledger*, *balance*. The balance shown in its bank account as available to spend is called its *available*, or *collected*, *balance*. The difference between the available balance and the ledger balance is called the **float**, and it represents the net effect of checks in the process of *clearing* (moving through the banking system).

float

The difference between the book, or ledger, cash balance and the available, or collected, balance, representing the net effect of checks in the process of clearing.

Disbursement Float Checks written by a firm generate *disbursement float*, causing a decrease in the firm's book balance but no change in its available balance. For example, suppose General Mechanics, Inc. (GMI), currently has \$100,000 on deposit with its bank. On June 8, it buys some raw materials and pays with a check for \$100,000. The company's book balance is immediately reduced by \$100,000 as a result.

GMI's bank, however, will not find out about this check until it is presented to GMI's bank for payment on, say, June 14. Until the check is presented, the firm's available balance is greater than its book balance by \$100,000. In other words, before June 8, GMI has a zero float:

$$\begin{aligned}\text{Float} &= \text{Firm's available balance} - \text{Firm's book balance} \\ &= \$100,000 - 100,000 \\ &= \$0\end{aligned}$$

GMI's position from June 8 to June 14 is:

$$\begin{aligned}\text{Disbursement float} &= \text{Firm's available balance} - \text{Firm's book balance} \\ &= \$100,000 - 0 \\ &= \$100,000\end{aligned}$$

During this period of time while the check is clearing, GMI has a balance with the bank of \$100,000. It can obtain the benefit of this cash while the check is clearing. For example, the available balance could be temporarily invested in marketable securities and thus earn some interest. We will return to this subject a little later.

Collection Float and Net Float Checks received by the firm create *collection float*. Collection float increases book balances but does not immediately change available balances. For example, suppose GMI receives a check from a customer for

\$100,000 on October 8. Assume, as before, that the company has \$100,000 deposited at its bank and a zero float. It deposits the check and increases its book balance by \$100,000, to \$200,000. However, the additional cash is not available to GMI until its bank has presented the check to the customer's bank and received \$100,000. This will occur on, say, October 14. In the meantime, the cash position at GMI will reflect a collection float of \$100,000. We can summarize these events. Before October 8, GMI's position is:

$$\begin{aligned}\text{Float} &= \text{Firm's available balance} - \text{Firm's book balance} \\ &= \$100,000 \qquad \qquad \qquad - 100,000 \\ &= \$0\end{aligned}$$

GMI's position from October 8 to October 14 is:

$$\begin{aligned}\text{Collection float} &= \text{Firm's available balance} - \text{Firm's book balance} \\ &= \$100,000 \qquad \qquad \qquad - 200,000 \\ &= -\$100,000\end{aligned}$$

In general, a firm's payment (disbursement) activities generate disbursement float, and its collection activities generate collection float. The net effect, that is, the sum of the total collection and disbursement floats, is the *net float*. The net float at any point in time is simply the overall difference between the firm's available balance and its book balance. If the net float is positive, then the firm's disbursement float exceeds its collection float and its available balance exceeds its book balance. If the available balance is less than the book balance, then the firm has a negative net float.

A firm should be concerned with its net float and available balance more than its book balance. If a financial manager knows that a check written by the company will not clear for several days, that manager will be able to keep a lower cash balance at the bank than might be true otherwise. This can generate a great deal of money.

For example, take the case of petroleum giant ExxonMobil. The average daily sales for ExxonMobil were about \$1.31 billion in 2008. If ExxonMobil's collections could have been speeded up by a single day, then ExxonMobil could have freed up \$1.31 billion for investing. At a relatively modest .01 percent daily rate, the interest earned would have been on the order of \$131,000 *per day*.

EXAMPLE 17.1

Staying Afloat

Suppose you have \$5,000 on deposit. One day you write a check for \$1,000 to pay for books, and you deposit \$2,000. What are your disbursement, collection, and net floats?

After you write the \$1,000 check, you show a balance of \$4,000 on your books, but the bank shows \$5,000 while the check is clearing. This means you have a disbursement float of \$1,000.

After you deposit the \$2,000 check, you show a balance of \$6,000. Your available balance doesn't rise until the check clears. This means you have a collection float of -\$2,000. Your net float is the sum of the collection and disbursement floats, or -\$1,000.

Overall, you show \$6,000 on your books. The bank shows a \$7,000 balance, but only \$5,000 is available because your deposit has not cleared. The discrepancy between your available balance and your book balance is the net float (-\$1,000), and it is bad for you. If you write another check for \$5,500, there may not be sufficient available funds to cover it, and it might bounce. This is the reason that the financial manager has to be more concerned with available balances than book balances.

Float Management Float management involves controlling the collection and disbursement of cash. The objective in cash collection is to speed up collections and reduce the lag between the time customers pay their bills and the time the cash becomes available.

The objective in cash disbursement is to control payments and minimize the firm's costs associated with making payments.

Total collection or disbursement times can be broken down into three parts: mailing time, processing delay, and availability delay:

1. *Mailing time* is the part of the collection and disbursement process during which checks are trapped in the postal system.
2. *Processing delay* is the time it takes the receiver of a check to process the payment and deposit it in a bank for collection.
3. *Availability delay* refers to the time required to clear a check through the banking system.

Speeding up collections involves reducing one or more of these components. Slowing up disbursements involves increasing one or more of them. We will describe some procedures for managing collection and disbursement times below.

Ethical and Legal Questions The cash manager must work with collected bank cash balances and not the firm's book balance (which reflects checks that have been deposited but not collected). If this is not done, a cash manager could be drawing on uncollected cash as a source of funds for short-term investing. Most banks charge a penalty rate for the use of uncollected funds. However, banks may not have good enough accounting and control procedures to be fully aware of the use of uncollected funds. This raises some ethical and legal questions for the firm.

For example, in May 1985, Robert Fomon, chairman of E. F. Hutton (a large investment bank), pleaded guilty to 2,000 charges of mail and wire fraud in connection with a scheme the firm had operated from 1980 to 1982. E. F. Hutton employees wrote checks totaling hundreds of millions of dollars against uncollected cash. The proceeds were then invested in short-term money market assets. This type of systematic overdrafting of accounts (or check *kiting*, as it is sometimes called) is neither legal nor ethical and is apparently not a widespread practice among corporations. Also, the particular inefficiencies in the banking system that Hutton was exploiting have been largely eliminated.

For its part, E. F. Hutton paid a \$2 million fine, reimbursed the government (the U.S. Department of Justice) \$750,000, and reserved an additional \$8 million for restitution to defrauded banks. We should note that the key issue in the case against Hutton was not its float management per se, but, rather, its practice of writing checks for no economic reason other than to exploit float. Unfortunately, check kiting is still not dead. In September 2008, an Ohio man was sentenced to 33 months in prison for a check kiting case involving more than 300 checks for \$824 million. FirstMerit, the bank that was the target of the scheme, estimated that it lost around \$4.12 million as a result.

Electronic Data Interchange and Check 21: The End of Float? *Electronic data interchange* (EDI) is a general term that refers to the growing practice of direct, electronic information exchange between all types of businesses. One important use of EDI, often called financial EDI, or FEDI, is to electronically transfer financial information and funds between parties, thereby eliminating paper invoices, paper checks, mailing, and handling. For example, it is possible to arrange to have your checking account directly debited each month to pay many types of bills, and corporations now routinely directly deposit paychecks into employee accounts. More generally, EDI allows a seller to send a bill electronically to a buyer, thereby avoiding the mail. The buyer can then authorize payment, which also occurs electronically. Its bank then transfers the funds to the seller's account at a different bank. The net effect is that the length of time required to initiate and

on cash management.

complete a business transaction is shortened considerably, and much of what we normally think of as float is sharply reduced or eliminated. As the use of FEDI increases (which it will), float management will evolve to focus much more on issues surrounding computerized information exchange and funds transfers.

On October 29, 2004, the Check Clearing Act for the 21st Century, also known as Check 21, took effect. Before Check 21, a bank receiving a check was required to send the physical check to the customer's bank before payment could be made. Now a bank can transmit an electronic image of the check to the customer's bank and receive payment immediately. Previously, an out-of-state check might take three days to clear, but with Check 21, the clearing time is typically one day, and often, a check can clear the same day it is written. Thus, Check 21 promises to significantly reduce float.

CONCEPT QUESTIONS

- 17.1a** What is the transaction motive for holding cash?
- 17.1b** What is the cost to the firm of holding excess cash?
- 17.1c** Which of these would a firm be more interested in reducing: collection float or disbursement float? Why?
- 17.1d** What is the benefit from reducing or eliminating float?

17.2

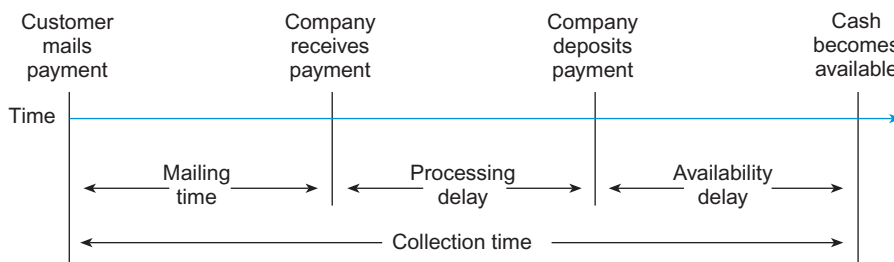

CASH MANAGEMENT: COLLECTION, DISBURSEMENT, AND INVESTMENT

As a part of managing its cash, a firm must make arrangements to collect from its customers, pay its suppliers, and invest any excess cash on hand. We begin by examining how firms collect and concentrate cash.

Cash Collection and Concentration

From our previous discussion, we know that collection delays work against the firm. All other things being the same, then, a firm will adopt procedures to speed up collections and thereby decrease collection times. In addition, even after cash is collected, firms need procedures to funnel, or concentrate, that cash where it can be best used. We discuss some common collection and concentration procedures next.

Components of Collection Time Based on our discussion above, we can depict the basic parts of the cash collection process as follows: The total time in this process is made up of mailing time, check-processing delay, and the bank's availability delay.

The amount of time that cash spends in each part of the cash collection process depends on where the firm's customers and banks are located and how efficient the firm is at collecting cash.

Cash Collection How a firm collects from its customers depends in large part on the nature of the business. The simplest case would be a business such as a restaurant chain. Most of its customers will pay with cash, check, or credit card at the point of sale (this is called *over-the-counter collection*), so there is no problem with mailing delay. Normally, the funds would be deposited in a local bank, and the firm would have some means (discussed next) of gaining access to the funds.

When some or all of the payments a company receives are checks that arrive through the mail, all three components of collection time become relevant. The firm may choose to have all the checks mailed to one location, or, more commonly, the firm might have a number of different mail collection points to reduce mailing times. Also, the firm may run its collection operation itself or might hire an outside firm that specializes in cash collection. We discuss these issues in more detail below.

Other approaches to cash collection exist. One that is becoming more common is the preauthorized payment system. With this arrangement, the payment amounts and payment dates are fixed in advance. When the agreed-upon date arrives, the amount is automatically transferred from the customer's bank account to the firm's bank account, sharply reducing or even eliminating collection delays. The same approach is used by firms that have online terminals, meaning that when a sale is rung up, the money is immediately transferred to the firm's accounts.

Lockboxes When a firm receives its payments by mail, it must decide where the checks will be mailed and how the checks will be picked up and deposited. Careful selection of the number and locations of collection points can greatly reduce collection times. Many firms use special post office boxes called **lockboxes** to intercept payments and speed cash collection.

Figure 17.1 illustrates a lockbox system. The collection process is started by customers mailing their checks to a post office box instead of sending them to the firm. The lockbox is maintained by a local bank. A large corporation may actually have more than 20 lockboxes around the country.

In the typical lockbox system, the local bank collects the lockbox checks from the post office several times a day. The bank deposits the checks directly to the firm's account. Details of the operation are recorded (in some computer-usable form) and sent to the firm.

A lockbox system reduces mailing time because checks are received at a nearby post office instead of at corporate headquarters. Lockboxes also reduce the processing time because the corporation doesn't have to open the envelopes and deposit checks for collection. In all, a bank lockbox should enable a firm to get its receipts processed, deposited, and cleared faster than if it were to receive checks at its headquarters and deliver them itself to the bank for deposit and clearing.

Cash Concentration As we discussed earlier, a firm will typically have a number of cash collection points, and, as a result, cash collections may end up in many different banks and bank accounts. From here, the firm needs procedures to move the cash into its main accounts. This is called **cash concentration**. By routinely pooling its cash, the firm greatly simplifies its cash management by reducing the number of accounts that must be tracked. Also, by having a larger pool of funds available, a firm may be able to negotiate a better rate on any short-term investments.

lockboxes

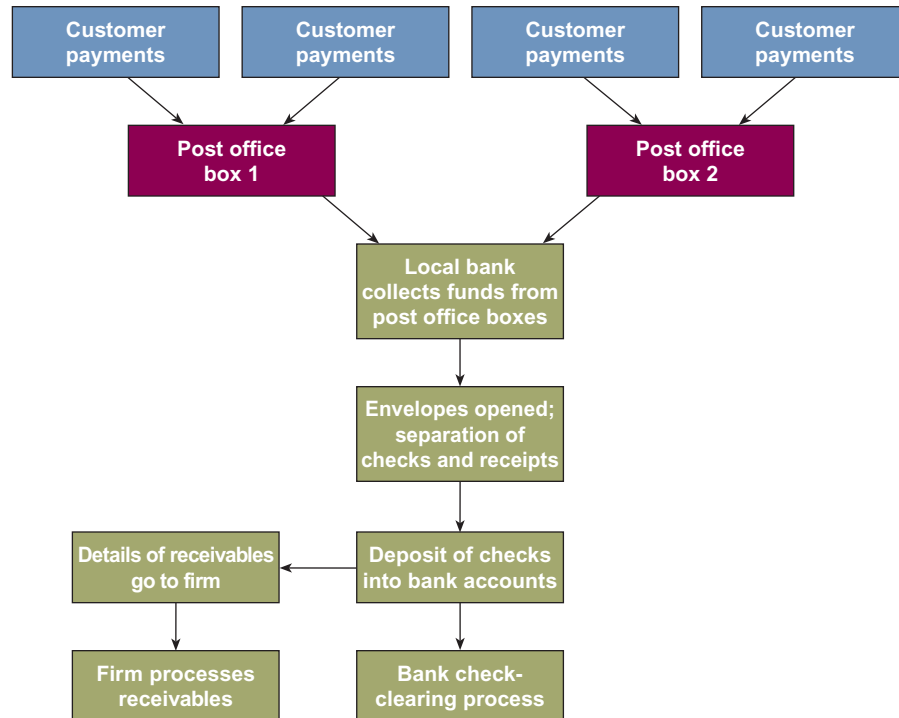

Special post office boxes set up to intercept and speed up accounts receivable collections.

cash concentration

The practice of and procedures for moving cash from multiple banks into the firm's main accounts.

FIGURE 17.1

Overview of lockbox processing

The flow starts when a customer mails remittances to a post office box instead of to the corporation. Several times a day the bank collects the lockbox receipts from the post office. The checks are then put into the company bank accounts.

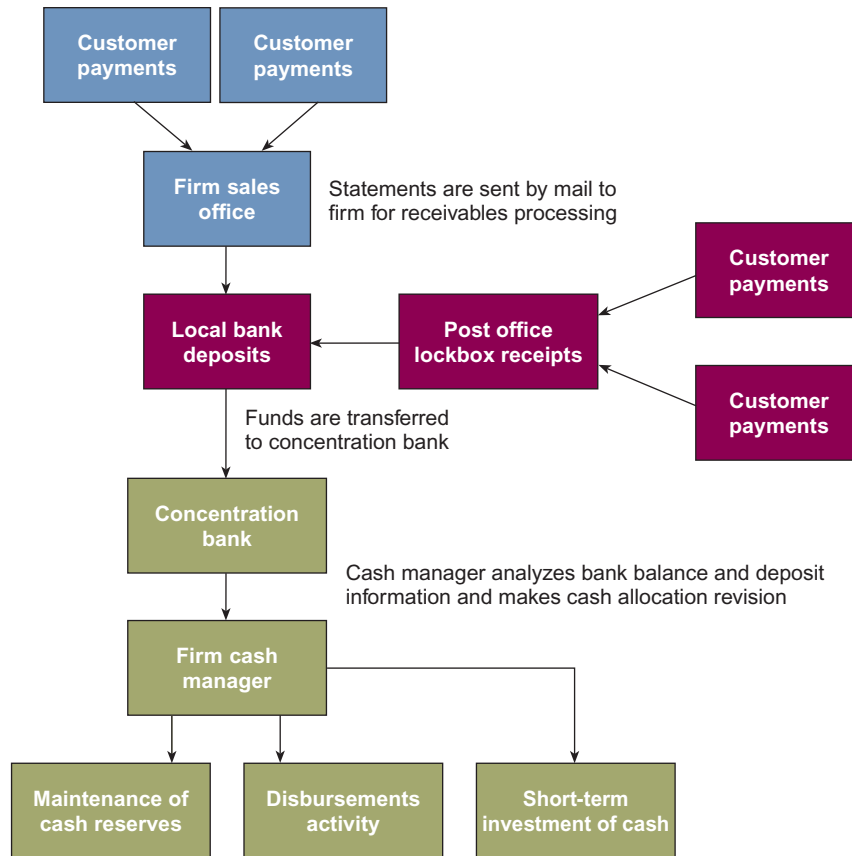

In setting up a concentration system, firms will typically use one or more *concentration banks*. A concentration bank pools the funds obtained from local banks contained within some geographic region. Concentration systems are often used in conjunction with lockbox systems. Figure 17.2 illustrates how an integrated cash collection and cash concentration system might look.

Cash concentration can result in significant savings. For example, in 2008, Honeywell International implemented a cash concentration program for its European, Middle Eastern, and African divisions. The reorganization and resulting reduction in cash management fees were thought to save the company about \$2.7 million per year. Of course, Honeywell is not alone. It has been estimated that the largest 2,000 global companies could free up \$200 billion in excess cash with better management techniques, resulting in annual savings of about \$8 billion.

Managing Cash Disbursements

From the firm's point of view, disbursement float is desirable, so the goal in managing disbursement float is to slow down disbursements as much as possible. To do this, the firm may develop strategies to *increase* mail float, processing float, and availability float on the checks it writes. Beyond this, firms have developed procedures for minimizing cash held for payment purposes. We discuss the most common of these below.

Increasing Disbursement Float As we have seen, float in terms of slowing down payments comes from the time involved in mail delivery, check processing, and collection

**FIGURE 17.2**

Lockboxes and concentration banks in a cash management system

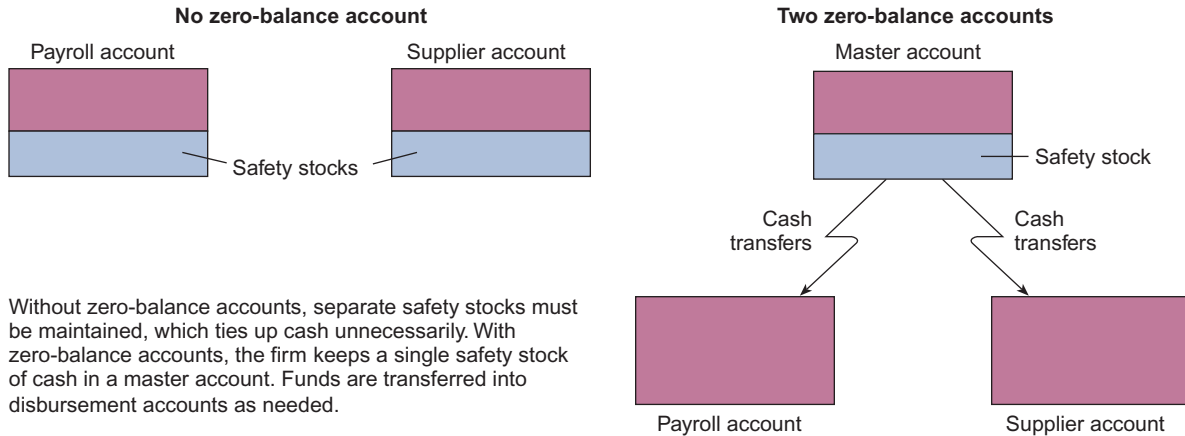

of funds. Disbursement float can be increased by writing a check on a geographically distant bank. For example, a New York supplier might be paid with checks drawn on a Los Angeles bank. This will increase the time required for the checks to clear through the banking system. Mailing checks from remote post offices is another way firms slow down disbursement.

Tactics for maximizing disbursement float are debatable on both ethical and economic grounds. First, as we discuss later, payment terms very frequently offer a substantial discount for early payment. The discount is usually much larger than any possible savings from “playing the float game.” In such cases, increasing mailing time will be of no benefit if the recipient dates payments based on the date received (as is common) as opposed to the postmark date.

Beyond this, suppliers are not likely to be fooled by attempts to slow down disbursement. The negative consequences from poor relations with suppliers can be costly. In broader terms, intentionally delaying payments by taking advantage of mailing times or unsophisticated suppliers may amount to avoiding paying bills when they are due, an unethical business procedure.

Controlling Disbursements We have seen that maximizing disbursement float is probably poor business practice. However, a firm will still wish to tie up as little cash as possible in disbursements. Firms have therefore developed systems for efficiently

For a free cash budgeting spreadsheet, go to www.toolkit.cch.com/tools/tools.asp.

FIGURE 17.3**Zero-balance accounts**

managing the disbursement process. The general idea in such systems is to have no more than the minimum amount necessary to pay bills on deposit in the bank. We discuss some approaches to accomplishing this goal next.

zero-balance account

A disbursement account in which the firm maintains a zero balance, transferring funds in from a master account only as needed to cover checks presented for payment.

controlled disbursement account

A disbursement account to which the firm transfers an amount that is sufficient to cover demands for payment.

Zero-balance accounts With a **zero-balance account**, the firm, in cooperation with its bank, maintains a master account and a set of subaccounts. When a check written on one of the subaccounts must be paid, the necessary funds are transferred in from the master account. Figure 17.3 illustrates how such a system might work. In this case, the firm maintains two disbursement accounts, one for suppliers and one for payroll. As is shown, if the firm does not use zero-balance accounts, then each of these accounts must have a safety stock of cash to meet unanticipated demands. If the firm does use zero-balance accounts, then it can keep one safety stock in a master account and transfer the funds to the two subsidiary accounts as needed. The key is that the total amount of cash held as a buffer is smaller under the zero-balance arrangement, which frees up cash to be used elsewhere.

Controlled disbursement accounts Almost all payments that must be made in a given day are known in the morning. With a **controlled disbursement account**, the bank informs the firm of the day's total, and the firm transfers (usually by wire) the amount needed.

Investing Idle Cash

If a firm has a temporary cash surplus, it can invest in short-term securities. As we have mentioned at various times, the market for short-term financial assets is called the *money market*. The maturity of short-term financial assets that trade in the money market is one year or less.

Most large firms manage their own short-term financial assets, transacting through banks and dealers. Some large firms and many small firms use money market mutual funds. These are funds that invest in short-term financial assets for a management fee. The management fee is compensation for the professional expertise and diversification provided by the fund manager.

Among the many money market mutual funds, some specialize in corporate customers. In addition, banks offer arrangements in which the bank takes all excess available funds at the close of each business day and invests them for the firm.

**FIGURE 17.4****Seasonal cash demands**

Time 1: A surplus cash position exists. Seasonal demand for current assets is low. The surplus is invested in short-term marketable securities.

Time 2: A deficit cash position exists. Seasonal demand for current assets is high. The financial deficit is financed by selling marketable securities and by bank borrowing.

Temporary Cash Surpluses Firms have temporary cash surpluses for various reasons. Two of the most important are the financing of seasonal or cyclical activities of the firm and the financing of planned or possible expenditures.

Seasonal or cyclical activities Some firms have a predictable cash flow pattern. They have surplus cash flows during part of the year and deficit cash flows the rest of the year. For example, Toys “Я” Us, a retail toy firm, has a seasonal cash flow pattern influenced by Christmas.

A firm such as Toys “Я” Us may buy marketable securities when surplus cash flows occur and sell marketable securities when deficits occur. Of course, bank loans are another short-term financing device. The use of bank loans and marketable securities to meet temporary financing needs is illustrated in Figure 17.4. In this case, the firm is following a compromise working capital policy in the sense we discussed in the previous chapter.

Planned or possible expenditures Firms frequently accumulate temporary investments in marketable securities to provide the cash for a plant construction program, dividend payment, or other large expenditure. Thus, firms may issue bonds and stocks before the cash is needed, investing the proceeds in short-term marketable securities and then selling the securities to finance the expenditures. Also, firms may face the possibility of having to make a large cash outlay. An obvious example would be the possibility of losing a large lawsuit. Firms may build up cash surpluses against such a contingency.

Characteristics of Short-Term Securities Given that a firm has some temporarily idle cash, there are a variety of short-term securities available for investing. The most important characteristics of these short-term marketable securities are their maturity, default risk, marketability, and taxability.

Maturity Maturity refers to the time period over which interest and principal payments are made. From Chapter 6, we know that for a given change in the level of interest rates, the prices of longer-maturity securities will change more than those of shorter-maturity

securities. As a consequence, firms often limit their investments in marketable securities to those maturing in less than 90 days to avoid the risk of losses in value from changing interest rates.

Default risk Default risk refers to the probability that interest and principal will not be paid in the promised amounts on the due dates (or not paid at all). Of course, some securities have negligible default risk, such as U.S. Treasury bills. Given the purposes of investing idle corporate cash, firms typically avoid investing in marketable securities with significant default risk.

Marketability Marketability refers to how easy it is to convert an asset to cash; so, marketability and liquidity mean much the same thing. Some money market instruments are much more marketable than others. At the top of the list are U.S. Treasury bills, which can be bought and sold very cheaply and very quickly.

Taxability Interest earned on money market securities that are not some kind of government obligation (either federal or state) is taxable at the local, state, and federal levels. U.S. Treasury obligations such as T-bills are exempt from state taxation, but other government-backed debt is not. Municipal securities are exempt from federal taxes, but they may be taxed at the state level.

Some Different Types of Money Market Securities Money market securities are generally highly marketable and short term. They usually have low risk of default. They are issued by the U.S. government (for example, U.S. Treasury bills), domestic and foreign banks (for example, certificates of deposit), and business corporations (for example, commercial paper). There are many types in all, and we only illustrate a few of the most common here.

U.S. Treasury bills are obligations of the U.S. government that mature in 90, 180, or 360 days. The 90-day and 180-day bills are sold by auction every week, and 360-day bills are sold quarterly.

Short-term tax-exempts are short-term securities issued by states, municipalities, and certain other agencies. Since these are all considered municipal securities, they are exempt from federal taxes. Short-term tax-exempts have more default risk than U.S. Treasury issues and are less marketable. Since the interest is exempt from federal income tax, the pre-tax yield on tax-exempts is lower than that on comparable securities such as U.S. Treasury bills. Also, corporations face some restrictions on holding tax-exempts as investments.

Commercial paper refers to short-term securities issued by finance companies, banks, and corporations. Typically, commercial paper is unsecured. Maturities range from a few weeks to 270 days.

There is no especially active secondary market in commercial paper. As a consequence, the marketability can be low; however, firms that issue commercial paper will often repurchase it directly before maturity. The default risk of commercial paper depends on the financial strength of the issuer.

Certificates of deposit (CDs) are short-term loans to commercial banks. These are normally jumbo CDs—those in excess of \$100,000. There are active markets in CDs of 3-month, 6-month, 9-month, and 12-month maturities.

Because 70 to 80 percent of the dividends received by one corporation from another are exempt from taxation, the relatively high dividend yields on preferred stock provide a strong incentive for investment. The only problem is that the dividend is fixed with ordinary preferred stock, so the price can fluctuate more than is desirable in a short-term investment.

So-called money market preferred stock is a recent innovation featuring a floating dividend. The dividend is reset fairly often (usually every 49 days), so this type of preferred has much less price volatility than ordinary preferred, and it has become a popular short-term investment.

CREDIT AND RECEIVABLES

17.3

When a firm sells goods and services, it can demand cash on or before the delivery date, or it can extend credit to customers and allow some delay in payment.

Why would firms grant credit? The obvious reason is that offering credit is a way of stimulating sales. The costs associated with granting credit are not trivial. First, there is the chance that the customer will not pay. Second, the firm has to bear the costs of carrying the receivables. The credit policy decision thus involves a trade-off between the benefits of increased sales and the costs of granting credit.

From an accounting perspective, when credit is granted, an account receivable is created. These receivables include credit to other firms, called *trade credit*, and credit granted to consumers, called *consumer credit*, and they represent a major investment of financial resources by U.S. businesses. Furthermore, trade credit is a very important source of financing for corporations. However we look at it, receivables and receivables management are very important aspects of a firm's short-term financial policy.

Components of Credit Policy

If a firm decides to grant credit to its customers, then it must establish procedures for extending credit and collecting. In particular, the firm will have to deal with the following components of credit policy:

- Terms of sale.** The terms of sale establish how the firm proposes to sell its goods and services. If the firm grants credit to a customer, the terms of sale will specify (perhaps implicitly) the credit period, the cash discount and discount period, and the type of credit instrument.
- Credit analysis.** In granting credit, a firm determines how much effort to expend trying to distinguish between customers who will pay and customers who will not pay. Firms use a number of devices and procedures to determine the probability that customers will not pay, and, put together, these are called credit analysis.
- Collection policy.** After credit has been granted, the firm has the potential problem of collecting the cash when it becomes due, for which it must establish a collection policy.

In the next several sections, we will discuss these components of credit policy that collectively make up the decision to grant credit.

terms of sale

Conditions under which a firm sells its goods and services for cash or credit.

credit analysis

The process of determining the probability that customers will not pay.

collection policy

Procedures followed by a firm in collecting accounts receivable.

Terms of Sale

As we described above, the terms of a sale are made up of three distinct elements:

1. The period for which credit is granted (the credit period).
2. The cash discount and the discount period.
3. The type of credit instrument.

Within a given industry, the terms of sale are usually fairly standard, but these terms vary quite a bit across industries. In many cases, the terms of sale are remarkably archaic and literally date to previous centuries. Organized systems of trade credit that resemble current practice can be easily traced to the great fairs of medieval Europe, and they almost surely existed long before then.

The Basic Form The easiest way to understand the terms of sale is to consider an example. For bulk candy, terms of 2/10, net 60 might be quoted.¹ This means that customers have 60 days from the invoice date (discussed next) to pay the full amount. However, if payment is made within 10 days, a 2 percent cash discount can be taken.

Consider a buyer who places an order for \$1,000, and assume that the terms of the sale are 2/10, net 60. The buyer has the option of paying $\$1,000 \times (1 - .02) = \980 in 10 days, or paying the full \$1,000 in 60 days. If the terms were stated as just net 30, then the customer would have 30 days from the invoice date to pay the entire \$1,000, and no discount would be offered for early payment.

In general, credit terms are interpreted in the following way:

**(take this discount off the invoice price)/(if you pay in this many days),
(else pay the full invoice amount in this many days)**

Thus, 5/10, net 45 means take a 5 percent discount from the full price if you pay within 10 days, or else pay the full amount in 45 days.

credit period

The length of time for which credit is granted.

The Credit Period The **credit period** is the basic length of time for which credit is granted. The credit period varies widely from industry to industry, but it is almost always between 30 and 120 days. If a cash discount is offered, then the credit period has two components: the net credit period and the cash discount period.

The net credit period is the length of time the customer has to pay. The cash discount period, as the name suggests, is the time during which the discount is available. With 2/10, net 30, for example, the net credit period is 30 days and the cash discount period is 10 days.

invoice

Bill for goods or services provided by the seller to the purchaser.

The invoice date The invoice date is the beginning of the credit period. An **invoice** is a written account of merchandise shipped to the buyer. For individual items, by convention, the invoice date is usually the shipping date or the billing date, *not* the date that the buyer receives the goods or the bill.

Length of the credit period A number of factors influence the length of the credit period. Two of the most important are the *buyer's* inventory period and operating cycle. All other things being equal, the shorter these are, the shorter the credit period will normally be.

¹ The terms of sale cited from specific industries in this section and elsewhere are drawn from Theodore N. Beckman, *Credits and Collections: Management and Theory* (New York: McGraw-Hill, 1962).

Based on our discussion in Chapter 16, the operating cycle has two components: the inventory period and the receivables period. The inventory period is the time it takes the buyer to acquire inventory (from us), process it, and sell it. The receivables period is the time it then takes the buyer to collect on the sale. Note that the credit period that we offer is effectively the buyer's payables period.

By extending credit, we finance a portion of our buyer's operating cycle and thereby shorten the buyer's cash cycle. If our credit period exceeds the buyer's inventory period, then we are financing not only the buyer's inventory purchases, but part of the buyer's receivables as well.

Furthermore, if our credit period exceeds our buyer's operating cycle, then we are effectively providing financing for aspects of our customer's business beyond the immediate purchase and sale of our merchandise. The reason is that the buyer effectively has a loan from us even after the merchandise is resold, and the buyer can use that credit for other purposes. For this reason, the length of the buyer's operating cycle is often cited as an appropriate upper limit to the credit period.

There are a number of other factors that influence the credit period. Many of these also influence our customers' operating cycles; so, once again, these are related subjects. Among the most important are:

1. *Perishability and collateral value.* Perishable items have relatively rapid turnover and relatively low collateral value. Credit periods are thus shorter for such goods.
2. *Consumer demand.* Products that are well established generally have more rapid turnover. Newer or slow-moving products will often have longer credit periods associated with them to entice buyers.
3. *Cost, profitability, and standardization.* Relatively inexpensive goods tend to have shorter credit periods. The same is true for relatively standardized goods and raw materials. These all tend to have lower markups and higher turnover rates, both of which lead to shorter credit periods.
4. *Credit risk.* The greater the credit risk of the buyer, the shorter the credit period is likely to be (assuming that credit is granted at all).
5. *The size of the account.* If the account is small, the credit period may be shorter, because small accounts are more costly to manage, and the customers are less important.
6. *Competition.* When the seller is in a highly competitive market, longer credit periods may be offered as a way of attracting customers.
7. *Customer type.* A single seller might offer different credit terms to different buyers. A food wholesaler, for example, might supply groceries, bakeries, and restaurants. Each group would probably have different credit terms. More generally, sellers often have both wholesale and retail customers, and they frequently quote different terms to the two types.

Cash Discounts As we have seen, **cash discounts** are often part of the terms of sale. The practice of granting discounts for cash purchases in the United States dates to the Civil War and is widespread today. One reason discounts are offered is to speed up the collection of receivables. This will have the effect of reducing the amount of credit being offered, and the firm must trade this off against the cost of the discount.

Notice that when a cash discount is offered, the credit is essentially free during the discount period. The buyer only pays for the credit after the discount expires. With 2/10, net 30, a rational buyer either pays in 10 days to make the greatest possible use of the free

For more on the credit process for small businesses, see www.newyorkfed.org/education/addpub/credit.html.

cash discount

A discount given to induce prompt payment. Also, sales discount.

credit or pays in 30 days to get the longest possible use of the money in exchange for giving up the discount. So, by giving up the discount, the buyer effectively gets $30 - 10 = 20$ days' credit.

Another reason for cash discounts is that they are a way of charging higher prices to customers that have had credit extended to them. In this sense, cash discounts are a convenient way of charging for the credit granted to customers.

In our examples, it might seem that the discounts are rather small. With 2/10, net 30, for example, early payment only gets the buyer a 2 percent discount. Does this provide a significant incentive for early payment? The answer is yes because the implicit interest rate is extremely high.

To see why the discount is important, we will calculate the cost to the buyer of not paying early. To do this, we will find the interest rate that the buyer is effectively paying for the trade credit. Suppose the order is for \$1,000. The buyer can pay \$980 in 10 days or wait another 20 days and pay \$1,000. It's obvious that the buyer is effectively borrowing \$980 for 20 days and that the buyer pays \$20 in interest on the "loan." What's the interest rate?

With \$20 in interest on \$980 borrowed, the rate is $\$20/\$980 = 2.0408\%$. This is relatively low, but remember that this is the rate per 20-day period. There are $365/20 = 18.25$ such periods in a year, so, by not taking the discount, the buyer is paying an effective annual rate of:

$$\text{EAR} = 1.020408^{18.25} - 1 = 44.6\%$$

From the buyer's point of view, this is an expensive source of financing!

Given that the interest rate is so high here, it is unlikely that the seller benefits from early payment. Ignoring the possibility of default by the buyer, the decision by a customer to forgo the discount almost surely works to the seller's advantage.

EXAMPLE 17.2

What's the Rate?

Ordinary tiles are often sold with terms of 3/30, net 60. What effective annual rate does a buyer pay by not taking the discount? What would the APR be if one were quoted?

Here we have 3 percent discount interest on $60 - 30 = 30$ days' credit. The rate per 30 days is $.03/.97 = 3.093\%$. There are $365/30 = 12.17$ such periods in a year, so the effective annual rate is:

$$\text{EAR} = 1.03093^{12.17} - 1 = 44.9\%$$

The APR, as always, would be calculated by multiplying the rate per period by the number of periods:

$$\text{APR} = .03093 \times 12.17 = 37.6\%$$

An interest rate calculated like this APR is often quoted as the cost of the trade credit, and, as this example illustrates, this can seriously understate the true cost.

credit instrument

The evidence of indebtedness.

For business reports on credit, visit www.creditworthy.com.

Credit Instruments The **credit instrument** is the basic evidence of indebtedness. Most trade credit is offered on *open account*. This means that the only formal instrument of credit is the invoice, which is sent with the shipment of goods and which the customer signs as evidence that the goods have been received. Afterwards, the firm and its customers record the exchange on their books of account.

At times, the firm may require that the customer sign a *promissory note*. This is a basic IOU and might be used when the order is large or when the firm anticipates a problem in collections. Promissory notes are not common, but they can eliminate possible controversies later about the existence of debt.

One problem with promissory notes is that they are signed after delivery of the goods. One way to obtain a credit commitment from a customer before the goods are delivered is to arrange a *commercial draft*. Typically, the firm draws up a commercial draft calling

for the customer to pay a specific amount by a specified date. The draft is then sent to the customer's bank with the shipping invoices.

If immediate payment on the draft is required, it is called a *sight draft*. If immediate payment is not required, then the draft is a *time draft*. When the draft is presented and the buyer "accepts" it, meaning that the buyer promises to pay it in the future, then it is called a *trade acceptance* and is sent back to the selling firm. The seller can then keep the acceptance or sell it to someone else. If a bank accepts the draft, meaning that the bank is guaranteeing payment, then the draft becomes a *banker's acceptance*. This arrangement is common in international trade.

Optimal Credit Policy

In principle, the optimal amount of credit is determined by the point at which the incremental cash flows from increased sales are exactly equal to the incremental costs of carrying the increased investment in accounts receivable.

The Total Credit Cost Curve The trade-off between granting credit and not granting credit isn't hard to identify, but it is difficult to quantify precisely. As a result, we can only describe an optimal credit policy.

To begin, the carrying costs associated with granting credit come in three forms:

1. The required return on receivables.
2. The losses from bad debts.
3. The cost of managing credit and credit collections.

We have already discussed the first and second of these. The third cost, the cost of managing credit, is the expense associated with running the credit department. Firms that don't grant credit have no such department and no such expense. These three costs will all increase as credit policy is relaxed.

If a firm has a very restrictive credit policy, then all of the above costs will be low. In this case, the firm will have a "shortage" of credit, so there will be an opportunity cost. This opportunity cost is the extra potential profit from credit sales that is lost because credit is refused. This forgone benefit comes from two sources: the increase in quantity sold and, potentially, a higher price. These costs go down as credit policy is relaxed.

The sum of the carrying costs and the opportunity costs of a particular credit policy is called the total **credit cost curve**. We have drawn such a curve in Figure 17.5. As Figure 17.5 illustrates, there is a point, C^* , where the total credit cost is minimized. This point corresponds to the optimal amount of credit, or, equivalently, the optimal investment in receivables.

If the firm extends more credit than this amount, the additional net cash flow from new customers will not cover the carrying costs of the investment in receivables. If the level of receivables is below this amount, then the firm is forgoing valuable profit opportunities.

In general, the costs and benefits from extending credit will depend on characteristics of particular firms and industries. All other things being equal, for example, it is likely that firms with (1) excess capacity, (2) low variable operating costs, and (3) repeat customers will extend credit more liberally than other firms. See if you can explain why each of these contributes to a more liberal credit policy.

Organizing the Credit Function Firms that grant credit have the expense of running a credit department. In practice, firms often choose to contract out all or part of the credit function to a factor, an insurance company, or a captive finance company. Chapter 16 discussed factoring, an arrangement in which the firm sells its receivables. Depending on the specific arrangement, the factor may have full responsibility for credit checking,

credit cost curve

FIGURE 17.5

The costs of granting credit

Carrying costs are the cash flows that must be incurred when credit is granted. They are positively related to the amount of credit extended.

Opportunity costs are the lost sales from refusing credit. These costs go down when credit is granted.

authorization, and collection. Smaller firms may find such an arrangement cheaper than running a credit department.

Firms that manage internal credit operations are self-insured against default, meaning that they bear all the risk of nonpayment. An alternative is to buy credit insurance through an insurance company. The insurance company offers coverage up to a preset dollar limit for accounts. As you would expect, accounts with a higher credit rating merit higher insurance limits. This type of insurance is particularly important for exporters, and government insurance is available for certain types of exports.

Large firms often extend credit through a **captive finance company**, which is simply a partially or wholly owned subsidiary that handles the credit function for the parent company. Toyota Financial Services, or TFS, is a well-known example. Toyota sells to car dealers who in turn sell to customers. TFS finances the dealer's inventory of cars and also finances customers who buy the cars.

captive finance company

A partially or wholly owned subsidiary that handles the credit function for the parent company.

Credit Analysis

Thus far, we have focused on establishing credit terms. Once a firm decides to grant credit to its customers, it must then establish guidelines for determining who will and who will not be allowed to buy on credit. *Credit analysis* refers to the process of deciding whether or not to extend credit to a particular customer. It usually involves two steps: gathering relevant information and determining creditworthiness.

Credit Information If a firm does want credit information on customers, there are a number of sources. Information sources commonly used to assess creditworthiness include the following:

1. *Financial statements.* A firm can ask a customer to supply financial statements such as balance sheets and income statements. Minimum standards and rules of thumb based on financial ratios like the ones we discussed in Chapter 3 can then be used as a basis for extending or refusing credit.

2. *Credit reports on the customer's payment history with other firms.* Quite a few organizations sell information on the credit strength and credit history of business firms. The best-known and largest firm of this type is Dun & Bradstreet, which provides subscribers with a credit reference book and credit reports on individual firms. Experian (formerly TRW) is another well-known credit-reporting firm. Ratings and information are available for a huge number of firms, including very small ones. Equifax, Trans Union, and Experian are the major suppliers of consumer credit information.
3. *Banks.* Banks will generally provide some assistance to their business customers in acquiring information on the creditworthiness of other firms.
4. *The customer's payment history with the firm.* The most obvious way to obtain information about the likelihood of a customer's not paying is to examine whether they have settled past obligations and how quickly they have met these obligations.

Web-surfing students should visit the Dun & Bradstreet home page—this major supplier of credit information can be found at www.dnb.com.

Credit Evaluation and Scoring There are no magical formulas for assessing the probability that a customer will not pay. In very general terms, the classic **five Cs of credit** are the basic factors to be evaluated:

1. *Character.* The customer's willingness to meet credit obligations.
2. *Capacity.* The customer's ability to meet credit obligations out of operating cash flows.
3. *Capital.* The customer's financial reserves.
4. *Collateral.* Assets pledged by the customer for security in case of default.
5. *Conditions.* General economic conditions in the customer's line of business.

five Cs of credit

The five basic credit factors to be evaluated: character, capacity, capital, collateral, and conditions.

Credit scoring refers to the process of calculating a numerical rating for a customer based on information collected; credit is then granted or refused based on the result. For example, a firm might rate a customer on a scale of 1 (very poor) to 10 (very good) on each of the five Cs of credit using all the information available about the customer. A credit score could then be calculated based on the total. From experience, a firm might choose to grant credit only to customers with a score above, say, 30.

credit scoring

The process of quantifying the probability of default when granting consumer credit.

Firms such as credit card issuers have developed elaborate statistical models for credit scoring. Usually, all of the legally relevant and observable characteristics of a large pool of customers are studied to find their historic relation to default rates. Based on the results, it is possible to determine the variables that best predict whether or not a customer will pay and then calculate a credit score based on those variables.

Because credit-scoring models and procedures determine who is and who is not credit worthy, it is not surprising that they have been the subject of government regulation. In particular, the kinds of background and demographic information that can be used in the credit decision are limited.

Collection Policy

Collection policy is the final element in credit policy. Collection policy involves monitoring receivables to spot trouble and obtaining payment on past-due accounts.

Monitoring Receivables To keep track of payments by customers, most firms will monitor outstanding accounts. First, a firm will normally keep track of its average collection period, ACP, through time. If a firm is in a seasonal business, the ACP will fluctuate during the year, but unexpected increases in the ACP are a cause for concern. Either

customers in general are taking longer to pay, or some percentage of accounts receivable is seriously overdue.

aging schedule
A compilation of accounts receivable by the age of each account.

The **aging schedule** is a second basic tool for monitoring receivables. To prepare one, the credit department classifies accounts by age.² Suppose a firm has \$100,000 in receivables. Some of these accounts are only a few days old, but others have been outstanding for quite some time. The following is an example of an aging schedule.

Aging Schedule		
Age of Account	Amount	Percentage of Total Value of Accounts Receivable
0–10 days	\$ 50,000	50%
11–60 days	25,000	25
61–80 days	20,000	20
Over 80 days	5,000	5
	<u>\$100,000</u>	<u>100%</u>

If this firm has a credit period of 60 days, then 25 percent of its accounts are late. Whether or not this is serious depends on the nature of the firm’s collections and customers. It is often the case that accounts beyond a certain age are almost never collected. Monitoring the age of accounts is very important in such cases.

Firms with seasonal sales will find the percentages on the aging schedule changing during the year. For example, if sales in the current month are very high, then total receivables will also increase sharply. This means that the older accounts, as a percentage of total receivables, become smaller and might appear less important. Some firms have refined the aging schedule so that they have an idea of how it should change with peaks and valleys in their sales.

Collection Effort A firm usually goes through the following sequence of procedures for customers whose payments are overdue:

1. It sends out a delinquency letter informing the customer of the past-due status of the account.
2. It makes a telephone call to the customer.
3. It employs a collection agency.
4. It takes legal action against the customer.

At times, a firm may refuse to grant additional credit to customers until arrearages are cleared up. This may antagonize a normally good customer, and it points to a potential conflict of interest between the collections department and the sales department.

CONCEPT QUESTIONS

17.3a

What are the basic components of credit policy?

17.3b

Explain what terms of “3/45, net 90” mean. What is the effective interest rate?

17.3c

What are the five Cs of credit?

² Aging schedules are used elsewhere in business. For example, aging schedules are often prepared for inventory items.

INVENTORY MANAGEMENT

17.4

Like receivables, inventories represent a significant investment for many firms. For a typical manufacturing operation, inventories will often exceed 15 percent of assets. For a retailer, inventories could represent more than 25 percent of assets. From our discussion in Chapter 16, we know that a firm's operating cycle is made up of its inventory period and its receivables period. This is one reason for considering credit and inventory policy in the same chapter. Beyond this, both credit policy and inventory policy are used to drive sales, and the two must be coordinated to ensure that the process of acquiring inventory, selling it, and collecting on the sale proceeds smoothly. For example, changes in credit policy designed to stimulate sales must be simultaneously accompanied by planning for adequate inventory.

The Financial Manager and Inventory Policy

Despite the size of a typical firm's investment in inventories, the financial manager of a firm will not normally have primary control over inventory management. Instead, other functional areas such as purchasing, production, and marketing will usually share decision-making authority. Inventory management has become an increasingly important specialty in its own right, and financial management will often only have input into the decision. However, as the accompanying *Reality Bytes* box describes, inventory policy can have dramatic financial effects. We will therefore survey some basics of inventory and inventory policy in the sections ahead.

Inventory Types

For a manufacturer, inventory is normally classified into one of three categories. The first category is *raw material*. This is whatever the firm uses as a starting point in its production process. Raw materials might be something as basic as iron ore for a steel manufacturer or something as sophisticated as disk drives for a computer manufacturer.

The second type of inventory is *work-in-progress*, which is just what the name suggests—unfinished product. How big this portion of inventory is depends in large part on the length of the production process. For an airframe manufacturer, for example, work-in-progress can be substantial. The third and final type of inventory is *finished goods*, that is, products ready to ship or sell.

There are three things to keep in mind concerning inventory types. First, the names for the different types can be a little misleading because one company's raw materials could be another's finished goods. For example, going back to our steel manufacturer, iron ore would be a raw material, and steel would be the final product. An auto body panel stamping operation will have steel as its raw material and auto body panels as its finished goods, and an automobile assembler will have body panels as raw materials and automobiles as finished products.

The second thing to keep in mind is that the various types of inventory can be quite different in terms of their liquidity. Raw materials that are commoditylike or relatively standardized can be easy to convert to cash. Work-in-progress, on the other hand, can be quite illiquid and have little more than scrap value. As always, the liquidity of finished goods depends on the nature of the product.

Finally, a very important distinction between finished goods and other types of inventories is that the demand for an inventory item that becomes a part of another item is usually termed *derived*, or *dependent*, demand because the firm's need for these inventory types depends on its need for finished items. In contrast, the firm's demand for finished goods is not derived from demand for other inventory items, so it is sometimes said to be *independent*.

Inventory Management: From Cars to RFIDs

So you want to be a CEO? We suggest you learn working capital management and pay particular attention to inventory. Proper inventory levels are important in every industry, but perhaps none more so than the auto industry. Particularly in recent years, U.S. auto manufacturers have struggled with overproduction, which can often lead to inventory problems. Excess inventory became even more problematic with the recession that began in 2008. In the auto industry, an inventory level of 60 days is considered normal. In March 2009, all the large automakers had inventory levels well above that target. General Motors, for example, had 122 days in sales, which was actually down from 147 days in February. The excess inventory, coupled with lower demand, forced automakers to cut back production. For example, Toyota announced plans to reduce production in Japan by 54 percent. Similarly, Honda announced a 59 percent cut, and Nissan planned a 59 percent cut.

A major reason the U.S. auto industry hadn't had to face up to overproduction problems is that manufacturers sell the automobiles to the dealers, who then sell to customers. Since the dealers tend to be small and restricted to one manufacturer, automakers would often force dealers to buy inventory that the dealers did not want or need. In fact, in early 2009, General Motors forced dealers to take on unwanted inventory

in order to get incentives offered by the company. However, with the rise of large dealers such as AutoNation, Detroit is being forced to reevaluate its sales and manufacturing processes. And AutoNation has reason to be concerned: The company reported that the interest cost for carrying its 2008 inventory was about \$84 million.

Given the costs associated with incorrect inventory decisions, companies are willing to try new technology to improve inventory management. For example, in 2004, Walmart began requiring its largest suppliers to attach radio frequency identification (RFID) tags to pallets. These high-tech tags are replacing bar codes because they can be read from a distance. By 2007, the 600 largest suppliers had met this requirement, and Walmart had a goal of adding 700 more suppliers soon.

The reason Walmart began this ambitious project was that the company expected to save \$8.35 billion per year in reduced inventory costs. Apparently, the RFID tags did not meet these goals as Walmart abandoned the pallet approach in October 2007. The company focused instead on shipments going to Sam's stores, promotional displays, and improving category management. Then, in February 2009, Proctor & Gamble ended its association with the promotional displays program, an indication that it too failed to live up to Walmart's expectations.

Inventory Costs

As we discussed in Chapter 16, there are two basic types of costs associated with current assets in general and with inventory in particular. The first of these are *carrying costs*. Here, carrying costs represent all of the direct and opportunity costs of keeping inventory on hand. These include:

1. Storage and tracking costs.
2. Insurance and taxes.
3. Losses due to obsolescence, deterioration, or theft.
4. The opportunity cost of capital for the invested amount.

The sum of these costs can be substantial, roughly ranging from 20 to 40 percent of inventory value per year.

The other types of costs associated with inventory are *shortage costs*. These are costs associated with having inadequate inventory on hand. The two components of shortage costs are restocking costs and costs related to safety reserves. Depending on the firm's business, order, or restocking, costs are either the costs of placing an order with suppliers or the cost of setting up a production run. The costs related to safety reserves are opportunity losses such as lost sales and loss of customer goodwill that result from having inadequate inventory.

A basic trade-off in inventory management exists because carrying costs increase with inventory levels while shortage, or restocking, costs decline with inventory levels. The basic

goal of inventory management is thus to minimize the sum of these two costs. We consider ways to reach this goal in the next section.

CONCEPT QUESTIONS

17.4a What are the different types of inventory?

17.4b What are three things to remember when examining inventory types?

17.4c What is the basic goal of inventory management?

INVENTORY MANAGEMENT TECHNIQUES

17.5

As we described earlier, the goal of inventory management is usually framed as cost minimization. Three techniques are discussed in this section, ranging from the relatively simple to the very complex.

The ABC Approach

The ABC approach is a simple approach to inventory management where the basic idea is to divide inventory into three (or more) groups. The underlying rationale is that a small portion of inventory in terms of quantity might represent a large portion in terms of inventory value. For example, this situation would exist for a manufacturer that uses some relatively expensive, high-tech components and some relatively inexpensive basic materials in producing its products.³

Figure 17.6 illustrates an ABC comparison of items in terms of the percentage of inventory value represented by each group versus the percentage of items represented. As Figure 17.6 shows, the A Group constitutes only 10 percent of inventory by item count, but it represents over half of the value of inventory. The A Group items are thus monitored closely, and inventory levels are kept relatively low. At the other end, basic inventory items, such as nuts and bolts, will also exist, but because these are crucial and inexpensive, large quantities are ordered and kept on hand. These would be C Group items. The B Group is made up of in-between items.

The Economic Order Quantity Model

The economic order quantity (EOQ) model is the best-known approach to explicitly establishing an optimal inventory level. The basic idea is illustrated in Figure 17.7, which plots the various costs associated with holding inventory (on the vertical axis) against inventory levels (on the horizontal axis). As is shown, inventory carrying costs rise and restocking costs decrease as inventory levels increase. From our discussion of the total credit cost curve in this chapter, the general shape of the total inventory cost curve is familiar. With the EOQ model, we will attempt to specifically locate the minimum total cost point, Q^* .

In our discussion below, an important point to keep in mind is that the actual cost of the inventory itself is not included. The reason is that the *total* amount of inventory the firm needs in a given year is dictated by sales. What we are analyzing here is how much the firm

³ The ABC approach to inventory should not be confused with activity-based costing, a common topic in managerial accounting.

FIGURE 17.6
ABC inventory analysis

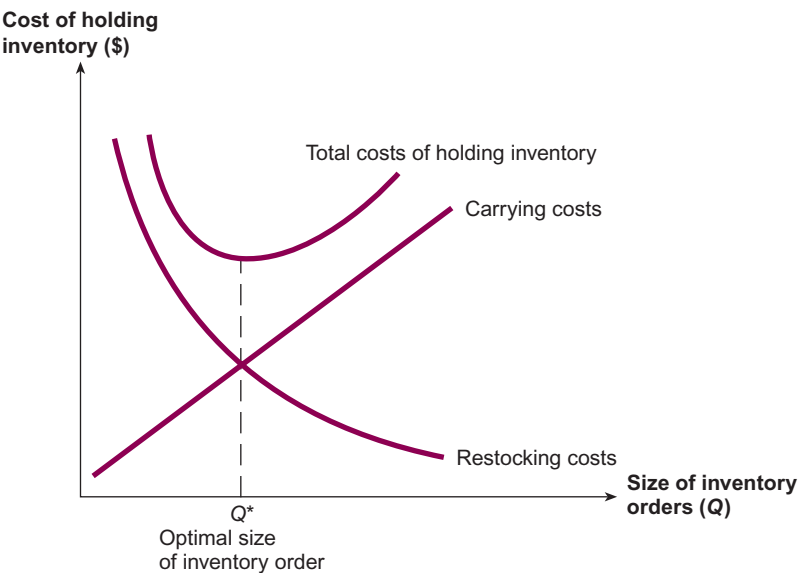

FIGURE 17.7
Costs of holding inventory

Restocking costs are greatest when the firm holds a small quantity of inventory. Carrying costs are greatest when there is a large quantity of inventory on hand. Total costs are the sum of the carrying and restocking costs.

should have on hand at any particular time. More precisely, we are trying to determine what order size the firm should use when it restocks its inventory.

Inventory Depletion To develop the EOQ, we will assume that the firm’s inventory is sold off at a steady rate until it hits zero. At that point, the firm restocks its inventory back to some optimal level. For example, suppose the Eyssell Corporation starts out today with 3,600 units of a particular item in inventory. Annual sales of this item are 46,800 units, which is about 900 per week. If Eyssell sells off 900 units in inventory each week, then, after four weeks, all the available inventory will be sold, and Eyssell will restock by

**FIGURE 17.8**

**Inventory holdings
for the Eyssell
Corporation**

The Eyssell Corporation starts with inventory of 3,600 units. The quantity drops to zero by the end of the fourth week. The average inventory is $Q/2 = 3,600/2 = 1,800$ over the period.

ordering (or manufacturing) another 3,600 and start over. This selling and restocking process produces a sawtooth pattern for inventory holdings; this pattern is illustrated in Figure 17.8. As the figure shows, Eyssell always starts with 3,600 units in inventory and ends up at zero. On average, then, inventory is half of 3,600, or 1,800 units.

The Carrying Costs As Figure 17.7 illustrates, carrying costs are normally assumed to be directly proportional to inventory levels. Suppose we let Q be the quantity of inventory that Eyssell orders each time (3,600 units); we will call this the restocking quantity. Average inventory would then just be $Q/2$, or 1,800 units. If we let CC be the carrying cost per unit per year, Eyssell's total carrying costs will be:

$$\begin{aligned} \text{Total carrying costs} &= \text{Average inventory} \times \text{Carrying costs per unit} \\ &= (Q/2) \times CC \end{aligned} \quad [17.1]$$

In Eyssell's case, if carrying costs were \$.75 per unit per year, then total carrying costs would be the average inventory of 1,800 multiplied by \$.75, or \$1,350 per year.

The Shortage Costs For now, we will focus only on the restocking costs. In essence, we will assume that the firm never actually runs short on inventory, so that costs relating to safety reserves are not important. We will return to this issue below.

Restocking costs are normally assumed to be fixed. In other words, every time we place an order, there are fixed costs associated with that order (remember that the cost of the inventory itself is not considered here). Suppose we let T be the firm's total unit sales per year. If the firm orders Q units each time, then it will need to place a total of T/Q orders. For Eyssell, annual sales were 46,800, and the order size was 3,600. Eyssell thus places a total of $46,800/3,600 = 13$ orders per year. If the fixed cost per order is F , the total restocking cost for the year would be:

$$\begin{aligned} \text{Total restocking cost} &= \text{Fixed cost per order} \times \text{Number of orders} \\ &= F \times (T/Q) \end{aligned} \quad [17.2]$$

For Eyssell, order costs might be \$50 per order, so the total restocking cost for 13 orders would be $\$50 \times 13 = \650 per year.

The Total Costs The total costs associated with holding inventory are the sum of the carrying costs and the restocking costs:

$$\begin{aligned} \text{Total costs} &= \text{Carrying costs} + \text{Restocking costs} \\ &= (Q/2) \times CC + F \times (T/Q) \end{aligned} \quad [17.3]$$

Our goal is to find the value of Q , the restocking quantity, that minimizes this cost. To see how we might go about this, we can calculate total costs for some different values of Q . For the Eyssell Corporation, we had carrying costs (CC) of \$.75 per unit per year, fixed costs (F) of \$50 per order, and total unit sales (T) of 46,800 units. With these numbers, some possible total costs are (check some of these for practice):

Restocking Quantity (Q)	Total Carrying Costs ($Q/2 \times CC$)	+	Restocking Costs ($F \times T/Q$)	=	Total Costs
500	\$ 187.5		\$4,680.0		\$4,867.5
1,000	375.0		2,340.0		2,715.0
1,500	562.5		1,560.0		2,122.5
2,000	750.0		1,170.0		1,920.0
2,500	937.5		936.0		1,873.5
3,000	1,125.0		780.0		1,905.0
3,500	1,312.5		668.6		1,981.1

Inspecting the numbers, we see that total costs start out at almost \$5,000, and they decline to just under **\$1,900**. The cost-minimizing quantity appears to be approximately **2,500**.

To find the precise cost-minimizing quantity, we can take a look back at Figure 17.7. What we notice is that the minimum point occurs right where the two lines cross. At this point, carrying costs and restocking costs are the same. For the particular types of costs we have assumed here, this will always be true, so we can find the minimum point just by setting these costs equal to each other and solving for Q^* :

$$\begin{aligned} \text{Carrying costs} &= \text{Restocking costs} \\ (Q^*/2) \times CC &= F \times (T/Q^*) \end{aligned} \quad [17.4]$$

With a little algebra, we get:

$$(Q^*)^2 = \frac{2T \times F}{CC} \quad [17.5]$$

To solve for Q^* , we take the square root of both sides to find:

$$Q^* = \sqrt{\frac{2T \times F}{CC}} \quad [17.6]$$

economic order quantity (EOQ)

The restocking quantity that minimizes the total inventory costs.

This reorder quantity, which minimizes the total inventory cost, is called the **economic order quantity**, or **EOQ**. For the Eyssell Corporation, the EOQ is:

$$\begin{aligned} Q^* &= \sqrt{\frac{2T \times F}{CC}} \\ &= \sqrt{\frac{(2 \times 46,800) \times \$50}{.75}} \\ &= \sqrt{6,240,000} \\ &= \mathbf{2,498 \text{ units}} \end{aligned} \quad [17.7]$$

Thus, for Eyssell, the economic order quantity is actually 2,498 units. At this level, verify that the restocking costs and carrying costs are identical (they're both \$936.75).

Carrying Costs

EXAMPLE 17.3

Thiewes Shoes begins each period with 100 pairs of hiking boots in stock. This stock is depleted each period and reordered. If the carrying cost per pair of boots per year is \$3, what are the total carrying costs for the hiking boots?

Inventories always start at 100 items and end up at 0, so average inventory is 50 items. At an annual cost of \$3 per item, total carrying costs are \$150.

Restocking Costs

EXAMPLE 17.4

In our previous example (Example 17.3), suppose Thiewes sells a total of 600 pairs of boots in a year. How many times per year does Thiewes restock? Suppose the restocking cost is \$20 per order. What are total restocking costs?

Thiewes orders 100 items each time. Total sales are 600 items per year, so Thiewes restocks six times per year, or about every two months. The restocking costs would be 6 orders \times \$20 per order = \$120.

The EOQ

EXAMPLE 17.5

Based on our previous two examples, what size orders should Thiewes place to minimize costs? How often will Thiewes restock? What are the total carrying and restocking costs? The total costs?

We have that the total number of pairs of boots ordered for the year (T) is 600. The restocking cost (F) is \$20 per order, and the carrying cost (CC) is \$3. We can calculate the EOQ for Thiewes as follows:

$$\begin{aligned} \text{EOQ} &= \sqrt{\frac{2T \times F}{CC}} \\ &= \sqrt{\frac{(2 \times 600) \times \$20}{3}} \\ &= \sqrt{8,000} \\ &= 89.44 \text{ units} \end{aligned}$$

Since Thiewes sells 600 pairs per year, it will restock $600/89.44 = 6.71$ times. The total restocking costs will be $\$20 \times 6.71 = \134.16 . Average inventory will be $89.44/2 = 44.72$. The carrying costs will be $\$3 \times 44.72 = \134.16 , the same as the restocking costs. The total costs are thus \$268.33.

Extensions to the EOQ Model

Thus far, we have assumed that a company will let its inventory run down to zero and then reorder. In reality, a company will wish to reorder before its inventory goes to zero for two reasons. First, by always having at least some inventory on hand, the firm minimizes the risk of a stockout and the resulting losses of sales and customers. Second, when a firm does reorder, there will be some time lag before the inventory arrives. Thus, to finish our discussion of the EOQ, we consider two extensions, safety stocks and reorder points.

FIGURE 17.9**Safety stocks and reorder points**

Safety Stocks A *safety stock* is the minimum level of inventory that a firm keeps on hand. Inventories are reordered whenever the level of inventory falls to the safety stock level. Part A of Figure 17.9 illustrates how a safety stock can be incorporated into an EOQ model. Notice that adding a safety stock simply means that the firm does not run its inventory all the way down to zero. Other than this, the situation here is identical to that considered in our earlier discussion of the EOQ.

Reorder Points To allow for delivery time, a firm will place orders before inventories reach a critical level. The *reorder points* are the times at which the firm will actually place its inventory orders. These points are illustrated in Part B of Figure 17.9. As is shown, the reorder points simply occur some fixed number of days (or weeks or months) before inventories are projected to reach zero.

One of the reasons that a firm will keep a safety stock is to allow for uncertain delivery times. We can therefore combine our reorder point and safety stock discussions in Part C

of Figure 17.9. The result is a generalized EOQ model in which the firm orders in advance of anticipated needs and also keeps a safety stock of inventory to guard against unforeseen fluctuations in demand and delivery times.

Managing Derived-Demand Inventories

The third type of inventory management technique is used to manage derived-demand inventories. As we described previously, demand for some inventory types is derived from, or dependent on, other inventory needs. A good example is given by the auto manufacturing industry, where the demand for finished products derives from consumer demand, marketing programs, and other factors related to projected unit sales. The demand for inventory items such as tires, batteries, headlights, and other components is then completely determined by the number of autos planned. Materials requirements planning and just-in-time inventory management are two methods for managing demand-dependent inventories.

Materials Requirements Planning Production and inventory specialists have developed computer-based systems for ordering and/or scheduling production of demand-dependent types of inventories. These systems fall under the general heading of **materials requirements planning (MRP)**. The basic idea behind MRP is that, once finished goods inventory levels are set, it is possible to determine what levels of work-in-progress inventories must exist to meet the need for finished goods. From there, it is possible to calculate the quantity of raw materials that must be on hand. This ability to schedule backwards from finished goods inventories stems from the dependent nature of work-in-progress and raw materials inventories. MRP is particularly important for complicated products for which a variety of components are needed to create the finished product.

materials requirements planning (MRP)

A set of procedures used to determine inventory levels for demand-dependent inventory types such as work-in-progress and raw materials.

Just-in-Time Inventory **Just-in-time**, or **JIT, inventory** is a modern approach to managing dependent inventories. The goal of JIT is essentially to minimize such inventories, thereby maximizing turnover. The approach began in Japan, and it is a fundamental part of much of Japanese manufacturing philosophy. As the name suggests, the basic goal of JIT is to have only enough inventory on hand to meet immediate production needs.

just-in-time (JIT) inventory

A system for managing demand-dependent inventories that minimizes inventory holdings.

The result of the JIT system is that inventories are reordered and restocked frequently. Making such a system work and avoiding shortages requires a high degree of cooperation among suppliers. Japanese manufacturers often have a relatively small, tightly integrated group of suppliers with whom they work closely to achieve the needed coordination. These suppliers are a part of a large manufacturer's (such as Toyota's) industrial group, or *keiretsu*. Each large manufacturer tends to have its own *keiretsu*. It also helps to have suppliers located nearby, a situation that is common in Japan.

The *kanban* is an integral part of a JIT inventory system, and JIT systems are sometimes called *kanban systems*. The literal meaning of *kanban* is "card" or "sign," but, broadly speaking, a *kanban* is a signal to a supplier to send more inventory. For example, a *kanban* could literally be a card attached to a bin of parts. When a worker pulls that bin, the card is detached and routed back to the supplier, who then supplies a replacement bin.

A JIT inventory system is an important part of a larger production planning process. A full discussion of it would necessarily shift our focus away from finance to production and operations management, so we will leave it here.

CONCEPT QUESTIONS

17.5a What does the EOQ model determine for the firm?

17.5b Which cost component of the EOQ model does JIT inventory minimize?

SUMMARY AND CONCLUSIONS

This chapter has covered cash, receivables, and inventory management. Along the way, we have touched on a large number of subjects. Some of the more important issues we examined are:

1. Firms seek to manage their cash by keeping no more than is needed on hand. The reason is that holding cash has an opportunity cost, namely, the returns that could be earned by investing the money.
2. Float is an important consideration in cash management, and firms seek to manage collections and disbursements in ways designed to optimize the firm's net float.
3. A firm's credit policy includes the terms of sale, credit analysis, and collection policy. The terms of sale cover three related subjects: the credit period, cash discount, and credit instrument.
4. The optimal credit policy for a firm depends on many specific factors, but generally involves trading off the costs of granting credit, such as the carrying costs of receivables and the possibility of nonpayment, against the benefits in terms of increased sales.
5. There are different types of inventories that differ greatly in their liquidity and management. The basic trade-off in inventory management is the cost of carrying inventory versus the cost of restocking. We developed the famous EOQ model, which explicitly balances these costs.
6. Firms use different inventory management techniques; we described a few of the better known, including the ABC approach and just-in-time, or JIT, inventory management.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

- 17.1 Calculating Float.** You have \$10,000 on deposit with no outstanding checks or uncleared deposits. One day you write a check for \$4,000 and then deposit a check for \$3,000. What are your disbursement, collection, and net floats?
- 17.2 The EOQ.** Heusen Computer Manufacturing starts each period with 4,000 central processing units (CPUs) in stock. This stock is depleted each month and reordered. If the carrying cost per CPU is \$1 and the fixed order cost is \$10, is Heusen following an economically advisable strategy?

■ Answers to Chapter Review and Self-Test Problems

- 17.1** First, after you write the check for \$4,000, you show a balance of \$6,000. However, while the check is clearing, your bank shows a balance of \$10,000. This is a \$4,000 disbursement float, and it is good for you. Next, when you deposit the \$3,000, you show a balance of \$9,000, but your account will not be credited for the \$3,000 until it clears. This is a $-\$3,000$ collection float, and it is bad for you. The sum of the disbursement float and the collection float is your net float of \$1,000. In other words, on a net basis, you show a balance of \$9,000, but your bank shows a \$10,000 balance, so, in net terms, you are benefiting from the float.
- 17.2** We can answer by first calculating Heusen's carrying and restocking costs. The average inventory is 2,000 CPUs, and, since the carrying costs are \$1 per CPU,

total carrying costs are \$2,000. Heusen restocks every month at a fixed order cost of \$10, so the total restocking costs are \$120. What we see is that carrying costs are large relative to reorder costs, so Heusen is carrying too much inventory.

To determine the optimal inventory policy, we can use the EOQ model. Because Heusen orders 4,000 CPUs 12 times per year, total needs (T) are 48,000 CPUs. The fixed order cost is \$10, and the carrying cost per unit (CC) is \$1. The EOQ is therefore:

$$\begin{aligned} \text{EOQ} &= \sqrt{\frac{2T \times F}{CC}} \\ &= \sqrt{\frac{(2 \times 48,000) \times \$10}{1}} \\ &= \sqrt{960,000} \\ &= 979.80 \text{ units} \end{aligned}$$

We can check this by noting that the average inventory is about 490 CPUs, so the carrying cost is \$490. Heusen will have to reorder $48,000/979.8 = 49$ times. The fixed order cost is \$10, so the total restocking cost is also \$490.

CRITICAL THINKING AND CONCEPTS REVIEW

- L0 1** **17.1 Cash Management.** Is it possible for a firm to have too much cash? Why would shareholders care if a firm accumulates large amounts of cash?
- L0 1** **17.2 Cash Management.** What options are available to a firm if it believes it has too much cash? How about too little?
- L0 1** **17.3 Agency Issues.** Are stockholders and creditors likely to agree on how much cash a firm should keep on hand?
- L0 1** **17.4 Motivations for Holding Cash.** In the chapter opening, we discussed the cash positions of several companies. Automobile manufacturers also have enormous cash reserves. At the beginning of 2009, Ford Motor Co. had \$28.2 billion in cash, General Motors had \$14 billion, and Toyota had about \$30.3 billion. Why would firms such as these hold such large quantities of cash?
- L0 1** **17.5 Short-Term Investments.** Why is a preferred stock with a dividend tied to short-term interest rates an attractive short-term investment for corporations with excess cash?
- L0 2** **17.6 Collection and Disbursement Floats.** Which would a firm prefer: a net collection float or a net disbursement float? Why?
- L0 1** **17.7 Float.** Suppose a firm has a book balance of \$2 million. At the automatic teller machine (ATM), the cash manager finds out that the bank balance is \$2.5 million. What is the situation here? If this is an ongoing situation, what ethical dilemma arises?
- L0 1** **17.8 Short-Term Investments.** For each of the short-term marketable securities given here, provide an example of the potential disadvantages the investment has for meeting a corporation's cash management goals.
 - a. U.S. Treasury bills
 - b. Ordinary preferred stock

- c. Negotiable certificates of deposit (NCDs)
- d. Commercial paper

L0 1

17.9 Agency Issues. It is sometimes argued that excess cash held by a firm can aggravate agency problems (discussed in Chapter 1) and, more generally, reduce incentives for shareholder wealth maximization. How would you frame the issue here?

L0 1

17.10 Use of Excess Cash. One option a firm usually has with any excess cash is to pay its suppliers more quickly. What are the advantages and disadvantages of this use of excess cash?

L0 1

17.11 Use of Excess Cash. Another option usually available for dealing with excess cash is to reduce the firm's outstanding debt. What are the advantages and disadvantages of this use of excess cash?

L0 1

17.12 Float. An unfortunately common practice goes like this (Warning: don't try this at home): Suppose you are out of money in your checking account; however, your local grocery store will, as a convenience to you as a customer, cash a check for you. So you cash a check for \$200. Of course, this check will bounce unless you do something. To prevent this, you go to the grocery the next day and cash another check for \$200. You take this \$200 and deposit it. You repeat this process every day, and, in doing so, you make sure that no checks bounce. Eventually, manna from heaven arrives (perhaps in the form of money from home) and you are able to cover your outstanding checks.

To make it interesting, suppose you are absolutely certain that no checks will bounce along the way. Assuming this is true, and ignoring any question of legality (what we have described is probably illegal check kiting), is there anything unethical about this? If you say yes, then why? In particular, who is harmed?

L0 2

17.13 Credit Instruments. Describe each of the following:

- a. Sight draft
- b. Time draft
- c. Banker's acceptance
- d. Promissory note
- e. Trade acceptance

L0 2

17.14 Trade Credit Forms. In what form is trade credit most commonly offered? What is the credit instrument in this case?

L0 2

17.15 Receivables Costs. What are the costs associated with carrying receivables? What are the costs associated with not granting credit? What do we call the sum of the costs for different levels of receivables?

L0 2

17.16 Five Cs of Credit. What are the five Cs of credit? Explain why each is important.

L0 2

17.17 Credit Period Length. What are some of the factors that determine the length of the credit period? Why is the length of the buyer's operating cycle often considered an upper bound on the length of the credit period?

L0 2

17.18 Credit Period Length. In each of the following pairings, indicate which firm would probably have a longer credit period and explain your reasoning.

- a. Firm A sells a miracle cure for baldness; Firm B sells toupees.
- b. Firm A specializes in products for landlords; Firm B specializes in products for renters.
- c. Firm A sells to customers with an inventory turnover of 10 times; Firm B sells to customers with an inventory turnover of 20 times.

- d. Firm A sells fresh fruit; Firm B sells canned fruit.
- e. Firm A sells and installs carpeting; Firm B sells rugs.

L0 3

17.19 Inventory Types. What are the different inventory types? How do the types differ? Why are some types said to have dependent demand whereas other types are said to have independent demand?

L0 3

17.20 Just-in-Time Inventory. If a company moves to a JIT inventory management system, what will happen to inventory turnover? What will happen to total asset turnover? What will happen to return on equity, ROE? (Hint: Remember the Du Pont equation from Chapter 3.)

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

L0 1

- 1. Calculating Float.** You have \$145,000 on deposit with no outstanding checks or uncleared deposits. One day you write a check for \$39,000. Does this create a disbursement float or a collection float? What is your available balance? Book balance?

Basic
(Questions 1–14)

L0 1

- 2. Calculating Float.** You have \$13,200 on deposit with no outstanding checks or uncleared deposits. If you deposit a check for \$4,800, does this create a disbursement float or a collection float? What is your available balance? Book balance?

L0 1

- 3. Calculating Float.** You have \$35,400 on deposit with no outstanding checks or uncleared deposits. One day you write a check for \$4,700 and then deposit a check for \$6,300. What are your disbursement, collection, and net floats?

L0 2

- 4. Cash Discounts.** You place an order for 900 units of Good X at a unit price of \$46. The supplier offers terms of 1/20, net 35.
- a. How long do you have to pay before the account is overdue? If you take the full period, how much should you remit?
 - b. What is the discount being offered? How quickly must you pay to get the discount? If you do take the discount, how much should you remit?
 - c. If you don't take the discount, how much interest are you paying implicitly? How many days' credit are you receiving?

L0 1

- 5. Calculating Float.** In a typical month, the Tanner Corporation receives 100 checks totaling \$78,000. These are delayed three days on average. What is the average daily float? Assume 30 days in a month.

L0 1

- 6. Calculating Net Float.** Each business day, on average, a company writes checks totaling \$32,000 to pay its suppliers. The usual clearing time for the checks is four days. Meanwhile, the company is receiving payments from its customers each day, in the form of checks, totaling \$43,000. The cash from the payments is available to the firm after two days.

- a. Calculate the company's disbursement float, collection float, and net float.
- b. How would your answer to part (a) change if the collected funds were available in one day instead of two?

L0 2

- 7. Size of Accounts Receivable.** Essence of Skunk Fragrances, Ltd., sells 5,000 units of its perfume collection each year at a price per unit of \$380. All sales are on credit with terms of 1/10, net 30. The discount is taken by 35 percent of the customers. What is the amount of the company's accounts receivable? In reaction

to sales by its main competitor, Sewage Spray, Essence of Skunk is considering a change in its credit policy to terms of 3/10, net 30 to preserve its market share. How will this change in policy affect accounts receivable?

L0 2

8. **Size of Accounts Receivable.** The Johnson Corporation has annual credit sales of \$31 million. The average collection period is 33 days. What is the average investment in accounts receivable as shown on the balance sheet?

L0 2

9. **ACP and Accounts Receivable.** Miyagi Data, Inc., sells earnings forecasts for Japanese securities. Its credit terms are 1/10, net 30. Based on experience, 65 percent of all customers will take the discount.

- What is the average collection period?
- If the company sells 1,200 forecasts every month at a price of \$2,300 each, what is its average balance sheet amount in accounts receivable?

L0 2

10. **Size of Accounts Receivable.** Two Doors Down, Inc., has weekly credit sales of \$38,600, and the average collection period is 34 days. What is TDD's average accounts receivable figure?

L0 2

11. **Terms of Sale.** A firm offers terms of 2/15, net 40. What effective annual interest rate does the firm earn when a customer does not take the discount? Without doing any calculations, explain what will happen to this effective rate if:

- The discount is changed to 3 percent.
- The credit period is increased to 60 days.
- The discount period is decreased to 20 days.
- What is the EAR for each scenario?

L0 2

12. **ACP and Receivables Turnover.** Vang, Inc., has an average collection period of 28 days. Its average daily investment in receivables is \$87,000. What are annual credit sales? What is the receivables turnover?

L0 3

13. **EOQ.** Clap Off Manufacturing uses 1,300 switch assemblies per week and then reorders another 1,300. If the relevant carrying cost per switch assembly is \$5 and the fixed order cost is \$575, is the company's inventory policy optimal? Why or why not?

L0 3

14. **EOQ.** The Trektronics store begins each month with 950 phasers in stock. This stock is depleted each month and reordered. If the carrying cost per phaser is \$32 per year and the fixed order cost is \$540, what is the total carrying cost? What is the restocking cost? Should the company increase or decrease its order size? Describe an optimal inventory policy for the company in terms of order size and order frequency.

L0 3

15. **EOQ Derivation.** Prove that when carrying costs and restocking costs are as described in the chapter, the EOQ must occur at the point where the carrying costs and restocking costs are equal.

L0 3

16. **Safety Stocks and Order Points.** Saché, Inc., expects to sell 700 of its designer suits every week. The store is open seven days a week and expects to sell the same number of suits every day. The company has an EOQ of 500 suits and a safety stock of 100 suits. Once an order is placed, it takes three days for Saché to get the suits in. How many orders does the company place per year? Assume that it is Monday morning before the store opens, and a shipment of suits has just arrived. When will Saché place its next order?

(Question 15)

Challenge
(Question 16)

- 17.1 Commercial Paper.** Chevron sells commercial paper to interested institutional investors. Go to the Chevron Web site at www.chevron.com to find information on Chevron's commercial paper. What is the credit rating for Chevron's commercial paper? What is the minimum size Chevron will sell? What size do they require for one- to four-day commercial paper?
- 17.2 Commercial Paper Rates.** What were the highest and lowest historical interest rates for commercial paper? Go to www.stlouisfed.org, find the "FRED® data" link, then the "Interest Rates" link. What were the highest and lowest interest rates for one-, two-, and three-month AA nonfinancial commercial paper? What about for financial commercial paper? Did these occur at the same time? Why might the nonfinancial and financial commercial paper rates be different?

CHAPTER CASE

PIEPKORN MANUFACTURING WORKING CAPITAL MANAGEMENT, PART 2

After completing the short-term financial plan for next year (at the end of Chapter 16), Gary Piepkorn approaches you and asks about the company's credit policy. In looking at the competition, most companies in the industry offer credit to customers, so Piepkorn Manufacturing appears to be one of the few companies that does not. Several customers have expressed the possibility of changing to a different supplier because of the lack of credit. Gary is interested in knowing how implementing a credit policy will affect the short-term

financial plan for next year. Additionally, he would like you to inquire as to the possibility of getting improved credit terms for the company's purchases.

To analyze the possible switch to the new credit terms, Gary has asked you to investigate industry standard credit terms and rework the short-term financial plan assuming Piepkorn Manufacturing offers credit to its customers. He would also like to investigate how better credit terms from the company's suppliers would affect the short-term financial plan. ■

QUESTIONS

1. You have looked at the credit policy offered by your competitors and have determined that the industry standard credit policy is 1/10, net 45. The discount will begin to be offered on the first day of the year. You want to examine how this credit policy would affect the cash budget and short-term financial plan. If this credit policy is implemented, you believe that 60 percent of customers will take advantage of the credit offer and the accounts receivable period will be 24 days. Rework the cash budget and short-term financial plan under the new credit policy and a target cash balance of \$80,000. What interest rate are you effectively offering customers?
2. You have talked to the company's suppliers about the credit terms Piepkorn receives. Currently, the company receives terms of net 45. Your suppliers have stated that they would offer new credit terms of 2/25, net 40. The discount would begin to be offered on the first day of the year. What interest rate are the suppliers offering the company? Rework your cash budget and short-term financial plan from the previous question assuming you take advantage of the discount offered.

International Aspects of Financial Management

AFTER STUDYING THIS CHAPTER, YOU SHOULD BE ABLE TO:

- LO 1** Explain how exchange rates are quoted, assess what they mean, and differentiate between spot and forward exchange rates.
- LO 2** Discuss purchasing power parity and interest rate parity and analyze their implications for exchange rate changes.
- LO 3** Identify the different types of exchange rate risk and ways firms manage exchange rate risk.
- LO 4** Discuss the impact of political risk on international business investing.

In the fall of 2007, Canadians cheered as the Canadian dollar, popularly known as the “loonie,” reached parity with the U.S. dollar for the first time in 31 years, meaning that one loonie could be exchanged for one greenback. As recently as five years before, one loonie was worth only \$.62. By November 2007, the loonie reached \$1.10, a level not seen since the 1870s, though it fell back to about \$.77 by March 2009. The dollar took a dive Down Under as well. In June 2008, the Australian dollar reached a high of Australian \$.96 per U.S. dollar, its highest level in more than 23 years, although it fell back to about \$.64 in February 2009.

So what were the effects of these exchange rate shifts? Using Canada as an example, the higher value of the loonie meant that Canadian exports were more expensive in the United States, so exports declined. The increased value of the loonie was also blamed for the loss of more than 268,000 manufacturing jobs in Canada, primarily in areas near the U.S.–Canadian border. Since Canada became more expensive for U.S. visitors, tourism dropped as well, reaching its lowest level in 35 years.

As businesses of all types have increased their reliance on international operations, all areas of business have been strongly affected. Human resources, production, marketing, accounting, and strategy, for example, all become much more complex when nondomestic considerations come into play. This chapter discusses one of the most important aspects of international business: the impact of shifting exchange rates and what companies (and individuals) can do to protect themselves against adverse exchange rate movements.

Visit us at www.mhhe.com/rwj

Companies with significant foreign operations are often called *international corporations*, or *multinationals*. Such companies must consider many financial factors that do not directly affect purely domestic firms. These include foreign exchange rates, differing interest rates from country to country, complex accounting methods for foreign operations, foreign tax rates, and foreign government intervention.

The basic principles of corporate finance still apply to international corporations; like domestic companies, they seek to invest in projects that create more value for the shareholders (or owners) than they cost and to arrange financing that raises cash at the lowest possible cost. In other words, the net present value principle holds for both foreign and domestic operations, but it is usually more complicated to apply the NPV rule to foreign investments.

We won't have much to say here about the role of cultural and social differences in international business. We also will not be discussing the implications of differing political and economic systems. These factors are of great importance to international businesses, but it would take another book to do them justice. Consequently, we will focus only on some purely financial considerations in international finance and some key aspects of foreign exchange markets.

18.1

American Depositary Receipt (ADR)

Security issued in the U.S. representing shares of a foreign stock, allowing that stock to be traded in the U.S.

See

www.adr.com for more.

cross-rate

The implicit exchange rate between two currencies (usually non-U.S.) quoted in some third currency (usually the U.S. dollar).

Eurobonds

International bonds issued in multiple countries but denominated in a single currency (usually the issuer's currency).

Eurocurrency

Money deposited in a financial center outside of the country whose currency is involved.

TERMINOLOGY

A common buzzword for the student of business finance is *globalization*. The first step in learning about the globalization of financial markets is to conquer the new vocabulary. As with any specialty, international finance is rich in jargon. Accordingly, we get started on the subject with a highly eclectic vocabulary exercise.

The terms that follow are presented alphabetically, and they are not all of equal importance. We choose these particular ones because they appear frequently in the financial press or because they illustrate some of the colorful language of international finance.

1. An **American Depositary Receipt**, or **ADR**, is a security issued in the United States that represents shares of a foreign stock, allowing that stock to be traded in the United States. Foreign companies use ADRs, which are issued in U.S. dollars, to expand the pool of potential U.S. investors. ADRs are available in two forms: company sponsored, which are listed on an exchange, and unsponsored, which usually are held by the investment bank that deals in the ADR. Both forms are available to individual investors, but only company-sponsored issues are quoted daily in newspapers.
2. The **cross-rate** is the implicit exchange rate between two currencies (usually non-U.S.) when both are quoted in some third currency, usually the U.S. dollar.
3. A **Eurobond** is a bond issued in multiple countries, but denominated in a single currency, usually the issuer's home currency. Such bonds have become an important way to raise capital for many international companies and governments. Eurobonds are issued outside the restrictions that apply to domestic offerings and are syndicated and traded mostly from London. Trading can and does take place anywhere there is a buyer and a seller.
4. **Eurocurrency** is money deposited in a financial center outside of the country whose currency is involved. For instance, Eurodollars—the most widely used Eurocurrency—are U.S. dollars deposited in banks outside the U.S. banking system.

5. **Foreign bonds**, unlike Eurobonds, are issued in a single country and are usually denominated in that country's currency. Often, the country in which these bonds are issued will draw distinctions between them and bonds issued by domestic issuers, including different tax laws, restrictions on the amount issued, and tougher disclosure rules.

Foreign bonds often are nicknamed for the country where they are issued: Yankee bonds (United States), Samurai bonds (Japan), Rembrandt bonds (the Netherlands), and Bulldog bonds (Britain). Partly because of tougher regulations and disclosure requirements, the foreign-bond market hasn't grown in past years with the vigor of the Eurobond market. A substantial portion of all foreign bonds are issued in Switzerland.

6. **Gilts**, technically, are British and Irish government securities, although the term also includes issues of local British authorities and some overseas public-sector offerings.
7. The **London Interbank Offer Rate (LIBOR)** is the rate that most international banks charge one another for loans of Eurodollars overnight in the London market. LIBOR is a cornerstone in the pricing of money market issues and other debt issues by both government and corporate borrowers. Interest rates are frequently quoted as some spread over LIBOR, and they then float with the LIBOR rate.
8. There are two basic kinds of **swaps**: interest rate and currency. An interest rate swap occurs when two parties exchange a floating-rate payment for a fixed-rate payment or vice versa. Currency swaps are agreements to deliver one currency in exchange for another. Often, both types of swaps are used in the same transaction when debt denominated in different currencies is swapped.

foreign bonds

International bonds issued in a single country, usually denominated in that country's currency.

gilts

British and Irish government securities.

London Interbank Offer Rate (LIBOR)

The rate most international banks charge one another for overnight Eurodollar loans.

For current LIBOR rates, see www.hsh.com.

CONCEPT QUESTIONS

- 18.1a What are the differences between a Eurobond and a foreign bond?
- 18.1b What are Eurodollars?

swaps

Agreements to exchange two securities or currencies.

FOREIGN EXCHANGE MARKETS AND EXCHANGE RATES

18.2

The **foreign exchange market** is undoubtedly the world's largest financial market. It is the market where one country's currency is traded for another's. Most of the trading takes place in a few currencies such as the U.S. dollar (\$), the British pound sterling (£), the Japanese yen (¥), and the euro (€). Table 18.1 lists some of the more common currencies and their symbols.

The foreign exchange market is an over-the-counter market, so there is no single location where traders get together. Instead, market participants are located in the major commercial and investment banks around the world. They communicate using computer terminals, telephones, and other telecommunications devices. For example, one communications network for foreign transactions is the Society for Worldwide Interbank Financial Telecommunication (SWIFT), a Belgian not-for-profit cooperative. Using data transmission lines, a bank in New York can send messages to a bank in London via SWIFT regional processing centers.

Information on doing business globally can be found at www.internationalist.com.

foreign exchange market

The market in which one country's currency is traded for another.

For online currency rates, go to www.bloomberg.com/markets/currencies/fxc.html.

The many different types of participants in the foreign exchange market include the following:

1. Importers who pay for goods in foreign currencies.
2. Exporters who receive foreign currency and may want to convert to their domestic currency.
3. Portfolio managers who buy or sell foreign stocks and bonds.
4. Foreign exchange brokers who match buy and sell orders.
5. Traders who “make a market” in foreign currencies.
6. Speculators who try to profit from changes in exchange rates.

Exchange Rates

exchange rate
The price of one country's currency expressed in terms of another country's currency.

An **exchange rate** is simply the price of one country's currency expressed in terms of another country's currency. In practice, almost all trading of currencies takes place in terms of the U.S. dollar. For example, both the Swiss franc and the Japanese yen are traded with their prices quoted in U.S. dollars. Exchange rates are constantly changing. Our nearby *Work the Web* box shows you how to get up-to-the-minute rates.

Exchange Rate Quotations Figure 18.1 reproduces exchange rate quotations as they appear in *The Wall Street Journal*. The first column (labeled “in U.S. \$”) gives the number of dollars it takes to buy one unit of foreign currency. For example, the Australian

WORK THE WEB

You just returned from your dream vacation to Jamaica and feel rich since you have 10,000 Jamaican dollars left over. You now need to convert this to U.S. dollars. How much will you have? You can look up the current exchange rate and do the conversion yourself, or simply work the Web. We went to www.xe.com and used the currency converter on the site to find out. This is what we found:

Live rates at 2009.04.09 18:04:43 UTC		
10,000.00 JMD	=	113.636 USD
Jamaica Dollars		United States Dollars
1 JMD = 0.0113636 USD		1 USD = 88.0000 JMD

Looks like you left Jamaica just before you ran out of money.

Get up-to-the-minute exchange rates at www.xe.com and www.exchangerate.com.

dollar is quoted at .7113, which means that you can buy one Australian dollar with .7113 U.S. dollars.

The second column shows the amount of foreign currency per U.S. dollar. The Australian dollar is quoted here at 1.4059, so you can get 1.4059 Australian dollars for one U.S. dollar. Naturally, this second exchange rate is just the reciprocal of the first one; $1/.7113 = 1.4059$, allowing for a possible rounding error.

EXAMPLE 18.1

A Yen for Euros

Suppose you have \$1,000. Based on the rates in Figure 18.1, how many Japanese yen can you get? Alternatively, if a Porsche costs € 200,000 (€ is the symbol for the euro), how many dollars will you need to buy it?

The exchange rate in terms of yen per dollar is 100.37. Your \$1,000 will thus get you:

$$\text{\$1,000} \times 100.37 \text{ yen per \$1} = 100,370 \text{ yen}$$

Since the exchange rate in terms of dollars per euro is 1.3266, you will need:

$$\text{€ 200,000} \times 1.3266 \text{ \$ per euro} = \text{\$265,320}$$

Cross-Rates and Triangle Arbitrage Using the U.S. dollar as the common denominator in quoting exchange rates greatly reduces the number of necessary cross-currency quotes. For example, with five major currencies, there would potentially be 10 exchange rates instead of just 4. Also, the fact that the dollar is used throughout cuts down on inconsistencies in the exchange rate quotations.

Earlier, we defined the cross-rate as the exchange rate for a non-U.S. currency expressed in terms of another non-U.S. currency. For example, suppose we observed the following for the Mexican peso (Ps) and the Swiss franc (SF):

$$\text{Ps per \$1} = 10.00$$

$$\text{SF per \$1} = 2.00$$

Suppose the cross-rate is quoted as:

$$\text{Ps per SF} = 4.00$$

What do you think?

The cross-rate here is inconsistent with the exchange rates. To see this, suppose you have \$100. If you convert this to Swiss francs, you will receive:

$$\text{\$100} \times \text{SF 2 per \$1} = \text{SF 200}$$

If you convert this to pesos at the cross-rate, you will have:

$$\text{SF 200} \times \text{Ps 4 per SF 1} = \text{Ps 800}$$

However, if you just convert your dollars to pesos without going through francs, you will have:

$$\text{\$100} \times \text{Ps 10 per \$1} = \text{Ps 1,000}$$

What we see is that the peso has two prices, Ps 10 per \$1 and Ps 8 per \$1, depending on how we get the pesos.

Current and historical foreign exchange data are available at many Web sites. A particularly good site is maintained by the Federal Reserve Bank of St. Louis. Go to www.stlouisfed.org and find their “FRED®” link for up-to-date exchange rate data.

To make money, we want to buy low, sell high. The important thing to note is that pesos are cheaper if you buy them with dollars because you get 10 pesos instead of just 8. You should proceed as follows:

1. Buy 1,000 pesos for \$100.
2. Use the 1,000 pesos to buy Swiss francs at the cross-rate. Since it takes four pesos to buy a franc, you will receive $\text{Ps } 1,000/4 = \text{SF } 250$.
3. Use the SF 250 to buy dollars. Since the exchange rate is SF 2 per dollar, you receive $\text{SF } 250/2 = \$125$, for a round-trip profit of \$25.
4. Repeat Steps 1 through 3.

This particular activity is called *triangle arbitrage* because the arbitrage involves moving through three different exchange rates:

To prevent such opportunities, it is not difficult to see that since a dollar will buy you either 10 pesos or two francs, the cross-rate must be:

$$(\text{Ps } 10/\$1)/(\text{SF } 2/\$1) = \text{Ps } 5/\text{SF } 1$$

That is, five pesos per franc. If it were anything else, there would be a triangle arbitrage opportunity.

Shedding Some Pounds

EXAMPLE 18.2

Suppose the exchange rates for the British pound and Swiss franc are:

$$\text{Pounds per } \$1 = .60$$

$$\text{SF per } \$1 = 2.00$$

The cross-rate is three francs per pound. Is this consistent? Explain how to go about making some money.

The cross-rate should be $\text{SF } 2.00/\text{£ } .60 = \text{SF } 3.33$ per pound. You can buy a pound for SF 3 in one market, and you can sell a pound for SF 3.33 in another. So, we want to first get some francs, then use the francs to buy some pounds, and then sell the pounds. Assuming you had \$100, you could:

1. Exchange dollars for francs: $\$100 \times 2 = \text{SF } 200$.
2. Exchange francs for pounds: $\text{SF } 200/3 = \text{£}66.67$.
3. Exchange pounds for dollars: $\text{£}66.67/.60 = \$111.12$.

This would result in an \$11.12 round-trip profit.

Types of Transactions

There are two basic types of trades in the foreign exchange market: spot trades and forward trades. A **spot trade** is an agreement to exchange currency “on the spot,” which actually means that the transaction will be completed, or settled, within two business days. The exchange rate on a spot trade is called the **spot exchange rate**. Implicitly, all of the exchange rates and transactions we have discussed so far have referred to the spot market.

For international news and events, visit www.ft.com.

spot trade

An agreement to trade currencies based on the exchange rate today for settlement within two business days.

spot exchange rate

The exchange rate on a spot trade.

forward trade

Agreement to exchange currency at some time in the future.

forward exchange rate

The agreed-upon exchange rate to be used in a forward trade.

A **forward trade** is an agreement to exchange currency at some time in the future. The exchange rate that will be used is agreed upon today and is called the **forward exchange rate**. A forward trade will normally be settled sometime in the next 12 months.

If you look back at Figure 18.1, you will see forward exchange rates quoted for some of the major currencies. For example, the spot exchange rate for the Swiss franc is SF 1 = \$.8752. The six-month forward exchange rate is SF 1 = \$.8788. This means that you can buy a Swiss franc today for \$.8752, or you can agree to take delivery of a Swiss franc in six months and pay \$.8788 at that time.

Notice that the Swiss franc is more expensive in the forward market (\$.8788 versus \$.8752). Since the Swiss franc is more expensive in the future than it is today, it is said to be selling at a *premium* relative to the dollar. For the same reason, the dollar is said to be selling at a *discount* relative to the Swiss franc.

Why does the forward market exist? One answer is that it allows businesses and individuals to lock in a future exchange rate today, thereby eliminating any risk from unfavorable shifts in the exchange rate.

EXAMPLE 18.3**Looking Forward**

Suppose you are expecting to receive a million British pounds in six months, and you agree to a forward trade to exchange your pounds for dollars. Based on Figure 18.1, how many dollars will you get in six months? Is the pound selling at a discount or a premium relative to the dollar?

In Figure 18.1, the spot exchange rate and the six-month forward rate in terms of dollars per pound are \$1.4729 = £1 and \$1.4741 = £1, respectively. If you expect £1 million in six months, then you will get £1 million \times \$1.4741 per £ = \$1.4741 million. Since it is more expensive to buy a pound in the forward market than in the spot market (\$1.4741 versus \$1.4729), the pound is selling at a premium relative to the dollar.

As we mentioned earlier, it is standard practice around the world (with a few exceptions, including the euro) to quote exchange rates in terms of the U.S. dollar. This means that rates are quoted as the amount of currency per U.S. dollar. For the remainder of this chapter, we will stick with this form. Things can get extremely confusing if you forget this. Thus, when we say things like “the exchange rate is expected to rise,” it is important to remember that we are talking about the exchange rate quoted as units of foreign currency per U.S. dollar.

CONCEPT QUESTIONS

18.2a What is triangle arbitrage?

18.2b What do we mean by the three-month forward exchange rate?

18.2c If we say that the exchange rate is SF 1.90, what do we mean?

18.3**PURCHASING POWER PARITY**

Now that we have discussed what exchange rate quotations mean, we can address an obvious question: What determines the level of the spot exchange rate? In addition, we know that exchange rates change through time. A related question is thus, What determines the rate of change in exchange rates? At least part of the answer in both cases goes by the name

of **purchasing power parity (PPP)**, and it is the idea that the exchange rate adjusts to keep purchasing power constant among currencies. As we discuss next, there are two forms of PPP: *absolute* and *relative*.

purchasing power parity (PPP)

The idea that the exchange rate adjusts to keep purchasing power constant among currencies.

Absolute Purchasing Power Parity

The basic idea behind *absolute purchasing power parity* is that a commodity costs the same regardless of what currency is used to purchase it or where it is selling. This is a very straightforward concept. If a beer costs £2 in London, and the exchange rate is £.60 per dollar, then a beer costs $£2/.60 = \$3.33$ in New York. In other words, absolute PPP says that \$1 will buy you the same number of, say, cheeseburgers anywhere in the world.

More formally, let S_0 be the spot exchange rate between the British pound and the U.S. dollar today (Time 0), and remember that we are quoting exchange rates as the amount of foreign currency per dollar. Let P_{US} and P_{UK} be the current U.S. and British prices, respectively, on a particular commodity, say, apples. Absolute PPP simply says that:

$$P_{UK} = S_0 \times P_{US}$$

This tells us that the British price for something is equal to the U.S. price for that same something, multiplied by the exchange rate.

The rationale behind PPP is similar to that behind triangle arbitrage. If PPP did not hold, arbitrage would be possible (in principle) if apples were moved from one country to another. For example, suppose apples in New York are selling for \$4 per bushel, while in London the price is £2.40 per bushel. Absolute PPP implies that:

$$\begin{aligned} P_{UK} &= S_0 \times P_{US} \\ £2.40 &= S_0 \times \$4 \\ S_0 &= £2.40/\$4 = £.60 \end{aligned}$$

That is, the implied spot exchange rate is £.60 per dollar. Equivalently, a pound is worth $\$1/£.60 = \1.67 .

Suppose, instead, that the actual exchange rate is £.50. Starting with \$4, a trader could buy a bushel of apples in New York, ship it to London, and sell it there for £2.40. Our trader could then convert the £2.40 into dollars at the prevailing exchange rate, $S_0 = £.50$, yielding a total of $£2.40/.50 = \$4.80$. The round-trip gain is 80 cents.

Because of this profit potential, forces are set in motion to change the exchange rate and/or the price of apples. In our example, apples would begin moving from New York to London. The reduced supply of apples in New York would raise the price of apples there, and the increased supply in Britain would lower the price of apples in London.

In addition to moving apples around, apple traders would be busily converting pounds back into dollars to buy more apples. This activity increases the supply of pounds and simultaneously increases the demand for dollars. We would expect the value of a pound to fall. This means that the dollar is getting more valuable, so it will take more pounds to buy one dollar. Since the exchange rate is quoted as pounds per dollar, we would expect the exchange rate to rise from £.50.

For absolute PPP to hold absolutely, several things must be true:

1. The transaction costs of trading apples—shipping, insurance, spoilage, and so on—must be zero.
2. There must be no barriers to trading apples, such as tariffs, taxes, or other political barriers such as VRAs (voluntary restraint agreements).
3. Finally, an apple in New York must be identical to an apple in London. It won't do for you to send red apples to London if the English eat only green apples.

Given the fact that the transaction costs are not zero and that the other conditions are rarely exactly met, it is not surprising that absolute PPP is really applicable only to traded goods, and then only to very uniform ones.

For this reason, absolute PPP does not imply that a Mercedes costs the same as a Ford or that a nuclear power plant in France costs the same as one in New York. In the case of the cars, they are not identical. In the case of the power plants, even if they were identical, they are expensive and very difficult to ship. On the other hand, we would be very surprised to see a significant violation of absolute PPP for gold. See our nearby *Reality Bytes* box for an interesting example of PPP violations.

Relative Purchasing Power Parity

As a practical matter, a relative version of purchasing power parity has evolved. *Relative purchasing power parity* does not tell us what determines the absolute level of the exchange rate. Instead, it tells what determines the *change* in the exchange rate over time.

The Basic Idea Suppose the British pound–U.S. dollar exchange rate is currently $S_0 = \text{£}50$. Further suppose that the inflation rate in Britain is predicted to be 10 percent over the coming year and (for the moment) the inflation rate in the United States is predicted to be zero. What do you think the exchange rate will be in a year?

If you think about it, a dollar currently costs .50 pound in Britain. With 10 percent inflation, we expect prices in Britain to generally rise by 10 percent. So we expect that the price of a dollar will go up by 10 percent, and the exchange rate should rise to $\text{£}50 \times 1.1 = \text{£}55$.

If the inflation rate in the United States is not zero, then we need to worry about the *relative* inflation rates in the two countries. For example, suppose the U.S. inflation rate is predicted to be 4 percent. Relative to prices in the United States, prices in Britain are rising at a rate of $10\% - 4\% = 6\%$ per year. So we expect the price of the dollar to rise by 6 percent, and the predicted exchange rate is $\text{£}50 \times 1.06 = \text{£}53$.

The Result In general, relative PPP says that the change in the exchange rate is determined by the difference in the inflation rates of the two countries. To be more specific, we will use the following notation:

- S_0 = Current (Time 0) spot exchange rate (foreign currency per dollar)
- $E(S_t)$ = Expected exchange rate in t periods
- h_{US} = Inflation rate in the United States
- h_{FC} = Foreign country inflation rate

Based on our discussion above, relative PPP says that the expected percentage change in the exchange rate over the next year, $[E(S_1) - S_0]/S_0$, is:

$$[E(S_1) - S_0]/S_0 = h_{FC} - h_{US} \quad [18.1]$$

In words, relative PPP simply says that the expected percentage change in the exchange rate is equal to the difference in inflation rates. If we rearrange this slightly, we get:

$$E(S_1) = S_0[1 + (h_{FC} - h_{US})] \quad [18.2]$$

McPricing

As we discussed in the chapter, absolute purchasing power parity (PPP) does not seem to hold in practice. One of the more famous violations of absolute PPP is the Big Mac Index constructed by *The Economist*. To construct the index, prices for a Big Mac in different countries are gathered from McDonald's. Below you will find the February 2009 Big Mac index from www.economist.com (we will leave it to you to find the most recent index).

The hamburger standard

* Purchasing-power parity: local price divided by price in the United States
† Average of New York, Chicago, Atlanta and San Francisco ‡ Dollars per pound § Weighted average of prices in euro area ** Dollars per euro

As you can see from the index, absolute PPP does not seem to hold, at least for the Big Mac. In fact, in only 6 of the 33 currencies surveyed by *The Economist* is the exchange rate within 10 percent of that predicted by absolute PPP. The largest disparity is in Iceland, where the currency is apparently overvalued by 63 percent. And 12 of the 33 currencies are “incorrectly” priced by more than 40 percent. Why?

There are several reasons. First, a Big Mac is not really transportable. Yes, you can load a ship with Big Macs and send it to Denmark where the currency is supposedly overvalued by 50 percent. But do you really think people would buy your Big Macs? Probably not. Even though it is relatively easy to transport a Big Mac, it would be relatively expensive, and the hamburger would suffer in quality along the way.

Also, if you look, the price of the Big Mac in the United States is the average price from New York, Chicago, San Francisco, and Atlanta. The reason is that the Big Mac does not sell for the same price in different parts of the United States, where presumably they are all purchased with the dollar. The cost of living and competition are only a few of the factors that will affect the price of a Big Mac in the United States. Since Big Macs are not priced the same in the same currency, would we expect absolute PPP to hold across currencies?

Finally, differing tastes can account for the apparent discrepancy. In the United States, hamburgers and fast food have become a staple of the American diet. In other countries, hamburgers have not become as entrenched. We would expect the price of the Big Mac to be lower in the United States since there is more fast food competition.

Having examined the Big Mac prices, we should say that absolute PPP should hold more closely for more easily transportable items. For instance, there are many companies with stock listed on both the NYSE and the stock exchange of another country. If you examine the share prices on the two exchanges, you will find that the price of the stock is almost exactly what absolute PPP would predict. The reason is that a share of stock in a particular company is (usually) the same wherever you buy it and whatever currency is used.

This result makes a certain amount of sense, but care must be used in quoting the exchange rate.

In our example involving Britain and the United States, relative PPP tells us that the exchange rate will rise by $h_{FC} - h_{US} = 10\% - 4\% = 6\%$ per year. Assuming that the

difference in inflation rates doesn't change, the expected exchange rate in two years, $E(S_2)$, will therefore be:

$$\begin{aligned} E(S_2) &= E(S_1) \times (1 + .06) \\ &= .53 \times 1.06 \\ &= .562 \end{aligned}$$

Notice that we could have written this as:

$$\begin{aligned} E(S_2) &= .53 \times 1.06 \\ &= (.50 \times 1.06) \times 1.06 \\ &= .50 \times 1.06^2 \end{aligned}$$

In general, relative PPP says that the expected exchange rate at some time in the future, $E(S_t)$, is:

$$E(S_t) = S_0 \times [1 + (h_{FC} - h_{US})]^t \quad [18.3]$$

Because we don't really expect absolute PPP to hold for most goods, we will focus on relative PPP in any future discussion. Henceforth, when we refer to PPP without further qualification, we mean relative PPP.

EXAMPLE 18.4

It's All Relative

Suppose the Japanese exchange rate is currently 105 yen per dollar. The inflation rate in Japan over the next three years will run, say, 2 percent per year, while the U.S. inflation rate will be 6 percent. Based on relative PPP, what will the exchange rate be in three years?

Since the U.S. inflation rate is higher, we expect that a dollar will become less valuable. The exchange rate change will be $2\% - 6\% = -4\%$ per year. Over three years, the exchange rate will fall to:

$$\begin{aligned} E(S_3) &= S_0 \times [1 + (h_{FC} - h_{US})]^3 \\ &= 105 \times [1 + (-.04)]^3 \\ &= 92.90 \text{ yen per dollar} \end{aligned}$$

Currency Appreciation and Depreciation We frequently hear things like “the dollar strengthened (or weakened) in financial markets today” or “the dollar is expected to appreciate (or depreciate) relative to the pound.” When we say that the dollar strengthens, or appreciates, we mean that the value of a dollar rises, so it takes more foreign currency to buy a dollar.

What happens to the exchange rates as currencies fluctuate in value depends on how exchange rates are quoted. Since we are quoting them as units of foreign currency per dollar, the exchange rate moves in the same direction as the value of the dollar: It rises as the dollar strengthens, and it falls as the dollar weakens.

Relative PPP tells us that the exchange rate will rise if the U.S. inflation rate is lower than the foreign country's. This happens because the foreign currency depreciates in value and therefore weakens relative to the dollar.

CONCEPT QUESTIONS

18.3a What does absolute PPP say? Why might it not hold for many types of goods?

18.3b According to relative PPP, what determines the change in exchange rates?

EXCHANGE RATES AND INTEREST RATES

18.4

The next issue we need to address is the relationship between spot exchange rates, forward exchange rates, and nominal interest rates. To get started, we need some additional notation:

F_t = Forward exchange rate for settlement at time t

R_{US} = U.S. nominal risk-free interest rate

R_{FC} = Foreign country nominal risk-free interest rate

As before, we will use S_0 to stand for the spot exchange rate. You can take the U.S. nominal risk-free rate, R_{US} , to be the T-bill rate.

Covered Interest Arbitrage

Suppose we observe the following information about U.S. and Swiss currency in the market:

$$S_0 = \text{SF } 2.00 \quad R_{US} = 10\%$$

$$F_1 = \text{SF } 1.90 \quad R_S = 5\%$$

where R_S is the nominal risk-free rate in Switzerland. The period is one year, so F_1 is the 360-day forward rate.

Do you see an arbitrage opportunity here? There is one. Suppose you have \$1 to invest, and you want a riskless investment. One option you have is to invest the \$1 in a riskless U.S. investment such as a 360-day T-bill. We will call this Strategy 1. If you do this, then, in one period, your \$1 will be worth:

$$\begin{aligned} \text{\$ value in 1 period} &= \$1(1 + R_{US}) \\ &= \$1.10 \end{aligned}$$

Alternatively, you can invest in the Swiss risk-free investment. To do this, you need to convert your \$1 to francs and simultaneously execute a forward trade to convert francs back to dollars in one year. We will call this Strategy 2. The necessary steps would be as follows:

1. Convert your \$1 to $\$1 \times S_0 = \text{SF } 2.00$.
2. At the same time, enter into a forward agreement to convert francs back to dollars in one year. Since the forward rate is SF 1.90, you get \$1 for every SF 1.90 that you have in one year.
3. Invest your SF 2.00 in Switzerland at R_S . In one year, you will have:

$$\begin{aligned} \text{SF value in 1 year} &= \text{SF } 2.00 \times (1 + R_S) \\ &= \text{SF } 2.00 \times 1.05 \\ &= \text{SF } 2.10 \end{aligned}$$

4. Convert your SF 2.10 back to dollars at the agreed-upon rate of $\text{SF } 1.90 = \$1$. You end up with:

$$\begin{aligned} \text{\$ value in 1 year} &= \text{SF } 2.10 / 1.90 \\ &= \$1.1053 \end{aligned}$$

Notice that the value in one year from this strategy can be written as:

$$\begin{aligned} \text{\$ value in 1 year} &= \$1 \times S_0 \times (1 + R_S) / F_1 \\ &= \$1 \times 2.00 \times 1.05 / 1.90 \\ &= \$1.1053 \end{aligned}$$

For exchange rates and even pictures of non-U.S. currencies, see www.travlang.com/money.

How are the international markets doing? Find out at marketwatch.com.

The return on this investment is apparently 10.53 percent. This is higher than the 10 percent we get from investing in the United States. Since both investments are risk-free, there is an arbitrage opportunity.

To exploit the difference in interest rates, you need to borrow, say, \$5 million at the lower U.S. rate and invest it at the higher Swiss rate. What is the round-trip profit from doing this? To find out, we can work through the steps above:

1. Convert the \$5 million at $SF\ 2.00 = \$1$ to get SF 10 million.
2. Agree to exchange francs for dollars in one year at $SF\ 1.90$ to the dollar.
3. Invest the SF 10 million for one year at $R_S = 5\%$. You end up with SF 10.5 million.
4. Convert the SF 10.5 million back to dollars to fulfill the forward contract. You receive $SF\ 10.5\ \text{million} / 1.90 = \$5,526,316$.
5. Repay the loan with interest. You owe \$5 million plus 10 percent interest, for a total of \$5.5 million. You have \$5,526,316, so your round-trip profit is a risk-free \$26,316.

The activity that we have illustrated here goes by the name of *covered interest arbitrage*. The term *covered* refers to the fact that we are covered in the event of a change in the exchange rate since we lock in the forward exchange rate today.

Interest Rate Parity

If we assume that significant covered interest arbitrage opportunities do not exist, then there must be some relationship between spot exchange rates, forward exchange rates, and relative interest rates. To see what this relationship is, note that, in general, Strategy 1 above, investing in a riskless U.S. investment, gives us $(1 + R_{US})$ for every dollar we invest. Strategy 2, investing in a foreign risk-free investment, gives us $S_0 \times (1 + R_{FC})/F_1$ for every dollar we invest. Since these have to be equal to prevent arbitrage, it must be the case that:

$$1 + R_{US} = S_0 \times (1 + R_{FC})/F_1$$

Rearranging this a bit gets us the famous **interest rate parity (IRP)** condition:

$$F_1/S_0 = (1 + R_{FC})/(1 + R_{US}) \quad [18.4]$$

There is a very useful approximation for IRP that illustrates very clearly what is going on and is not difficult to remember. If we define the percentage forward premium or discount as $(F_1 - S_0)/S_0$, then IRP says that this percentage premium or discount is *approximately* equal to the difference in interest rates:

$$(F_1 - S_0)/S_0 = R_{FC} - R_{US} \quad [18.5]$$

Very loosely, what IRP says is that any difference in interest rates between two countries for some period is just offset by the change in the relative value of the currencies, thereby eliminating any arbitrage possibilities. Notice that we could also write:

$$F_1 = S_0 \times [1 + (R_{FC} - R_{US})] \quad [18.6]$$

In general, if we have t periods instead of just one, the IRP approximation will be written as:

$$F_t = S_0 \times [1 + (R_{FC} - R_{US})]^t \quad [18.7]$$

Parity Check**EXAMPLE 18.5**

Suppose the exchange rate for Japanese yen, S_0 , is currently $¥120 = \$1$. If the interest rate in the United States is $R_{US} = 10\%$ and the interest rate in Japan is $R_J = 5\%$, then what must the one-year forward rate be to prevent covered interest arbitrage?

From IRP, we have:

$$\begin{aligned} F_1 &= S_0 \times [1 + (R_J - R_{US})] \\ &= ¥120 \times [1 + (.05 - .10)] \\ &= ¥120 \times .95 \\ &= ¥114 \end{aligned}$$

Notice that the yen will sell at a premium relative to the dollar (why?).

CONCEPT QUESTIONS

18.4a What is interest rate parity?

18.4b Do you expect that interest rate parity will hold more closely than purchasing power parity? Why?

EXCHANGE RATE RISK**18.5**

Exchange rate risk is the natural consequence of international operations in a world where relative currency values move up and down. As we discuss next, there are three different types of exchange rate risk, or exposure: short-run exposure, long-run exposure, and translation exposure.

exchange rate risk

The risk related to having international operations in a world where relative currency values vary.

Short-Run Exposure

The day-to-day fluctuations in exchange rates create short-run risks for international firms. Most such firms have contractual agreements to buy and sell goods in the near future at set prices. When different currencies are involved, such transactions have an extra element of risk.

For example, imagine that you are importing imitation pasta from Italy and reselling it in the United States under the Impasta brand name. Your largest customer has ordered 10,000 cases of Impasta. You place the order with your supplier today, but you won't pay until the goods arrive in 60 days. Your selling price is \$6 per case. Your cost is €4.48 per case, and the exchange rate is currently €0.80, so it takes €0.80 to buy \$1.

At the current exchange rate, your cost in dollars from filling the order is $€4.48/€0.80 = \$5.60$ per case, so your pretax profit on the order is $10,000 \times (\$6 - \$5.60) = \$4,000$. However, the exchange rate in 60 days will probably be different, so your profit will depend on what the exchange rate in the future turns out to be.

For example, if the rate goes to €0.85, your cost is $€4.48/€0.85 = \$5.27$ per case. Your profit goes to \$7,294. If the exchange rate goes to, say, €0.747, then your cost is $€4.48/€0.747 = \$6$ per case, and your profit is zero.

The short-run exposure in our example can be reduced or eliminated in several ways. The most obvious way is to enter into a forward exchange agreement to lock in an exchange rate. For example, suppose the 60-day forward rate is €0.82. What will your profit be if you hedge?

If you hedge, you lock in an exchange rate of €0.82. Your cost in dollars will thus be $\text{€}4.48/\text{€}0.82 = \5.46 per case, so your profit will be $10,000 \times (\$6 - 5.46) = \$5,400$.

Long-Run Exposure

In the long run, the value of a foreign operation can fluctuate because of unanticipated changes in relative economic conditions. For example, imagine that we own a labor-intensive assembly operation located in another country to take advantage of lower wages. Through time, unexpected changes in economic conditions can raise the foreign wage levels to the point where the cost advantage is eliminated or even becomes negative.

Hedging long-run exposure is more difficult than hedging short-term risks. For one thing, organized forward markets don't exist for such long-term needs. Instead, the primary option that firms have is to try to match up foreign currency inflows and outflows. The same thing goes for matching foreign currency-denominated assets and liabilities. For example, a firm that sells in a foreign country might try to concentrate its raw material purchases and labor expense in that country. That way, the dollar values of its revenues and costs will move up and down together.

Similarly, a firm can reduce its long-run exchange rate risk by borrowing in the foreign country. Fluctuations in the value of the foreign subsidiary's assets will then be at least partially offset by changes in the value of its liabilities.

One of the more common methods used to reduce long-term exchange rate exposure is to build a plant in the country that imports the products. This method is often used in the automotive industry. Honda, Toyota, and BMW, to name a few, have built plants in the United States. BMW's situation is particularly interesting. It produces about 160,000 cars per year in South Carolina and exports about 100,000 of them. The costs of manufacturing the cars are mostly paid in dollars, and when BMW exports the cars to Europe, it receives euros. So, when the dollar weakens, these vehicles become more profitable for BMW. At the same time, BMW imports about 217,000 more cars to the United States each year. The costs of manufacturing these imported cars are mostly in euros, so they become less profitable when the dollar weakens. Taken together, these gains and losses tend to offset each other and provide BMW with a natural hedge.

Translation Exposure

When a U.S. company calculates its accounting net income and EPS for some period, it must "translate" everything into dollars. This can create some problems for the accountants when there are significant foreign operations. In particular, two issues arise:

1. What is the appropriate exchange rate to use for translating each balance sheet account?
2. How should balance sheet accounting gains and losses from foreign currency translation be handled?

To illustrate the accounting problem, suppose that we started a small foreign subsidiary in Lilliputia a year ago. The local currency is the gulliver, abbreviated GL. At the beginning of the year, the exchange rate was $\text{GL } 2 = \$1$, and the balance sheet in gullivers looked like this:

Assets	GL 1,000	Liabilities	GL 500
		Equity	500

At two gullivers to the dollar, the beginning balance sheet in dollars was:

Assets	\$500	Liabilities	\$250
		Equity	250

Lilliputia is a quiet place, and nothing at all actually happened during the year. As a result, net income was zero (before consideration of exchange rate changes). However, the exchange rate did change to 4 gullivers = \$1, perhaps because the Lilliputian inflation rate is much higher than the U.S. inflation rate.

Since nothing happened, the accounting ending balance sheet in gullivers is the same as the beginning one. However, if we convert it to dollars at the new exchange rate, we get:

Assets	\$250	Liabilities	\$125
		Equity	125

Notice that the value of the equity has gone down by \$125, even though net income was exactly zero. Despite the fact that absolutely nothing really happened, there is a \$125 accounting loss. How to handle this \$125 loss has been a controversial accounting question.

One obvious and consistent way to handle this loss is simply to report the loss on the parent's income statement. During periods of volatile exchange rates, this kind of treatment can dramatically impact an international company's reported EPS. This is purely an accounting phenomenon, but, even so, such fluctuations are disliked by some financial managers.

The current approach to translation gains and losses is based on rules set out in Financial Accounting Standards Board (FASB) Statement Number 52, issued in December 1981. For the most part, FASB 52 requires that all assets and liabilities be translated from the subsidiary's currency into the parent's currency using the exchange rate that currently prevails.

Any translation gains and losses that occur are accumulated in a special account within the shareholders' equity section of the balance sheet. This account might be labeled something like "unrealized foreign exchange gains (losses)." These gains and losses are not reported on the income statement. As a result, the impact of translation gains and losses will not be recognized explicitly in net income until the underlying assets and liabilities are sold or otherwise liquidated.

Managing Exchange Rate Risk

For a large multinational firm, the management of exchange rate risk is complicated by the fact that there can be many different currencies involved for many different subsidiaries. It is very likely that a change in some exchange rate will benefit some subsidiaries and hurt others. The net effect on the overall firm depends on its net exposure.

For example, suppose a firm has two divisions. Division A buys goods in the United States for dollars and sells them in Britain for pounds. Division B buys goods in Britain for pounds and sells them in the United States for dollars. If these two divisions are of roughly equal size in terms of their inflows and outflows, then the overall firm obviously has little exchange rate risk.

In our example, the firm's net position in pounds (the amount coming in less the amount going out) is small, so the exchange rate risk is small. However, if one division, acting on

its own, were to start hedging its exchange rate risk, then the overall firm's exchange rate risk would go up. The moral of the story is that multinational firms have to be conscious of the overall position that the firm has in a foreign currency. For this reason, management of exchange rate risk is probably best handled on a centralized basis.

CONCEPT QUESTIONS

18.5a What are the different types of exchange rate risk?

18.5b How can a firm hedge short-run exchange rate risk? Long-run exchange rate risk?

18.6

political risk

Risk related to changes in value that arise because of political actions.

POLITICAL RISK

One final element of risk in international investing is **political risk**. Political risk is related to changes in value that arise as a consequence of political actions. This is not a problem faced only by international firms. For example, changes in U.S. tax laws and regulations may benefit some U.S. firms and hurt others, so political risk exists nationally as well as internationally.

Some countries do have more political risk than others, however. When firms have operations in these riskier countries, the extra political risk may lead them to require higher returns on overseas investments to compensate for the risk that funds will be blocked, critical operations interrupted, or contracts abrogated. In the most extreme case, the possibility of outright confiscation may be a concern in countries with relatively unstable political environments.

Political risk also depends on the nature of the business; some businesses are less likely to be confiscated because they are not particularly valuable in the hands of a different owner. An assembly operation supplying subcomponents that only the parent company uses would not be an attractive "takeover" target, for example. Similarly, a manufacturing operation that requires the use of specialized components from the parent is of little value without the parent company's cooperation.

Natural resource developments, such as copper mining or oil drilling, are just the opposite. Once the operation is in place, much of the value is in the commodity. The political risk for such investments is much higher for this reason. Also, the issue of exploitation is more pronounced with such investments, again increasing the political risk.

Political risk can be hedged in several ways, particularly when confiscation or nationalization is a concern. The use of local financing, perhaps from the government of the foreign country in question, reduces the possible loss because the company can refuse to pay on the debt in the event of unfavorable political activities. Based on our discussion above, structuring the operation in such a way that it requires significant parent company involvement to function is another way to reduce political risk.

CONCEPT QUESTIONS

18.6a What is political risk?

18.6b What are some ways of hedging political risk?

SUMMARY AND CONCLUSIONS

The international firm has a more complicated life than the purely domestic firm. Management must understand the connection between interest rates, foreign currency exchange rates, and inflation, and it must become aware of a large number of different financial market regulations and tax systems. This chapter was intended to be a concise introduction to some of the financial issues that come up in international investing.

Our coverage was necessarily brief. The main topics we discussed included:

1. Some basic vocabulary. We briefly defined some exotic terms such as *LIBOR* and *Eurocurrency*.
2. The basic mechanics of exchange rate quotations. We discussed the spot and forward markets and how exchange rates are interpreted.
3. The fundamental relationships between international financial variables:
 - a. Absolute and relative purchasing power parity, or PPP.
 - b. Interest rate parity, or IRP.

Absolute purchasing power parity states that \$1 should have the same purchasing power in each country. This means that an orange costs the same whether you buy it in New York or in Tokyo.

Relative purchasing power parity means that the expected percentage change in exchange rates between the currencies of two countries is equal to the difference in their inflation rates.

Interest rate parity implies that the percentage difference between the forward exchange rate and the spot exchange rate is equal to the interest rate differential. We showed how covered interest arbitrage forces this relationship to hold.

4. Exchange rate and political risk. We described the various types of exchange rate risk and discussed some commonly used approaches to managing the effect of fluctuating exchange rates on the cash flows and value of the international firm. We also discussed political risk and some ways of managing exposure to it.

CHAPTER REVIEW AND SELF-TEST PROBLEMS

- 18.1 Relative Purchasing Power Parity.** The inflation rate in the United States is projected at 6 percent per year for the next several years. The Australian inflation rate is projected to be 2 percent during that time. The exchange rate is currently A\$2.2. Based on relative PPP, what is the expected exchange rate in two years?
- 18.2 Covered Interest Arbitrage.** The spot and 360-day forward rates on the Swiss franc are SF 1.8 and SF 1.7, respectively. The risk-free interest rate in the United States is 8 percent, and the risk-free rate in Switzerland is 5 percent. Is there an arbitrage opportunity here? How would you exploit it?

■ Answers to Chapter Review and Self-Test Problems

- 18.1** From relative PPP, the expected exchange rate in two years, $E(S_2)$, is:

$$E(S_2) = S_0 \times [1 + (h_A - h_{US})]^2$$

where h_A is the Australian inflation rate. The current exchange rate is A\$2.2, so the expected exchange rate is:

$$\begin{aligned} E(S_2) &= \text{A\$}2.2 \times [1 + (.02 - .06)]^2 \\ &= \text{A\$}2.2 \times .96^2 \\ &= \text{A\$}2.03 \end{aligned}$$

18.2 From interest rate parity, the forward rate should be (approximately):

$$\begin{aligned} F_1 &= S_0 \times [1 + (R_S - R_{US})] \\ &= 1.8 \times [1 + .05 - .08] \\ &= 1.75 \end{aligned}$$

Since the forward rate is actually SF 1.7, there is an arbitrage opportunity.

To exploit the arbitrage opportunity, we first note that dollars are selling for SF 1.7 each in the forward market. From IRP, this is too cheap because they should be selling for SF 1.75. So, we want to arrange to buy dollars with Swiss francs in the forward market. To do this, we can:

1. Today: Borrow, say, \$10 million for 360 days. Convert it to SF 18 million in the spot market, and buy a forward contract at SF 1.7 to convert it back to dollars in 360 days. Invest the SF 18 million at 5 percent.
2. In one year: Your investment has grown to $\text{SF } 18 \times 1.05 = \text{SF } 18.9 \text{ million}$. Convert this to dollars at the rate of $\text{SF } 1.7 = \$1$. You will have SF 18.9 million / 1.7 = **\$11,117,647**. Pay off your loan with 8 percent interest at a cost of $\$10 \text{ million} \times 1.08 = \text{\$10,800,000}$ and pocket the difference of **\$317,647**.

CRITICAL THINKING AND CONCEPTS REVIEW

L0 1

- 18.1 Spot and Forward Rates.** Suppose the exchange rate for the Swiss franc is quoted as SF 1.50 in the spot market and SF 1.53 in the 90-day forward market.
- a. Is the dollar selling at a premium or a discount relative to the franc?
 - b. Does the financial market expect the franc to strengthen relative to the dollar? Explain.
 - c. What do you suspect is true about relative economic conditions in the United States and Switzerland?

L0 2

- 18.2 Purchasing Power Parity.** Suppose the rate of inflation in Russia will run about 3 percent higher than the U.S. inflation rate over the next several years. All other things being the same, what will happen to the ruble versus dollar exchange rate? What relationship are you relying on in answering?

L0 2

- 18.3 Exchange Rates.** The exchange rate for the Australian dollar is currently A\$1.40. This exchange rate is expected to rise by 10 percent over the next year.
- a. Is the Australian dollar expected to get stronger or weaker?
 - b. What do you think about the relative inflation rates in the United States and Australia?
 - c. What do you think about the relative nominal interest rates in the United States and Australia? Relative real rates?

L0 3

- 18.4 Yankee Bonds.** Which of the following most accurately describes a Yankee bond?
- a. A bond issued by General Motors in Japan with the interest payable in U.S. dollars.

- b. A bond issued by General Motors in Japan with the interest payable in yen.
- c. A bond issued by Toyota in the United States with the interest payable in yen.
- d. A bond issued by Toyota in the United States with the interest payable in dollars.
- e. A bond issued by Toyota worldwide with the interest payable in dollars.

L0 1 18.5 **Exchange Rates.** Are exchange rate changes necessarily good or bad for a particular company?

L0 4 18.6 **International Risks.** In January 2005, South Korea's Hynix Semiconductor, Inc., the world's second largest producer of dynamic random access memory, or DRAM, chips announced an alliance with Taiwan's ProMOS Technologies, Inc., to produce computer chips. For ProMOS, the alliance was needed to provide the company with a steady supply of chips. For Hynix, the motive for the alliance was tariffs placed on computer chips manufactured in South Korea. In 2004, both the United States and the European Union had enacted steep tariffs on computer chips from that country. What advantages might Hynix see from the alliance? What are some of the risks to Hynix?

L0 3 18.7 **Multinational Corporations.** Given that many multinationals based in many countries have much greater sales outside their domestic markets than within them, what is the particular relevance of their domestic currency?

L0 2 18.8 **Exchange Rate Movements.** Are the following statements true or false? Explain why.

- a. If the general price index in Great Britain rises faster than that in the United States, we would expect the pound to appreciate relative to the dollar.
- b. Suppose you are a German machine tool exporter and you invoice all of your sales in foreign currency. Further suppose that the European monetary authorities begin to undertake an expansionary monetary policy. If it is certain that the easy money policy will result in higher inflation rates in "Euroland" relative to those in other countries, then you should use the forward markets to protect yourself against future losses resulting from the deterioration in the value of the euro.
- c. If you could accurately estimate differences in the relative inflation rates of two countries over a long period of time while other market participants were unable to do so, you could successfully speculate in spot currency markets.

L0 2 18.9 **Exchange Rate Movements.** Some countries encourage movements in their exchange rate relative to those of some other country as a short-term means of addressing foreign trade imbalances. For each of the following scenarios, evaluate the impact the announcement would have on an American importer and an American exporter doing business with the foreign country.

- a. Officials in the administration of the United States government announce that they are comfortable with a rising Mexican peso relative to the dollar.
- b. British monetary authorities announce that they feel the pound has been driven too low by currency speculators relative to the dollar.
- c. The Brazilian government announces that it will print billions of new reais and inject them into the economy in an effort to reduce the country's 40 percent unemployment rate.

L0 3

18.10 International Investment. If financial markets are perfectly competitive and the Eurodollar rate is above that offered in the U.S. loan market, you would immediately want to borrow money in the United States and invest it in Eurodollars. True or false? Explain.

QUESTIONS AND PROBLEMS

Select problems are available in McGraw-Hill Connect. Please see the packaging options section of the preface for more information.

L0 1

Basic

(Questions 1–10)

1. **Using Exchange Rates.** Take a look back at Figure 18.1 to answer the following questions:
 - a. If you have \$100, how many Polish zlotys can you get?
 - b. How much is one euro worth?
 - c. If you have five million euros, how many dollars do you have?
 - d. Which is worth more, a New Zealand dollar or a Singapore dollar?
 - e. Which is worth more, a Mexican peso or a Chilean peso?
 - f. How many Swiss francs can you get for a euro? What do you call this rate?
 - g. Per unit, what is the most valuable currency of those listed? The least valuable?

L0 1

2. **Using the Cross-Rate.** Use the information in Figure 18.1 to answer the following questions:
 - a. Which would you rather have, \$100 or £100? Why?
 - b. Which would you rather have, \$100 Canadian or £100? Why?
 - c. What is the cross-rate for Canadian dollars in terms of British pounds? For British pounds in terms of Canadian dollars?

L0 1

3. **Forward Exchange Rates.** Use the information in Figure 18.1 to answer the following questions:
 - a. What is the six-month forward rate for the Japanese yen in yen per U.S. dollar? Is the yen selling at a premium or a discount? Explain.
 - b. What is the three-month forward rate for the Canadian dollar in U.S. dollars per Canadian dollar? Is the dollar selling at a premium or a discount? Explain.
 - c. What do you think will happen to the value of the dollar relative to the yen and the Canadian dollar, based on the information in the figure? Explain.

L0 1

4. **Using Spot and Forward Exchange Rates.** Suppose the spot exchange rate for the Canadian dollar is Can\$1.23 and the six-month forward rate is Can\$1.27.
 - a. Which is worth more, a U.S. dollar or a Canadian dollar?
 - b. Assuming absolute PPP holds, what is the cost in the United States of an Elkhead beer if the price in Canada is Can\$3.10? Why might the beer actually sell at a different price in the United States?
 - c. Is the U.S. dollar selling at a premium or a discount relative to the Canadian dollar?
 - d. Which currency is expected to appreciate in value?
 - e. Which country do you think has higher interest rates—the United States or Canada? Explain.

L0 1

5. **Cross-Rates and Arbitrage.** Suppose the Japanese yen exchange rate is ¥106 = \$1, and the British pound exchange rate is £1 = \$1.51.
 - a. What is the cross-rate in terms of yen per pound?
 - b. Suppose the cross-rate is ¥165 = £1. Is there an arbitrage opportunity here? If there is, explain how to take advantage of the mispricing.

- L0 2** 6. **Interest Rate Parity.** Use Figure 18.1 to answer the following questions. Suppose interest rate parity holds, and the current risk-free rate in the United States is 4 percent per six months. What must the six-month risk-free rate be in Canada? In Japan? In Great Britain?
- L0 2** 7. **Interest Rates and Arbitrage.** The treasurer of a major U.S. firm has \$30 million to invest for three months. The interest rate in the United States is .47 percent per month. The interest rate in Great Britain is .51 percent per month. The spot exchange rate is £.68, and the three-month forward rate is £.69. Ignoring transaction costs, in which country would the treasurer want to invest the company's funds? Why?
- L0 2** 8. **Inflation and Exchange Rates.** Suppose the current exchange rate for the Russian ruble is RUB 34.50. The expected exchange rate in three years is RUB 37.78. What is the difference in the annual inflation rates for the United States and Russia over this period? Assume that the anticipated rate is constant for both countries. What relationship are you relying on in answering?
- L0 3** 9. **Exchange Rate Risk.** Suppose your company imports computer motherboards from Singapore. The exchange rate is given in Figure 18.1. You have just placed an order for 30,000 motherboards at a cost to you of 230.75 Singapore dollars each. You will pay for the shipment when it arrives in 90 days. You can sell the motherboards for \$160 each. Calculate your profit if the exchange rate goes up or down by 10 percent over the next 90 days. What is the break-even exchange rate? What percentage rise or fall does this represent in terms of the Singapore dollar versus the U.S. dollar?
- L0 2** 10. **Exchange Rates and Arbitrage.** Suppose the spot and six-month forward rates on the South Korean won are SKW 1,304.81 and SKW 1,315.16, respectively. The annual risk-free rate in the United States is 5 percent, and the annual risk-free rate in South Korea is 7 percent.
- Is there an arbitrage opportunity here? If so, how would you exploit it?
 - What must the six-month forward rate be to prevent arbitrage?
- L0 2** 11. **Spot versus Forward Rates.** Suppose the spot and three-month forward rates for the yen are ¥102.16 and ¥101.23, respectively.
- Is the yen expected to get stronger or weaker?
 - What would you estimate is the difference between the inflation rates of the United States and Japan?
- L0 2** 12. **Expected Spot Rates.** Suppose the spot exchange rate for the Hungarian forint is HUF 221. Interest rates in the United States are 3.2 percent per year. They are 5.1 percent in Hungary. (a) What do you predict the exchange rate will be in one year? (b) In two years? (c) In five years? What relationship are you using?
- L0 2** 13. **Cross-Rates and Arbitrage.** The £ trades at \$1.4934 in London and \$1.4872 in New York. How much profit could you earn on each trade with \$10,000?
- L0 2** 14. **Purchasing Power Parity and Exchange Rates.** According to purchasing power parity, if a Big Mac sells for \$3.29 in the United States and kronur 127.49 in Iceland, what is the kronur/\$ exchange rate?
- L0 3** 15. **Translation Exposure.** Betancourt International has operations in Arrakis. The balance sheet for this division in Arrakeen solaris shows assets of 20,000 solaris, debt in the amount of 6,000 solaris, and equity of 14,000 solaris.
- If the current exchange ratio is 1.30 solaris per dollar, what does the balance sheet look like in dollars?

Intermediate
(Questions 11–15)

Challenge
(Question 16)

LO 3

- b. Assume that one year from now the balance sheet in solaris is exactly the same as at the beginning of the year. If the exchange rate is 1.45 solaris per dollar, what does the balance sheet look like in dollars now?
- c. Rework part (b) assuming the exchange rate is 1.15 solaris per dollar.
- 16. Translation Exposure.** In the previous problem, assume the equity increases by 1,100 solaris due to retained earnings. If the exchange rate at the end of the year is 1.24 solaris per dollar, what does the balance sheet look like?

**WHAT'S ON
THE WEB?**

- 18.1 Purchasing Power Parity.** One of the more famous examples of a violation of absolute purchasing power parity is the Big Mac index calculated by *The Economist*. This index calculates the dollar price of a McDonald's Big Mac in different countries. You can find the Big Mac index by going to www.economist.com. Using the most recent index, which country has the most expensive Big Macs? Which country has the cheapest Big Macs? Why is the price of a Big Mac not the same in every country?
- 18.2 Inflation and Exchange Rates.** Go to www.marketvector.com and find exchange rates for the Australian dollar. Is the U.S. dollar expected to appreciate or depreciate compared to the Australian dollar over the next six months? What is the difference in the annual inflation rates for the United States and Australia over this period? Assume that the anticipated rate is constant for both countries. What relationship are you relying on in answering?
- 18.3 Interest Rate Parity.** Go to the *Financial Times* site at www.ft.com, and find the current exchange rate between the U.S. dollar and the euro. Next, find the U.S. dollar LIBOR and the Euro LIBOR interest rates. What must the one-year forward rate be to prevent arbitrage? What principle are you relying on in your answer?

CHAPTER CASE

S&S AIR GOES INTERNATIONAL

Mark Sexton and Todd Story, the owners of S&S Air, have been in discussions with an aircraft dealer in Europe about selling the company's Eagle airplane. The Eagle sells for \$78,000 and has a variable cost of \$60,000 per airplane. Amalie Diefenbaker, the dealer, wants to add the Eagle to her current retail line. Amalie has told Mark and Todd that she feels she will be able to sell 15 airplanes per month in Europe. All sales will be made in euros, and Amalie will pay the company €60,000 for each plane. Amalie proposes that she order 15 aircraft today for the first month's sales. She will pay for all 15 aircraft in 90 days. This order and payment schedule will continue each month.

Mark and Todd are confident they can handle the extra volume with their existing facilities, but they are unsure about the potential financial risks of selling their aircraft in Europe. In their discussion with Amalie, they found out that the current exchange rate is \$1.30/€. This means that they can convert the €60,000 per airplane paid by Amalie to \$78,000. Thus, the profit on the international sales is the same as the profit on dollar-denominated sales.

Mark and Todd decided to ask Chris Guthrie, their financial analyst, to prepare an analysis of the proposed international sales. Specifically, they ask Chris to answer the following questions. ■

QUESTIONS

1. What are the pros and cons of the international sales? What additional risks will the company face?
2. What happens to the company's profits if the dollar strengthens? What if the dollar weakens?
3. Ignoring taxes, what are S&S Air's projected gains or losses from this proposed arrangement at the current exchange rate of \$1.30/€? What happens to profits if the exchange rate changes to \$1.37/€? At what exchange rate will the company break even?
4. How could the company hedge its exchange rate risk? What are the implications of this approach?
5. Taking all factors into account, should the company pursue the international sales deal further? Why or why not?

Mathematical Tables

APPENDIX A.1

Future value of \$1 at the end of t periods = $(1 + r)^t$

Number of Periods	Interest Rate								
	1%	2%	3%	4%	5%	6%	7%	8%	9%
1	1.0100	1.0200	1.0300	1.0400	1.0500	1.0600	1.0700	1.0800	1.0900
2	1.0201	1.0404	1.0609	1.0816	1.1025	1.1236	1.1449	1.1664	1.1881

B

Key Equations

CHAPTER 2

1. The balance sheet identity, or equation:
Assets = Liabilities + Shareholders' equity [2.1]
 2. The income statement equation:
Revenues - Expenses = Income [2.2]
 3. The cash flow identity:
Cash flow from assets = Cash flow to creditors
+ Cash flow to stockholders [2.3]
- where
- a. Cash flow from assets = Operating cash flow (OCF) -
Net capital spending - Change in net working capital (NWC)
 - (1) Operating cash flow = Earnings before interest and taxes
(EBIT) + Depreciation - Taxes
 - (2) Net capital spending = Ending net fixed assets -
Beginning net fixed assets + Depreciation
 - (3) Change in net working capital = Ending NWC -
Beginning NWC
 - b. Cash flow to creditors = Interest paid - Net new borrowing
 - c. Cash flow to stockholders = Dividend paid - Net new
equity raised

CHAPTER 3

1. The current ratio:
Current ratio = $\frac{\text{Current assets}}{\text{Current liabilities}}$ [3.1]
2. The quick, or acid-test, ratio:
Quick ratio = $\frac{\text{Current assets} - \text{Inventory}}{\text{Current liabilities}}$ [3.2]
3. The cash ratio:
Cash ratio = $\frac{\text{Cash}}{\text{Current liabilities}}$ [3.3]
4. The total debt ratio:
Total debt ratio = $\frac{\text{Total assets} - \text{Total equity}}{\text{Total assets}}$ [3.4]
5. The debt-equity ratio:
Debt-equity ratio = Total debt/Total equity [3.5]
6. The equity multiplier:
Equity multiplier = Total assets/Total equity [3.6]
7. The times interest earned (TIE) ratio:
Times interest earned ratio = $\frac{\text{EBIT}}{\text{Interest expense}}$ [3.7]

8. The cash coverage ratio:
Cash coverage ratio = $\frac{\text{EBIT} + \text{Depreciation}}{\text{Interest expense}}$ [3.8]
9. The inventory turnover ratio:
Inventory turnover = $\frac{\text{Cost of goods sold}}{\text{Inventory}}$ [3.9]
10. The average days' sales in inventory:
Days' sales in inventory = $\frac{365 \text{ days}}{\text{Inventory turnover}}$ [3.10]
11. The receivables turnover ratio:
Receivables turnover = $\frac{\text{Sales}}{\text{Accounts receivable}}$ [3.11]
12. The days' sales in receivables:
Days' sales in receivables = $\frac{365 \text{ days}}{\text{Receivables turnover}}$ [3.12]
13. The total asset turnover ratio:
Total asset turnover = $\frac{\text{Sales}}{\text{Total assets}}$ [3.13]
14. Profit margin:
Profit margin = $\frac{\text{Net income}}{\text{Sales}}$ [3.14]
15. Return on assets (ROA):
Return on assets = $\frac{\text{Net income}}{\text{Total assets}}$ [3.15]
16. Return on equity (ROE):
Return on equity = $\frac{\text{Net income}}{\text{Total equity}}$ [3.16]
17. Earnings per share (EPS):
EPS = $\frac{\text{Net income}}{\text{Shares outstanding}}$ [3.17]
18. The price-earnings (PE) ratio:
PE ratio = $\frac{\text{Price per share}}{\text{Earnings per share}}$ [3.18]
19. The market-to-book ratio:
Market-to-book ratio = $\frac{\text{Market value per share}}{\text{Book value per share}}$ [3.19]
20. The Du Pont identity:
ROE = $\frac{\text{Net income}}{\text{Sales}} \times \frac{\text{Sales}}{\text{Assets}} \times \frac{\text{Assets}}{\text{Total equity}}$ [3.20]
Return on assets (ROA)

$$\begin{aligned} \text{ROE} &= \text{Profit margin} \\ &\times \text{Total asset turnover} \\ &\times \text{Equity multiplier} \end{aligned}$$

21. The dividend payout ratio:

$$\text{Dividend payout ratio} = \frac{\text{Cash dividend}}{\text{Net income}} \quad [3.21]$$

22. The retention ratio:

$$\text{Retention ratio} = \frac{\text{Addition to retained earnings}}{\text{Net income}} \quad [3.22]$$

23. The internal growth rate:

$$\text{Internal growth rate} = \frac{\text{ROA} \times b}{1 - \text{ROA} \times b} \quad [3.23]$$

24. The sustainable growth rate:

$$\text{Sustainable growth rate} = \frac{\text{ROE} \times b}{1 - \text{ROE} \times b} \quad [3.24]$$

CHAPTER 4

1. The future value of \$1 invested for t periods at a rate of r per period:

$$\text{Future value} = \$1 \times (1 + r)^t \quad [4.1]$$

2. The present value of \$1 to be received t periods in the future at a discount rate of r :

$$\text{PV} = \$1 \times [1/(1 + r)^t] = \$1/(1 + r)^t \quad [4.2]$$

3. The relationship between future value and present value (the basic present value equation):

$$\begin{aligned} \text{PV} \times (1 + r)^t &= \text{FV}_t \\ \text{PV} &= \text{FV}_t / (1 + r)^t = \text{FV}_t \times [1/(1 + r)^t] \end{aligned} \quad [4.3]$$

CHAPTER 5

1. The present value of an annuity of C dollars per period for t periods when the rate of return, or interest rate, is r :

$$\begin{aligned} \text{Annuity present value} &= C \times \left(\frac{1 - \text{Present value factor}}{r} \right) \\ &= C \times \left\{ \frac{1 - [1/(1 + r)^t]}{r} \right\} \end{aligned} \quad [5.1]$$

2. The future value factor for an annuity:

$$\begin{aligned} \text{Annuity FV factor} &= (\text{Future value factor} - 1)/r \\ &= [(1 + r)^t - 1]/r \end{aligned} \quad [5.2]$$

3. Annuity due value

$$= \text{Ordinary annuity value} \times (1 + r) \quad [5.3]$$

4. Present value for a perpetuity:

$$\text{PV for a perpetuity} = C/r = C \times (1/r) \quad [5.4]$$

5. Effective annual rate (EAR), where m is the number of times the interest is compounded during the year:

$$\text{EAR} = (1 + \text{Quoted rate}/m)^m - 1 \quad [5.5]$$

CHAPTER 6

1. Bond value if bond has (1) a face value of F paid at maturity, (2) a coupon of C paid per period, (3) t periods to maturity, and (4) a yield of r per period:

$$\begin{aligned} \text{Bond value} &= C \times [1 - 1/(1 + r)^t]/r + F/(1 + r)^t \\ \text{Bond value} &= \frac{\text{Present value of the coupons}}{+} \frac{\text{Present value of the face amount}}{+} \end{aligned} \quad [6.1]$$

2. The Fisher effect:

$$1 + R = (1 + r) \times (1 + h) \quad [6.2]$$

where h is the inflation rate

$$3. R = r + h + r \times h \quad [6.3]$$

$$4. R \approx r + h \quad [6.4]$$

CHAPTER 7

$$1. P_0 = (D_1 + P_1)/(1 + R) \quad [7.1]$$

$$2. P_0 = D/R \quad [7.2]$$

$$3. P_0 = \frac{D_0 \times (1 + g)}{R - g} = \frac{D_1}{R - g} \quad [7.3]$$

$$4. P_t = \frac{D_t \times (1 + g)}{R - g} = \frac{D_{t+1}}{R - g} \quad [7.4]$$

$$5. R = D_1/P_0 + g \quad [7.5]$$

CHAPTER 8

1. Net present value (NPV):

$$\text{NPV} = \text{Present value of future cash flows} - \text{Investment cost}$$

2. Payback period:

$$\text{Payback period} = \text{Number of years that pass before the sum of an investment's cash flows equals the cost of the investment}$$

3. The average accounting return (AAR):

$$\text{AAR} = \frac{\text{Average net income}}{\text{Average book value}}$$

4. Internal rate of return (IRR):

$$\text{IRR} = \text{Discount rate of required return such that the net present value of an investment is zero}$$

5. Profitability index:

$$\text{Profitability index} = \frac{\text{PV of cash flows}}{\text{Cost of investment}}$$

CHAPTER 9

1. Project cash flow = Project operating cash flow

$$\begin{aligned} &- \text{Project change in net working capital} \\ &- \text{Project capital spending} \end{aligned}$$

2. Operating cash flow = EBIT + Depreciation - Taxes

CHAPTER 10

$$1. \text{Total dollar return} = \text{Dividend income} + \text{Capital gain (or loss)} \quad [10.1]$$

$$2. \text{Total cash if stock is sold} = \text{Initial investment} + \text{Total return} \quad [10.2]$$

3. Variance of returns, $\text{Var}(R)$, or σ^2 :

$$\text{Var}(R) = \frac{1}{T-1} [(R_1 - \bar{R})^2 + \dots + (R_T - \bar{R})^2] \quad [10.3]$$

CHAPTER 11

$$\begin{aligned} 1. \text{Risk premium} &= \text{Expected return} - \text{Risk-free rate} \\ &= E(R) - R_f \end{aligned} \quad [11.1]$$

2. Expected return on a portfolio:

$$E(R_p) = x_1 \times E(R_1) + x_2 \times E(R_2) + \cdots + x_n \times E(R_n) \quad [11.2]$$

3. Total return = Expected return + Unexpected return

$$R = E(R) + U \quad [11.3]$$

4. Announcement = Expected part + Surprise

$$[11.4]$$

5. $R = E(R) + \text{Systematic portion}$

$$+ \text{Unsystematic portion}$$

$$[11.5]$$

6. Total risk = Systematic risk + Unsystematic risk

$$[11.6]$$

7. The capital asset pricing model (CAPM):

$$E(R_i) = R_f + [E(R_M) - R_f] \beta_i \quad [11.7]$$

CHAPTER 12

1. $R_E = D_1/P_0 + g$

$$[12.1]$$

2. $R_E = R_f + \beta_E \times (R_M - R_f)$

$$[12.2]$$

3. $R_p = D/P_0$

$$[12.3]$$

4. $V = E + D$

$$[12.4]$$

5. $100\% = E/V + D/V$

$$[12.5]$$

6. Weighted average cost of capital (WACC)

$$= (E/V) \times R_E + (D/V) \times R_D \times (1 - T_c) \quad [12.6]$$

CHAPTER 13

1. Modigliani-Miller Proposition II, no taxes:

$$R_E = R_A + (R_A - R_D) \times (D/E) \quad [13.1]$$

2. Modigliani-Miller propositions, with taxes:

- a. Present value of the interest tax shield:

$$= (T_c \times D \times R_D)/R_D$$

$$= T_c \times D$$

- b. Proposition I:

$$V_L = V_U + T_c \times D \quad [13.3]$$

CHAPTER 16

1. Net working capital + Fixed assets

$$= \text{Long-term debt} + \text{Equity} \quad [16.1]$$

2. Net working capital = (Cash + Other current assets)

$$- \text{Current liabilities} \quad [16.2]$$

3. Cash = Long-term debt + Equity + Current liabilities

$$- \text{Current assets other than cash}$$

$$- \text{Fixed assets} \quad [16.3]$$

4. The operating cycle:

$$\text{Operating cycle} = \text{Inventory period}$$

$$+ \text{Accounts receivable period} \quad [16.4]$$

5. The cash cycle:

$$\text{Cash cycle} = \text{Operating cycle}$$

$$- \text{Accounts payable period} \quad [16.5]$$

CHAPTER 17

The economic order quantity (EOQ) model:

1. Total carrying costs = Average inventory

$$\times \text{Carrying costs per unit} \quad [17.1]$$

$$= (Q/2) \times CC$$

2. Total restocking cost = Fixed cost per order

$$\times \text{Number of orders} \quad [17.2]$$

$$= F \times (T/Q)$$

3. Total costs = Carrying costs + Restocking costs

$$= (Q/2) \times CC + F \times (T/Q) \quad [17.3]$$

4. Carrying costs = Restocking costs

$$(Q^*/2) \times CC = F \times (T/Q^*) \quad [17.4]$$

5. $(Q^*)^2 = \frac{2T \times F}{CC}$

$$[17.5]$$

6. The optimal order size Q^* :

$$Q^* = \sqrt{\frac{2T \times F}{CC}} \quad [17.6]$$

CHAPTER 18

1. $[E(S_1) - S_0]/S_0 = h_{FC} - h_{US}$ [18.1]

2. $E(S_1) = S_0 \times [1 + (h_{FC} - h_{US})]$ [18.2]

3. Relative purchasing power parity (PPP):

$$E(S_t) = S_0 \times [1 + (h_{FC} - h_{US})]^t \quad [18.3]$$

4. Interest rate parity (IRP), exact, single period:

$$F_1/S_0 = (1 + R_{FC})/(1 + R_{US}) \quad [18.4]$$

5. $(F_1 - S_0)/S_0 = R_{FC} - R_{US}$ [18.5]

6. $F_1 = S_0 \times [1 + (R_{FC} - R_{US})]$ [18.6]

7. IRP, approximate, multiperiod:

$$F_t = S_0 \times [1 + (R_{FC} - R_{US})]^t \quad [18.7]$$

C

D

Using the HP-10B and TI BA II Plus Financial Calculators

This appendix is intended to help you use your Hewlett-Packard HP-10B or Texas Instruments BA II Plus financial calculator to solve problems encountered in the introductory finance course. It describes the various calculator settings and provides keystroke solutions for nine selected problems from this book. Please see your owner's manual for more complete instructions. For more examples and problem-solving techniques, please see *Financial Analysis with an Electronic Calculator*, 4th edition, by Mark A. White (New York: McGraw-Hill, 2000).

CALCULATOR SETTINGS

Most calculator errors in the introductory finance course are the result of inappropriate settings. Before beginning a calculation, you should ask yourself the following questions:

1. Did I clear the financial registers?
2. Is the compounding frequency set to once per period?
3. Is the calculator in END mode?
4. Did I enter negative numbers using the **+/-** key?

Clearing the Registers

All calculators have areas of memory, called registers, where variables and intermediate results are stored. There are two sets of financial registers, the time value of money (TVM) registers and the cash flow (CF) registers. These must be cleared before beginning a new calculation. On the Hewlett-Packard HP-10B, pressing **{CLEAR ALL}** clears both the TVM and the CF registers.¹ To clear the TVM registers on the BA II Plus, press **2nd {CLR TVM}**. Press **2nd {CLR Work}** from within the cash flow worksheet to clear the CF registers.

Compounding Frequency

Both the HP-10B and the BA II Plus are hardwired to assume monthly compounding, that is, compounding 12 times per period. Because very few problems in the introductory finance course make this assumption, you should change this default setting to once per period. On the HP-10B, press **1 {P/YR}**. To verify that the default has been changed, press the **{}** key, then press and briefly hold the **INPUT** key.² The display should read "1P_Yr".

¹ The **{}** key is colored orange and serves as a Shift key for the functions in curly brackets.

² This is the same keystroke used to clear all registers; pretty handy, eh?

On the BA II Plus, you can specify both payment frequency and compounding frequency, although they should normally be set to the same number. To set both to once per period, press the key sequence **2nd {P/Y} 1 ENTER**, then press **↓ 1 ENTER**. Pressing **2nd {QUIT}** returns you to standard calculator mode.

END Mode and Annuities Due

In most problems, payment is made at the end of a period, and this is the default setting (end mode) for both the HP-10B and the BA II Plus. *Annuities due* assume payments are made at the *beginning* of each period (begin mode). On the HP-10B, pressing **{BEG/END}** toggles between begin and end mode. Press the key sequence **2nd {BGN} 2nd {SET} 2nd {QUIT}** to accomplish the same task on the BA II Plus. Both calculators will indicate on the display that your calculator is set for begin mode.

Sign Changes

Sign changes are used to identify the direction of cash inflows and outflows. Generally, cash inflows are entered as positive numbers and cash outflows are entered as negative numbers. To enter a negative number on either the HP-10B or the BA II Plus, first press the appropriate digit keys and then press the change sign key, **+/-**. Do not use the minus sign key, **-**, as its effects are quite unpredictable.

SAMPLE PROBLEMS

This section provides keystroke solutions for selected problems from the text illustrating the nine basic financial calculator skills.

1. Future Value or Present Value of a Single Sum

Compute the future value of \$2,250 at a 17 percent annual rate for 30 years.

HP-10B	BA II PLUS
-2,250.00 PV	-2,250.00 PV
30.00 N	30.00 N
17.00 I/YR	17.00 I/Y
FV 249,895.46	CPT FV 249,895.46

The future value is \$249,895.46.

2. Present Value or Future Value of an Ordinary Annuity

Betty's Bank offers you a \$20,000, seven-year term loan at 11 percent annual interest. What will your annual loan payment be?

HP-10B	BA II PLUS
-20,000.00 PV	-20,000.00 PV
7.00 N	7.00 N
11.00 I/YR	11.00 I/Y
PMT 4,244.31	CPT PMT 4,244.31

Your annual loan payment will be \$4,244.31.

3. Finding an Unknown Interest Rate

Assume that the total cost of a college education will be \$75,000 when your child enters college in 18 years. You presently have \$7,000 to invest. What rate of interest must you earn on your investment to cover the cost of your child's college education?

HP-10B	BA II PLUS
-7,000.00 PV	-7,000.00 PV
18.00 N	18.00 N
75,000.00 FV	75,000.00 FV
I/YR 14.08	CPT I/Y 14.08

You must earn an annual interest rate of at least 14.08 percent to cover the expected future cost of your child's education.

4. Finding an Unknown Number of Periods

One of your customers is delinquent on his accounts payable balance. You've mutually agreed to a repayment schedule of \$374 per month. You will charge 1.4 percent per month interest on the overdue balance. If the current balance is \$12,000, how long will it take for the account to be paid off?

HP-10B	BA II PLUS
-12,000.00 PV	-12,000.00 PV
1.40 I/YR	1.40 I/Y
374.00 PMT	374.00 PMT
N 42.90	CPT N 42.90

The loan will be paid off in 42.90 months.

5. Simple Bond Pricing

Mullineaux Co. issued 11-year bonds one year ago at a coupon rate of 8.25 percent. The bonds make semiannual payments. If the YTM on these bonds is 7.10 percent, what is the current bond price?

HP-10B	BA II PLUS
41.25 PMT	41.25 PMT
1,000.00 FV	1,000.00 FV
20.00 N	20.00 N
3.55 I/YR	3.55 I/Y
PV -1,081.35	CPT PV -1,081.35

Because the bonds make semiannual payments, we must halve the coupon payment ($8.25 \div 2 = 4.125 \Rightarrow \41.25), halve the YTM ($7.10 \div 2 \Rightarrow 3.55$), and double the number of periods (10 years remaining $\times 2 = 20$ periods). Then, the current bond price is \$1,081.35.

6. Simple Bond Yields to Maturity

Vasicek Co. has 12.5 percent coupon bonds on the market with eight years left to maturity. The bonds make annual payments. If one of these bonds currently sells for \$1,145.68, what is its YTM?

HP-10B	BA II PLUS
-1,145.68 PV	-1,145.68 PV
125.00 PMT	125.00 PMT
1,000.00 FV	1,000.00 FV
8.00 N	8.00 N
I/YR 9.79	CPT I/Y 9.79

The bond has a yield to maturity of 9.79 percent.

7. Cash Flow Analysis

What are the IRR and NPV of the following set of cash flows? Assume a discount rate of 10 percent.

Year	Cash Flow
0	-\$1,300
1	400
2	300
3	1,200

HP-10B	BA II PLUS
-1,300.00 CFj	CF
400.00 CFj	2nd {CLR Work}
1.00 {Nj}	-1,300.00 ENTER ↓
300.00 CFj	400.00 ENTER ↓
1.00 {Nj}	1.00 ENTER ↓
1,200.00 CFj	300.00 ENTER ↓
1.00 {Nj}	1.00 ENTER ↓
{IRR/YR} 17.40	1,200.00 ENTER ↓
10.00 I/YR	1.00 ENTER ↓
{NPV} 213.15	IRR CPT 17.40
	NPV
	10.00 ENTER
	↓ CPT 213.15

The project has an IRR of 17.40 percent and an NPV of \$213.15.

8. Loan Amortization

Prepare an amortization schedule for a three-year loan of \$24,000. The interest rate is 16 percent per year, and the loan calls for equal annual payments. How much interest is paid in the third year? How much total interest is paid over the life of the loan?

To prepare a complete amortization schedule, you must amortize each payment one at a time:

HP-10B	BA II PLUS
<div><div>-24,000.00</div><div>PV</div><div>16.00</div><div>I/YR</div><div>3.00</div><div>N</div><div>PMT</div><div>10,686.19</div></div>	<div><div>-24,000.00</div><div>PV</div><div>16.00</div><div>I/Y</div><div>3.00</div><div>N</div><div>CPT</div><div>PMT</div><div>10,686.19</div></div>

Interest of \$1,473.96 is paid in the third year.
Enter both a beginning and an ending period to compute the total amount of interest or principal paid over a particular period of time.

HP-10B	BA II PLUS
<div><div>-24,000.00</div><div>PV</div><div>16.00</div><div>I/YR</div><div>3.00</div><div>N</div><div>PMT</div><div>10,686.19</div></div>	<div><div>-24,000.00</div><div>PV</div><div>16.00</div><div>I/Y</div><div>3.00</div><div>N</div><div>CPT</div><div>PMT</div><div>10,686.19</div></div>
<div>1.00</div> <div>INPUT</div>	<div>2nd</div> <div>{AMORT}</div> <div>2nd</div> <div>{CLR Work}</div>
<div>3.00</div> <div>{AMORT}</div> <div>=</div> <div>8,058.57</div> <div><=</div> <div>Interest</div> <div>=</div> <div>24,000.00</div> <div><=</div> <div>Principal</div> <div>=</div> <div>0.00</div> <div><=</div> <div>Balance</div>	<div>1.00</div> <div>ENTER</div> <div>↓</div> <div>3.00</div> <div>ENTER</div> <div>↓</div> <div>0.00</div> <div><=</div> <div>Balance</div> <div>↓</div> <div>24,000.00</div> <div><=</div> <div>Principal</div> <div>↓</div> <div>8,058.57</div> <div><=</div> <div>Interest</div>

Total interest of \$8,058.57 is paid over the life of the loan.

9. Interest Rate Conversions

Find the effective annual rate, EAR, corresponding to a 7 percent annual percentage rate, APR, compounded quarterly.

HP-10B	BA II PLUS
<div>4.00</div> <div>{P/YR}</div> <div>7.00</div> <div>{NOM%}</div> <div>{EFF%}</div> <div>7.19</div>	<div>2nd</div> <div>{IConv}</div> <div>7.00</div> <div>ENTER</div> <div>↓</div> <div>↓</div> <div>4.00</div> <div>ENTER</div> <div>↑</div> <div>CPT</div> <div>7.19</div>

The effective annual rate equals 7.19 percent.

Glossary

absolute priority rule (APR) The rule establishing priority of claims in liquidation.

Accelerated Cost Recovery System (ACRS) Depreciation method under U.S. tax law allowing for the accelerated write-off of property under various classifications.

accounts payable period The time between receipt of inventory and payment for it.

accounts receivable financing A secured short-term loan that involves either the assignment or factoring of receivables.

accounts receivable period The time between sale of inventory and collection of the receivable.

agency problem The possibility of conflict of interest between the owners and management of a firm.

aging schedule A compilation of accounts receivable by the age of each account.

American Depositary Receipt (ADR) A security issued in the United States representing shares of a foreign stock and allowing that stock to be traded in the United States.

annual percentage rate (APR) The interest rate charged per period multiplied by the number of periods per year.

annuity A level stream of cash flows for a fixed period of time.

annuity due An annuity for which the cash flows occur at the beginning of the period.

arithmetic average return The return earned in an average year over a particular period.

asked price The price a dealer is willing to take for a security.

asset-specific risk A risk that affects at most a small number of assets. Also *unique* or *unsystematic risk*.

average accounting return (AAR) An investment's average net income divided by its average book value.

average tax rate Total taxes paid divided by total taxable income.

balance sheet Financial statement showing a firm's accounting value on a particular date.

bankruptcy A legal proceeding for liquidating or reorganizing a business. Also, the transfer of some or all of a firm's assets to its creditors.

bearer form A bond issued without record of the owner's name; payment is made to whoever holds the bond.

benefit-cost ratio The present value of an investment's future cash flows divided by its initial cost. Also *profitability index*.

best efforts underwriting The underwriter sells as much of the issue as possible, but can return any unsold shares to the issuer without financial responsibility.

beta coefficient Amount of systematic risk present in a particular risky asset relative to that in an average risky asset.

bid-ask spread The difference between the bid price and the asked price.

bid price The price a dealer is willing to pay for a security.

broker An agent who arranges security transactions among investors.

business risk The equity risk that comes from the nature of the firm's operating activities.

call premium The amount by which the call price exceeds the par value of the bond.

call protected bond Bond during period in which it cannot be redeemed by the issuer.

call provision Agreement giving the issuer the option to repurchase a bond at a specific price prior to maturity.

capital asset pricing model (CAPM) Equation of the security market line showing the relationship between expected return and beta.

capital budgeting The process of planning and managing a firm's long-term investments.

capital gains yield The dividend growth rate, or the rate at which the value of an investment grows.

capital rationing The situation that exists if a firm has positive net present value projects but cannot obtain the necessary financing.

capital structure The mixture of debt and equity maintained by a firm.

captive finance company A partially or wholly owned subsidiary that handles the credit function for the parent company.

carrying costs Costs that rise with increases in the level of investment in current assets.

cash budget A forecast of cash receipts and disbursements for the next planning period.

cash concentration The practice of and procedures for moving cash from multiple banks into the firm's main accounts.

cash cycle The time between cash disbursement and cash collection.

cash discount A discount given to induce prompt payment. Also *sales discount*.

cash flow from assets The total of cash flow to creditors and cash flow to stockholders, consisting of the following: operating cash flow, capital spending, and changes in net working capital.

cash flow to creditors A firm's interest payments to creditors less net new borrowings.

cash flow to stockholders Dividends paid out by a firm less net new equity raised.

cash flow time line Graphical representation of the operating cycle and the cash cycle.

clean price The price of a bond net of accrued interest; this is the price that is typically quoted.

cliente effect Argument that stocks attract particular groups based on dividend yield and the resulting tax effects.

collection policy Procedures followed by a firm in collecting accounts receivable.

commission brokers NYSE members who execute orders to buy and sell stock transmitted to the exchange floor.

common-size statement A standardized financial statement presenting all items in percentage terms. Balance sheet items are shown as a percentage of assets and income statement items as a percentage of sales.

common stock Equity without priority for dividends or in bankruptcy.

compounding The process of accumulating interest in an investment over time in order to earn more interest.

compound interest Interest earned on both the initial principal and the interest reinvested from prior periods.

compound value The amount an investment is worth after one or more periods. Also *future value*.

consol A type of perpetuity.

contingency planning Taking into account the managerial options implicit in a project.

controlled disbursement account A disbursement practice under which the firm transfers an amount to a disbursing account that is sufficient to cover demands for payment.

corporation A business created as a distinct legal entity owned by one or more individuals or entities.

cost of capital The minimum required return on a new investment.

cost of debt The return that lenders require on the firm's debt.

cost of equity The return that equity investors require on their investment in the firm.

coupon The stated interest payment made on a bond.

coupon rate The annual coupon divided by the face value of a bond.

credit analysis The process of determining the probability that customers will or will not pay.

credit cost curve Graphical representation of the sum of the carrying costs and the opportunity costs of a credit policy.

credit instrument The evidence of indebtedness.

credit period The length of time for which credit is granted.

credit scoring The process of quantifying the probability of default when granting consumer credit.

cross-rate The implicit exchange rate between two currencies (usually non-U.S.) quoted in some third currency (usually the U.S. dollar).

cumulative voting A procedure in which a shareholder may cast all votes for one member of the board of directors.

current yield A bond's coupon payment divided by its closing price.

date of payment Date that the dividend checks are mailed.

date of record Date on which holders must be on record to receive a dividend.

dealer An agent who buys and sells securities from inventory.

debenture Unsecured debt, usually with a maturity of 10 years or more.

declaration date Date on which the board of directors passes a resolution to pay a dividend.

default risk premium The portion of a nominal interest rate or bond yield that represents compensation for the possibility of default.

deferred call provision Bond call provision prohibiting the company from redeeming the bond prior to a certain date.

depreciation tax shield The tax saving that results from the depreciation deduction, calculated as depreciation multiplied by the corporate tax rate.

direct bankruptcy costs The costs that are directly associated with bankruptcy, such as legal and administrative expenses.

dirty price The price of a bond including accrued interest, also known as the full or invoice price. This is the price the buyer actually pays.

discount Calculation of the present value of some future amount.

discounted cash flow (DCF) valuation (a) Valuation calculating the present value of a future cash flow to determine its value today. (b) The process of valuing an investment by discounting its future cash flows.

discount rate The rate used to calculate the present value of future cash flows.

distribution Payment made by a firm to its owners from sources other than current or accumulated retained earnings.

dividend Payment made out of a firm's earnings to its owners, in the form of either cash or stock.

dividend growth model Model that determines the current price of a stock as its dividend next period divided by the discount rate less the dividend growth rate.

dividend yield A stock's expected cash dividend divided by its current price.

Du Pont identity Popular expression breaking ROE into three parts: operating efficiency, asset use efficiency, and financial leverage.

Dutch auction underwriting The type of underwriting in which the offer price is set based on competitive bidding by investors. Also known as a *uniform price auction*.

economic order quantity (EOQ) The restocking quantity that minimizes the total inventory costs.

effective annual rate (EAR) The interest rate expressed as if it were compounded once per year.

efficient capital market Market in which security prices reflect available information.

efficient markets hypothesis (EMH) The hypothesis that actual capital markets, such as the New York Stock Exchange, are efficient.

electronic communications networks (ECNs) Web sites that allow investors to trade directly with one another.

erosion The cash flows of a new project that come at the expense of a firm's existing projects.

estimation risk The possibility that errors in projected cash flows will lead to incorrect decisions. Also *forecasting risk*.

Eurobonds International bonds issued in multiple countries but denominated in a single currency (usually the issuer's currency).

Eurocurrency Money deposited in a financial center outside of the country whose currency is involved.

exchange rate The price of one country's currency expressed in terms of another country's currency.

exchange rate risk The risk related to having international operations in a world where relative currency values vary.

ex dividend date Date two business days before the date of record, establishing those individuals entitled to a dividend.

expected return Return on a risky asset expected in the future.

face value The principal amount of a bond that is repaid at the end of the term. Also *par value*.

financial distress costs The direct and indirect costs associated with going bankrupt or experiencing financial distress.

financial ratios Relationships determined from a firm's financial information and used for comparison purposes.

financial risk The equity risk that comes from the financial policy (i.e., capital structure) of the firm.

firm commitment underwriting The underwriter buys the entire issue, assuming full financial responsibility for any unsold shares.

Fisher effect The relationship between nominal returns, real returns, and inflation.

five Cs of credit The five basic credit factors to be evaluated: character, capacity, capital, collateral, and conditions.

float The difference between book cash and bank cash, representing the net effect of checks in the process of clearing.

floor brokers NYSE members who execute orders for commission brokers on a fee basis; sometimes called \$2 brokers.

floor traders NYSE members who trade for their own accounts, trying to anticipate temporary price fluctuations.

forecasting risk The possibility that errors in projected cash flows will lead to incorrect decisions. Also *estimation risk*.

foreign bonds International bonds issued in a single country, usually denominated in that country's currency.

foreign exchange market The market in which one country's currency is traded for another's.

forward exchange rate The agreed-upon exchange rate to be used in a forward trade.

forward trade Agreement to exchange currency at some time in the future.

free cash flow Another name for cash flow from assets.

future value (FV) The amount an investment is worth after one or more periods. Also *compound value*.

general cash offer An issue of securities offered for sale to the general public on a cash basis.

Generally Accepted Accounting Principles (GAAP) The common set of standards and procedures by which audited financial statements are prepared.

geometric average return The average compound return earned per year over a particular period.

gilts British and Irish government securities.

Green Shoe provision A contract provision giving the underwriter the option to purchase additional shares from the issuer at the offering price. Also *overallotment option*.

hard rationing The situation that occurs when a business cannot raise financing for a project under any circumstances.

homemade leverage The use of personal borrowing to change the overall amount of financial leverage to which an individual is exposed.

income statement Financial statement summarizing a firm's performance over a period of time.

incremental cash flows The difference between a firm's future cash flows with a project and those without the project.

indenture The written agreement between the corporation and the lender detailing the terms of the debt issue.

indirect bankruptcy costs The costs of avoiding a bankruptcy filing incurred by a financially distressed firm.

inflation premium The portion of a nominal interest rate that represents compensation for expected future inflation.

initial public offering (IPO) A company's first equity issue made available to the public. Also *unseasoned new issue*.

inside quotes The highest bid quotes and the lowest ask quotes for a security.

interest on interest Interest earned on the reinvestment of previous interest payments.

interest rate parity (IRP) The condition stating that the interest rate differential between two countries is equal to the percentage difference between the forward exchange rate and the spot exchange rate.

interest rate risk premium The compensation investors demand for bearing interest rate risk.

interest tax shield The tax savings attained by a firm from the tax deductibility of interest expense.

internal growth rate The maximum possible growth rate a firm can achieve without external financing of any kind.

internal rate of return (IRR) The discount rate that makes the net present value of an investment zero.

inventory loan A secured short-term loan to purchase inventory.

inventory period The time it takes to acquire and sell inventory.

invoice Bill for goods or services provided by the seller to the purchaser.

just-in-time (JIT) inventory A system for managing demand-dependent inventories that minimizes inventory holdings.

line of credit A formal (committed) or informal (non-committed) prearranged, short-term bank loan.

liquidation Termination of the firm as a going concern.

liquidity premium The portion of a nominal interest rate or bond yield that represents compensation for lack of liquidity.

lockboxes Special post office boxes set up to intercept and speed up accounts receivable collections.

lockup agreement The part of the underwriting contract that specifies how long insiders must wait after an IPO before they can sell stock.

London Interbank Offer Rate (LIBOR) The rate most international banks charge one another for overnight Eurodollar loans.

M&M Proposition I The value of a firm is independent of its capital structure.

M&M Proposition II A firm's cost of equity capital is a positive linear function of its capital structure.

managerial options Opportunities that managers can exploit if certain things happen in the future. Also known as "real" options.

marginal tax rate Amount of tax payable on the next dollar earned.

market risk A risk that influences a large number of assets. Also *systematic risk*.

market risk premium Slope of the security market line, the difference between the expected return on a market portfolio and the risk-free rate.

materials requirements planning (MRP) A set of procedures used to determine inventory levels for demand-dependent inventory types, such as work-in-progress and raw materials.

maturity Specified date on which the principal amount of a bond is paid.

member The owner of a seat on the NYSE.

multiple rates of return The possibility that more than one discount rate will make the net present value of an investment zero.

mutually exclusive investment decisions A situation where taking one investment prevents the taking of another.

net present value (NPV) The difference between an investment's market value and its cost.

net present value profile A graphical representation of the relationship between an investment's net present values and various discount rates.

net working capital Current assets less current liabilities.

nominal rates Interest rates or rates of return that have not been adjusted for inflation.

noncash items Expenses charged against revenues that do not directly affect cash flow.

normal distribution A symmetric, bell-shaped frequency distribution that is completely defined by its mean and standard deviation.

note Unsecured debt, usually with a maturity of under 10 years.

operating cash flow Cash generated from a firm's normal business activities.

operating cycle The time period between the acquisition of inventory and the collection of cash from receivables.

opportunity cost The most valuable alternative that is given up if a particular investment is undertaken.

order flow The flow of customer orders to buy and sell securities.

overallotment option A contract provision giving the underwriter the option to purchase additional shares from the issuer at the offering price. Also *Green Shoe provision*.

partnership A business formed by two or more individuals or entities.

par value The principal amount of a bond that is repaid at the end of the term. Also *face value*.

payback period The amount of time required for an investment to generate cash flows sufficient to recover its initial cost.

perpetuity An annuity in which the cash flows continue forever.

political risk Risk related to changes in value that arise because of political actions.

portfolio Group of assets such as stocks and bonds held by an investor.

portfolio weight Percentage of a portfolio's total value in a particular asset.

precautionary motive The need to hold cash as a safety margin to act as a financial reserve.

preferred stock Stock with dividend priority over common stock, normally with a fixed dividend rate, sometimes without voting rights.

present value (PV) The current value of future cash flows discounted at the appropriate discount rate.

primary market The market in which new securities are originally sold to investors.

principle of diversification Spreading an investment across a number of assets will eliminate some, but not all, of the risk.

private placements Loans, usually long-term in nature, provided directly by a limited number of investors.

profitability index (PI) The present value of an investment's future cash flows divided by its initial cost. Also *benefit-cost ratio*.

pro forma financial statements Financial statements projecting future years' operations.

prospectus A legal document describing details of the issuing corporation and the proposed offering to potential investors.

protective covenant A part of the indenture limiting certain actions that might be taken during the term of the loan, usually to protect the lender's interest.

proxy A grant of authority by a shareholder allowing another individual to vote his or her shares.

purchasing power parity (PPP) The idea that the exchange rate adjusts to keep purchasing power constant among currencies.

pure play approach Use of a weighted average cost of capital that is unique to a particular project, based on companies in similar lines of business.

quoted interest rate The interest rate expressed in terms of the interest payment made each period. Also *stated interest rate*.

real rates Interest rates or rates of return that have been adjusted for inflation.

real return Return adjusted for the effects of inflation.

red herring A preliminary prospectus distributed to prospective investors in a new issue of securities.

registered form The registrar of a company records who owns each bond, and bond payments are made directly to the owner of record.

registration statement A statement filed with the SEC that discloses all material information concerning the corporation making a public offering.

regular cash dividend Cash payment made by a firm to its owners in the normal course of business, usually four times a year.

reorganization Financial restructuring of a failing firm to attempt to continue operations as a going concern.

repurchase Refers to a firm's purchase of its own stock; an alternative to a cash dividend.

residual dividend approach Policy under which a firm pays dividends only after meeting its investment needs while maintaining a desired debt-equity ratio.

reverse split Stock split under which a firm's number of shares outstanding is reduced.

rights offer A public issue of securities in which securities are first offered to existing shareholders. Also known as *rights offering*.

risk premium The excess return required from an investment in a risky asset over that required from a risk-free investment.

sales discount A discount given to induce prompt payment. Also known as *cash discount*.

scenario analysis The determination of what happens to net present value estimates when we ask what-if questions.

seasoned equity offering (SEO) A new equity issue of securities by a company that has previously issued securities to the public.

secondary market The market in which previously issued securities are traded among investors.

security market line (SML) Positively sloped straight line displaying the relationship between expected return and beta.

sensitivity analysis Investigation of what happens to net present value when only one variable is changed.

shelf registration Registration permitted by SEC Rule 415, which allows a company to register all issues it expects to sell within two years at one time, with subsequent sales at any time within those two years.

shortage costs Costs that fall with increases in the level of investment in current assets.

simple interest Interest earned only on the original principal amount invested.

sinking fund An account managed by the bond trustee for early bond redemption.

soft rationing The situation that occurs when units in a business are allocated a certain amount of financing for capital budgeting.

sole proprietorship A business owned by a single individual.

specialist An NYSE member acting as a dealer in a small number of securities on the exchange floor; often called a market maker.

specialist's post A fixed place on the exchange floor where the specialist operates.

speculative motive The need to hold cash to take advantage of additional investment opportunities, such as bargain purchases.

spot exchange rate The exchange rate on a spot trade.

spot trade An agreement to trade currencies based on the exchange rate today for settlement within two business days.

spread Compensation to the underwriter, determined by the difference between the underwriter's buying price and offering price.

stakeholder Someone other than a stockholder or creditor who potentially has a claim on the cash flows of the firm.

stand-alone principle The assumption that evaluation of a project may be based on the project's incremental cash flows.

standard deviation The positive square root of the variance.

Standard Industrial Classification (SIC) code U.S. government code used to classify a firm by its type of business operations.

stated interest rate The interest rate expressed in terms of the interest payment made each period. Also *quoted interest rate*.

static theory of capital structure Theory that a firm borrows up to the point where the tax benefit from an extra dollar in debt is exactly equal to the cost that comes from the increased probability of financial distress.

stock dividend Payment made by a firm to its owners in the form of stock, diluting the value of each share outstanding.

stock repurchase The purchase, by a corporation, of its own stock; also known as buyback.

stock split An increase in a firm's shares outstanding without any change in owners' equity.

straight voting A procedure in which a shareholder may cast all votes for each member of the board of directors.

strategic options Options for future, related business products or strategies.

sunk cost A cost that has already been incurred and cannot be recouped and therefore should not be considered in an investment decision.

SuperDOT system An electronic NYSE system allowing orders to be transmitted directly to the specialist.

sustainable growth rate The maximum possible growth rate a firm can achieve without external equity financing while maintaining a constant debt-equity ratio.

swaps Agreements to exchange two securities or currencies.

syndicate A group of underwriters formed to share the risk and to help sell an issue.

systematic risk A risk that influences a large number of assets. Also *market risk*.

systematic risk principle The expected return on a risky asset depends only on that asset's systematic risk.

taxability premium The portion of a nominal interest rate or bond yield that represents compensation for unfavorable tax status.

term loans Direct business loans of, typically, one to five years.

terms of sale Conditions under which a firm sells its goods and services for cash or credit.

term structure of interest rates The relationship between nominal interest rates on default-free, pure discount securities and time to maturity; that is, the pure time value of money.

tombstone An advertisement announcing a public offering.

trading range Price range between highest and lowest prices at which a stock is traded.

transaction motive The need to hold cash to satisfy normal disbursement and collection activities associated with a firm's ongoing operations.

Treasury yield curve A plot of the yields on Treasury notes and bonds relative to maturity.

underwriters Investment firms that act as intermediaries between a company selling securities and the investing public.

unique risk A risk that affects at most a small number of assets. Also *unsystematic* or *asset-specific risk*.

unseasoned new issue A company's first equity issue made available to the public. Also *initial public offering*.

unsystematic risk A risk that affects at most a small number of assets. Also *unique* or *asset-specific risk*.

variance The average squared difference between the actual return and the average return.

venture capital (VC) Financing for new, often high-risk ventures.

weighted average cost of capital (WACC) The weighted average of the cost of equity and the aftertax cost of debt.

working capital A firm's short-term assets and liabilities.

yield to maturity (YTM) The rate required in the market on a bond.

zero-balance account A disbursement account in which the firm maintains a zero balance, transferring funds in from a master account only as needed to cover checks presented for payment.

zero coupon bond A bond that makes no coupon payments, and thus is initially priced at a deep discount.
